CONTENTS

PART I **Cisco Security Cloud Control Management: Cloud-Delivered Firewall Management Center** 95

CHAPTER 1 **Configure Cloud-Delivered Firewall Management Center-Managed Secure Firewall Threat Defense** 1

Overview of Cloud-Delivered Firewall Management Center 1

Navigate to the Cloud-Delivered Firewall Management Center in your Security Cloud Control Tenant 3

Determine the Cloud-Delivered Firewall Management Center Version in Security Cloud Control Firewall Management 3

Enable Cloud-Delivered Firewall Management Center 4

Hardware and Software Support 5

Security Cloud Control Firewall Management Platform Maintenance Schedule 5

Licensing 6

Integrate an On-Premises Firewall Management Center With Cisco Security Cloud 6

Security Cloud Control Firewall Management Integrations Page 9

CHAPTER 2 **Manage Multicloud Defense-Onboarded Secure Firewall Threat Defense Virtual Devices** 13

Overview of Multicloud Defense-Onboarded Firewall Threat Defense Virtual Devices 13

Onboard and Configure a Secure Firewall Threat Defense Virtual Device in Multicloud Defense 15

PART II **Onboard Devices to Cloud-Delivered Firewall Management Center** 17

CHAPTER 3 **Onboard a Secure Firewall Threat Defense to the Cloud-Delivered Firewall Management Center** 19

Onboarding Overview 19

Maximum Firewall Threat Defense devices supported in Cloud-Delivered Firewall Management Center 20

Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center 21

Onboard a Device with a CLI Registration Key 22

Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning 24

Onboard a Firewall Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning 25

Onboard Firewall Threat Defense Devices using Device Templates to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning 27

Cloud Deployment 29

Configure FTDv enforcement point 29

Configure Multicloud Defense enforcement point 37

Onboard a Secure Firewall Threat Defense Cluster 46

Onboard a Chassis 49

Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI 51

Delete Devices from Cloud-Delivered Firewall Management Center 54

Troubleshooting 55

Troubleshoot Cloud-Delivered Firewall Management Center Connectivity with TCP 55

Troubleshoot Firewall Threat Defense Device Connectivity 56

Troubleshoot Device Connectivity Loss After Cloud-Delivered Firewall Management Center Update 56

Troubleshoot Onboarding a Device to the Cloud-Delivered Firewall Management Center Using the CLI Registration Key 57

Error: Device Remains in Pending Setup State After Onboarding 57

Troubleshoot Onboarding a Device to Cloud-Delivered Firewall Management Center Using the Serial Number 58

Device is Offline or Unreachable 58

Error: Serial Number Already Claimed 58

Error: Claim Error 60

Error: Failed to Claim 60

Error: Provisional Error 61

CHAPTER 4 **Migrate On-Premises Firewall Management Center Managed Secure Firewall Threat Defense to Cloud-delivered Firewall Management Center 63**

Overview of Firewall Threat Defense to Cloud-Delivered Firewall Management Center migration 63

How Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center Works 64

About 14-day evaluation period 65

How Firewall Threat Defense licenses are handled during migration to Cloud-Delivered Firewall Management Center 65
End-to-End Workflow for Migrating Firewall Threat Defense to Cloud-Delivered Firewall Management Center 66
Event and Analytics Management options during Firewall Threat Defense migration 67
Supported features 68
Unsupported features 70
User Identity Migration Guidelines and Limitations for Firewall Threat Defense Devices 71
Migration guidelines and limitations for VPN configuration 71
Supported On-Premises Firewall Management Center and Firewall Threat Defense software versions for migration 73
Prerequisites for Migrating Firewall Threat Defense to Cloud-Delivered Firewall Management Center 75
Migrate Firewall Threat Defense to Cloud-Delivered Firewall Management Center 78
View a Firewall Threat Defense Migration Job 81
Proceed Migration Process 82
Commit Migration Changes Manually to Cloud-Delivered Firewall Management Center 83
Revert the Firewall Threat Defense Management to On-Premises Firewall Management Center 84
View Migrated Devices 84
Generate a Firewall Threat Defense Migration Report 86
Delete a Migration Job 86
Enable Notification Settings 86
Verify Firewall Threat Defense Connectivity with Cloud-Delivered Firewall Management Center 87
Use the Troubleshoot Feature for Failed Migrations 88
Resolving Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center Issues 90

CHAPTER 5 **Device Registration** 99
Log into the Command-Line Interface on the device 99
Device registration management 101
About the device management page 101
Add a Device Group 102
Device management page enhancements 103
Use the enhanced filters in device management page 105
Add a device group 105

Move devices to another group 106
Managed device list download 107
Shut down or restart the device 107
Download the managed device list 108
Migrate Firewall Threat Defense devices 108
Supported Devices for Migration 109
License for Firewall Threat Defense migration 110
Prerequisites for migration 110
Configurations that the wizard migrates 112
Guidelines and limitations for migration 113
Migrate a secure Firewall Threat Defense 115
Best practices for Threat Defense device migration 117
Use the Security Cloud Control command line interface tool 118

CHAPTER 6 **Device Registration Using Device Templates** 119
Device registration using device templates 119
Variables and network object overrides 119
Model mapping 120
Templates and high availability 120
Validating template configurations before and after application on devices 121
Prerequisites for device registration using device templates 121
Licenses for device registration using device templates 122
Guidelines for device registration using device templates 123
Configure device templates 126
Add a device template 126
Create a new device template 126
Generate a new device template from an existing device 126
Import a device template 127
Configure device settings in the template 128
Add a physical interface 128
Add a logical interface 128
Edit an interface 129
Configure other device settings 130
Template settings 130

Edit general settings 131
Edit licenses 131
Edit applied policies 132
Edit advanced settings 132
Edit deployment settings 133
Configure template parameters 134
Add model mapping 137
Configure Site-to-Site VPN connections in a device template 138
Configure an SD-WAN VPN connection 138
Configure a route-based Site-to-Site VPN connection 139
Configure a policy-based Site-to-Site VPN connection 140
Add a device to an SD-WAN topology in a dual ISP deployment 142
Configure a Template for Firewall Threat Defense Devices Managed Using the Data Interface 143
Use templates with devices 145
Apply templates to existing devices 145
Apply a template 145
Reapply a template 146
Monitor device templates 147
View associated devices 147
Template Apply reports 148
Audit logs 148
Troubleshoot device templates 149

CHAPTER 7 **Transparent or Routed Firewall Mode 153**
Firewall mode 153
Routed firewall mode 153
Transparent firewall mode 154
Transparent firewall network usage 154
Passing traffic for routed-mode features 155
Bridge groups 155
Bridge virtual interfaces 155
Bridge groups in transparent firewall mode 156
Bridge groups in routed firewall mode 157
Allow layer 3 traffic 158

Allowed MAC addresses 158
BPDUs handling 158
MAC address and route lookups 159
Unsupported features for bridge groups in transparent mode 161
Unsupported features for bridge groups in routed mode 162
Default settings 163
Guidelines for firewall mode 163
Set the firewall mode 164

CHAPTER 8 Change Management 167
Change management 167
Make configuration changes in the change management workflow 167
Create separate approver and configuration roles 168
Policies and objects that support change management 169
Requirements and prerequisites for change management 171
Guidelines and limitations for change management 172
Enabling or disabling change management 172
Manage tickets 173
Create change management tickets 175
Opening a ticket for configuration changes 176
Preview a ticket 176
Submit a ticket 177
Discard a ticket 177
Approving or rejecting a ticket 178
Take over or reassign tickets 179

CHAPTER 9 CLI Users 181
CLI users 181
Internal and external users 181
CLI access 182
CLI user roles 182
Guidelines for CLI users 183
Add an internal user at the CLI 183
Troubleshoot LDAP authentication connections 186

CHAPTER 10 **Configuration Deployment** 189

Configuration deployment 189

Configuration changes that require deployment 189

Deployment preview 190

Guidelines for selective policy deployment 191

System username 193

Auto-enabling of application detectors 194

Asset rediscovery with network discovery policy changes 194

Snort restart scenarios 194

Inspection interruption warnings during deployment 195

Inspect traffic during policy apply 196

Snort restart traffic behavior 196

Configurations that restart the snort process when deployed or activated 198

Actions that immediately restart the snort process 199

Requirements and prerequisites for deployment management 200

Best practices for deploying configuration changes 200

Configuration deployment 201

Deploy configuration changes 202

Redeploy existing configurations to a device 208

Deployment management 209

Deployment status 209

View deployment history 210

Deployment rollback 214

Perform a rollback 216

View the deployment rollback transcript 217

Download policy changes report for multiple devices 218

Compare policies 219

Generate current policy reports 220

PART III **System Settings** 223

CHAPTER 11 **System Configuration** 225

Meet requirements and prerequisites for the system configuration 225

Manage the Cloud-Delivered Firewall Management Center system configuration 226
Configure access control preferences 226
Audit logs 227
Stream audit logs to syslog 228
Stream audit logs to an HTTP server 230
Audit log certificates 231
Secure audit log streaming 232
Obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center 233
Import an audit log client certificate into the Cloud-Delivered Firewall Management Center 234
Require valid audit log server certificates 235
View the audit log client certificate on the Cloud-Delivered Firewall Management Center 237
Change reconciliation 237
Configure change reconciliation 238
Change reconciliation options 239
Email notifications 239
Intrusion policy preferences 239
Set intrusion policy preferences 240
Network analysis policy preferences 241

CHAPTER 12 Users 243
CLI users 243
Internal and external users 243
User roles 244
Create a User Record with Your Security Cloud Control Username 246
External authentication configuration for Cloud-Delivered Firewall Management Center 247
External authentication objects for Cloud-Delivered Firewall Management Center 247
LDAP 248
RADIUS 248
Add an LDAP external authentication object for the Security Cloud Control 249
Add a RADIUS external authentication object for Security Cloud Control 255
Troubleshoot LDAP authentication connections 261
Configure User Preferences 261
Change the web interface appearance 261
Set your default time zone 262

CHAPTER 13 **Updates** 263

Content updates 263

Product upgrades 264

Guidelines for content updates 264

Vulnerability database (VDB) updates 264

Manually update the VDB 265

Geolocation database (GeoDB) updates 266

Schedule GeoDB updates 267

Manually update the GeoDB 267

Intrusion rule updates 268

Schedule intrusion rule updates 269

Manually update intrusion rules 269

Guidelines for importing custom Snort 2 rules 270

Import custom Snort 2 rules 271

Intrusion rule update logs 272

CHAPTER 14 **Licenses** 275

Licenses 275

Smart Software Manager and accounts 276

Licensing for Management Center and devices 276

Periodic communications with the Smart Software Manager 276

Cloud-Delivered Firewall Management Center licensing and registration 276

Out-of-compliance state 279

Unregistered state 279

End-user license agreement 279

License types and restrictions 279

Essentials licenses 281

Malware Defense Licenses 282

IPS licenses 282

Carrier license 283

URL Filtering licenses 284

Secure Client licenses 285

License for export-controlled functionality 286

Firewall Threat Defense Virtual Licenses 287
Prerequisites for licensing 289
Prerequisites for licensing in high availability, clustering, and multi-instance 289
License requirements for Firewall Threat Defense device high availability 289
License for device clusters 289
Create a Cisco account 290
Create a smart account and add licenses 291
Configure Smart Licensing 292
Register the Cloud-Delivered Firewall Management Center for Smart Licensing 292
Register the Cloud-Delivered Firewall Management Center with the Smart Software Manager 293
Assign licenses to devices 295
Assign licenses to a single device 295
Assign licenses to multiple managed devices 296
Manage Smart Licensing 297
Deregister the Cloud-Delivered Firewall Management Center 297
Monitor Smart License status 298
Monitor Smart Licensing 298
Troubleshoot Smart Licensing 299
Configure Legacy Cloud-Delivered Firewall Management Center PAK-Based Licenses 300
Additional information about licensing 301
Overview 301
Requirements 302
Supported Platforms and Versions 302
How to Implement Universal Permanent Licensing 302
Prerequisites 303
Verify that your Smart Account is Ready to Deploy Universal Permanent License Reservation 304
Enable the Permanent Licensing Menu Option 305
Generate a Reservation Request Code from the Firepower Management Center 306
Generate a Reservation Authorization Code from Cisco Smart Software Manager 306
Enter the Reservation Authorization Code into the Firepower Management Center 307
Apply Permanent Licenses to Managed Firepower Threat Devices 307
Maintain your air-gapped deployment 308
Universal Permanent License Status 308
Maintain Your UPLR Deployment 309

Deactivate and Return a Universal Permanent License 309
Troubleshooting 312
For Assistance 313

CHAPTER 15 **Security certifications compliance 315**
Security certifications compliance modes 315
Security certifications compliance characteristics 316
Security certifications compliance recommendations 317
Appliance hardening 318
Protect your network 319

PART IV **Optimize Firewall Performance with AgenticOps 321**

CHAPTER 16 **Introduction to AgenticOps insights 323**
About AgenticOps insights 323
AgenticOps licensing requirements 325
Prerequisites to use AgenticOps 325
View summary dashboard 325
View AgenticOps insights 329
AgenticOps for On-Premises Firewall Management Center 330
About capacity and traffic insights 331
Analyze capacity trends and forecast resource usage 333
About policy change impact insights 334
Analyze policy change impact 338
About best practices and recommendations 339
Implement best practices and recommendations 340
About feature adoption insights 342
Assess and improve feature adoption 342
About software upgrade insights 343
Manage software upgrades 344
About application insights 345
Detect application outages 346
About compliance insights 346
Generate compliance reports 347

Manage insight preferences 349
Enable AgenticOps insights 349
Disable AgenticOps insights 349
Manage AgenticOps data sources 350
Capacity and traffic insights 351
Best practices and recommendations insights 352
Policy change impact analyzer insights 352
Policy change impact analyzer insights 353
Operational insights 353
Application insights 354
Frequently asked questions about AgenticOps 354
Additional resources 355

PART V **Simplify Firewall Operations with Agent Workforce** 357

CHAPTER 17 **Introduction to Agent Workforce** 359
About Agent Workforce 359
Available agents in Agent Workforce 359
Manage Conversations in Agent Workforce 360
Limitations and considerations 361
Troubleshoot site-to-site VPN issues with VPN agent 361
Benefits of using the VPN agent 361
How VPN agent works 361
Best practices for using the VPN agent 362
Example prompts and expected outcomes for the VPN agent 363
Remediate traffic congestion with Elephant flow agent 363
Benefits of using the Elephant flow agent 364
How Elephant flow remediation works 364
Best practices for using the Elephant flow agent 365
Analyze firewall data with Firewall insight agent 365
Benefits of using the Firewall insight agent 365
How Firewall insight agent works 365
Best practices for using the Firewall insight agent 366
Example prompts and expected outcomes for the Firewall insight agent 366

PART VI Health and Monitoring 369

CHAPTER 18 Health 371

Requirements and prerequisites for health monitoring 371
Health monitoring in Cloud-Delivered Firewall Management Center 371
Health modules 373
Configure health monitoring 383
Health policies 383
Default health policy 384
Create a health policy 385
Apply a health policy 385
Edit a health policy 386
Set a default health policy 388
Delete a health policy 388
Device exclusion in health monitoring 389
Exclude devices from health monitoring 390
Exclude health policy modules on a device 391
Exclude interface health monitoring 392
Manage expired health monitor exclusions 392
Health monitor alerts 393
Health monitor alert information 393
Health alerts for Secure Firewall 200 Series device 394
Health event external notifications 395
Create a health monitor alert 396
Edit a health monitor alert 397
Delete health monitor alerts 397
About the health monitor 398
Device health monitors 399
View system details and troubleshoot devices 400
View the device health monitor 401
Cluster health monitor 404
View the cluster health monitor 405
Health monitor status categories 407

Health event views 407
View health events 408
View the health events table 408
Health event fields 409
Sending device health metrics to OpenConfig 410
Generate certificates and private keys 411
Configure OpenConfig streaming telemetry 413
Troubleshoot OpenConfig streaming telemetry 414
system auditing 416
Audit records 416
Audit log workflow fields 416
The audit events table view 417

CHAPTER 19 Troubleshooting 419
Guidelines and best practices for troubleshooting 419
System messages 420
Message types 420
Message management 422
View basic system information 422
View appliance information 423
Manage system messages 423
View deployment messages 424
View upgrade messages 425
View health messages 425
View task messages 426
Manage task messages 427
Memory usage thresholds for health monitor alerts 427
Disk usage and drain of events health monitor alerts 428
Clear disk space 432
Health monitor reports for troubleshooting 433
Generate troubleshooting files for specific system functions 433
Download advanced troubleshooting files 434
Enhanced troubleshooting experience using Cisco RADKit integration 435
Guidelines and limitations for RADKit integration 435

Enroll RADKit service 436
Manage RADKit service authorization 436
Enable sudo access for devices 438
Download session logs 438
General troubleshooting 439
Connection-based troubleshooting 439
Troubleshoot a connection 439
Advanced troubleshooting for the Secure Firewall Threat Defense device 440
Packet capture 440
Use a packet capture trace 442
Packet tracer tool overview 444
Run a packet trace 444
CPU profiler overview 448
Use the CPU profiler 448
Rule profiler overview 450
Use the rule profiler 450
Use the Firewall Threat Defense diagnostic CLI from the web interface 451
Feature-specific troubleshooting 453

PART VII **Tools** 455

CHAPTER 20 **Backup/Restore** 457
About Backup and Restore 457
Requirements for Backup and Restore 458
Guidelines and Limitations for Backup and Restore 459
Best Practices for Backup and Restore 460
Back Up Managed Devices 462
Back Up a Firewall Threat Defense Device from Cloud-delivered Firewall Management Center 463
Restore Security Cloud Control-Managed Devices 464
Restore a Firewall Threat Defense Device 464
Restore Firewall Threat Defense from Backup: Firewall Threat Defense Virtual 467

CHAPTER 21 **Scheduling** 471
Task scheduling 471

Guidelines for scheduled tasks 471
Scheduled task types 472
Schedule a task 474

CHAPTER 22 Import/Export 477
Import/Export feature overview 477
Exceptions to export behavior 477
Import objects and object groups 478
Conflict resolution for duplicate configurations 479
Requirements and prerequisites for import/export 480
Guidelines for Import/Export 480
Export configurations 481
Import configurations 482

PART VIII Reporting and Alerting 485

CHAPTER 23 External Alerting with Alert Responses 487
Configuring external alerts with alert responses 487
External alert types 488
Prerequisites for external alerting with alert responses 488
Guidelines for notifying external systems with alert responses 488
Alert responses 489
Create an SNMP alert response 489
Syslog alert responses 491
SYSLOG alert facilities 491
Syslog severity levels 492
Create a syslog alert response 493
Create an email alert response 493
Create a webhook alert response 494
Troubleshoot external alerts and alert response configuration 495

CHAPTER 24 External Alerting for Intrusion Events 497
External alerts for intrusion events 497
License requirements for external alerting for intrusion events 498

Requirements for configuring external alerting for intrusion events 498
Configure SNMP alerting for intrusion events 498
Intrusion SNMP alert configuration options 499
Configure syslog alerting for intrusion events 500
Facility and severity values for intrusion syslog alerts 501
Configure email alerting for intrusion events 503
Intrusion email alert options 503

PART IX Event and Asset Analysis Tools 505

CHAPTER 25 Unified Events 507
Unified events 507
Work with unified events 507
Set a time range in unified events 510
Filters in unified events 511
Save a search in unified events 512
Load a saved search in unified events 513
Save a column set 513
Load a saved column set 514
Unified events column details 514

CHAPTER 26 Lookups 517
Lookups in Cloud-Delivered Firewall Management Center 517
Lookup IP address details using Whois 517

CHAPTER 27 Event searches 519
Search constraints 520
Best practice for general search constraints 520
Wildcards and symbols in searches 521
Objects and application filters in searches 521
Time constraints in searches 521
IP addresses in searches 522
URLs in searches 523
Managed devices in searches 523

Ports in searches 523
Perform a search 524
Save a search 524
Load a saved search 524

CHAPTER 28 Send Firewall Threat Defense Events to Cisco Splunk 527
Splunk integration: Send events directly from Cloud-Delivered Firewall Management Center 527
Guidelines and limitations for Splunk integration 527
Configure Splunk in Cloud-Delivered Firewall Management Center 528
Configure Splunk server 530
Select event types 530
Select devices and interfaces 531
Configure Firewall certificates for TLS 532
Review and submit the Splunk profile 532
Configure Secure Firewall App in Splunk 533

CHAPTER 29 Event Investigation Using Web-Based Resources 535
Event investigation using web-based resources 535
Manage contextual cross-launch resources 536
Requirements for custom contextual cross-launch resources 536
Add contextual cross-launch resources 536
Investigate events using contextual Cross-Launch 537

PART X Events and Assets 539

CHAPTER 30 Monitor Cloud-Delivered Firewall Management Center-Managed Threat Defense Device Events 541
About Security Analytics and Logging 541
Comparison of SAL Remote Event Storage and Monitoring Options 542
About SAL (OnPrem) 542
Licensing for SAL (OnPrem) 543
Manage SAL (OnPrem) for Security Cloud Control-Managed Firewall Threat Defense Devices 543
Configure SAL (OnPrem) Integration 545
Configure a Secure Network Analytics Manager 545
Configure a Secure Network Analytics Data Store 546

About Security Analytics and Logging(SaaS) for Firewall Threat Defense 548
Licensing for SAL (SaaS) 548
Configure the SAL (SaaS) Integration 548
Requirements and Guidelines 549
Send Cloud-Delivered Firewall Management Center-Managed Events to SAL (SaaS) Using Syslog 553
Send Cloud-Delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection 555
Enable Individual Threat Defense Devices to Send Events to SAL (SaaS) Using a Direct Connection 556
View and Work with Events in Security Cloud Control 557
View AI Defense Events in Security Cloud Control 558

CHAPTER 31 FTD Dashboard 559
About the FTD Dashboard 559
View the FTD Dashboard 560
FTD Dashboard Widgets 561
Top Intrusion Rules Widget 561
Top Intrusion Attackers Widget 561
Top Intrusion Targets Widget 562
Top Malware Signatures Widget 562
Top Malware Senders Widget 562
Top Malware Receivers Widget 562
Malware Events by Disposition Widget 562
Network Activity Widget 562
Event Activity Widget 562
Access Control Actions Widget 562
Top Access Control Policies Widget 562
Top Access Control Rules Widget 563
Top Devices Widget 563
Top Users Widget 563
Top Users by Blocked Connections Widget 563
Top Devices with Health Alerts Widget 563
Top Loaded Devices Widget 563

Top Web Applications Widget 563
Top Client Applications Widget 563
Top Blocked Web Applications Widget 563
Modify Time Settings for the FTD Dashboard 564

CHAPTER 32 **Connection Logging** 565
Connection logging 565
Logged connections 566
Other Connections You Can Log 567
Rules and policy actions effect on logging 568
Logging for fastpathed connections 568
Logging for monitored connections 568
Logging for trusted connections 569
Logging for blocked connections 569
Logging for allowed connections 571
Connection logging modes 572
Connection logging limitations 574
Best practices for connection logging 574
Requirements and prerequisites for connection logging 576
Connection logging 576
Logging connections with tunnel and prefilter rules 576
Configure logging for decryptable connections with TLS/SSLDecryption rules 577
Logging connections with security intelligence 578
Logging connections with access control rules 579
Logging connections with a policy default action 580
Limiting logging of long URLs 580
Application-aware and protocol-aware syslogs 581
Advanced logging guidelines and limitations 582
Enable advanced logging 582
Configure protocols for advanced logging 584
Monitor and troubleshoot advanced logging 585

CHAPTER 33 **Advanced Logging Syslog Fields** 587
Common fields 587

CONN protocol fields 588
DNS protocol fields 589
FTP fields 590
HTTP fields 591
Notice protocol fields 592
Weird protocol fields 592

CHAPTER 34 User Identity and Activity 595
User-related fields 595
Active sessions data 602
View active session data 602
User data 603
View user data 605
User activity data 606

PART XI High Availability and Scalability 611

CHAPTER 35 Multi-Instance Mode 613
Multi-instance mode 613
Multi-instance modes and appliance modes 613
Chassis management interface 614
Instance interfaces 614
Interface types 615
Chassis interfaces vs. instance interfaces 615
Shared interface scalability 617
Shared interface best practices 618
How the chassis classifies packets 620
Classification examples 621
Cascading container instances 621
Typical multi-instance deployments 622
Automatic MAC addresses for instance interfaces 623

Performance scaling factors for multi-instance modes 624
Instances and high availability 624
Licenses for instances 625
Requirements and prerequisites for instances 625
Guidelines and limitations for instances 626
Instance configuration 629
Convert a device to Multi-Instance mode 629
Chassis interface configuration 633
Configure a physical interface 633
Configure an EtherChannel 636
Configure a subinterface 640
Add an instance 642
System configuration customization 649
Configure SNMP 649
Import or export the chassis configuration 650
Chassis platform settings 652
Create a chassis platform settings policy 652
Configure DNS 653
Configure SSH and SSH access list 654
Configure syslog 659
Configure time synchronization 664
Configure time zones 666
Multi-instance mode management 667
Onboard the multi-instance chassis using the CLI 667
Change interfaces assigned to an instance 671
Change chassis management settings at the FXOS CLI 673
Multi-instance mode 676
Multi-instance setups 676
Instance interfaces 677

CHAPTER 36 **High Availability for Devices** 681
Secure Firewall Threat Defense high availability 681
High availability support on Firewall Threat Defense devices in a remote branch office deployment 682

High availability system requirements 682
Hardware requirements 682
Software requirements 683
License requirements for Firewall Threat Defense devices in a high availability pair 684
Failover and stateful failover links 684
Failover link 684
Stateful failover links 686
Failover and data link interruption avoidance 687
MAC addresses and IP addresses in High availability 688
Stateful failover 690
Supported features 691
Unsupported features 693
Bridge group requirements for high availability 693
Failover health monitoring 694
Unit health monitoring 694
Heartbeat module redundancy 695
Interface monitoring 695
Failover triggers and detection timing 697
Active/standby failover 698
Primary/secondary roles and active/standby status 699
Active unit determination at startup 699
Failover events 699
Config-sync optimization 700
Requirements and prerequisites for high availability 702
Guidelines for High availability 702
Add a high availability pair 705
Configure optional high availability parameters 708
Configure standby IP addresses and interface monitoring 708
Edit high availability failover criteria 709
Configure virtual MAC addresses 709
Manage High availability 710
Switch the Active Peer in the Firewall Threat Defense High Availability Pair 710
Refresh node status for a single Firewall Threat Defense high availability pair 711
Suspend and resume high availability 711

Replace a unit in Firewall Threat Defense high availability pair 712
Replace a Primary Firewall Threat Defense HA Unit with no Backup 712
Replace a Secondary Firewall Threat Defense HA Unit with no Backup 713
Break a high availability pair 714
Remove a High Availability Pair 716
Monitoring High availability 717
View failover history 717
View stateful failover statistics 717
High availability break troubleshooting in remote branch deployments 718
Break a high availability pair in active-active state 718
Break a high availability pair when active or standby unit has lost connectivity 720
Break a high availability pair when the secondary device is in a failed or disabled state 721

CHAPTER 37 **Clustering: Secure Firewall 3100/4200** 723
Clustering for the Secure Firewall 3100/4200 723
How a cluster fits into your network 723
Control and data node roles 724
Cluster interfaces 724
Cluster control links 724
Configuration replication 724
Management network 725
Licenses for clustering 725
Prerequisites for clustering 725
Guidelines for clustering 726
Clustering configuration 731
Cluster interfaces 731
Cluster control link 731
Spanned EtherChannels (Recommended) 734
Individual interfaces 737
Cable and add devices to the Cloud-Delivered Firewall Management Center 739
Create a Cluster 741
Configure interfaces 748
Configure spanned EtherChannels 748
Configure individual interfaces 749

Configure cluster health monitor settings 751
Configure distributed Site-to-Site VPN 756
Distributed site-to-site VPN 756
License for distributed site-to-site VPN 758
Prerequisites for distributed site-to-site VPN 758
Guidelines for distributed site-to-site VPN 759
Enable distributed site-to-site VPN 760
Redistribute distributed site-to-site VPN sessions 760
Cluster node management 762
Add a new cluster node 762
Break a node 764
Break the cluster 765
Disable clustering 766
Rejoin the cluster 767
Change the control node 767
Edit the cluster configuration 768
Reconcile cluster nodes 769
Unregister the Cluster or Nodes and Register to a New Cloud-Delivered Firewall Management Center 771
Monitor the cluster 772
Cluster health monitor dashboard 774
View cluster health 775
Cluster metrics 777
Troubleshoot the cluster 777
Perform a ping on the cluster control link 778
Clustering examples 780
Firewall on a stick 780
Traffic segregation 781
Reference for Clustering 782
Firewall Threat Defense features and clustering 782
Unsupported features with clustering 782
Centralized features for clustering 783
Connection settings and clustering 784
FTP and Clustering 784

Multicast routing in individual interface mode 784
NAT and clustering 784
Dynamic routing 786
Dynamic routing in individual interface mode 787
SIP inspection and clustering 788
SNMP and clustering 788
Syslog and clustering 788
Cisco TrustSec and clustering 788
VPN and clustering 788
Performance scaling factor 789
Control node election 789
High availability within clusters 790
Node health monitoring 790
Interface monitoring 790
Status after failure 791
Rejoin the cluster 791
Data path connection state replication 791
How the cluster manages connections 792
Connection roles 792
New connection ownership 793
Sample data flow for TCP 794
Sample data flows for ICMP and UDP 795
History for Clustering 796

CHAPTER 38 **Clustering: Private Cloud** 799
About clustering: private cloud 799
How the cluster fits into your network 799
Control and data node roles 800
Individual interfaces 800
Policy-based routing 801
Equal-cost multi-path routing 801
Cluster Control Link 802
Cluster control link traffic overview 802
Configuration replication 803

Management network 803
Licenses for clustering: Private cloud 803
Prerequisites for clustering: Private cloud 804
Guidelines for clustering: Private cloud 805
Configure clustering: private cloud 806
Add nodes to the Management Center 806
Create a cluster 806
Configure interfaces 813
Configure Cluster Health Monitor Settings 814
Manage cluster nodes 817
Add a new cluster node 817
Break a node 819
Break the cluster 820
Disable clustering 821
Rejoin the cluster 822
Change the control node 822
Edit the cluster configuration 823
Reconcile cluster nodes 824
Delete the cluster or nodes from the Management Center 825
Monitor cluster status 826
Cluster health monitor 828
View the cluster health monitor 829
Reference for clustering 832
Threat Defense features and clustering 832
Unsupported features and clustering 832
Centralized features for clustering 832
Connection settings and clustering 833
Dynamic routing and clustering 833
FTP and clustering 834
NAT and clustering 834
SIP inspection and clustering 836
SNMP and clustering 836
Syslog and clustering 836
Cisco trustsec and clustering 836

VPN and clustering 836
Performance scaling factor 837
Control node election 837
High availability within the cluster 838
Node health monitoring 838
Interface monitoring 838
Status after failure 838
Rejoining the cluster 839
Data path connection state replication 839
How the cluster manages connections 840
Connection roles 840
New connection ownership 841
Sample data flow for TCP 841
Sample data flow for ICMP and UDP 842
History for clustering: private cloud 844

CHAPTER 39 **Clustering: Public Cloud** 845
About Threat Defense Virtual clustering in the public cloud 845
How the cluster fits into your network 846
Individual interfaces 846
Control and data node roles 847
Cluster Control Link 847
Cluster control link traffic overview 848
Configuration replication 848
Management network 848
Licenses for Threat Defense Virtual clustering 848
Requirements and prerequisites for Threat Defense Virtual clustering 849
Guidelines for Threat Defense Virtual clustering 851
Deploy the cluster in AWS 852
AWS gateway load balancer and Geneve single-arm proxy 852
Sample topology 853
End-to-end process for deploying Threat Defense Virtual cluster on AWS 854
Templates 856
Deploy the Stack in AWS Using a CloudFormation template 856

Manual cluster deployment in AWS 869
Create the Day0 configuration for AWS 869
Deploy cluster nodes 871
Deploy the cluster in Azure 872
Sample topology for GWLB-based cluster deployment 872
Azure gateway load balancer and paired proxy 873
End-to-end process for deploying Threat Defense Virtual cluster in Azure with GWLB 874
Templates 876
Prerequisites for Azure GWLB cluster deployment 876
Deploy cluster on Azure with GWLB using an Azure resource manager template 876
Sample topology for NLB-based cluster deployment 879
End-to-end process for deploying Threat Defense Virtual cluster in Azure with NLB 880
Templates 882
Prerequisites for Azure NLB cluster deployment 882
Deploy cluster on Azure with NLB using an Azure resource manager template 883
Manual cluster deployment in Azure 885
Create the Day0 configuration for Azure 885
Deploy cluster nodes manually - GWLB-based deployment 887
Deploy cluster nodes manually - NLB-based deployment 888
Troubleshoot cluster deployment in Azure 889
Deploy the cluster in GCP 891
Sample topology for GCP clustering autoscale solution 891
End-to-end process for deploying Threat Defense Virtual cluster in GCP 892
Templates 893
Deploy the instance group in GCP using an instance template 893
Manual cluster deployment in GCP 895
Create the Day0 configuration with a fixed configuration for GCP 895
Deploy cluster nodes manually 896
Allow health checks for GCP network load balancers 897
Add the cluster to the Management Center (manual deployment) 898
Onboard a Secure Firewall Threat Defense Cluster 904
Edit cluster health monitor settings 907
Manage cluster nodes 910
Disable clustering 910

Rejoin the cluster 911
Reconcile Cluster Nodes 911
Unregister the cluster or nodes and register with a new Cloud-Delivered Firewall Management Center 912
Monitor cluster status 913
Cluster health monitor 915
View the cluster health monitor 916
Upgrade the cluster 919
Reference for clustering 919
Threat Defense features and clustering 919
Unsupported features and clustering 920
Centralized features for clustering 920
Cisco Trustsec and clustering 920
Connection settings and clustering 921
Dynamic routing and clustering 921
FTP and clustering 922
NAT and clustering 922
SIP inspection and clustering 924
SNMP and clustering 924
Syslog and clustering 924
VPN and Clustering 924
Performance scaling factor 925
Control node election 925
High availability within the cluster 926
Node health monitoring 926
Interface monitoring 926
Status after failure 926
Rejoining the cluster 927
Data path connection state replication 927
How the cluster manages connections 928
Connection roles 928
New connection ownership 929
Sample data flow for TCP 929
Sample data flow for ICMP and UDP 930

History for Threat Defense Virtual clustering in the public cloud 932

CHAPTER 40 **Clustering: Firepower 4100/9300** 935

About clustering on the Firepower 4100/9300 chassis 935

Bootstrap configuration 936

Cluster members 936

Cluster control link 936

Size the cluster control link 937

Cluster control link redundancy 937

Cluster control link reliability for inter-chassis clustering 938

Cluster control link network 938

Management network 938

Management interface 938

Cluster interfaces 938

Spanned EtherChannels 939

Configuration replication 939

Licenses for clustering 939

Requirements and prerequisites for clustering 940

Clustering guidelines and limitations 944

Configure clustering 947

FXOS: Add a Firewall Threat Defense cluster 947

Create a Firewall Threat Defense cluster 947

Add more cluster nodes 950

Cloud-Delivered Firewall Management Center: Add a cluster 951

Cloud-Delivered Firewall Management Center: Configure cluster, data interfaces 957

Cloud-Delivered Firewall Management Center: Configure Cluster Health Monitor Settings 959

FXOS: Remove a cluster node 962

Cloud-Delivered Firewall Management Center: Manage cluster members 964

Add a new cluster member 964

Replace a cluster member 964

Deactivate a member 966

Rejoin the cluster 967

Unregister a data node 967

Change the control unit 968

Reconcile cluster members 969
Cloud-Delivered Firewall Management Center: Monitor the cluster 969
Cluster Health Monitor Dashboard 972
Viewing cluster health 973
Cluster metrics 975
Examples for Clustering 976
Firewall on a stick 976
Traffic segregation 976
Reference for clustering 977
Firewall Threat Defense features and clustering 977
Unsupported features with clustering 977
Centralized features for clustering 978
Connection settings 978
Dynamic routing and clustering 979
FTP and clustering 979
Multicast routing and clustering 979
NAT and clustering 979
SIP inspection and clustering 981
SNMP and clustering 981
Syslog and clustering 981
TLS/SSL connections and clustering 981
Cisco TrustSec and clustering 981
VPN and clustering 981
Performance scaling factor 982
Control unit election 982
High availability within the cluster 983
Chassis-application monitoring 983
Unit health monitoring 983
Interface monitoring 983
Decorator application monitoring 984
Status after failure 984
Rejoining the cluster 984
Data path connection state replication 985
How the cluster manages connections 985

Connection roles 985
New connection ownership 987
Sample data flow for TCP 987
Sample data flow for ICMP and UDP 988
History for clustering 989

PART XII **Interfaces and Device Settings** 995

CHAPTER 41 **Interface Overview** 997
Management interface 997
Management interface 997
Diagnostic interface 998
Interface Mode and Types 999
Security zones and interface groups 999
Auto-MDI/MDIX feature 1001
Redundant interfaces (deprecated) 1001
Default settings for interfaces 1001
Create security zone and interface group objects 1002
Enable the physical interface and configure Ethernet settings 1003
Configure EtherChannel interfaces 1006
About EtherChannels 1006
EtherChannels 1006
Guidelines for EtherChannels and redundant interfaces 1009
Configure an EtherChannel 1011
Sync Interface Changes with the Cloud-Delivered Firewall Management Center 1014
Network module management for Secure Firewall 3100/4200 1015
Configure breakout ports 1016
Add a network module 1020
Hot swap the network module 1022
Replace the network module with a different type 1024
Remove the network module 1028
Merge the management and diagnostic interfaces 1030
Unmerge the management interface 1034
History for interfaces 1035

CHAPTER 42 **Regular Firewall Interfaces** 1039

Requirements and prerequisites for regular firewall interfaces 1039
Configure switch ports 1040
About switch ports 1040
Switch ports and interfaces 1040
Auto-MDI/MDIX feature 1041
Prerequisites for switch ports 1041
Guidelines for switch ports 1041
Configure switch ports and power over ethernet 1043
Enable or disable switch port mode 1043
Configure a VLAN interface 1044
Configure switch ports as access ports 1046
Configure switch ports as trunk ports 1048
Configure Power over Ethernet 1051
Loopback interfaces 1052
Guidelines for Loopback Interfaces 1053
Configure a loopback interface 1053
Rate-Limit traffic to the loopback interface 1054
VLAN subinterfaces and 802.1Q trunking 1058
Guidelines for VLAN subinterfaces 1058
Maximum number of VLAN subinterfaces by device model 1059
Add a subinterface 1060
Configure VXLAN Interfaces 1062
VXLAN interfaces 1062
encapsulation 1062
VXLAN tunnel endpoints 1062
VTEP source interface 1063
VNI interfaces 1063
How VXLAN and Geneve packets are processed 1064
Peer VTEPs 1065
VXLAN use cases 1066
Requirements and prerequisites for VXLAN interfaces 1070
Guidelines for VXLAN interfaces 1070

Configure VXLAN or Geneve interfaces 1071
Configure VXLAN interfaces 1071
Configure geneve interfaces 1074
Allow gateway load balancer health checks 1076
Configure routed and transparent mode interfaces 1077
Routed and transparent mode interfaces 1077
Dual IP stack (IPv4 and IPv6) 1077
31-bit subnet masks 1077
Guidelines and limitations for routed and transparent mode interfaces 1078
Configure routed mode interfaces 1080
Bridge group interfaces 1086
Configure general bridge group member interface parameters 1086
Configure the bridge virtual interface (BVI) 1088
Configure IPv6 addressing 1090
About IPv6 1090
IPv6 prefix delegation client configuration 1091
Configure a global IPv6 address 1095
Configure IPv6 neighbor discovery 1099
Advanced interface settings 1103
About advanced interface configuration 1103
MAC addresses 1103
MTU 1104
TCP MSS 1106
ARP inspection for bridge group traffic 1107
MAC address tables 1108
Default settings 1108
Guidelines for ARP inspection and the MAC address table 1108
Configure the MTU 1109
Configure the MAC address 1110
Add a static ARP entry 1111
Add a static MAC address and disable MAC learning for a bridge group 1112
Set security configuration parameters 1112
History for Regular Firewall Interfaces 1115

CHAPTER 43 **Inline Sets and Passive Interfaces** 1119

IPS interfaces 1119

Inline sets 1119

Multiple inline pairs and asynchronous routing 1120

Passive interfaces 1121

Hardware Bypass for inline sets 1122

Hardware Bypass triggers 1122

Hardware bypass switchover 1122

Snort Fail Open vs. Hardware Bypass 1123

Hardware Bypass status 1123

Requirements and prerequisites for inline sets 1123

Guidelines for configuring inline sets and passive interfaces 1125

Configure a passive interface 1127

Configure Inline Sets 1128

CHAPTER 44 **Device Settings** 1133

Edit general settings 1133

Copy a configuration to another device 1135

Export and import the device configuration 1136

Edit license settings 1140

View system information 1141

View device inventory 1142

View the inspection engine 1142

Edit health settings 1143

Out-of-band configuration detection 1143

Guidelines for out-of-band configuration 1144

Access recovery-config mode in the diagnostic CLI 1146

Acknowledge the out-of-band configuration 1149

Edit management settings 1153

Configure a redundant manager access data interface 1153

Change manager access interface settings 1158

Change the device IP address 1158

Change the Cloud-Delivered Firewall Management Center IP Address 1169

Change both Cloud-Delivered Firewall Management Center and Threat Defense IP addresses 1171
Change the manager access interface 1174
Troubleshoot the management connection 1181
Manually Roll Back the configuration if the Cloud-Delivered Firewall Management Center loses Connectivity 1181
Troubleshoot Management Connectivity on a Data Interface 1183
Troubleshoot management connectivity on a data interface in a High Availability pair 1184
View inventory details 1186
Edit applied policies 1186
Edit advanced settings 1188
Configure automatic application bypass 1189
Configure object group search 1190
Configure interface object optimization 1192
Edit deployment settings 1192
Edit cluster health monitor settings 1195
Hot swap an SSD 1198
Disable the USB port 1201
Disable the USB port on a device 1201
Disable the USB port in multi-instance mode 1202
Configure SNMP for FXOS 1204
Enable SNMP for FXOS 1204
Create an SNMP Trap for FXOS 1205
Create an SNMP user for FXOS 1207
Configure alarms for the ISA 3000 1207
About alarms 1208
Alarm input interfaces 1208
Alarm output interface 1209
Syslog alarms 1209
SNMP Alarms 1209
Defaults for alarms 1209
Prerequisites for alarms 1210
Configure alarms for the ISA 3000 1210
Configure alarm input contacts 1210
Configure power supply alarms 1213

Configure temperature alarms 1215
Turn off the external alarm 1218
Monitoring alarms 1218
Monitoring alarm status 1218
Monitoring syslog messages for alarms 1218
History for Device Settings 1219

CHAPTER 45 DHCP and DDNS 1223
About DHCP and DDNS services 1223
DHCPv4 servers 1223
DHCP options 1224
DHCPv6 stateless server 1224
DHCP relay agents 1225
Requirements and prerequisites for DHCP and DDNS 1225
Guidelines for DHCP and DDNS services 1225
Configure the DHCPv4 server 1227
DHCPv6 stateless server configuration 1229
Create a DHCP IPv6 pool 1229
Enable the DHCPv6 stateless server 1232
Configure the DHCP relay agent 1233
Configure Dynamic DNS 1234
History for DHCP and DDNS 1239

CHAPTER 46 Platform Settings 1241
Platform settings policies 1242
List requirements and prerequisites for platform settings policies 1242
Manage platform settings policies 1243
Configure ARP inspection 1244
Configure a banner 1245
Configure DNS server settings 1246
Configure external authentication 1249
Configure an LDAP External Authentication Object 1251
Configure a RADIUS Authentication Object 1253
Enable a virtual-router-aware interface for platform external authentication 1255

Configure fragment settings 1256
Configure HTTP access 1257
Configure ICMP access 1258
Configure NetFlow 1260
Add a collector in NetFlow 1260
Add a traffic class to NetFlow 1261
Configure Secure Shell (SSH) access 1262
Configure an SMTP server 1264
Configure SNMP for a security device 1264
SNMP protocol 1266
List SNMP terminology 1266
Describe MIBs and traps 1267
List of supported tables and objects in MIBs 1267
Add SNMPv3 users 1271
Add SNMP hosts 1274
Configure SNMP traps 1276
Configure SSL Settings 1278
Configure SSL settings 1279
Syslog 1283
Syslog messages 1283
Syslog message severity levels 1284
Syslog message filters 1285
Syslog message classes and associated message ID numbers 1285
Guidelines for logging 1288
Configure syslog logging for Firewall Threat Defense devices 1290
Firewall Threat Defense platform settings that apply to security event syslog messages 1291
Configure logging and basic settings 1291
Enable logging destinations 1293
Configure syslog messages to be sent to an e-mail address 1294
Create a custom event list 1295
Configure syslog rate limits 1296
Configure syslog settings 1297
Configure a syslog server 1298
Configure timeouts 1301

Synchronize time on FTD devices 1303
Configure a time zone for a device 1304
Configure UCAPL/CC compliance 1305
Configure a performance profile 1306

CHAPTER 47 FlexConfig policies 1309
FlexConfig policy overview 1309
Recommended usage for FlexConfig policies 1310
CLI commands in FlexConfig objects 1310
Determine the ASA software version and current CLI configuration 1311
Prohibited CLI commands 1312
Template scripts 1314
FlexConfig variables 1314
Variable processing 1315
Evaluate device variable results 1318
FlexConfig policy object variables 1320
FlexConfig system variables 1321
Predefined FlexConfig objects 1322
Predefined text objects 1327
Requirements and prerequisites for FlexConfig policies 1330
Guidelines and limitations for FlexConfig 1331
Customize device configuration with FlexConfig policies 1331
Configure FlexConfig objects 1333
Add a policy object variable to a FlexConfig object 1336
Configure secret keys 1337
Configure FlexConfig text objects 1337
Configure the FlexConfig policy 1339
Set target devices for a FlexConfig policy 1340
Preview the FlexConfig policy 1341
Verify the deployed configuration 1342
Remove features configured using FlexConfig 1344
Convert from FlexConfig to managed feature 1345
Examples for FlexConfig 1346
Configure precision time protocol (ISA 3000) 1346

Configure automatic hardware bypass for power failure (ISA 3000) 1350
Migrate FlexConfig policies 1352

PART XIII **Routing** 1355

CHAPTER 48 **Static and Default Routes** 1357
Static and default routes overview 1357
Default routes 1357
Static routes 1358
Route to null0 interface to drop unwanted traffic 1358
Route priorities 1358
Transparent firewall mode and bridge group routes 1359
Static route tracking 1359
Requirements and prerequisites for static routes 1360
Guidelines for static and default routes 1360
Add a static route 1361
Reference for routing 1362
Path determination 1362
Supported route types 1363
Static versus dynamic routing algorithms 1363
Single-path versus multipath 1363
Flat versus hierarchical routing 1363
Link-state versus distance vector 1364
Supported internet protocols for routing 1364
Routing tables 1365
How the routing table is populated 1365
How forwarding decisions are made 1367
Dynamic routing and High availability 1368
Dynamic routing in Clustering 1368
Dynamic routing in individual interface mode 1369
Routing table for management traffic 1370
Equal-cost multi-path routing 1371
Routing GRE traffic 1372
About route maps 1372

Permit and deny clauses 1372
Match and set clause values 1373

CHAPTER 49 Virtual Routers 1375
Virtual routers and virtual routing and forwarding (VRF) 1375
Virtual router applications 1376
Global and user-defined virtual routers 1376
Virtual-router-aware policies 1377
Virtual router interconnection 1378
Best practice for overlapping IP addresses 1380
Configuring SNMP on user-defined virtual routers 1381
Maximum number of virtual routers by device model 1381
Requirements and prerequisites for virtual routers 1383
Guidelines and limitations for virtual routers 1383
Manage virtual routers 1386
Create a virtual router 1386
Configure a virtual router 1387
Modify a virtual router 1388
Remove Virtual Routers 1389
Monitor virtual routers 1390
Configuration examples for virtual routers 1390
Route to a distant server through virtual routers 1390
How to Provide Internet Access with Overlapping Address Spaces 1395
Allow RA VPN access to internal networks in virtual routing 1402
Secure traffic from networks in multiple virtual routers over a site-to-site VPN 1405
Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI 1409
Route traffic between two overlapping network hosts in virtual routing 1411
Manage overlapping segments in routed firewall mode with BVI interfaces 1414
Configure user authentication with overlapping networks 1418
Interconnect virtual routers using BGP 1424

CHAPTER 50 ECMP 1431
ECMP routing methods 1431

Guidelines and limitations for ECMP 1432
Manage ECMP zones for virtual routers 1433
Create an ECMP zone 1433
Configure an equal cost static route 1434
Modify an ECMP zone 1435
Remove an ECMP zone 1436
Configure ECMP zones on your device 1436

CHAPTER 51 **Bidirectional Forwarding Detection Routing** 1441
BFD routing protocol 1441
Guidelines for BFD routing 1442
Configure BFD 1443
Configure BFD policies 1443
Configure a single-hop BFD policy 1444
Configure a multi-hop BFD policy 1445
History for BFD routing 1446

CHAPTER 52 **OSPF** 1447
OSPF 1447
OSPF routing 1447
OSPF support for fast hello packets 1449
OSPF fast hello packets configuration prerequisites 1449
OSPF hello interval and dead interval 1449
OSPF fast hello packets 1449
Benefits of OSPF fast hello packets 1450
OSPFv2 and OSPFv3 implementation differences 1450
Requirements and prerequisites for OSPF 1451
Guidelines for OSPF 1451
OSPFv2 configuration 1454
Configure OSPF areas, ranges, and virtual links 1454
Configure OSPF redistribution 1457
Configure OSPF Inter-Area filtering 1459
Configure OSPF filter rules 1460
Configure OSPF summary addresses 1461

Configure OSPF interfaces and neighbors 1462
Configure OSPF Advanced Properties 1465
OSPFv3 configuration 1467
Configure OSPFv3 Areas, Route Summaries, and Virtual Links 1467
Configure OSPFv3 redistribution 1470
Configure OSPFv3 summary prefixes 1471
Configure OSPFv3 interfaces, authentication, and neighbors 1472
Configure OSPFv3 Advanced Properties 1475
History for OSPF 1477

CHAPTER 53 EIGRP 1479
EIGRP routing 1479
Requirements and prerequisites for EIGRP 1480
Guidelines and limitations for EIGRP routing 1481
Configure EIGRP routing on firewall devices 1482
Configure EIGRP settings 1483
Configure EIGRP neighbors settings 1483
Configure EIGRP filter rules 1484
Configure EIGRP redistribution settings 1485
Configure EIGRP summary address settings 1486
Configure EIGRP interfaces settings 1487
Configure EIGRP advanced settings 1488

CHAPTER 54 BGP 1491
BGP 1491
Routing tables 1491
BGP usage scenarios 1492
BGP path selection 1493
BGP multipath 1493
Requirements and prerequisites for BGP 1495
Guidelines for BGP 1495
Configure BGP 1496
Configure basic BGP settings 1497
Configure BGP general settings 1499

Configure BGP Neighbor Settings 1500
Configure BGP aggregate address settings 1504
Configure BGPv4 filtering settings 1505
Configure BGP network settings 1506
Configure BGP redistribution settings 1507
Configure BGP route injection settings 1508
Configure BGP route import and export 1509

CHAPTER 55 RIP 1513
RIP 1513
How RIP routing updates work 1514
RIP routing metric 1514
RIP stability features 1514
RIP timers 1515
Requirements and prerequisites for RIP 1516
Guidelines for RIP 1516
Configure RIP 1517

CHAPTER 56 Multicast 1521
Multicast routing 1521
IGMP Protocol 1522
Stub multicast routing 1522
PIM multicast routing 1523
PIM sparse mode 1523
PIM source specific multicast support 1523
Multicast Bidirectional PIM 1524
PIM bootstrap router (BSR) 1524
PIM bootstrap router (BSR) terminology 1525
Multicast group concept 1525
Multicast Addresses 1526
Clustering 1526
Prerequisites for Multicast Routing 1526
Guidelines for multicast routing 1526
Configure IGMP features 1527

Enable multicast routing 1528
Configure IGMP protocol 1529
Configure IGMP access groups 1530
Configure IGMP static groups 1531
Configure IGMP join groups 1531
Configure PIM features 1532
Configure PIM protocol 1533
Configure PIM neighbor filters 1534
Configure PIM bidirectional neighbor filters 1534
Configure PIM rendezvous points 1535
Configure PIM route trees 1536
Configure PIM request filters 1537
Configure the Firewall Threat Defense device as a candidate bootstrap router 1538
Configure multicast routes 1538
Configure multicast boundary filters 1539

CHAPTER 57 **Policy-Based Routing** 1541
About policy-based routing 1541
Licenses for policy-based routing 1543
Best practices for policy-based routing 1543
Path monitoring metrics for best path route determination 1545
Configure path monitoring settings 1547
Add path monitoring dashboard 1548
Configure policy-based routing policy 1548
Configure policy-based routing 1551
Configure PBR with path monitoring 1556
Useful CLIs for monitoring PBR 1558
Troubleshoot PBR 1560

PART XIV **Network Policies** 1565

CHAPTER 58 **Network Address Translation** 1567
NAT functions 1567
NAT basics 1568

NAT terminology 1568
NAT types 1568
NAT in routed and transparent mode 1569
NAT in routed mode 1569
NAT in transparent mode or within a bridge group 1570
Auto NAT and Manual NAT 1571
Auto NAT 1571
Manual NAT 1571
Comparing Auto NAT and Manual NAT 1572
NAT rule order 1572
NAT interfaces 1574
NAT exemption 1575
Configuring routing for NAT 1575
Addresses on the same network as the mapped interface 1576
Addresses on a unique network 1576
The same address as the real address (identity NAT) 1576
Requirements and prerequisites for NAT policies 1577
Guidelines for NAT 1577
Firewall mode guidelines for NAT 1577
IPv6 NAT guidelines 1578
IPv6 NAT best practices 1578
NAT support for inspected protocols 1578
FQDN destination guidelines 1580
Additional guidelines for NAT 1581
Manage NAT policies 1583
Create NAT policies 1584
Configure NAT policy targets 1584
Configure NAT for threat defense 1585
Customize NAT rules for multiple devices 1587
Search and filter the NAT rule table 1589
Enable, disable, or delete multiple rules 1590
NAT templates 1590
Create a NAT rule for internal hosts 1591
Create a NAT rule for external hosts 1592

Dynamic NAT 1593
About dynamic NAT 1593
Dynamic NAT disadvantages and advantages 1594
Configure dynamic auto NAT 1594
Configure dynamic manual NAT 1596
Dynamic PAT 1598
About dynamic PAT 1598
Dynamic PAT disadvantages and advantages 1599
PAT pool object guidelines 1599
Configure dynamic auto PAT 1600
Configure dynamic manual PAT 1602
Configure PAT with port block allocation 1605
Static NAT 1608
About static NAT 1608
Configure static auto NAT 1612
Configure static manual NAT 1614
Identity NAT 1617
Configure identity auto NAT 1618
Configure identity manual NAT 1619
NAT rule properties for Firewall Threat Defense 1621
Interface objects NAT properties 1622
Translation properties for auto NAT 1623
Translation properties for manual NAT 1624
PAT pool NAT properties 1625
Advanced NAT properties 1626
Translating IPv6 networks 1627
NAT64/46: translating IPv6 addresses to IPv4 1628
NAT64/46 example: inside IPv6 network with outside IPv4 internet 1628
NAT64/46 example: inside IPv6 network with outside IPv4 internet and DNS translation 1630
NAT66: translating IPv6 addresses to different IPv6 addresses 1634
NAT66 example, static translation between networks 1634
NAT66 example, simple IPv6 interface PAT 1637
Monitoring NAT 1640
Examples for NAT 1641

Providing access to an inside web server (static auto NAT) 1641
Dynamic auto NAT for inside hosts and static NAT for an outside web server 1643
Configure inside load balancer with multiple mapped addresses 1650
Single address for FTP, HTTP, and SMTP (static auto NAT with port translation) 1652
Different translation depending on the destination (dynamic manual PAT) 1660
Configure dynamic manual PAT with different destination ports 1666
NAT and site-to-site VPN 1672
DNS query and response rewriting using NAT 1677
DNS64 reply modification 1678
Create DNS reply modification with DNS server on outside 1685
Configure DNS reply modification with DNS server on host network 1688

CHAPTER 59 **Quality of Service** 1693
QoS 1693
QoS policies 1694
Requirements and prerequisites for QoS 1694
Guidelines and limitations for QoS policies 1695
Rate limiting with QoS policies 1695
Create a QoS policy 1696
Set target devices for a QoS policy 1696
Filter QoS rules by device 1697
Configuring QoS rules 1698
QoS rule components 1699
QoS rule conditions 1700
Interface rule conditions 1700
Network rule conditions 1701
User rule conditions 1701
Application rule conditions 1701
Best practice: use application-based rules over port-based rules 1703
Recommendation: use URL conditions for website access control 1704
Custom SGT rule conditions 1704
ISE SGT versus custom SGT rule conditions 1705
Autotransition from custom Security Group Tags to ISE Security Group Tags 1705

PART XV Secure Connections 1707

CHAPTER 60 Secure Connections Overview 1709

VPN types 1709
VPN basics 1710
Internet Key Exchange (IKE) 1711
IPsec 1712
VPN packet flow 1713
IPsec flow offload 1713
VPN licensing 1714
VPN encryption and performance 1714
Comply with security certification requirements 1714
Decide encryption algorithms for VPN policies 1715
Decide which hash algorithms to use 1715
Decide which Diffie-Hellman modulus group to use 1716
Decide VPN authentication methods 1717
Pre-shared keys 1717
PKI infrastructure and digital certificates 1718
Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups 1720
VPN topologies 1720
Point-to-point VPN topologies 1720
Hub and spoke VPN topology 1721
Full mesh VPN topology 1722
Implicit topologies 1723

CHAPTER 61 Site-to-Site VPN 1725

Site-to-site VPN 1725
Guidelines for configuring site-to-site VPN in Secure Firewall Threat Defense devices 1727
Limitations for configuring site-to-site VPN in Threat Defense devices 1727
Types of site-to-site VPN topologies 1728
License requirements for site-to-site VPN 1728
Prerequisites for site-to-site VPN 1729
Manage site-to-site VPNs 1730

Configure a policy-based site-to-site VPN 1731
Firewall Threat Defense VPN endpoint options 1732
Firewall Threat Defense VPN IKE options 1736
Firewall Threat Defense VPN IPsec options 1739
Firewall Threat Defense advanced site-to-site VPN deployment options 1741
Firewall Threat Defense VPN advanced IKE options 1741
Firewall Threat Defense VPN advanced IPsec options 1743
Firewall Threat Defense advanced site-to-site VPN tunnel options 1743
Configure virtual tunnel interfaces 1745
Virtual tunnel interfaces 1745
Static VTI 1746
Dynamic VTI 1747
Guidelines for virtual tunnel interfaces 1749
Limitations for Virtual Tunnel Interfaces 1752
Add a VTI interface 1752
Create a route-based site-to-site VPN 1754
Configure endpoints for a point-to-point VPN topology 1755
Configure endpoints for a hub and spoke topology 1757
Configure multiple hubs in a route-based VPN 1761
Route traffic through a backup VTI tunnel 1764
Configure dynamic VTI for a route-based site-to-site VPN 1765
Configure a virtual router with dynamic VTI 1765
Configure routing and AC policies for VTI 1766
View virtual tunnel interface details 1769
Deploy a SASE tunnel on Umbrella 1769
Guidelines for configuring SASE tunnels on Umbrella 1769
Limitations for configuring SASE tunnels on Umbrella 1770
Deploy a SASE tunnel on Umbrella 1770
Prerequisites for configuring Umbrella SASE tunnels 1771
Map Management Center Umbrella parameters and Cisco Umbrella API keys 1771
Configure a SASE tunnel for Umbrella 1773
Secure traffic using Cisco Secure Access and Firewall Threat Defense devices 1776
Licenses for automatic tunnel between Secure Access and Firewall Threat Defense devices 1776
Prerequisites for an automatic tunnel between Secure Access and Firewall Threat Defense devices 1777

Guidelines for an automatic tunnel between Secure Access and Firewall Threat Defense devices 1777
Limitation for automatic tunnel between Secure Access and Firewall Threat Defense devices 1777
Configure automatic tunnel between Secure Access and Firewall Threat Defense devices using SASE wizard 1778
Validate Secure Access integration with Firewall Threat Defense devices 1780
Monitor site-to-site topologies 1781
Monitor site-to-site VPNs using Site-to-Site VPN summary page 1781
Monitor site-to-site VPNs using Site-to-Site VPN dashboard 1781
Tunnel status widget 1782
Site-to-site VPN connection event monitoring 1785
View site-to-site VPN connection events 1786

CHAPTER 62 SD-WAN 1787
SD-WAN capabilities 1787
SD-WAN features 1788
SD-WAN wizard for secure branch network deployment 1789
Guidelines for using SD-WAN wizard 1790
Limitations for using SD-WAN wizard 1791
License requirements to use the SD-WAN wizard 1791
Prerequisites for using SD-WAN wizard 1792
Configure an SD-WAN topology using the SD-WAN wizard 1792
Add a dynamic virtual tunnel interface for a hub 1797
Sample configurations for dual-ISP deployment using SD-WAN wizard 1797
Dual ISP deployment: Two hubs and four spokes in the same region 1798
Dual ISP deployment: Two hubs and four spokes in different regions 1799
Verify tunnel statuses of an SD-WAN topology 1802
Monitor SD-WAN topologies 1805
SD-WAN summary dashboard 1805
Prerequisites for using SD-WAN summary dashboard 1806
Monitor WAN devices and interfaces using the SD-WAN summary dashboard 1807
Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard 1809

CHAPTER 63 Remote Access VPN 1811

Remote Access VPN Overview 1811
Remote Access VPN Features 1812
Secure Client Components 1814
Remote Access VPN Authentication 1814
Understanding Policy Enforcement of Permissions and Attributes 1816
Understanding AAA Server Connectivity 1816
License Requirements for Remote Access VPN 1817
Requirements and Prerequisites for Remote Access VPN 1817
Remote Access VPN Guidelines and Limitations 1818
Configuring a New Remote Access VPN Connection 1821
Prerequisites for Configuring Remote Access VPN 1822
Create a New Remote Access VPN Policy 1822
Update the Access Control Policy on the Secure Firewall Threat Defense Device 1825
(Optional) Configure NAT Exemption 1826
Configure DNS 1827
Add Secure Client Profile XML File 1827
(Optional) Configure Split Tunneling 1828
(Optional) Configure Dynamic Split Tunneling 1829
Verify Dynamic Split Tunneling Configuration 1830
Verify the Configuration 1830
Create a Copy of an Existing Remote Access VPN Policy 1831
Set Target Devices for a Remote Access VPN Policy 1831
Associate Local Realm with Remote Access VPN Policy 1832
Additional Remote Access VPN Configurations 1832
Configure Connection Profile Settings 1832
Configure IP Addresses for VPN Clients 1833
Configure AAA Settings for Remote Access VPN 1835
Create or Update Aliases for a Connection Profile 1850
Configure Access Interfaces for Remote Access VPN 1851
Configure Advanced Options for Remote Access VPN 1853
Cisco Secure Client Image 1853
Remote Access VPN Address Assignment Policy 1855
Configure Certificate to Connection Profile Mapping 1856
Configure Group Policies 1857

Configuring LDAP Attribute Mapping 1858
Configuring VPN Load Balancing 1859
Configure IPsec Settings 1862
Customize Cisco Secure Client 1868
Configure Secure Client Management VPN Tunnel 1881
Requirements and Prerequisites for Secure Client Management VPN Tunnel 1881
Limitations of Secure Client Management VPN Tunnel 1882
Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense 1882
Multiple Certificate Authentication 1884
Guidelines and Limitations of Multiple Certificate Authentication 1884
Configuring Multiple Certificate Authentication 1885
Manage VPN Access of Remote Users Based on Geolocation 1886
Workflow to Manage VPN Access of Remote Users Based on Geolocation 1886
Guidelines and Limitations for Managing Remote Access VPN Users Based on Geolocation 1886
Monitor and Troubleshoot Service Access Policies 1887
Customizing Remote Access VPN AAA Settings 1890
Authenticate VPN Users via Client Certificates 1890
Configure VPN User Authentication via Client Certificate and AAA Server 1891
Manage Password Changes over VPN Sessions 1893
Send Accounting Records to the RADIUS Server 1894
Delegating Group Policy Selection to Authorization Server 1894
Override the Selection of Group Policy or Other Attributes by the Authorization Server 1895
Deny VPN Access to a User Group 1896
Restrict Connection Profile Selection for a User Group 1897
Update the Secure Client Profile for Remote Access VPN Clients 1898
RADIUS Dynamic Authorization 1899
Configuring RADIUS Dynamic Authorization 1899
Two-Factor Authentication 1900
Configuring RSA Two-Factor Authentication 1900
Configuring Duo Two-Factor Authentication 1901
Secondary Authentication 1903
Configure Remote Access VPN Secondary Authentication 1904
Single Sign-On Authentication with SAML 2.0 1906
Guidelines and Limitations for SAML 2.0 1906

Configuring a SAML Single Sign-On Authentication 1908
Configuring SAML Authorization 1909
Advanced Secure Client Configurations 1910
Configure Secure Client Modules on a Firewall Threat Defense 1910
Types of Secure Client Modules 1911
Prerequisites for Configuring Secure Client Modules 1912
Guidelines for Configuring Secure Client Modules 1913
Install Secure Client Modules using a Firewall Threat Defense 1914
Configure a Remote Access VPN Group Policy with Secure Client Modules 1914
Verify Secure Client Modules Configuration 1915
Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices 1916
Prerequisites and Licensing for Configuring Per App VPN Tunnels 1916
Determine the Application IDs for Mobile Applications 1917
Configure Application-Based VPN Tunnels 1917
Verify Per App Configuration 1919
Remote Access VPN Examples 1919
How to Limit Secure Client Bandwidth Per User 1919
How to Use VPN Identity for User-Id Based Access Control Rules 1920
Configure Firewall Threat Defense Multiple Certificate Authentication 1920
Monitor Remote Access VPNs 1924
Remote Access VPN Dashboard 1924
VPN Session and User Information 1926
Viewing Remote Access VPN Active Sessions 1926
Viewing Remote Access VPN User Activity 1926

CHAPTER 64 **Dynamic Access Policies** 1927
Firewall Threat Defense dynamic access policies 1927
Hierarchy of policy enforcement of permissions and attributes in a Firewall Threat Defense device 1928
Prerequisites for dynamic access policy 1929
Guidelines and limitations for dynamic access policies 1929
Configure a Dynamic Access Policy (DAP) 1930
Create a dynamic access policy 1930
Create a dynamic access policy record 1930
Configure posture assessment criteria 1931

Configure AAA criteria settings for a DAP record 1932
Configure endpoint attribute selection criteria in DAP 1933
Add an anti-malware endpoint attribute to a DAP record 1933
Add a device endpoint attribute to a DAP record 1934
Add Secure Client endpoint attributes to a DAP record 1935
Add NAC endpoint attributes to a DAP record 1936
Add an application attribute to a DAP record 1936
Add a personal firewall endpoint attribute to a DAP record 1937
Add an operating system endpoint attribute to a DAP record 1937
Add a process endpoint attribute to a DAP 1938
Add a registry endpoint attribute to a DAP record 1939
Add a file endpoint attribute to a DAP record 1939
Add certificate authentication attributes to a DAP record 1940
Configure advanced settings for DAP 1941
Associate dynamic access policy with remote access VPN 1941

CHAPTER 65 **VPN Monitoring and Troubleshooting in Security Cloud Control** 1943
Monitor site-to-site VPNs using Site-to-Site VPN summary page 1943
Monitor Remote Access VPN Sessions 1943
SD-WAN summary dashboard 1943
Prerequisites for using SD-WAN summary dashboard 1944
Monitor WAN devices and interfaces using the SD-WAN summary dashboard 1945
Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard 1947

PART XVI **Zero Trust Network Access** 1949

CHAPTER 66 **Zero Trust Network Access Overview** 1951
Clientless and universal zero trust network access 1951
Zero trust network access 1952
Comparison of clientless and universal ZTNA 1952
History for zero trust network access 1953

CHAPTER 67 **Clientless Zero Trust Network Access** 1955
Zero Trust Access 1955

Components of a Clientless Zero Trust Network Access configuration 1956
How Clientless Zero Trust Network Access works 1957
How threat defense works with zero trust access 1958
Prerequisites for zero trust application policy 1960
Limitations for Clientless Zero Trust Network Access 1960
Create a zero trust application policy 1961
Create an application group 1963
Add certificate enrollment 1964
Create an application 1965
Create an ungrouped application 1967
Set targeted devices for zero trust access policy 1968
Edit a zero trust application policy 1969
Manage zero trust application policies 1970
Monitor zero trust sessions 1971

CHAPTER 68 **Universal Zero Trust Network Access** 1975
Universal Zero Trust Network Access 1975
Threat Defense with Universal ZTNA 1976
Prerequisites for Universal Zero Trust Network Access 1977
Restrictions for Universal Zero Trust Network Access 1978
Enable Cloud-Delivered Firewall Management Center in security cloud control 1979
Configure Security Devices 1979
Configure network connections 1985
Related documentation 1993

PART XVII **Access Control Policy Basics** 1995

CHAPTER 69 **Access Control Policies** 1997
Access control policies 1997
Access control policy components 1998
Access control policy default actions 1998
Access control policy inheritance 2000
Rule and other policy warnings 2001
Requirements and prerequisites for access control policies 2002

Manage access control policies 2002
Creating a basic access control policy 2004
Editing an access control policy 2004
Lock an access control policy 2006
Merge concurrent edits to an access control policy 2008
Configure the access control default action 2010
Manage access control policy inheritance 2011
Choose a base access control policy 2011
Lock settings in descendant access control policies 2012
Inherit access control policy settings from the base policy 2012
Enforce an access control policy in a domain 2013
Assign access control policy to devices 2014
Logging settings for access control policies 2014
Associate prefilter, decryption, and identity policies with an access control 2016
Identify and fix anomalies with policy analyzer & optimizer 2017
View rule hit counts 2018
Analyzing rule conflicts and warnings 2020
Search for rules 2022
History for access control policies 2023

CHAPTER 70 **Security Intelligence** 2027
Security intelligence 2027
License requirements for security intelligence 2028
Requirements and prerequisites for security intelligence 2028
Best practices for security intelligence 2028
Guidelines and limitations for security intelligence 2029
Security intelligence sources 2029
Configure security intelligence 2030
Security intelligence options 2032
Security intelligence categories 2034
Block list icons 2036
Configuration example: Security intelligence blocking 2036
Security intelligence monitoring 2037
Override security intelligence blocking 2038

Troubleshooting security intelligence 2039
Security intelligence categories missing from the Available Options List 2039

CHAPTER 71 Access Control Rules 2041
Access control rules 2041
Access control rule management 2043
Access control rule components 2043
Access control rule order 2045
Access control rule actions 2046
Access control rule monitor action 2046
Access control rule trust action 2046
Access control rule blocking actions 2047
Access control rule interactive blocking actions 2047
Access control rule allow action 2048
Deep inspection using file and intrusion policies 2049
File and intrusion inspection order 2050
How access control traffic handling works with intrusion and file policies 2051
Requirements and prerequisites for access control rules 2052
Guidelines and limitations for access control rules 2053
Best practices for application control 2054
Recommendations for application control 2054
Best practice for choosing between application matching and port matching 2056
Application-specific requirements for filtering 2057
Best practices for access control rules 2058
General best practice for access control 2058
Best practices for ordering rules 2059
Application rule order 2060
Rule preemption 2060
Best practice for rule actions and rule order 2061
Best practices for simplifying and focusing rules 2061
Maximum number of access control rules and intrusion policies 2062
Access control rule management 2062
Add an access control rule category 2062
Introduction to real-time Policy Analyzer and Optimizer 2063

How real-time Policy Analyzer and Optimizer works 2064
Prerequisites for using real-time Policy Analyzer and Optimizer 2064
Limitations of real-time Policy Analyzer and Optimizer 2064
Manage rule anomalies 2065
Create and edit access control rules 2066
Access control rule conditions 2068
Enable and disable access control rules 2076
Copy access control rules from one access control policy to another 2077
Move access control rules to a prefilter policy 2077
Position an access control rule 2079
Add comments to an access control rule 2080
Examples for access control rules 2080
How to control access using security zones 2080
Control application usage 2081
Block threats 2082

CHAPTER 72 **URL Filtering Rules** 2085
URL filtering 2085
URL filtering with category and reputation 2086
URL category and reputation descriptions 2087
URL filtering data from the Cisco cloud 2087
Best practices for URL filtering 2088
HTTPS traffic filtering 2091
Use categories in URL filtering 2092
QUIC Fingerprinting 2093
License requirements for URL filtering 2093
Requirements and prerequisites for URL filtering 2094
Configure URL filtering with category and reputation 2094
Enable URL filtering using category and reputation 2096
URL filtering options 2096
Configure URL conditions 2097
Rules with URL conditions 2099
URL rule order 2099
DNS filtering 2099

Enable DNS filtering to identify URLs during domain lookup 2100
DNS filtering behavior for block actions 2101
DNS filtering and events 2101
Manual URL filtering 2101
Manual URL filtering options 2102
Supplement or selectively override category and reputation-based URL filtering 2102
HTTP response pages 2103
Limitations to HTTP response pages 2103
Requirements and prerequisites for HTTP response pages 2104
Choose HTTP response pages 2105
Interactive blocking with HTTP response pages 2105
Configure interactive blocking 2106
Set the user bypass timeout for a blocked website 2107
Configure URL filtering health monitors 2107
Dispute URL category and reputation 2107
Take action if the URL category set changes 2108
URL category and reputation changes 2109
Troubleshoot URL filtering 2110

PART XVIII **Decryption Policies and Encrypted Visibility for Access Control** 2113

CHAPTER 73 **Traffic Decryption Overview** 2115
Traffic decryption 2115
How TLS/SSL handshakes work 2116
ClientHello message handling 2117
How ServerHello and server certificate messages work 2120
Decryption rule and policy basics 2121
Guidelines for traffic decryption 2122
Best practice for deciding when to decrypt traffic 2122
Decryption policy types 2123
Decrypt and re-sign (outgoing traffic) 2125
Incoming traffic decryption 2125
Known key decryption for incoming traffic 2126
Other decryption rule actions 2126

Decryption rule components 2126
Rule-based decryption rule order evaluation 2127
Multi-rule example 2128
TLS crypto acceleration 2130
TLS crypto acceleration guidelines and limitations 2131
View the status of TLS crypto acceleration 2132
History for decryption policy 2133

CHAPTER 74 Standard Decryption Policies 2137
Standard decryption policies 2137
Decryption policy types 2137
Standard decryption policy deployment issues to versions earlier than 10.0.0 2139
Create a new standard decryption policy 2139
Create a standard decryption policy with inbound protection 2139
Security zones 2140
Internal server details (inbound decryption) 2142
Create a standard decryption policy with outbound protection 2144
Security zones 2145
Decrypt networks and users 2146
Internal certificate authority 2148
Bypass traffic when decrypting 2150
Block connections 2155
Standard decryption policy advanced options 2157
Add trusted CA certificates 2159
Decryption policy actions 2159
Convert a standard decryption policy to a rule-based decryption policy 2160
Copy a decryption policy 2160
Generate a decryption policy report 2161

CHAPTER 75 Rule-Based Decryption Policies 2163
Rule-based decryption policies 2163
Decryption policy types 2163
Create a rule-based decryption policy 2165
Create a rule-based decryption policy with outbound connection protection 2165

Create a rule-based decryption policy with inbound connection protection 2169
Rule-based decryption policy block connections 2171
Configure Rule-based decryption policy exclusions 2171
Generate an internal CA for outbound protection 2175
Upload an internal CA for outbound protection 2176
Upload an internal certificate for inbound protection 2177
Install an internal CA on client machines 2177
Create a rule-based decryption policy with other rule actions 2178
Rule-based decryption policy default actions 2179
Default handling options for undecryptable traffic 2180
Set default handling for undecryptable traffic 2181
Rule-based decryption policy advanced options 2182
TLS 1.3 decryption best practices 2184

CHAPTER 76 **Rule-Based Decryption Rules** 2187
Rule-based decryption 2187
Requirements and prerequisites for Rule-based decryption rules 2187
Rule-based decryption rules guidelines and limitations 2188
Guidelines for using TLS/SSL decryption 2188
Rule-based decryption rules unsupported features 2190
Guidelines for TLS/SSL Do Not Decrypt configuration 2190
Best practices for TLS/SSL incoming traffic decryption 2191
TLS/SSL Decrypt - Resign guidelines 2192
TLS/SSL block guidelines 2194
TLS/SSL certificate pinning guidelines 2194
TLS/SSL heartbeat guidelines 2195
TLS/SSL anonymous cipher suite limitation 2195
TLS/SSL normalizer guidelines 2195
Other Rule-based decryption rule guidelines 2195
Best practice for Decryption policy rule order 2196
Rule-based decryption rule traffic handling 2197
Encrypted traffic inspection configuration 2199
Rule-based decryption rule order evaluation 2200
Rule-based decryption rule conditions 2201

Security zone rule conditions 2202
Network rule conditions 2203
VLAN tag rule conditions 2203
User rule conditions 2204
Application rule conditions 2204
Best practice: use application-based rules over port-based rules 2206
Category rule conditions 2206
Server certificate-based rule conditions 2207
Certificate rule conditions 2207
Conditions for distinguished name rules in decryption policies 2208
Trust external certificate authorities 2213
Certificate Status Decryption rule conditions 2214
Cipher suite rule conditions 2217
Encryption protocol version rule conditions 2220
Rule-based decryption rule actions 2220
Decryption rule monitor action 2220
Decryption rule Do Not Decrypt action 2221
Decryption rule blocking actions 2222
Decryption rule decrypt actions 2222
Incoming traffic decryption actions 2223
Decrypt - Resign rule action 2226
Select internal certificate objects 2226
Monitor TLS/SSL hardware acceleration 2226
Informational counters 2226
Alert counters 2227
Error counters 2227
Fatal counters 2227
Troubleshoot Rule-based decryption rules 2228
TLS/SSL oversubscription 2228
Troubleshoot TLS/SSL oversubscription 2229
TLS heartbeat 2229
Troubleshoot TLS heartbeat 2230
TLS/SSL pinning 2231
Troubleshoot TLS/SSL pinning 2231

Troubleshoot unknown or bad certificates or certificate authorities 2233
Verify TLS/SSL cipher suites 2235
Troubleshoot using crypto archives 2236

CHAPTER 77 **Encrypted Visibility Engine** 2239
Encrypted Visibility Engine 2239
How EVE works 2240
Indications of compromise events 2241
QUIC fingerprinting in EVE 2241
Configure EVE 2242
View Encrypted Visibility Engine events 2242
Configure EVE exception rules 2243
Add exception rule from unified events 2245
Upgrade EVE exception rules 2245
Use case - Block Traffic Based on the EVE Threat Confidence Score 2247
About Encrypted Visibility Engine 2247
Benefits 2247
Sample Business Scenario 2247
Prerequisites 2247
High-Level Workflow 2247
Configure Block Thresholds in EVE 2248
View EVE Events 2251
Additional References 2252

PART XIX **Identity Policies for Access Control** 2253

CHAPTER 78 **Identity Overview** 2255
User identity 2255
Identity terminology 2255
About user identity sources 2256
Best practices for user identity 2258
Identity deployments 2260
Set up an identity policy 2263
User activity database 2267

Users database 2267
Recommendation: identity realm limit 2269
Cloud-Delivered Firewall Management Center host and user limits 2269
Cloud-Delivered Firewall Management Center host limit 2269
Cloud-Delivered Firewall Management Center user limit 2270
User limits for microsoft azure active directory realms 2271

CHAPTER 79 Realms 2273
Realms and realm sequences 2273
Realms and trusted domains 2275
Supported servers for realms 2278
Supported server object class and attribute names 2279
License requirements for realms 2280
Requirements and prerequisites for realms 2281
Prerequisites for kerberos authentication 2281
Realm fields 2281
Realm directory and synchronize fields 2285
Create a proxy sequence 2288
Create a Microsoft Azure AD (SAML) realm 2289
Create a Microsoft Azure AD realm for passive authentication 2290
How Entra ID and Cisco ISE authentication with resource owned password credentials works 2291
How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS 2292
Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD 2293
Configure Microsoft Entra ID for passive authentication 2293
Configure Entra ID basic settings 2295
Get required information For Your Microsoft Azure AD realm 2296
Create a Microsoft Azure AD (SAML) realm for passive authentication 2298
Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal) 2302
Configure Entra ID basic settings 2304
Configure a single sign-on (SSO) app in Entra ID 2305
Create a decryption rule with decrypt - resign action 2307
Get required information for your Microsoft Azure AD realm (active authentication only) 2307
Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal) 2310
Create a Microsoft Azure AD Realm 2316

How Entra ID and Cisco ISE authentication with resource owned password credentials works 2316
How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS 2317
Create a Microsoft Azure AD realm for passive authentication 2318
Configure Microsoft Entra ID for passive authentication 2319
Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD 2320
Get required information For Your Microsoft Azure AD realm 2321
Create an Azure AD realm 2323
Azure AD user session timeout 2325
Create an LDAP realm or an Active Directory realm and realm directory 2325
Configure the Realm 2327
Connect securely to Active Directory or LDAP 2328
Find the active directory server's name 2328
Export the active directory server's root certificate 2329
Synchronize users and groups 2330
Create a realm sequence 2332
Cross-domain trust setups with Cloud-Delivered Firewall Management Center 2333
Configure Security Cloud Control for cross-domain-trust step 1: Configure realms and directories 2334
Configure the Security Cloud Control for cross-domain trust Step 2: Synchronize users and groups 2339
Configure the Security Cloud Control for cross-domain trust step 3: Resolve issues 2340
Manage a realm 2341
Compare realms 2342
Troubleshoot realms and user downloads 2342
Troubleshoot cross-domain trust 2345
History for realms 2348

CHAPTER 80 **Identity Source: Captive Portal** 2351
Captive portal identity source 2351
Hostname redirect 2352
License requirements for captive portal 2352
Requirements and prerequisites for captive portal 2352
Best practices for captive portal guidelines and limitations 2353
Configure the captive portal for user control 2355
Create a network object 2357
Create an identity policy and active authentication rule 2358

Update a custom authentication form 2360
Create a TCP port access control rule 2360
Create a user access control rule 2362
Create a decryption policy with an outbound rule 2362
Create A decryption policy with a Decrypt-Resign rule 2365
Associate Identity and decryption policies with the access control policy 2366
Captive portal fields 2367
Exclude applications from captive portal 2368
Troubleshoot the captive portal identity source 2369
History for captive portal 2370

CHAPTER 81 **Identity Source: ISE/ISE-PIC** 2373
The ISE/ISE-PIC identity source 2373
Source and destination security group tag (SGT) matching 2374
License requirements for ISE/ISE-PIC 2375
Requirements and prerequisites for ISE/ISE-PIC 2375
Best practices for ISE/ISE-PIC integration 2376
ISE/ISE-PIC configurations for user control 2379
Configure ISE/ISE-PIC without a realm 2379
Configure ISE/ISE-PIC for user control using a realm 2380
ISE/ISE-PIC configuration 2382
Configure security groups and SXP publishing in ISE 2382
Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center 2384
Export a system certificate 2385
Generate a self-signed certificate 2386
Import ISE/ISE-PIC certificates 2387
Configure ISE for user control 2387
ISE/ISE-PIC configuration fields 2389
Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source 2390
Cisco ISE quick configuration 2391
Configure prerequisites for Cisco ISE quick configuration 2391
Quick configuration 2392
Cisco Identity Services Engine (Cisco ISE) quick configuration results 2394

Configure Cisco ISE advanced configuration 2396
ISE/ISE-PIC configuration fields 2398
Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues 2399
History for ISE/ISE-PIC 2401

CHAPTER 82 **Identity Source: Passive Identity Agent** 2403
The passive identity agent identity source 2403
Deploy the passive identity agent 2404
Simple passive identity agent deployment 2405
Single passive identity agent monitoring multiple domain controllers 2405
Multiple passive identity agents monitoring multiple domain controllers 2406
Configure Passive identity agent primary and secondary agent deployments 2408
How to configure a passive identity agent identity source 2409
Configure the passive identity agent 2410
Enable the dynamic attributes connector 2411
Create a Microsoft Active Directory realm 2411
Create a passive identity agent identity source 2411
Create a standalone passive identity agent identity source 2412
Create a primary or secondary passive identity agent identity source 2414
Passive identity agent roles 2417
Get an API token for the passive identity agent 2418
Passive identity agent installation 2418
Prerequisites to install the passive identity agent 2419
Install the passive identity agent software 2422
Uninstall the passive identity agent software 2425
Upgrade the passive identity agent software 2426
Monitor the passive identity agent 2426
Manage the passive identity agent 2427
Edit passive identity agents 2428
Delete a standalone passive identity agent 2428
Delete primary and secondary passive identity agents 2428
Troubleshoot the passive identity agent 2429
Security requirements for the passive identity agent 2430
Internet access requirements for the passive identity agent 2431

History for the passive identity agent 2431

CHAPTER 83 **Identity Source: pxGrid Cloud Identity (ISE 3.3 and Earlier)** 2433

pxGrid Cloud identity source 2433

Restrictions for the pxGrid Cloud identity source 2434

How the pxGrid Cloud identity source works 2434

pxGrid Cloud identity source configuration 2436

Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier) 2436

Enable the pxGrid Cloud service in Cisco ISE 2439

Register Cisco ISE with the Catalyst Cloud Portal 2439

Register the pxGrid Cloud connection with Cisco ISE 2442

Create a pxGrid Cloud identity source 2443

Create an app instance 2443

Create the identity source 2445

Activate the app instance 2446

Activate the pxGrid Cloud identity source 2448

Test the pxGrid Cloud identity source 2450

Create dynamic attributes filters 2455

Create access control rules or DNS rules using dynamic attributes filters 2456

Troubleshoot the pxGrid Cloud identity source 2457

Primary device cannot be processed 2458

Deactivating and deleting the pxGrid Cloud identity source 2459

Deactivate the pxGrid Cloud app instance 2459

Delete the pxGrid Cloud identity source 2462

CHAPTER 84 **Identity Source: pxGrid Cloud Identity (ISE 3.4 and Later)** 2465

pxGrid Cloud identity source 2465

Restrictions for the pxGrid Cloud identity source 2466

How the pxGrid Cloud identity source works 2466

pxGrid Cloud identity source configuration 2468

Configuring a pxGrid Cloud identity source 2468

Enable the pxGrid Cloud service in Cisco ISE 2470

Verify Cisco ISE registration in the Catalyst Cloud Portal 2472

Create an app instance 2473

Create the identity source 2474
Activate the app instance 2475
Activate the pxGrid Cloud identity source 2478
Test the pxGrid Cloud identity source 2480
Troubleshoot the pxGrid Cloud identity source 2485
Primary device cannot be processed 2485
Create dynamic attributes filters 2486
Create access control rules or DNS rules using dynamic attributes filters 2487
Deactivating and deleting the pxGrid Cloud identity source 2489
Deactivate the pxGrid Cloud app instance 2489
Delete the pxGrid Cloud identity source 2492

CHAPTER 85 **Identity Source: Remote Access VPN** 2495
Remote access VPN identity sources 2495
Configure Remote Access VPN for AD-authenticated users 2496
Hybrid Entra ID and on-premises AD deployments 2497
Troubleshooting guidelines for remote access VPN identity source 2497
Not Observing Correct Settings for VPN Statistics 2498

CHAPTER 86 **Identity source: TS agent** 2501
Terminal services agent identity source 2501
Best practices for TS agent configuration 2502
Identity source: TS agent 2502
Troubleshoot the TS agent identity source 2502
History for TS agent 2503

CHAPTER 87 **Identity Policies** 2505
Identity policies 2505
License requirements for identity policies 2506
Requirements and prerequisites for identity policies 2506
Create an identity policy 2507
Create an identity mapping filter 2508
Identity rule conditions 2509
Security zone rule conditions 2509

Network rule conditions 2510
Redirect to host name network rule conditions 2510
VLAN tag rule conditions 2511
Best practice: use application-based rules over port-based rules 2512
Port, protocol, and ICMP code rule conditions (concept) 2512
Realm & settings rule conditions 2513
Create an identity rule 2515
Identity rule fields 2517
Sample identity policies and rules 2518
Create an identity policy with a passive authentication rule 2519
Create a sample identity policy with an active authentication rule 2520
Active authentication using a realm 2522
Active authentication using a realm sequence 2523
Manage an identity policy 2524
Manage an identity rule 2525
Troubleshoot user control 2526

PART XX **Advanced Policies and Settings for Access Control** 2529

CHAPTER 88 **Prefilter Policies** 2531
Prefilter policies 2531
Default prefilter policy 2532
Prefilter policy rule order 2532
Tunnel vs prefilter rules 2533
How the system processes plain-text tunnels 2533
Using tunnel zones to apply access control at the tunnel level 2534
Large flow offloads 2535
Restrictions for flow offload implementation 2537
Prefilter vs access control policy 2539
Requirements and prerequisites for prefilter policies 2540
Guidelines and limitations for the prefilter policy 2541
Guidelines and limitations for encapsulated traffic handling 2541
Best practices for fastpath prefiltering 2542
Configure prefilter policies 2543

Configuring the default action 2545
Configure prefilter rules 2545
VLAN tags rule conditions 2547
Port rule conditions for prefilter rules 2547
Configure tunnel rules 2548
Creating tunnel zones 2550
Move prefilter rules to an access control policy 2551
Examples of prefilter policy 2552
Rezone tunnels for customized inspection 2552
Offload large flows 2554

CHAPTER 89 **DNS Policies for Security Intelligence** 2557
DNS policies 2557
Cisco umbrella DNS policies 2558
DNS policy components 2559
License requirements for DNS policies 2560
Requirements and prerequisites for DNS policies 2560
Managing DNS and Umbrella DNS Policies 2560
Create basic DNS policies 2561
Edit DNS policies 2562
DNS rules 2562
Create and edit DNS rules 2563
DNS rule management 2564
Enable and disable DNS rules 2564
DNS rule order evaluation 2565
DNS rule actions 2565
DNS rule conditions 2566
Security zone rule conditions 2567
Network rule conditions 2567
VLAN tag rule conditions 2568
DNS policy rule conditions 2568
Dynamic attributes rule conditions 2569
DNS rules 2569
Control traffic based on DNS and security zone 2569

Control traffic based on DNS and network 2570
Control traffic based on DNS and VLAN 2571
Control traffic based on DNS list or feed 2572
Controlling traffic based on security group tag or dynamic attributes 2572
Use a DNS sinkhole to enforce content restriction 2573
Requirement: deploy DNS policy configuration changes 2575
Cisco umbrella DNS policies 2575
Redirect DNS requests to Cisco umbrella 2576
Prerequisites for configure the umbrella DNS connector 2576
Configure Cisco umbrella connection settings 2578
Create an umbrella DNS policy 2579
Edit Umbrella DNS policies and rules 2579
Associate the umbrella DNS policy with an access control policy 2580

CHAPTER 90 File Policies for Network Malware Protection 2583
Network malware protection and file policies 2583
File policies 2583
Prerequisites for file policies 2584
License requirements for file and malware policies 2585
Best practices for file policies and malware detection 2585
File rule best practices 2585
File detection best practices 2586
File blocking best practices 2587
File policy best practices 2588
Configure malware protection 2589
Plan and prepare for malware protection 2590
Configure file policies 2591
Add file policies to your access control configuration 2591
Configure an access control rule to perform malware protection 2592
Verify and monitor malware protection 2593
Cloud connections for malware protection 2594
AMP cloud connection configurations 2594
Change AMP options 2594
Dynamic analysis connections 2595

Prerequisites for dynamic analysis 2595
View the default dynamic analysis connection 2595
Enable access to dynamic analysis results in the public cloud 2596
Maintain your system: file types eligible for dynamic analysis 2596
File policies and file rules 2597
Create or edit a file policy 2597
Advanced and archive file inspection options 2598
Manage file policies 2601
File rules 2602
File rule components 2603
File rule actions 2604
Create file rules 2611
Access control rule logging for malware protection 2613
Retrospective disposition changes 2613
File and malware inspection performance and storage options 2613
Tune file and malware inspection performance and storage 2615
(Optional) Malware protection with Secure Endpoint 2615
Comparison of malware protection: Firepower vs. Secure Endpoint 2616
Integrate Secure Firewall with Secure Endpoint 2617
Benefits of integrating Firepower and Secure Endpoint 2617
Secure Endpoint and AMP private cloud 2618
Integrate Firepower and Secure Endpoint 2618

CHAPTER 91 **Dynamic Attributes Connector** 2621
About the Dynamic Attributes Connector 2621
How It Works 2623
Enable the dynamic attributes connector 2624
Dashboard 2624
Dashboard of an unconfigured system 2625
Dashboard of a configured system 2626
Add, edit, or delete connectors 2627
Add, edit, or delete dynamic attributes filters 2629
Connectors 2631
Amazon Web Services connector user permissions and imported data 2631

Create an AWS user with minimal permissions for the dynamic attributes connector 2632
Create an AWS connector 2633
Amazon Web Services security groups connector—About user permissions 2634
Create an AWS security groups connector 2634
Create an AWS service tags connector 2635
Azure connector—About user permissions and imported data 2636
Create an Azure user with minimal permissions for the dynamic attributes connector 2637
Create an Azure connector 2639
Create an Azure service tags connector 2640
Create a Multicloud Defense connector 2641
Create a Cisco cyber vision connector 2643
Create a generic text connector 2645
Manually get a certificate authority (CA) chain 2646
Create a GitHub connector 2649
Google cloud connector user permissions and imported data 2650
Create a Google Cloud user with minimal permissions for the dynamic attributes connector 2651
Create a google cloud connector 2652
Create an office 365 connector 2653
Tenable connector 2654
About the Tenable connector 2654
Get the Tenable API key and secret 2655
Create a Tenable connector 2655
About Tenable dynamic objects in IDS, IPS, and access control policies 2657
Create a Webex connector 2657
Create a Zoom connector 2658
Create an adapter 2659
How to create an On-Premises Firewall Management Center adapter 2660
How to create a Cloud-Delivered Firewall Management Center adapter 2661
Create dynamic attributes filters 2661
Dynamic attribute filter examples 2663
Disable the dynamic attributes connector 2664
Dynamic firewall 2664
Dynamic Firewall 2664
How to configure the dynamic firewall 2665

Get required information for Identity Intelligence 2667
Create an identity source and realm for the dynamic firewall 2669
Create a dynamic firewall instance 2669
Associate an identity source with Identity Intelligence 2670
Configure Identity Intelligence 2671
View system-defined filters 2672
View system-defined access control rules 2673
Edit the user exclusion list 2675
View and edit the system-created access control policy 2676
Create dynamic attributes filters 2677
Use Dynamic Objects in Access Control Policies 2679
Dynamic objects in access control rules 2679
Create dynamic attributes filters 2679
Dynamic attributes rule conditions 2681
Create access control rules or DNS rules using dynamic attributes filters 2681
Use dynamic objects in DNS policies 2683
Troubleshoot the Dynamic Attributes Connector 2683
Troubleshoot error messages 2684
Get your tenant ID 2684

CHAPTER 92 **Advanced Settings for Access Control** 2687
Requirements and prerequisites for advanced settings 2687
Configure advanced settings for the access control policy 2688
General settings 2691
TLS server identity discovery 2692
Intelligent application bypass 2693
Configure intelligent application bypass 2694
IAB logging and analysis 2696
Transport/network layer preprocessor settings 2699
Detection enhancement settings 2700
Adaptive profile updates 2701
Adaptive profile updates and recommended rules 2702
Performance settings 2702
Latency-based performance settings 2704

CHAPTER 93 **Service Policies** 2707

Threat defense service policies 2707

Service policy relationships with FlexConfig and other features 2708

Connection settings 2708

Requirements and prerequisites for service policies 2709

Guidelines and limitations for service policies 2709

Configure threat defense service policies 2710

Configure a service policy rule 2711

Bypass TCP state checks for asymmetrical routing (TCP state bypass) 2714

The asymmetrical routing problem 2714

Guidelines and limitations for TCP state bypass 2715

Configure TCP state bypass 2716

Disable TCP sequence randomization 2718

Monitor service policies 2719

Examples for service policy rules 2720

Protect servers from a SYN flood DoS attack (TCP intercept) 2720

Configure the Firewall Threat Defense device to appear on traceroutes 2723

CHAPTER 94 **Threat Detection** 2725

Portscan detection and prevention 2725

Pre-defined sensitivity levels for portscan detection 2725

Detection in the low sensitivity level 2727

Requirements and prerequisites for threat detection 2727

Limitations for threat detection configuration 2728

Best practices for portscan prevention 2729

Configure portscan detection and prevention 2729

Monitoring threat detection 2731

View portscan alerts 2731

Monitor portscan on the firewall 2732

Unblocking a host 2733

CHAPTER 95 **Elephant Flow Detection** 2735

Elephant flow detection and remediation 2735

Elephant flow upgrade from Intelligent Application Bypass 2736
Configure elephant flow detection 2736
Use case - Configure Elephant Flow Detection Outcomes 2739
Elephant flows 2739
Benefits of elephant flow detection and remediation 2739
How elephant flows work 2739
Sample business scenarios 2740
Prerequisites 2741
Configure elephant flow parameters 2741
View events for elephant flows 2743
Configure elephant flow remediation exemption 2744
View events for elephant flow remediation exemption 2747
Additional references 2747

CHAPTER 96 **Policy Analyzer and Optimizer** 2749
About Policy Analyzer and Optimizer 2749
Common Policy Analyzer and Optimizer concepts 2750
Prerequisites to use Policy Analyzer and Optimizer 2751
Enable Policy Analyzer and Optimizer for Security Cloud Control-managed On-Premises Firewall Management Center 2752
Policy Analyzer and Optimizer licensing requirements 2753
Open Policy Analyzer and Optimizer and select a data source 2753
Sync and analysis behavior 2754
Search and filter policies in Policy Analyzer and Optimizer 2754
Access control policy analysis and optimization 2754
Analyze access control policies 2755
Access control policy analysis summary 2756
Analyze duplicate rules in access control policy 2757
Analyze expired rules in access control policy 2759
Analyze mergeable rules in access control policy 2759
Analyze overlapping objects in access control policy 2760
Analyze policy insights in access control policy 2761
Access control policy remediation 2762
Download access control analysis report 2764

Network Address Translation policy analysis 2764
Analyze NAT policies 2765
NAT rule sections and comparison behavior 2765
Supported NAT address families for Policy Analyzer and Optimizer 2766
NAT policy analysis summary 2766
Download NAT analysis report 2767

- Manage Multicloud Defense-Onboarded Secure Firewall Threat Defense Virtual Devices, on page 13

CHAPTER 1

Configure Cloud-Delivered Firewall Management Center-Managed Secure Firewall Threat Defense

This chapter provides information on how to manage the Cloud-Delivered Firewall Management Center-managed Firewall Threat Defense onboarded to Security Cloud Control.

- Overview of Cloud-Delivered Firewall Management Center, on page 1
- Navigate to the Cloud-Delivered Firewall Management Center in your Security Cloud Control Tenant, on page 3
- Determine the Cloud-Delivered Firewall Management Center Version in Security Cloud Control Firewall Management, on page 3
- Enable Cloud-Delivered Firewall Management Center , on page 4
- Hardware and Software Support, on page 5
- **Security Cloud Control Firewall Management Platform Maintenance Schedule**, on page 5
- Licensing, on page 6
- Integrate an On-Premises Firewall Management Center With Cisco Security Cloud, on page 6
- Security Cloud Control Firewall Management Integrations Page , on page 9

Overview of Cloud-Delivered Firewall Management Center

Cloud-Delivered Firewall Management Center is a software-as-a-service product that manages Secure Firewall Threat Defense devices through Security Cloud Control Firewall Management. It provides many of the same functions as an On-Premises Firewall Management Center.

Cloud-Delivered Firewall Management Center has the same appearance and behavior as an On-Premises Firewall Management Center and uses the same FMC API.

Because it is a SaaS product, the Security Cloud Control Firewall Management operations team deploys and maintains the Cloud-Delivered Firewall Management Center software. As new features are introduced, the operations team updates the Cloud-Delivered Firewall Management Center in your Security Cloud Control Firewall Management organization.

Migration and onboarding details

A migration wizard is available to help you migrate Threat Defense devices from an On-Premises Firewall Management Center to Cloud-Delivered Firewall Management Center.

Devices must run one of these Threat Defense software releases before you migrate them:

- Minimum On-Premises Firewall Management Center: 7.2
- Minimum Threat Defense: 7.2.x (not supported for Version 7.1)

Threat Defense 7.1 releases are not supported for migration.

You onboard Threat Defense devices in Security Cloud Control Firewall Management by using familiar methods, such as entering the serial number or using a CLI command that includes a registration key.

After onboarding:

- The device appears in both Security Cloud Control Firewall Management and Cloud-Delivered Firewall Management Center.
- You configure the device in Cloud-Delivered Firewall Management Center.
- In Security Cloud Control Firewall Management, you can review device information such as version, configuration status, connectivity, health status, and node status.
- When you click the health status in Security Cloud Control Firewall Management, the platform opens the device health monitoring page in the Cloud-Delivered Firewall Management Center user interface.

Availability and Security Analytics

Security Cloud Control Firewall Management supports high availability for the Threat Defense devices that it manages through the data interface. This feature is supported for devices that run software version 7.2 or later.

You can analyze security events from onboarded threat defense devices by using either Security Analytics and Logging (SaaS) or Security Analytics and Logging (On-Premises):

- Security Analytics and Logging (SaaS) stores events in the cloud, and you view those events in Security Cloud Control Firewall Management.
- Security Analytics and Logging (On-Premises) stores events on an on-premises Secure Network Analytics appliance, and analysis occurs in the On-Premises Firewall Management Center.

In both cases, you can still send logs directly from firewalls to a log collector of your choice.

Licenses

The license for Cloud-Delivered Firewall Management Center is a per-device-managed license and there is no license required for the Cloud-Delivered Firewall Management Center itself. Existing Secure Firewall Threat Defense devices re-use their existing smart licenses and new Secure Firewall Threat Defense devices provision new smart licenses for each feature implemented on the Secure Firewall Threat Defense For more information, see Cloud-Delivered Firewall Management Center license.

The **Unified Events** feature in Cloud-Delivered Firewall Management Center uses Cisco Security Analytics and Logging (SaaS) as its event data source. You must have a valid Cisco Security Analytics and Logging (SaaS) subscription plan to view firewall events on the **Unified Events** page. When you enable Cloud-Delivered Firewall Management Center, a 90-day trial subscription for Security Analytics and Logging (SaaS) is automatically issued.

To learn how to have a Cloud-Delivered Firewall Management Center provisioned on your tenant, see Enable Cloud-delivered Firewall Management Center on Your Security Cloud Control Tenant.

Navigate to the Cloud-Delivered Firewall Management Center in your Security Cloud Control Tenant

Procedure

Step 1 In the left pane, click **Administration** > **Integrations** > **Firewall Management Center** to view the **Services** page.

The **Services** page displays the information about the Cloud-Delivered Firewall Management Center provisioned for the Security Cloud Control tenant.

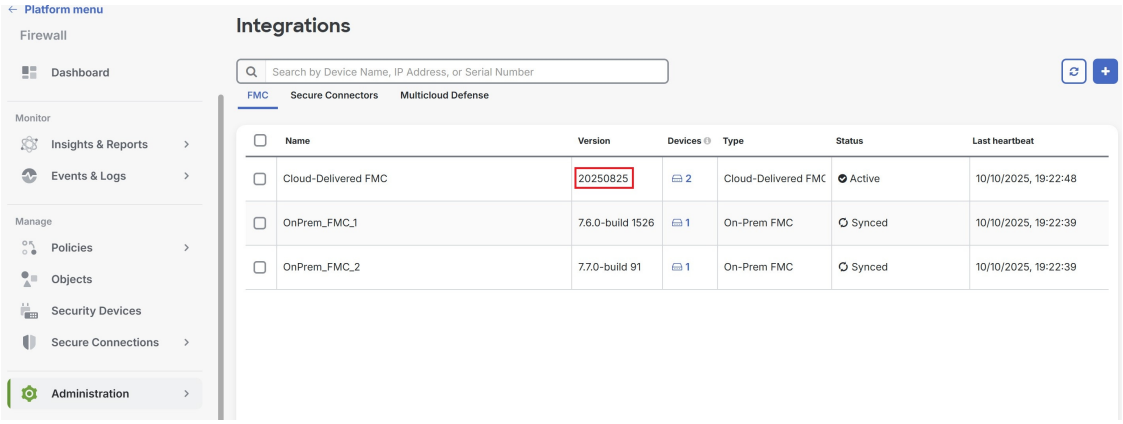
Step 2 Choose **Cloud-Delivered FMC** and click the links in the **Actions**, **Management**, or **Settings** pane to navigate to Cloud-Delivered Firewall Management Center to perform various actions. See Security Cloud Control Firewall Management Integrations Page , on page 9.

Once in the Cloud-Delivered Firewall Management Center, click the blue question mark button and select **Page-level Help** to learn more about the page you are on and further action you can take.

Determine the Cloud-Delivered Firewall Management Center Version in Security Cloud Control Firewall Management

Information about the Cloud-Delivered Firewall Management Center version is required primarily for migration planning, feature support verification, troubleshooting, licensing, and operational management.

Use this procedure to determine the current version of your Cloud-Delivered Firewall Management Center in Security Cloud Control Firewall Management.



Before you begin

Enable Enable Cloud-Delivered Firewall Management Center in your organzation.

Procedure

Step 1 In the left pane, click **Administration** > **Integrations** > **Firewall Management Center**.

Step 2 Under the **FMC** tab, the version is displayed under the **Version** column.

For more information about Cloud-Delivered Firewall Management Center versions, see Release Notes for Cloud-Delivered Firewall Management Center.

Enable Cloud-Delivered Firewall Management Center

If you want to manage your Secure Firewall Threat Defense devices, you can enable the Cloud-Delivered Firewall Management Center on your tenant. You need to have an admin or a super admin user role to perform this task.

Procedure

From the Security Cloud Control menu, click **Administration** > **Integrations** > **Firewall Management Center** and click **Enable Cloud-Delivered FMC**.

Security Cloud Control starts provisioning a Cloud-Delivered Firewall Management Center instance in the background; it typically takes 15 to 30 minutes for this to be complete. You can track the provisioning progress on the **Status** column of **Cloud-Delivered FMC**.

After the provisioning is complete, the status changes to **Active**. In addition, you get a **Cloud-Delivered Firewall Management Center is Ready** notification on the Security Cloud Control notifications panel and on the applications on which you have configured incoming webhooks. See Notification Settings for more information.

Note
After you receive the **Cloud-Delivered Firewall Management Center is Ready** notification, ensure that you log out of and log in back to your tenant once, to see the **Cloud-Delivered FMC** right pane options, such as **Actions**, **Management**, and **System**.

What to do next:

a. Register Cloud-Delivered Firewall Management Center with Cisco Smart Software Manager (CSSM) to activate smart license. For detailed steps, refer to Register the Cloud-Delivered Firewall Management Center with the Smart Software Manager.

b. Onboard your Firewall Threat Defense devices to the Cloud-Delivered Firewall Management Center and manage them.

Hardware and Software Support

Cloud-Delivered Firewall Management Center supports these Secure Firewall Threat Defense software versions when they are installed on any supported hardware or virtual device:

- Verion 7.0.3 or later 7.0.x versions.
- Version 7.2 and later versions.

Note Software Version 7.1 is _not_ supported.

See Firepower Threat Defense Support Specifics for more information.

Security Cloud Control Firewall Management Platform Maintenance Schedule

Security Cloud Control Firewall Management updates its platform every week with new features and quality improvements. Updates are made during a 3-hour period according to this schedule:

Day of the week	Time of day (24-hour time, UTC)
Thursday	09:00 UTC - 12:00 UTC

During the Security Cloud Control Firewall Management upgrade period, you can still access your organization and the Cloud-Delivered Firewall Management Center. Additionally, the devices that you have onboarded to Security Cloud Control Firewall Management continue to enforce their security policies.

Note

- During the maintenance period of the Security Cloud Control Firewall Management, refrain from creating or deploying configurations to the devices it manages.
- If there is any issue that stops Security Cloud Control Firewall Management from communicating, Cisco addresses that issue in all the affected tenants as quickly as possible, even if it is outside the maintenance window.

Licensing

The **Unified Events** page uses the Cisco Security Analytics and Logging data store as its event data source. You must have a valid Cisco Security Analytics and Logging subscription plan to view firewall events on the **Unified Events** page.

Integrate an On-Premises Firewall Management Center With Cisco Security Cloud

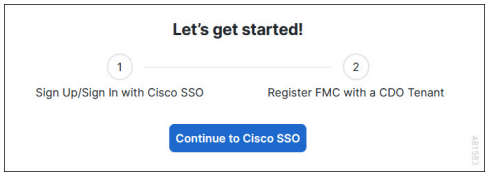
This procedure describes how to integrate the On-Premises Firewall Management Center with Cisco Security Cloud. By enabling Cisco Security Cloud integration, your management center gets registered to the Cisco cloud tenancy.

Before you begin

When onboarding an on-premises Firewall Management Center:

- If you already have a Security Cloud Control tenant, you will be prompted to confirm whether you want to attach the on-premises Firewall Management Center to that existing tenant.
- If you do not have a tenant or account, the on-premises Firewall Management Center integration wizard will automatically create a new tenant for you during the registration task the onboarding process. This tenant is a free tier provided exclusively for on-premises Firewall Management Center AI Assist enablement. Allow the wizard to manage tenant creation so that you do not receive a trial tenant that would later require conversion. The wizard manages this process to provide a seamless experience.
- If you intend to use the Cloud-Delivered Firewall Management Center or manage firewalls using the Security Cloud Control, you must purchase a base license and device entitlements. For detailed licensing information and product options, refer to the Security Cloud Control Licensing Overview.

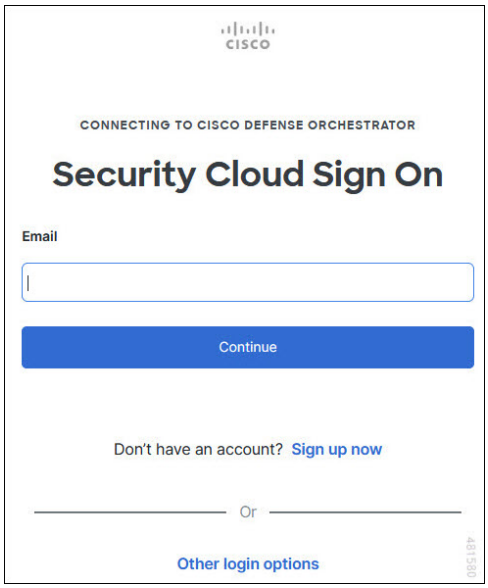
Procedure



Step 1 Based on your on-premises Firewall Management Center version, do the following:

- For on-premises Firewall Management Center version between 7.2 and 7.4.x, click **Enable Secure X**.
- For on-premises Firewall Management Center version 7.6 or later, click **Cisco Security Cloud**.
- For on-premises Firewall Management Center version 10.0 or later, click **Security Cloud Control**.

A separate browser tab opens to log you in to your Security Cloud Control account. Make sure this page is not blocked by a pop-up blocker.



Step 2 Click **Continue to Cisco SSO**.

Figure 1: Cisco Security Cloud Welcome Page

Step 3 Log in to your Security Cloud Control account.

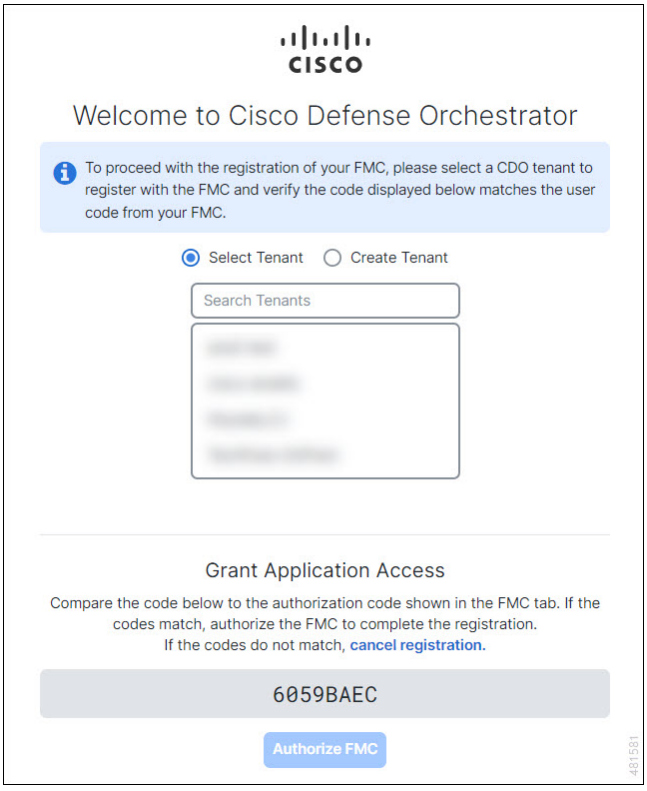


Figure 2: Cisco Security Cloud Sign On

If you do not have a security cloud sign on account to log in to Security Cloud Control and you want to create one, click **Sign up now** in the **Security Cloud Sign On** page.

Step 4 Choose a Security Cloud Control tenant that you want to use for this integration. The on-premises Firewall Management Center and the managed devices get onboarded to the Security Cloud Control tenant that you choose here.

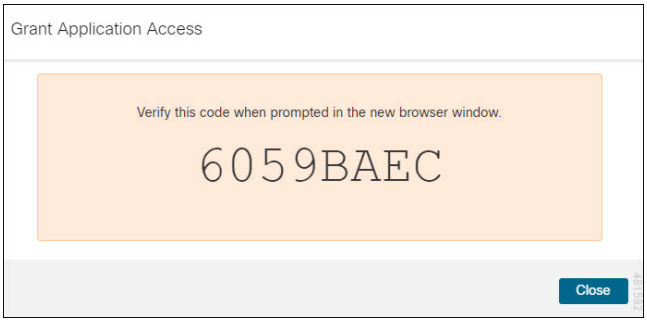

Figure 3: Choose the Security Cloud Control Tenant

If you do not have a security cloud sign on account to log in to Security Cloud Control and you want to create one, click **Sign up now** in the **Security Cloud Sign On** page. See Create a New Cisco Security Cloud Sign On Account.

Step 5 Verify that the code displayed in the Security Cloud Control login page matches the code provided by the on-premises Firewall Management Center.

Figure 4: Verification Code in the on-premises Firewall Management Center

Step 6 Click **Authorize FMC**.

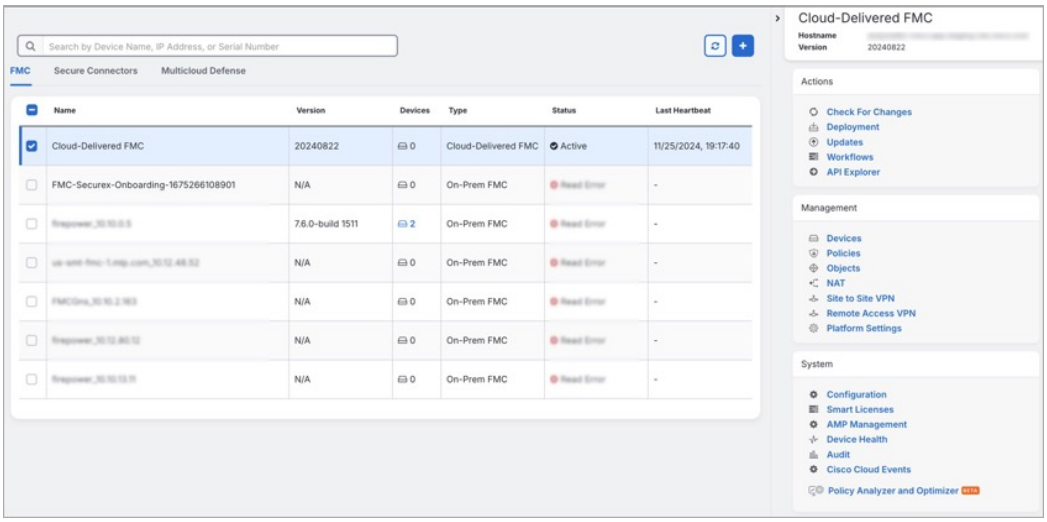
Step 7 In the on-premises Firewall Management Center UI, click **Save** to save the configuration.

You can view the task progress under **Notifications** > **Tasks**.

The registration task can take up to 90 seconds to complete. If you must use on-premises Firewall Management Center while the registration task is in progress, open the on-premises Firewall Management Center in a new window.

Security Cloud Control Firewall Management Integrations Page

The **Integrations** page provides a comprehensive view of your managed infrastructure within Security Cloud Control Firewall Management:



- **FMC** tab:
  - View the Cloud-Delivered Firewall Management Center that is linked to the Security Cloud Control Firewall Management account. Refer to Request a Cloud-delivered Firewall Management Center for your Security Cloud Control tenant .
  - View which on-premises Firewall Management Centers are onboarded to Security Cloud Control Firewall Management. Devices managed by these on-premises Firewall Management Centers appear in **Security Devices**. Refer to Managing On-Prem Firewall Management Center with Security Cloud Control.
  - Lists the **Secure Device Connector** and **Secure Event Connector** available under the **Secure Connectors**. Refer to Secure Device Connector and Secure Event Connectors.

Security Cloud Control. page. The **Integrations** page also lists tab.

Click the **FMC** tab, then click **Onboard FMC** () icon to onboard an on-premises Firewall Management Center. In the right pane, perform device actions as needed. Refer to Onboard an On-Prem Firewall Management Center.

View device information, including version, device count, device type, and synchronization status. Click the managed devices icon to go to the **Security Devices** page. Devices managed by the selected on-premises Firewall Management Center are filtered and displayed. On the **Integrations** page, select multiple on-premises Firewall Management Center to perform actions on several management centers at once. Deselect the Cloud-Delivered Firewall Management Center before selecting other on-premises Firewall Management Center. To add a new secure connector or perform actions on existing secure connectors, choose the **Secure Connectors** tab and click .

In the left pane, click **Administration** > **Firewall Management Center**.

For your Cloud-Delivered Firewall Management Center, the Integrations page displays this information:

- If you do not have a Cloud-Delivered Firewall Management Center deployed on your tenant, click **Enable Cloud-Delivered FMC**. Refer to Enable Cloud-Delivered Firewall Management Center on Your Security Cloud Control Tenant for more information.
- The number of Secure Firewall Threat Defense devices deployed on the Cloud-Delivered Firewall Management Center.
- Status of the connection between Security Cloud Control and the Cloud-Delivered Firewall Management Center page.
- The last heartbeat of the Cloud-Delivered Firewall Management Center. This time shows when the Cloud-Delivered Firewall Management Center's status and device count last synchronized with the table on this page..
- The hostname of the selected Cloud-Delivered Firewall Management Center.

Choose **Cloud-Delivered FMC** and using the links in the **Actions** , **Management**, or **Settings** pane, you open the Cloud-Delivered Firewall Management Center user interface to perform the configuration tasks that are associated with the link you clicked.

Actions:

- **Check For Changes**: The Device Count and Status information in the table is updated with the information available the last time this page and the Cloud-Delivered Firewall Management Center were synchronized. Synchronization happens every 10 minutes.
- **Deployment**: Takes you to the device configuration deployment page on Cloud-Delivered Firewall Management Center. Refer to Deploy Configuration Changes.
- **Workflows**: Takes you to the **Workflows** page to monitor every process that Security Cloud Control runs when communicating with devices. Refer to Workflows page.
- **API Explorer**: Takes you to the page that lists the Cloud-Delivered Firewall Management Center REST APIs. Refer to Secure Firewall Management Center REST API Guide .
- **Unified Events**: Takes you to the **Unified Events** page on the Cloud-Delivered Firewall Management Center portal, which provides a single-screen view of various firewall events, including connection,

intrusion, file, malware, and security-related connection events. For more information, refer to Unified Events .

Note The Unified Events feature requires activation. If you have not yet activated this feature, contact your Cisco sales representative to enable it.

Management:

- **Devices**: Takes you to the Firewall Threat Defense device listing page on the Cloud-Delivered Firewall Management Center portal. Refer to Configure Devices.
- **Policies**: Takes you to the policies page on the Cloud-Delivered Firewall Management Center portal to edit system-provided access control policies and create custom access control policies. Refer to Manage Access Control Policies.
- **Objects**: Takes you to the policies page on the Cloud-Delivered Firewall Management Center portal to manage reusable objects. Refer to Object Management.
- **NAT**: Takes you to the policies page on the Cloud-Delivered Firewall Management Center portal to configure Network Address Translation policies on the Firewall Threat Defense devices. Refer to Manage NAT policies.
- **Site to Site VPN**: Takes you to the site-to-site VPN dashboard page on the Cloud-Delivered Firewall Management Center portal to configure site-to-site VPN policy between two sites. Refer to Site-to-Site VPNs.
- **Remote Access VPN**: Takes you to the remote access VPN dashboard page on the Cloud-Delivered Firewall Management Center portal to configure a remote access VPN configuration. Refer to Remote Access VPN.
- **Platform Settings**: Takes you to the platform settings page on the Cloud-Delivered Firewall Management Center portal to configure a range of unrelated features whose values you might want to share among several devices. Refer to Platform Settings.

System:

- **Configuration**: Takes you to the system configuration settings page on the Cloud-Delivered Firewall Management Center portal to configure system configuration settings. Refer to System Configuration .
- **Smart Licenses**: Takes you to the smart licenses page on the Cloud-Delivered Firewall Management Center portal to assign licenses to devices. Refer to Assign Licenses to Devices.
- **AMP Management**: Takes you to the AMP management page on the Cloud-Delivered Firewall Management Center portal that supplies data the system uses to detect and block malware on your network. Refer to Cloud Connections for Malware Protection.
- **Device Health**: Takes you to the health monitoring page on the Cloud-Delivered Firewall Management Center portal, which tracks various health indicators to ensure the hardware and software in the system are working correctly. Refer to About Health Monitoring.
- **Audit**: Takes you to the audit log page on the Cloud-Delivered Firewall Management Center portal to show the generated audit record for each user interaction with the web interface.

- **Cisco Cloud Events**: Takes you to the configure Cisco Cloud events page on the Security Cloud Control portal to configure Cloud-Delivered Firewall Management Center to send events directly to SAL (SaaS). Refer to Send Events to SAL (SaaS).

After you open the Cloud-Delivered Firewall Management Center page, click the blue question mark button and select **Page-level Help** for more information.

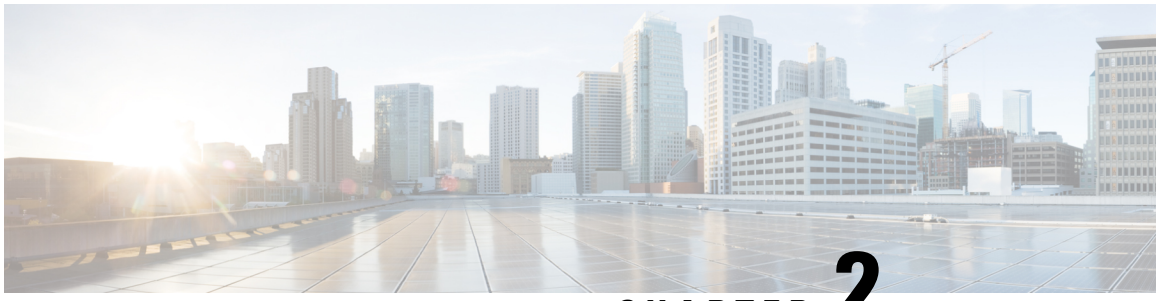
Support to open Security Cloud Control and Cloud-Delivered Firewall Management Center applications in separate tabs

As you configure Firewall Threat Defense devices or objects in Cloud-Delivered Firewall Management Center , you can open the appropriate configuration pages in additional browser tabs to work simultaneously in the Security Cloud Control and the Cloud-Delivered Firewall Management Center portals without logging off.

For example, you can create an object on Cloud-Delivered Firewall Management Center and simultaneously monitor event logs on Security Cloud Control that are generated from the security policies.

This feature is available for all Security Cloud Control links that navigate to the Cloud-Delivered Firewall Management Center portal. To open the Cloud-Delivered Firewall Management Center portal in a new tab:

On the Security Cloud Control portal, press and hold the Ctrl (Windows) or Command (Mac) button, then click the corresponding link.



Note A single click opens the Cloud-Delivered Firewall Management Center page in the same tab.

Here are some examples of opening the Cloud-Delivered Firewall Management Center portal page in a new tab:

- Choose **Administration** > **Firewall Management Center** and select **Cloud-Delivered FMC**. In the right pane, press and hold the Ctrl (Windows) or Command (Mac) button, and then click the page that you want to access.
- Choose **Objects** > **Other FTD Objects**.
- Click the search icon on the Security Cloud Control page and enter your search terms in the search field.

  From the search result, press and hold the Ctrl (Windows) or Command (Mac) button, and then click the arrow icon.
- Choose **Dashboard** > **Quick Actions**. Press and hold the Ctrl (Windows) or Command (Mac) button, and then click **Manage FTD Policies** or **Manage FTD Objects**.

Note If you switch to a new Security Cloud Control tenant, the Cloud-Delivered Firewall Management Center portal open in another tab logs out automatically.

CHAPTER 2

Manage Multicloud Defense-Onboarded Secure Firewall Threat Defense Virtual Devices

- Overview of Multicloud Defense-Onboarded Firewall Threat Defense Virtual Devices, on page 13
- Onboard and Configure a Secure Firewall Threat Defense Virtual Device in Multicloud Defense, on page 15

Overview of Multicloud Defense-Onboarded Firewall Threat Defense Virtual Devices

You can orchestrate your Secure Firewall Threat Defense virtual (FTDv) device in your cloud service provider manually and then register your device to Cloud-Delivered Firewall Management Center (Cloud-Delivered Firewall Management Center) for management of it. A lot of manual steps are involved in this method such as VPC creation, security groups creation, peer connection and routing in your cloud service provider, which can be cumbersome.

With Multicloud Defense available as part of Security Cloud Control, you can now easily orchestrate, deploy, and register an FTDv device using Multicloud Defense while retaining your FTDv as a gateway. Multicloud Defense communicates with Security Cloud Control for FTDv registration and orchestrates the initial setting up of the FTDv. For more details on deploying an FTDv using Multicloud Defense, see Secure Firewall Threat Defense.

HTTPS configuration under Platform Settings policy is managed by Multicloud Defense. Any other configurations related to Platform Settings need to be done in Firewall Management Center only. Multicloud Defense also adds one mandatory NAT rule under NAT policy. Additional NAT rules can be configured in the Firewall Management Center. You can create and assign access policies, rules, and objects in Cloud-Delivered Firewall Management Center For more details, see Access Control Policies.

Guidelines for Managing an FTDv Created in Multicloud Defense

Consider the following guidelines in the context of Cloud-Delivered Firewall Management Center, when creating gateways for FTDv using Multicloud Defense:

- FTDv registration and configuration can be done only in Multicloud Defense. This information is view-only and cannot be edited in Cloud-Delivered Firewall Management Center. You cannot edit any of the **Devices**, **Interface**, **Inline Sets**, **Routing**, **DHCP** and **VTEP** configuration details in the user interface of Cloud-Delivered Firewall Management Center, because all device-specific configurations are done in Multicloud Defense.

- HTTPS configuration under Platform Settings policy is managed by Multicloud Defense and any changes to it can impact devices or the FTDv gateway. You need to be cautious while changing any configurations in **Platform Settings** as the policy overall is a shared policy.
- Mandatory NAT rule is managed by Multicloud Defense and any changes to the mandatory rule can impact devices or the FTDv gateway.
- Configure NAT rules to translate incoming traffic from the external network to the internal network on the specified port and IP address. Multicloud Defense automatically opens the required port on the load balancer provided by the cloud service. This configuration ensures accurate translation and forwarding of inbound traffic, while the load balancer manages port access.
- Multicloud Defense devices are added under a logical device group for each gateway.
- You can use existing policies that you have in Cloud-Delivered Firewall Management Center or even create new policies from the Multicloud Defense application.
- You can configure or modify an existing policy from Cloud-Delivered Firewall Management Center.
- To add additional policies such as QoS policy or any other policy configuration for Multicloud Defense-related FTDv in Cloud-Delivered Firewall Management Center, the policies must be assigned at the device group level, so that it is applied to all devices in the group. This helps in addressing shared policies and the application of the policy to all devices that are added to the group in future. Note that policies are not applied at the single FTDv device level, but across the group.
- Don't remove an FTDv from Security Cloud Control. Contact your administrator to make any changes, if any, in Multicloud Defense.
- Don't move an FTDv across groups at any point in time or unassign an FTDv from groups in Cloud-Delivered Firewall Management Center.
- Don’t rename the device groups created by Multicloud Defense in Cloud-Delivered Firewall Management Center, because it can hamper the working of the devices.
- Don’t edit or delete the security zones or objects because they are managed in Multicloud Defense and can hamper the working of the devices. You can identify this when you access Platform Settings policies. If the policy is deployed to a device orchestrated by Multicloud Defense, you are notified with a message. For identification, Cloud-Delivered Firewall Management Center uses an additional field with the naming convention `mcdmanaged`. You can identify the security zones by the naming convention used – `ciscomcd-VNI`, `ciscomcd-inside`, or `ciscomcd-outside`.
- Licensing of the FTDv is according to the FTDv plan that you chose, that is, either Bring Your Own License (BYOL) or Software-as-a-Service (SaaS). You can use the existing license that you use for FTDv.
- We recommend that you upgrade the FTDv versions only in the Multicloud Defense application.
- This feature is supported for FTDv version 7.6 and above. You can upgrade or downgrade the FTDv in Multicloud Defense. This is done by creating a new instance. The upgrade or downgrade enables easy scaling up or scaling down of the instances too.
- Your FTDv is listed in Security Cloud Control Firewall Management and Cloud-Delivered Firewall Management Center. You can manage your policies in Cloud-Delivered Firewall Management Center.
- When you trigger a deployment on these FTDvs, you should select together all the FTDvs that belong to same gateway, otherwise the configuration will be out of sync among FTDvs and this can lead to inconsistent traffic behavior.

- Features such as Site-to-Site VPN and Remote Access VPN are not currently supported.
- Multicloud Defense can register FTDv devices with Cloud-Delivered Firewall Management Center by using the supported registration flow for the deployment. For Multicloud Defense-managed FTDv devices, registration can be device-initiated or Cloud-Delivered Firewall Management Center-triggered. In the Cloud-Delivered Firewall Management Center-triggered flow, Cloud-Delivered Firewall Management Center initiates the registration connection to the FTDv by using the registration information that Multicloud Defense provides through Security Cloud Control Firewall Management.

  This support applies only to FTDv devices that are deployed and managed by Multicloud Defense. It does not change the onboarding flow for manually onboarded FTD or FTDv devices in Cloud-Delivered Firewall Management Center.

Onboard and Configure a Secure Firewall Threat Defense Virtual Device in Multicloud Defense

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the Security Cloud Control platform menu, choose **Products > Multicloud Defense.**

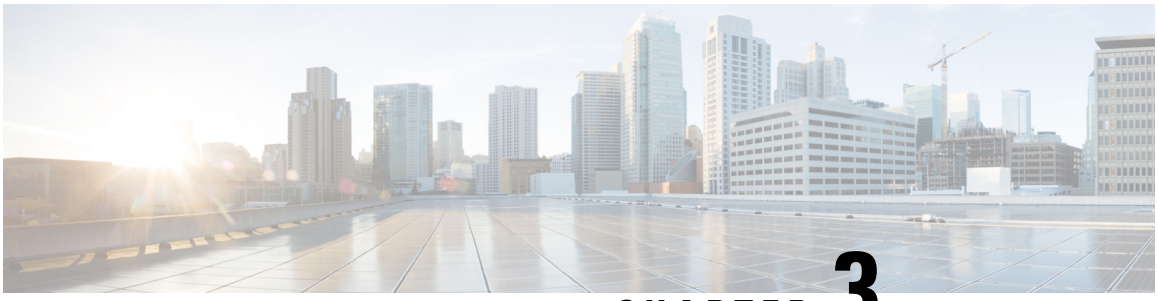
Step 3 Register your FTDv in Multicloud Defense and onboard your cloud security provider, either AWS or Azure. For more details, see Secure Firewall Threat Defense in the Cisco Multicloud Defense User Guide.

Step 4 Create a Service VPC or VNet in Multicloud Defense. For more details, see Create a VPC or VNet.

Step 5 Configure your gateway in Multicloud Defense. For more details, see Add a Gateway with an FTDv.

Step 6 Configure your policy in Cloud-Delivered Firewall Management Center. For more details, see Access Control Policies.

What to do next



You can view your FTDv in Multicloud Defense, Security Cloud Control platform, and Firewall Management Center in your Cloud-Delivered Firewall Management Center account.

PART II

Onboard Devices to Cloud-Delivered Firewall Management Center

- Onboard a Secure Firewall Threat Defense to the Cloud-Delivered Firewall Management Center, on page 19
- Migrate On-Premises Firewall Management Center Managed Secure Firewall Threat Defense to Cloud-delivered Firewall Management Center, on page 63
- Device Registration, on page 99
- Device Registration Using Device Templates, on page 119
- Transparent or Routed Firewall Mode, on page 153
- Change Management, on page 167
- CLI Users, on page 181
- Configuration Deployment, on page 189

CHAPTER 3

Onboard a Secure Firewall Threat Defense to the Cloud-Delivered Firewall Management Center

Read the following information for onboarding prerequisties and procedures.

- Onboarding Overview, on page 19
- Maximum Firewall Threat Defense devices supported in Cloud-Delivered Firewall Management Center, on page 20
- Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 21
- Onboard a Device with a CLI Registration Key, on page 22
- Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24
- Onboard a Firewall Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning, on page 25
- Onboard Firewall Threat Defense Devices using Device Templates to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 27
- Cloud Deployment, on page 29
- Onboard a Secure Firewall Threat Defense Cluster, on page 46
- Onboard a Chassis, on page 49
- Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI, on page 51
- Delete Devices from Cloud-Delivered Firewall Management Center, on page 54
- Troubleshooting, on page 55

Onboarding Overview

Review the following use cases and supported sofware versions that are compatible with Cloud-Delivered Firewall Management Center management.

Note You must ensure that the Firewall Threat Defense device ports have external and outbound access for the Cloud-Delivered Firewall Management Center to onboard them. There is no requirement for an on-premises or cloud-based Security Device Controller (SDC) for this operation. For more information, see Network Requirements.

To send Firewall Threat Defense Syslog events to the Cisco cloud, you can set up the Secure Event Connector (SEC). For more information, see Installing Secure Event Connectors.

Firewall Threat Defense Devices Currently Managed by Cloud-Delivered Firewall Management Center

The following scenarios occur when you either move or migrate a device to the Cloud-Delivered Firewall Management Center:

- If you delete a device from an on-premises Firewall Management Center or Secure Firewall Threat Defense Firewall Device Manager to onboard to the Cloud-Delivered Firewall Management Center, the change of managers wipes any policies configured through the on-premises Firewall Management Center.
- If you **migrate** a device from an on-premises Firewall Management Center to the Cloud-Delivered Firewall Management Center, the device retains the majority of your previously configured policies.

Note If you do not know if your device is already managed by an alternative manager, use the `show managers` command in the device's CLI.

Onboarding Methods

Cloud-Delivered Firewall Management Center supports the following onboarding methods:

- Registration Key - Onboard a device with a registration key. The initial device setup wizard is complete on the device.
- Zero-Touch Provisioning - Onboard a new factory-shipped device with its serial number. Note that this method only supports Firepower 1000, Firepower 2100, or Secure Firewall 3100 devices.
- Zero-Touch Provisioning using a device template - Onboard new factory-shipped devices using serial numbers and a device template. Note that this method only supports Firepower 1000, Firepower 2100, Secure Firewall 1200 or Secure Firewall 3100 devices.

Maximum Firewall Threat Defense devices supported in Cloud-Delivered Firewall Management Center

Cloud-Delivered Firewall Management Center supports up to 2,000 Firewall Threat Defense devices per deployment. This total can include a combination of standalone devices, devices in high-availability pairs, and devices that are cluster nodes.

The Cloud-Delivered Firewall Management Center can manage Firewall Threat Defense Version 7.2.0 and later.

Note The maximum number of supported Secure Firewall Threat Defense devices in Cloud-Delivered Firewall Management Center includes devices that are deployed for analytics on Firewall Management Center and onboarded to Cloud-Delivered Firewall Management Center for management. These devices count toward the platform device capacity limit and must be included in your capacity planning to ensure proper sizing and performance.

Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center

Onboard Limitations and Requirements

Be aware of the following limitations when onboarding a device to the Cloud-Delivered Firewall Management Center:

- Devices **must** be running version 7.2 and later.
- You can migrate an HA pair that is managed by an On-Premises Firewall Management Center by following the Migrate FTD to Cloud-Delivered Firewall Management Center process. Confirm both peers are in a healthy state prior to migrating.
- Devices managed locally by Firewall Device Manager can be onboarded using the serial number.
- Firewall Threat Defense devices can be onboarded to Cloud-Delivered Firewall Management Center using zero-touch provisioning if they are new (just unboxed) or have undergone a factory reset.
- If the device is managed by an on-premises Firewall Management Center, you can either onboard the device to Cloud-Delivered Firewall Management Center or migrate the device. Migrating retains any existing policies and objects, whereas onboarding the device removes most policies and all objects. See Migrate FTD to Cloud-Delivered Firewall Management Center for more information.
- If your device is currently managed by a Firewall Device Manager, unregister all your smart licenses before you onboard the device. Even if you switch device management, the Cisco Smart Software Manager will retain the smart licenses.
- If you have previously onboarded a device that was managed by a Firewall Device Manager and deleted the device from Security Cloud Control with the intention of re-onboarding for cloud management, you **must** register the Firewall Device Manager to the Security Services Exchange cloud after deleting the device. See the "Access Security Services Exchange" chapter in the *Firepower and Cisco SecureX Threat Response Integration Guide.*

Tip Onboarding a device to the Cloud-Delivered Firewall Management Center removes any policies and most objects configured through the previous manager. If your device is currently managed by an on-premises Firewall Management Center, it is possible to migrate the device and retain your policies and objects. See Migrate FTD to Cloud-Delivered Firewall Management Center for more information.

Network Requirements

Before you onboard a device, ensure the following ports have external and outbound access. Confirm the following ports on the device are allowed. If communication ports are blocked behind a firewall, onboarding the device may fail.

Note You cannot configure these ports in the Security Cloud Control UI. You must enable these ports through the device's SSH.

Table 1: Device Port Requirements

Port	Protocol / Feature	Details
443/tcp	HTTPS	Send and receive data from the internet.
443	HTTPS	Communicate with the AMP cloud (public or private)
8305/tcp	Appliance communications	Securely communicate between appliances in a deployment.

Management and Data Interfaces

Make sure your device is correctly configured with either a management or data interface.

To configure a management or data interface on your device, see Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI, on page 51.

Onboard a Device with a CLI Registration Key

Use the procedure below to onboard a device for Cloud-Delivered Firewall Management Center with a CLI registration key.

Note If your device is currently managed by an on-premises Firewall Management Center, onboarding the device will fail. You can either delete the device from the on-premises Firewall Management Center and onboard as a fresh, new device with no policies or objects, or you can migrate the device and retain the existing policies and objects. See Migrate FTD to Cloud-Delivered Firewall Managmenet Center for more information.

Important You can create a Security Cloud Control-managed, standalone logical Firewall Threat Defense device using the Secure Firewall chassis manager or the FXOS CLI.

Before you begin

Before you onboard a device, be sure to complete the following tasks:

- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- Confirm the device's CLI configuration is successfully completed. See Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI, on page 51 for more information.
- Review the prerequesites and limitations before you onboard the device. See "Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center" in Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control for more information.
- The device can be configured for either local management with Secure Firewall Device Manager or remote management with Cloud-Delivered Firewall Management Center.
- Device must be running version 7.2.0 and later.
- You have reset the device's SSH password as part of the bootstrap process. If you have you not reset the SSH password, Security Cloud Control recommends using the Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24 method.

Procedure

Step 1 In the left pane, click **Security Devices**.

Step 2 Click **Onboard device or service** () icon.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Select **Use CLI Registration Key** as the onboarding method.

Step 6 Enter the device name in the **Device Name** field and click **Next**.

Step 7 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 8 Specify whether the device you are onboarding is a physical or virtual device. If you are onboarding a virtual device, you must select the device's performance tier from the drop-down menu.

Step 9 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 10 Security Cloud Control generates a command with the registration key. Connect to the device you are onboarding using SSH. Log in as "admin" or a user with equivalent admin privileges and paste the entire registration key as is into the device's CLI.

Note: For Firepower 1000, Firepower 2100, ISA 3000, and Firewall Threat Defense Virtual devices, open an SSH connection to the device and log in as `admin`. Copy the entire registration command and paste it into the device's CLI interface at the prompt. In the CLI, enter **Y** to complete the registration. If your device was previously managed by Firewall Device Manager, enter **Yes** to confirm the submission.

Step 11 Click **Next** in the Security Cloud Control onboarding wizard.

Step 12 (Optional) Add labels to your device to help sort and filter the **Security Devices** page. Enter a label and select the blue plus button. Labels are applied to the device after it's onboarded to Security Cloud Control.

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning

Only the Firepower 1000, Firepower 2100, Secure Firewall 1200, and Secure Firewall 3100 devices can be onboarded with the zero-touch provisioning method.

Before you begin

Confirm that the following is completed before onboarding:

- You have a Security Cloud Control tenant. If you do not, see Request a Security Cloud Control Tenant for more information.
- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- The device is freshly installed but has never been logged into by either the device CLI, a Firewall Management Center, or the Firewall Device Manager.
- The device is running version 7.2 or later.
- The device's outside or management interface should be able to access the Security Services Exchange domain registration.us.sse.itd.cisco.com.

Procedure

Step 1 In the left pane, click **Security Devices**.

Step 2 Click **Onboard device or service** () icon.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Click the **Use Serial Number** tile.

Step 6 Select Cloud-Delivered Firewall Management Center from the drop-down list. Click **Next**.

For information on onboarding a threat defense device to On-Prem Firewall Management Center, see Onboard a Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning.

Step 7 Enter the **Device Serial Number** and the **Device Name**. Select **Next**.

Step 8 Choose an option depending on whether the device is logged into and configured for a manager:

- If your device is brand new and has never been configured for a manager, click **Yes, this new device has never been logged into or configured for a manager**.
- If your device has been previously registered for a manager or is **still** registered to a manager, click **No, this device has been logged into and configured for a manager**.

Step 9 Click **Next**.

Step 10 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 11 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 12 Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend these actions:

- If you did not already, create a custom access control policy to customize the security for your environment.

  For more information, see Access Control Overview.
- You can enable Cisco Security Analytics and Logging to view events in the Security Cloud Control dashboard, or register the device to a Secure Firewall Management Center for security analytics.

  For more information, see Cisco Security Analytics and Logging.

Onboard a Firewall Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning

Only the Firepower 1000, Firepower 2100, Secure Firewall 1200, and Secure Firewall 3100 devices can be onboarded to on-premises Firewall Management Center using the zero-touch provisioning method.

Before you begin

Confirm the following is completed prior to onboarding:

- You have a Security Cloud Control tenant. If you do not, see Request a Security Cloud Control Tenant for more information.
- Before onboarding any new devices, ensure an on-prem FMC is fully set up, configured, and recognized as a management center within your Security Cloud Control tenant.
- The device is freshly installed and has never been logged into through the device CLI, a Firewall Management Center, or the Firewall Device Manager.

- The device is running version 7.2 or later. .

Procedure

Step 1 In the left pane, click **Security Devices**.

Step 2 Click **Onboard device or service** ( ) icon.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Click **Use Serial Number**.

Step 6 Select an available on-prem FMC from the drop-down list. Click **Next**.

Note

- On-prem FMCs running version 7.4 or later and onboarded with Cisco Security Cloud are displayed in the drop-down.
- Provide the **Public IP address** or **FQDN** value of the selected on-prem FMC unless
  - The FTD is publicly reachable
  - The FTD is running a version earlier than 7.4
  - The connection is being made through the data interface

For information on onboarding a threat defense device to a Cloud-Delivered Firewall Management Center, see Onboard a Threat Defense Device to Cloud-delivered Firewall Management Center using Zero-Touch Provisioning.

Step 7 Enter the **Device Serial Number** and the **Device Name**. Click **Next**.

Step 8 Choose an option depending on whether the device is logged into and configured for a manager:

- If your device is brand new and has never been configured for a manager, click **Yes, this new device has never been logged into or configured for a manager**.
- If your device has been previously registered for a manager or is **still** registered to a manager, click **No, this device has been logged into and configured for a manager**.

Step 9 Click **Next**.

Step 10 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 11 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 12 Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend these actions:

- If you did not already, create a custom access control policy to customize the security for your environment.

  For more information, see Access Control Overview.

- You can enable Cisco Security Analytics and Logging to view events in the Security Cloud Control dashboard, or register the device to a Secure Firewall Management Center for security analytics.

  For more information, see Cisco Security Analytics and Logging.

Onboard Firewall Threat Defense Devices using Device Templates to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning

Only the Firepower 1000, Firepower 2100, Secure Firewall 1200, Secure Firewall 200, and Secure Firewall 3100 devices can be onboarded with the zero-touch provisioning method.

Before you begin

Confirm that the following is completed before onboarding:

- You have a Security Cloud Control tenant. If you do not, see Request a Security Cloud Control Tenant for more information.
- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- The device is freshly installed but has never been logged into by either the device CLI, a Firewall Management Center, or the Firewall Device Manager.
- The device is running version 7.4 or later.

Procedure

Step 1 In the left pane, click **Security Devices**.

Step 2 Click **Onboard device or service** ( ) icon.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Click the **Bulk Onboard using CSV File** tile.

Step 6 In the **Template Assignment** field, select a template from the drop-down list. The access control policy associated with the template and the supported device models for the selected template are then displayed. Click **Next**.

Step 7 In the **Upload CSV File** field, **Drag & drop** your CSV template file or **Click** to select the CSV template file that you want to upload.

You can download a **CSV Sample Template File** to have a look at the required header details that have to be used in the template. The CSV template file must be less than 2 MB in size. The filename must satisfy the following criteria:

- Can have a maximum of 64 characters.
- Only alphanumeric characters and special characters such as dash (-), period (.), and underscore (_) are allowed.
- Must not contain any spaces.

A properly formatted .csv file has the following fields:

- Mandatory fields
  - Display Name - Name of the device. Type: string. Example: test1
  - Serial Number - Serial number of the device. Type: string, Example: JADX345670EG
- Optional fields
  - Device Group - Name of the device group, Type: string, Example: testgroup
  - Admin Password - Password for admin access, Type: string, Example: E28@2OiUrhx
- Variables - Use the following format: $<*varName*>. Sample variable: $LAN-Devices-IPv4Address - IPv4 address of the LAN device. Type: string. Example: 1.2.3.4.
- Network object overrides - Use the following format:<*objType*>:<*objName*>. Sample network object override: Network:LAN-Devices-Network - IP address of the network of LAN devices. Type: string. Example: 1.2.3.4.

A sample CSV template file containing configuration for two devices is as given below.

DisplayName	SerialNumber	AdminPassword	$WANLinkIP	Host:gateway
Branch A FTD	JADX345410AB	C15c05n0rt#	10.20.30.1	10.2.3.1
Branch B FTD	JADX345670CE	Admin123!	10.20.30.5	10.2.3.1

Step 8 Click **Next**.

Step 9 A statement mentioning that the devices are being onboarded is displayed. You can check the onboarding status of the devices in the **Security Devices** window.

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See

Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Cloud Deployment

Cloud Deployment helps you deploy cloud-based enforcement points based on your intended outcomes and use cases. This provides the most cost-effective, scalable, and fully featured security for your multicloud needs.

With Cloud Deployment, you can:

- deploy faster with a guided, intuitive interface,
- select and launch the right enforcement point for your use case, and
- scale automatically to match demand and sustain performance.

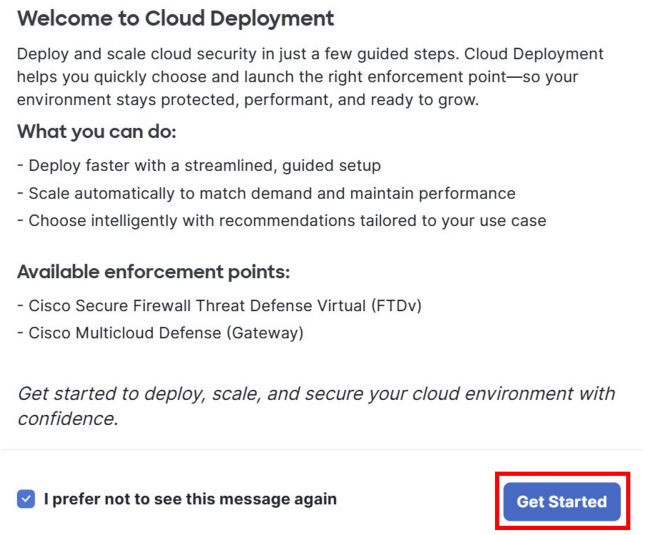
Available enforcement points:

- Cisco Secure Firewall Threat Defense Virtual (FTDv): recommended for TLS Decrypt, IDS/IPS, Antivirus, Geo IP, or Malicious IP.
- Multicloud Defense: recommended for Proxy, WAF – L7 DOS, DLP, or Two-Core Enforcement.

Supported cloud service providers are:

- AWS
- Azure
- Google Cloud Platform (GCP)
- Oracle Cloud Infrastructure (OCI): Supported in this release by Multicloud Defense gateway only

Configure FTDv enforcement point



Cloud Deployment helps you deploy cloud-based enforcement points based on your intended outcomes and use cases. If you select TLS Decrypt, IDS/IPS, Antivirus, Geo IP, or Malicious IP, Cloud Deployment uses the Cisco Secure Firewall Threat Defense Virtual (FTDv) gateway for deployment.

Follow these steps to configure your FTDv enforcement point:

Procedure

Step 1 Choose **Security Devices** > **Cloud Deployment**.

Step 2 Click **Get Started**.

Step 3 On the **Account & Enforcement Type** tab, enter these details.

Field	Description
Account	Select an account from the drop-down list: AWS, Azure, or Google Cloud Platform (GCP).
Region	Select the region this gateway will be deployed into.
Select the type of Traffic Flow	Select the type of traffic flow (at least one must be selected): Ingress: Traffic entering from external destination Egress: Traffic leaving a network to external destination East-West: Traffic communicated across workloads with the network
Select your architectural requirements	Select TLS Decrypt, IDS/IPS, Antivirus, Geo IP, or Malicious IP to deploy through the FTDv gateway. Select Proxy, WAF – L7 DOS, DLP, or Two-Core Enforcement to deploy through Multicloud Defense gateway. Note that if you select Two-Core Enforcement, Antivirus is unavailable as it is not supported.

Step 4 Click **Next**.

Step 5 On the **Configure Enforcement Point** tab, enter these details.

Firepower Threat Defense Virtual Enforcement Information	
Name	Enter a unique name for this enforcement point; the name can be up to 53 characters long and must be alphanumeric and include an underscore or a hyphen.

Description	(Optional) Enter a description for this enforcement point.

If you selected AWS account earlier, enter these details:

VPC/VNet	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. After creation and activation, the wizard auto-populates the related network fields. This step can take up to three to four minutes.
Mgmt. Security Group	Select the security group to associate with the management interface.
Datapath Security Group 1	Select the security group to associate with datapath 1 interface.
Datapath Security Group 2	Select the security group to associate with datapath 2 interface.
Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular FTDv gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet 1	(Optional) Select the subnet for the primary datapath interface in the selected availability zone.
Datapath Subnet 2	(Optional) Select the subnet for the secondary datapath interface.
Cisco Secure Firewall Threat Defense Virtual	
License Model	Select the licensing model for the deployment: **Smart Licensing**, **Gateway Hours**, or **Pay As You Go**
Smart Licensing/Gateway Hours/Pay As You Go	
Software Version	Select the FTDv release to deploy.
Admin Password	Enter the Admin password. It must be between 12 and 72 characters in length and include uppercase and lowercase letters, numeric digits, and special characters, excluding the backslash (\) and hyphen (-) characters. The password cannot contain more than two identical or sequential characters in a row (such as 'aaa' or '123').
Policy Ruleset	Select the FMC policy to attach to the FTDv deployment.
Performance Tier	(Smart Licensing only) Expand the drop-down menu and select the appropriate performance tier for your device. FTDv50 is selected by default.

License Types	(Smart Licensing only) Expand the drop-down menu and select the appropriate license type that you have purchased or will purchase in the future. The **Base** license is auto-selected. For more information about different licensing types, refer to Licensing. If you want to enable malware defense features, you must also have the THREAT license active. The THREAT license is required to support the MALWARE license functionalities.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances.
Minimum Instances	(Optional) Enter the minimum number of instances that you plan to deploy. This must be at least 1.
Maximum Instances	(Optional) Enter the maximum number instances that you plan to deploy. This is the maximum number that is used for auto-scaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	(Optional) Enter the port number that the load balancer uses to check instance health. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Cloud Configuration	
Key Pair	Select the key pair that is associated with the cloud account you selected earlier. You must select an existing key pair from the chosen region.
EBS Encryption	Select the appropriate EBS encryption for your AWS account.
Advanced Settings	
Disable Public IP	Check the **Disable Public IP** check box. Disabling this setting reduces the exposure of your network to external threats. Private IP addresses help protect against unauthorized access, potential attacks, and provide better control over internal traffic. This setting applies only when using NAT-based service and only for data interfaces.

If you selected Azure account earlier, enter these details:

VPC/VNet	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. After creation and activation, the wizard auto-populates the related network fields. This step can take up to three to four minutes.

Resource Group	Select the resource group that owns the deployment resources.
Mgmt. Security Group	Select the security group to associate with the management interface.
Datapath Security Group 1	Select the security group to associate with datapath 1 interface.
Datapath Security Group 2	Select the security group to associate with datapath 2 interface.
Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular FTDv gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet 1	(Optional) Select the subnet for the primary datapath interface in the selected availability zone.
Datapath Subnet 2	(Optional) Select the subnet for the secondary datapath interface.
Cisco Secure Firewall Threat Defense Virtual	
License Model	Select the licensing model for the deployment: **Smart Licensing** or **Gateway Hours**
Smart Licensing/Gateway Hours	
Software Version	Select the FTDv release to deploy.
Admin Password	Enter the Admin password. It must be between 12 and 72 characters in length and include uppercase and lowercase letters, numeric digits, and special characters, excluding the backslash (\) and hyphen (-) characters. The password cannot contain more than two identical or sequential characters in a row (such as 'aaa' or '123').
Policy Ruleset	Select the FMC policy to attach to the FTDv deployment.
Performance Tier	(Smart Licensing only) Expand the drop-down menu and select the appropriate performance tier for your device. FTDv50 is selected by default.

License Types	(Smart Licensing only) Expand the drop-down menu and select the appropriate license type that you have purchased or will purchase in the future. The **Base** license is auto-selected. For more information about different licensing types, refer to Licensing. If you want to enable malware defense features, you must also have the THREAT license active. The THREAT license is required to support the MALWARE license functionalities.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances.
Minimum Instances	(Optional) Enter the minimum number of instances that you plan to deploy. This must be at least 1.
Maximum Instances	(Optional) Enter the maximum number instances that you plan to deploy. This is the maximum number that is used for auto-scaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	(Optional) Enter the port number that the load balancer uses to check instance health. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Azure Configuration	
Key Selection	You can either provide an **SSH Public Key** directly or select an existing **SSH Key Pair** from the drop-down list.
Disk Encryption	Select either a provider-managed encryption key or a customer-managed key (CMK). If using a CMK, provide the **Disk Encryption Set ID**.
Advanced Settings	
Disable Public IP	Check the **Disable Public IP** check box. Disabling this setting reduces the exposure of your network to external threats. Private IP addresses help protect against unauthorized access, potential attacks, and provide better control over internal traffic. This setting applies only when using NAT-based service and only for data interfaces.

If you selected GCP account earlier, enter these details:

GCP Configuration

Datapath VPC	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. After creation and activation, the wizard auto-populates the related network fields. This step can take up to three to four minutes.
Datapath Network Tag 1	Select the network tag used for datapath firewall rules.
Datapath Network Tag 2	This is the second datapath tag used for dual-interface FTDv layouts. This identifies a separate management VPC.
Management VPC	Select the management VPC from the drop-down list.
Management Network Tag	Select the network tag used for management firewall rules from the drop-down list.
SSH Public Key	(Optional) Paste the SSH public key.
Disk Encryption	Select either a provider-managed encryption key or a customer-managed key (CMK). If using a CMK, provide the **Cloud KMS key resource name**.
Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular FTDv gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet 1	(Optional) Select the subnet for the primary datapath interface in the selected availability zone.
Datapath Subnet 2	(Optional) Select the subnet for the secondary datapath interface.
Cisco Secure Firewall Threat Defense Virtual	
License Model	Select the licensing model for the deployment: **Smart Licensing** or **Gateway Hours**
Smart Licensing/Gateway Hours	
Software Version	Select the FTDv release to deploy.
Admin Password	Enter the Admin password. It must be between 12 and 72 characters in length and include uppercase and lowercase letters, numeric digits, and special characters, excluding the backslash (\) and hyphen (-) characters. The password cannot contain more than two identical or sequential characters in a row (such as 'aaa' or '123').
Policy Ruleset	Select the FMC policy to attach to the FTDv deployment.

Performance Tier	(Smart Licensing only) Expand the drop-down menu and select the appropriate performance tier for your device. FTDv50 is selected by default.
License Types	(Smart Licensing only) Expand the drop-down menu and select the appropriate license type that you have purchased or will purchase in the future. The **Base** license is auto-selected. For more information about different licensing types, refer to Licensing. If you want to enable malware defense features, you must also have the THREAT license active. The THREAT license is required to support the MALWARE license functionalities.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances.
Minimum Instances	(Optional) Enter the minimum number of instances that you plan to deploy. This must be at least 1.
Maximum Instances	(Optional) Enter the maximum number instances that you plan to deploy. This is the maximum number that is used for auto-scaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	(Optional) Enter the port number that the load balancer uses to check instance health. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Advanced Settings	
Disable Public IP	Check the **Disable Public IP** check box. Disabling this setting reduces the exposure of your network to external threats. Private IP addresses help protect against unauthorized access, potential attacks, and provide better control over internal traffic. This setting applies only when using NAT-based service and only for data interfaces.

Step 6 Click **Next**. If you want to modify the settings, click **Back**

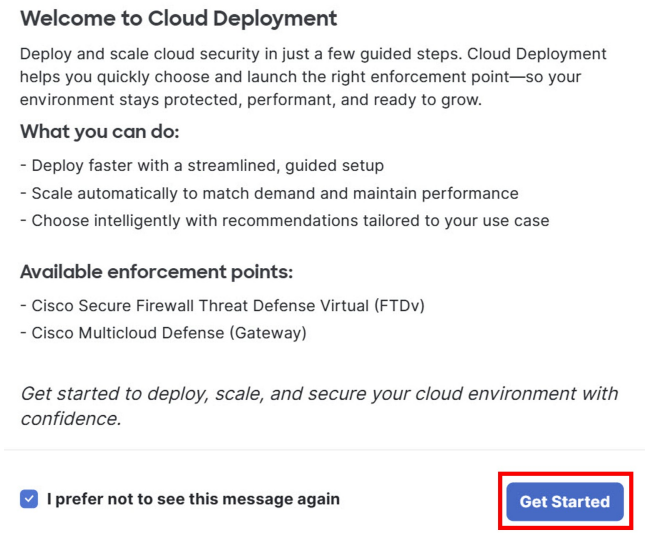
Step 7 On the **Review & Deploy** tab, review your configuration and deploy the enforcement point. If you encounter an error, return to the **Configure Enforcement Points** tab to correct it.

Step 8 Click **Deploy**.

Multicloud Defense deploys the gateway.

You must attach at least one ruleset to the gateway before you secure a spoke VPC/VNet. For more information about rule sets, refer to Rule Sets and Rule Set Groups.

Configure Multicloud Defense enforcement point



Cloud Deployment helps you deploy cloud-based enforcement points based on your intended outcomes and use cases. If you select Proxy, WAF – L7 DOS, DLP, or Two-Core Enforcement, Cloud Deployment uses the Multicloud Defense gateway for deployment.

Follow these steps to configure Multicloud Defense enforcement point:

Procedure

Step 1 Choose **Security Devices** > **Cloud Deployment**.

Step 2 Click **Get Started**.

Step 3 On the **Account & Enforcement Type** tab, enter these details.

Field	Description
Account	Select an account from the drop-down list: AWS, Azure, Google Cloud Platform (GCP), or Oracle Cloud Infrastructure (OCI).
Region	Select the region this gateway will be deployed into.
Select the type of Traffic Flow	Select the type of traffic flow (at least one must be selected): Ingress: Traffic entering from an external destination Egress: Traffic leaving a network to external destination East-West: Traffic communicated across workloads with the network

Select your architectural requirements	Select TLS Decrypt, IDS/IPS, Antivirus, Geo IP, or Malicious IP if you want to deploy these features through the FTDv gateway. Select Proxy, WAF – L7 DOS, DLP, or Two-Core Enforcement if you want to deploy through the Multicloud Defense gateway. Note that if you select Two-Core Enforcement, Antivirus is unavailable as it is not supported.

Step 4 Click **Next**.

Step 5 On the **Configure Enforcement Point** tab, enter these details.

Multicloud Defense Gateway Enforcement Information	
Name	Enter a unique name for this enforcement point; the name can be up to 53 characters long and must be alphanumeric and include an underscore or a hyphen.
Description	(Optional) Enter a description for this enforcement point.

If you selected AWS account earlier, enter these details:

Multicloud Defense Gateway Enforcement Information	
Deployment	Click **Centralized** or **Distributed** to select the deployment type. **Centralized** allows you to select only a Service VPC. **Distributed** allows you to select only a regular VPC/VNet. If you select a Service VPC, the deployment operates in Hub mode. If you select a regular VPC or VNet, the deployment operates in Edge mode.
VPC/VNet	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. You cannot create a new Service VPC/VNet if you selected **Distributed** earlier. After you create and activate the service, the wizard automatically fills in the related network fields. This step can take up to 3 to 4 minutes.
Mgmt. Security Group	Select the security group to associate with the management interface.
Datapath Security Group	Select the security group to associate with the datapath interface.

Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular Multicloud Defense gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet	(Optional) Select the subnet for the primary datapath interface in the selected availability zone.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances from the drop-down list.
Minimum Instances	(Optional) Enter the minimum number of instances you plan to deploy. This must be at least one.
Maximum Instances	(Optional) Enter the maximum number of instances you plan to deploy. This is the maximum number that is used for autoscaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	Enter the port number used by Multicloud Defense load balancer to check the health of the instances. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Gateway Image Group	Select the logical grouping of available gateway images from the drop-down list.
Gateway Image	Select the exact gateway image/version to deploy from the drop-down list.
Policy Ruleset	Select the Multicloud Defense policy ruleset to attach to the gateway.
Cloud Configuration	
Key Pair	Select the key pair associated with the cloud account you selected in the previous screen.
Gateway IAM Role	Select the IAM role that allows the gateway to perform READ and WRITE operations on your AWS account. Multicloud Defense creates this role for you when you save and deploy the gateway.
EBS Encryption	Select the appropriate EBS encryption for your specific AWS account.
Multicloud Defense Profiles	
Packet Capture Profile	(Optional) Select the packet capture profile for threat and flow PCAPs.

Log Forwarding Profile	(Optional) Select the log forwarding profile used to forward Events/Logs to a security information and event management (SIEM) system.
Metrics Profile	(Optional) Select the metrics profile.
NTP Profile	(Optional) Select the Network Time Protocol (NTP) for time synchronization.
Advanced Settings	
Use Global Accelerator	(Ingress only) Associate the gateway with an AWS Global Accelerator listener so that traffic uses your accelerator.
Disable Public IP	By default, the Multicloud Defense gateway enables the use of the public IP of the router available. If you do not want this enabled, check the **Disable Public IP** check box. This reduces the exposure of your network to external threats.
Use Internal Load Balancer	To reduce the exposure of your network to external threats, you can use an internal load balancer instead of a public one for the gateway front end (Ingress only). While the Multicloud Defense gateway enables a public router IP by default, you can opt for a private configuration by checking the **Disable Public IP** check box.

If you selected Azure account earlier, enter these details:

Multicloud Defense Gateway Enforcement Information	
Deployment	Click **Centralized** or **Distributed** to select the deployment type. **Centralized** allows the selection of only a Service VPC. **Distributed** allows the selection of only a regular VPC/VNet. If you select a Service VPC, the deployment operates in Hub mode. If you select a regular VPC or VNet, the deployment operates in Edge mode.
VPC/VNet	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. You cannot create a new Service VPC/VNet if you selected **Distributed** earlier. After you create and activate the service, the wizard automatically fills in the related network fields. This step can take up to 3 to 4 minutes.
Resource Group	Select the resource group that owns the deployment resources.

Mgmt. Security Group	Select the security group to associate with the management interface.
Datapath Security Group 1	Select the security group to associate with the datapath interface.
Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular Multicloud Defense gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet	(Optional) Select the subnet for the primary datapath interface in the selected availability zone.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances.
Minimum Instances	(Optional) Enter the minimum number of instances you plan to deploy. This must be at least one.
Maximum Instances	(Optional) Enter the maximum number of instances you plan to deploy. This is the maximum number that is used for autoscaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	Enter the port number that the load balancer uses to check instance health. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Gateway Image Group	Select the logical grouping of available gateway images from the drop-down list.
Gateway Image	Select the exact gateway image/version to deploy from the drop-down list.
Policy Ruleset	Select the Multicloud Defense policy ruleset to attach to the gateway.
Azure Configuration	
Key Selection	You can either provide an **SSH Public Key** directly or select an existing **SSH Key Pair** from the drop-down list.
Username	The default SSH username is centos.
User Assigned Identity ID	(Optional) Used for accessing Key Vault or writing PCAP files to Blob Storage.
Disk Encryption	(Optional) Select the disk encryption type from the drop-down list

Multicloud Defense Profiles	
Packet Capture Profile	(Optional) Select the packet capture profile for threat and flow PCAPs.
Log Forwarding Profile	(Optional) Select the log forwarding profile used to forward Events/Logs to a security information and event management (SIEM) system.
Metrics Profile	(Optional) Select the metrics profile.
NTP Profile	(Optional) Select the Network Time Protocol (NTP) for time synchronization.
Advanced Settings	
Management DNS Server	(Optional) Enter the IP address of a DNS server reachable by the gateway for management traffic.
Attach Additional Load Balancer	(Optional) Click **+ Add** to associate Azure Load Balancers with this gateway for advanced traffic distribution. Select the **Azure LB Name** from the drop-down list and enter the **Backend Pool Name** and **Resource Group**.
Disable Public IP	By default, the Multicloud Defense gateway enables the use of the public IP of the router available. If you do not want this enabled, check the **Disable Public IP** check box. This reduces the exposure of your network to external threats.
Use Internal Load Balancer	To reduce the exposure of your network to external threats, you can use an internal load balancer instead of a public one for the gateway front end (Ingress only). While the Multicloud Defense gateway enables a public router IP by default, you can opt for a private configuration by checking the **Disable Public IP** check box.

If you selected GCP account earlier, enter these details:

Deployment	Click **Centralized** or **Distributed** to select the deployment type. **Centralized** allows the selection of only a Service VPC. **Distributed** allows the selection of only a regular VPC/VNet. If you select a Service VPC, the deployment operates in Hub mode. If you select a regular VPC or VNet, the deployment operates in Edge mode.
GCP Configuration	
Service Account Email	Enter the service account email attached to gateway instances.

Datapath VPC	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. After you create and activate the service, the wizard automatically fills in the related network fields. This step can take up to 3 to 4 minutes.
Datapath Network Tag	Select the network tag used for datapath firewall rules.
Management VPC	Select the management VPC from the drop-down list.
Management Network Tag	Select the network tag used for management firewall rules from the drop-down list.
Username	The default SSH username is centos.
SSH Public Key	(Optional) Paste the SSH public key.
Disk Encryption	(Optional) Select the disk encryption type from the drop-down list
Network Details	
Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular Multicloud Defense gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet	(Optional) Select the subnet for datapath interface in the selected availability zone.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances.
Minimum Instances	(Optional) Enter the minimum number of instances you plan to deploy. This must be at least one.
Maximum Instances	(Optional) Enter the maximum number of instances you plan to deploy. This is the maximum number that is used for autoscaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	Enter the port number that the load balancer uses to check instance health. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Gateway Image Group	Select the logical grouping of available gateway images from the drop-down list.
Gateway Image	Select the exact gateway image/version to deploy from the drop-down list.

Policy Ruleset	Select the Multicloud Defense policy ruleset to attach to the gateway.
Multicloud Defense Profiles	
Packet Capture Profile	(Optional) Select the packet capture profile for threat and flow PCAPs.
Log Forwarding Profile	(Optional) Select the log forwarding profile used to forward Events/Logs to a security information and event management (SIEM) system.
Metrics Profile	(Optional) Select the metrics profile.
NTP Profile	(Optional) Select the Network Time Protocol (NTP) for time synchronization.
Advanced Settings	
Disable Public IP	By default, the Multicloud Defense gateway enables the use of the public IP of the router available. If you do not want this enabled, check the **Disable Public IP** check box. This reduces the exposure of your network to external threats.
GCP LB Protocol UDP	Check this check box to enable UDP on the gateway's GCP load balancer configuration.

If you selected Oracle Cloud Infrastructure (OCI) account earlier, enter these details:

Multicloud Defense Gateway Enforcement Information	
Deployment	Click **Centralized** or **Distributed** to select the deployment type. **Centralized** allows the selection of only a Service VPC. **Distributed** allows the selection of only a regular VPC/VNet. If you select a Service VPC, the deployment operates in Hub mode. If you select a regular VPC or VNet, the deployment operates in Edge mode.
VPC/VNet	You can select an existing Service VPC/VNet from the drop-down list or click **+ Create SVPC** to create a new one. You cannot create a new Service VPC/VNet if you selected **Distributed** earlier. After you create and activate the service, the wizard automatically fills in the related network fields. This step can take up to 3 to 4 minutes.
Mgmt. Security Group	(Optional) Select the security group to associate with the management interface.

Datapath Security Group	(Optional) Select the security group to associate with the datapath interface.
Availability Zone	(Optional) Select the specific availability zone within a cloud region where a particular Multicloud Defense gateway instance is deployed. Click **+ Add Availability Zone** to add a new availability zone.
Management Subnet	(Optional) Select the subnet for the management interface in the selected availability zone.
Datapath Subnet	(Optional) Select the subnet for the primary datapath interface in the selected availability zone.
Gateway Configuration	
Instance Type	Select the VM size used for the gateway instances from the drop-down list.
Minimum Instances	(Optional) Enter the minimum number of instances you plan to deploy. This must be at least one.
Maximum Instances	(Optional) Enter the maximum number of instances you plan to deploy. This is the maximum number that is used for autoscaling in each availability zone. This number must be greater than or equal to minimum instances.
Health Check Port	Enter the port number used by Multicloud Defense load balancer to check the health of the instances. Datapath security groups assigned to the instance(s) must allow traffic on this port. The default port is 65534, and the valid range is from 1 to 65535.
Gateway Image Group	Select the logical grouping of available gateway images from the drop-down list.
Gateway Image	Select the exact gateway image/version to deploy from the drop-down list.
Policy Ruleset	Select the Multicloud Defense policy ruleset to attach to the gateway.
OCI Configuration	
Compartment	OCI Compartment where Multicloud Defense gateway will be deployed.
SSH Public Key	Paste the SSH public key.
Multicloud Defense Profiles	
Packet Capture Profile	Select the packet capture profile for threat and flow PCAPs.
Log Forwarding Profile	Select the log forwarding profile used to forward Events/Logs to a security information and event management (SIEM) system.
Metrics Profile	Select the metrics profile.

NTP Profile	Select the Network Time Protocol (NTP) for time synchronization.
Advanced Settings	
Internal Load Balancer	To reduce the exposure of your network to external threats, you can use an internal load balancer instead of a public one for the gateway front end (Ingress only). While the Multicloud Defense gateway enables a public router IP by default, you can opt for a private configuration by selecting the **Disable Public IP** check box.
User ID	Enable User ID on the gateway if your account supports it.
Management DNS Server	Enter the IP address of a DNS server reachable by the gateway for management traffic.
Public IP	By default, the Multicloud Defense gateway enables the use of the public IP of the router available. If you do not want this enabled, check the **Disable Public IP** check box. This reduces the exposure of your network to external threats.

Step 6 Click **Next**. If you want to modify the settings, click **Back**.

Step 7 On the **Review & Deploy** tab, review your configuration and deploy the enforcement point. If you encounter an error, return to the **Configure Enforcement Points** tab to correct it.

Step 8 Click **Deploy**.

Multicloud Defense deploys the gateway.

You must attach at least one ruleset to the gateway before you secure a spoke VPC/VNet. For more information about rule sets, refer to Rule Sets and Rule Set Groups.

Onboard a Secure Firewall Threat Defense Cluster

This task enables you to register a Secure Firewall Threat Defense cluster with Cloud-Delivered Firewall Management Center for centralized management and policy enforcement.

The following table provides information about device models that support cluster onboarding and creation on the Cloud-Delivered Firewall Management Center:

Secure Firewall Threat Defense Platforms	Minimum Secure Firewall Threat Defense Version for Cluster Management	Support cluster creation from Cloud-Delivered Firewall Management Center?
VMware, KVM	7.2.1	Yes
AWS, GCP	7.2.1	No
Azure	7.3	No
Secure Firewall 3100	7.2.1	Yes

Secure Firewall Threat Defense Platforms	Minimum Secure Firewall Threat Defense Version for Cluster Management	Support cluster creation from Cloud-Delivered Firewall Management Center?
Firepower 4100	7.2.x	No
Secure Firewall 4200	7.4	Yes
Firepower 9300	7.2.x	No

Note When you onboard a Secure Firewall Threat Defense cluster to Cloud-Delivered Firewall Management Center, you register only the cluster CONTROL NODE. After the CONTROL NODE registers, Cloud-Delivered Firewall Management Center discovers the DATA nodes in the cluster.

Before you begin

Review these limitations:

- Firepower 4100 and Firepower 9300 devices must be clustered through the device's Firewall Chassis Manager.
- Secure Firewall 3100 devices, Secure Firewall 4200 devices, KVM, and VMware environments must be clustered through the Cloud-Delivered Firewall Management Center UI.
- Azure, AWS, and GCP environment clusters must be created through their own environment and onboarded to Cloud-Delivered Firewall Management Center.
- Verify that the Secure Firewall Threat Defense virtual devices are successfully configured as a cluster before you register the cluster with Cloud-Delivered Firewall Management Center.

  For example, in the Secure Firewall Threat Defense CLI, enter the `show cluster info` command. Confirm that the output shows the cluster as `On`, one unit in `CONTROL_NODE` state, and the remaining units in `DATA_NODE` state.

```
> show cluster info
Cluster mAZ-ngfw-cl: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "74-a" in state DATA_NODE
        ID        : 2
        Version   : 9.22(1)1
        Serial No.: 9AUVQ3DSF66
        CCL IP    : 1.1.1.74
        CCL MAC   : 02e2.778f.d3ed
        Module    : NGFWv
        Resource  : 4 cores / 7680 MB RAM
        Last join : 07:28:26 UTC Sep 25 2024
        Last leave: 07:28:11 UTC Sep 25 2024
Other members in the cluster:
    Unit "135-b" in state CONTROL_NODE
        ID        : 0
        Version   : 9.22(1)1

>
```

Follow these steps to onboard a Secure Firewall Threat Defense cluster:

Procedure

Step 1 In the left pane, click **Security Devices**.

Step 2 Click **Onboard device or service** ( ) icon.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Select **Use CLI Registration Key**.

Step 6 Enter the device name in the **Device Name** field and click **Next**.

Step 7 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 8 Specify whether the device you are onboarding is a physical or virtual device. If you are onboarding a virtual device, you must select the device's performance tier from the drop-down menu.

Step 9 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 10 Security Cloud Control generates a command with the registration key. Paste the entire registration key into the device's CLI without making changes.

Step 11 (Optional) Add labels to your device to help sort and filter the **Security Devices** page. Enter a label and select the blue plus button. Labels are applied to the device after it's onboarded to Security Cloud Control.

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Onboard a Chassis

You can add a Firepower 4100/9300 chassis to the Cloud-Delivered Firewall Management Center. The management center and the chassis share a separate management connection using the chassis MGMT interface. The Cloud-Delivered Firewall Management Center offers chassis-level health alerts. For configuration, you still need to use the Firewall Chassis Manager or FXOS CLI.

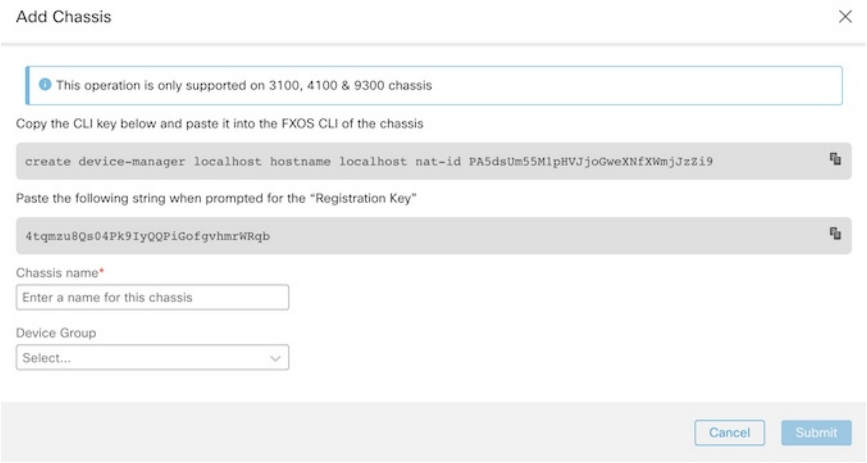
Security Cloud Control does not record the processes on the **Workflow** page when you onboard a chassis or provision a multi-instance Firewall Management CenterFirewall Threat Defense device from the Cloud-Delivered Firewall Management Center chassis manager page.

Note For the Secure Firewall 3100/4200, you need to first convert to multi-instance mode. See Onboard the multi-instance chassis using the CLI, on page 667.

Procedure

Step 1 Connect to the chassis FXOS CLI, either using the console port or SSH.

Step 2 In the left pane, click **Security Devices**.



Step 3 Click **Onboard device or service** ( ) icon.

Step 4 Click the **FTD Chassis** tile to open the **Add Chassis** dialog box.

Figure 5: FTD Chassis Tile

Figure 6: Add Chassis

Step 5 Click **Copy** ( ) to copy the top generated command, then paste it at the FXOS CLI of your chassis.

Step 6 When prompted for the Registration Key at the FXOS CLI, click **Copy** ( ) on the **Add Chassis** dialog box for the generated registration key and paste it at the FXOS CLI.

You can disconnect from the FXOS CLI at this point.

Step 7 In the Cloud-Delivered Firewall Management Center **Chassis Name** field, enter a name for the chassis as you want it to display in the Cloud-Delivered Firewall Management Center.

Step 8 (Optional) Add the chassis to a **Device Group**.

Step 9 Click **Submit**.

The chassis is added to the **Device** > **Device Management** page.

Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI

Connect to the device's CLI to perform initial setup, including setting the management IP address, gateway, and other basic networking settings using the setup wizard. Ensure all DNS and firewall ports are accessible for communication.

The dedicated management interface is a special interface with its own network settings. If you do not want to use the management interface, you can use the CLI to configure a data interface instead.

This configuration is ideal for devices that are going to be onboarded with their CLI registration key.

Note Do **not** use this configuration procedure for devices that are onboarding with zero-touch provisioning.

Procedure

Step 1 Connect to the device's CLI, either from the console port or using SSH to the management interface. If you intend to change the network settings, we recommend using the console port so you do not get disconnected.

(Firepower and Secure Firewall hardware models) The console port connects to the FXOS CLI. The SSH session connects directly to the Firewall Threat Defense CLI.

Step 2 Log in with the username **admin** and the password **Admin123** .

At the console port, you connect to the FXOS CLI. The first time you log in to FXOS, you are prompted to change the password. This password is also used for the Firewall Threat Defense login for SSH.

Note
If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default.

For Firepower and Secure Firewall hardware, see the Reimage Procedures in the Cisco FXOS Troubleshooting Guide for the Firewall Threat Defense .

For the ISA 3000, see the Cisco Secure Firewall ASA and Threat Defense Reimage Guide .

Example:

```
firepower login:
                        admin
Password:
                        Admin123
Successful login attempts for user 'admin' : 1
[...]
Hello admin. You must change your password.
Enter new password:
                        ********
Confirm new password:
                        ********
Your password was updated successfully.
```

```
[...]
firepower#
```

Step 3 If you connected to FXOS on the console port, connect to the Firewall Threat Defense CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 4 The first time you log in to the device, you are prompted to accept the End User License Agreement (EULA) and, if using an SSH connection, to change the admin password. You are then presented with the CLI setup script.

Note
You cannot repeat the CLI setup wizard unless you clear the configuration; for example, by reimaging. However, all of these settings can be changed later at the CLI using **configure network** commands. See the threat defense command reference.

Defaults or previously entered values appear in brackets. To accept previously entered values, press **Enter**.

Note
The management interface settings are used even when you enable Firewall Threat Defense access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the management interface DNS servers, and not the data interface DNS servers.

See the following guidelines:

- **Configure IPv4 via DHCP or manually?**—If you want to use a data interface for Firewall Threat Defense access instead of the management interface, choose **manual**. Although you do not plan to use the management interface, you must set an IP address, for example, a private address. You cannot configure a data interface for management if the management interface is set to DHCP, because the default route, which must be **data-interfaces** (see the next bullet), might be overwritten with one received from the DHCP server.
- **Enter the IPv4 default gateway for the management interface**—If you want to use a data interface for Firewall Threat Defense access instead of the management interface, set the gateway to be **data-interfaces**. This setting forwards management traffic over the backplane so it can be routed through the FMC access data interface.
- **If your networking information has changed, you will need to reconnect**—If you are connected with SSH but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected.
- **Manage the device locally?**—Enter **YES** to configure the device for the device to be managed by either the Cloud-Delivered Firewall Management Center or Secure Firewall Device Manager.

  Manage the device locally?—Enter **NO** to configure the device for remote management with the on-premises Firewall Management Center.
- **Configure firewall mode?**—We recommend that you set the firewall mode at initial configuration. Changing the firewall mode after initial setup erases your running configuration. Note that data interface Firewall Threat Defense access is only supported in routed firewall mode.

Step 5 (Optional) Configure a data interface for Cloud-Delivered Firewall Management Center access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

Note
You should use the console port when using this command. If you use SSH to the Management interface, you might get disconnected and have to reconnect to the console port. See below for more information about SSH usage.

See the following details for using this command. See About Data Interfaces, on page 3105 for more informatio.

- The original management interface cannot use DHCP if you want to use a data interface for management. If you did not set the IP address manually during initial setup, you can set it now using the **configure network** {**ipv4** | **ipv6**} **manual** command. If you did not already set the management interface gateway to **data-interfaces**, this command will set it now.
- When you onboard the device for Firewall Threat Defense management through Security Cloud Control, Security Cloud Control discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For more information about the DNS server configuration, see below. You can later make changes to the access interface configuration, but make sure you don't make changes that can prevent the device or Security Cloud Control from re-establishing the management connection. If the management connection is disrupted, the device includes the **configure policy rollback** command to restore the previous deployment.
- This command sets the *data* interface DNS server. The Management DNS server that you set with the setup script (or using the **configure network dns servers** command) is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface.

  Also, local DNS servers are only retained if the DNS servers were discovered at initial registration. For example, if you registered the device using the Management interface, but then later configure a data interface using the **configure network management-data-interface** command, then you must manually configure all of these settings in Security Cloud Control, including the DNS servers, to match the device configuration.
- You can change the management interface after you onboard the Firewall Threat Defense for Firewall Threat Defense management through threat defense, to either the management interface or another data interface.
- The FQDN that you set in the setup wizard will be used for this interface.
- You can clear the entire device configuration as part of the command; you might use this option in a recovery scenario, but we do not suggest you use it for initial setup or normal operation.
- To disable data managemement, enter the **configure network management-data-interface disable** command.

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]:
IP address (manual / dhcp) [dhcp]:
DDNS server update URL [none]:
https://jcrichton:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>
```

```
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Step 6 (Optional) Limit data interface access to Security Cloud Control on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

Delete Devices from Cloud-Delivered Firewall Management Center

Though devices may be registered to Cloud-Delivered Firewall Management Center, Security Cloud Control still manages device enrollment. You must delete the device from the Security Cloud Control dashboard to remove a device from Cloud-Delivered Firewall Management Center.

Note Security Cloud Control does not synchronize the deletion of devices that are associated with an AWS VPC environment. You must delete a device direclty from the AWS VPC UI. See AWS documentation for more information.

Procedure

Step 1 Log into Security Cloud Control and click **Security Devices**.

Step 2 Locate the device you want to delete by using the filters or search bar. Select it so the device row is highlighted. If your device is part of a high availability pair, locate and select the active device.

Step 3 In the Device Actions pane located to the right, click **Remove**.

Step 4 When prompted, select **OK** to confirm the removal of the selected device. Click **Cancel** to keep the device onboarded.

Troubleshooting

Use the following scenarios to troubleshoot any onboarding issues.

Troubleshoot Cloud-Delivered Firewall Management Center Connectivity with TCP

Use the following procedure to troubleshoot connectivity between the Cloud-Delivered Firewall Management Center and a Firewall Threat Defense device with TCP port 8305.

Procedure

Step 1 Log into Security Cloud Control.

Step 2 Navigate to **Tools & Services** in the left panel and select **Firewall Management Center** to open the **Services** page. Choose **Cloud-Delivered FMC** and locate the Cloud-Delivered Firewall Management Center's FQDN in the top righthand corner.

Step 3 Make sure the Firewall Threat Defense device's state in Security Cloud Control is currently **Onboarding**. Cloud-Delivered Firewall Management Center will not respond if the device is not in an onboarding state. If onboarding has failed, click **Retry Onboarding**.

Step 4 Log into the Firewall Threat Defense device with SSH.

Step 5 Enter into Expert mode with the following command:

```
> expert
admin@devicename:~$
```

Step 6 Execute a TCP handshake:

```
admin@devicename:~$ nc -v xxxxxx.cdo.cisco.com 8305
Connection to xxxxxx.cdo.cisco.com 8305 port [tcp/*] succeeded!
^C (CTRL-C to exit netcat)
admin@devicename:~$.
```

If there is still no response from the Cloud-Delivered Firewall Management Center, then there is a chance that outbound port TCP 8305 may be blocked upstream from your Firewall Threat Defense device and that

network path will need to be assured before your Firewall Threat Defense will be able to connect to Cloud-Delivered Firewall Management Center.

Troubleshoot Firewall Threat Defense Device Connectivity

Test connectivity to the Internet from the management-plane of the Firewall Threat Defense device:

Procedure

	Command or Action	Purpose
Step 1	Log into the Firewall Threat Defense device with SSH.	

Step 2	Ping one or both of the following:	`ping system 208.67.222.222`
		`ping system cisco.com`
		If either of these tests fail, there is likely an L1-L3 issue and you will need to check your management networking configuration (`show network`) and/or a DNS issue.

Troubleshoot Device Connectivity Loss After Cloud-Delivered Firewall Management Center Update

A Cloud-Delivered Firewall Management Center is assigned a dynamic IP address when it is added to a Security Cloud Control tenant. When the management center is updated, the management center receives a new dynamic IP address.

If you have a firewall inspecting the outbound traffic from your threat defense device to the Cloud-Delivered Firewall Management Center, your firewall rules must allow the threat defense traffic to flow to the FQDN and port of the management center rather than its IP address, or the management center will not be able to manage your threat defense device.

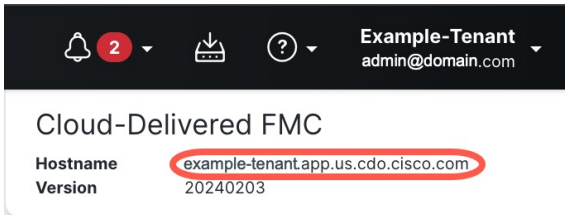
For example, if your network traffic rule allowing management traffic from your threat defense device to the Cloud-Delivered Firewall Management Center looks like this:

```
allow all traffic <my-threat-defense-ip-src> to 200.165.200.225
```

where 200.165.200.225 is the management address of the Cloud-Delivered Firewall Management Center, change the one allow rule to these two allow rules as both ports 443 and 8305 need to be open:

```
allow all traffic <my-threat-defense-ip-src > to <my-cdfFMC-FQDN>:443
```

```
allow all traffic <my-threat-defense-ip-src > to <my-cdfFMC-FQDN>:8305
```



See “Network Requirements” in Prerequisites to Onboard a Device to Cloud-delivered Firewall Management Center for more port information.

Where do I find the domain name of my Cloud-Delivered Firewall Management Center?

Where do I find the domain name of my Cloud-Delivered Firewall Management Center?

1. Log in to Security Cloud Control.
2. In the left pane, click **Administration** > **Integrations** > **Firewall Management Center**
3. Select **Cloud-Delivered FMC** in the FMC table.
4. In the top-right corner of the screen, you will see the Hostname of the management center. This is the FQDN.

Figure 7: Cloud-delivered FMC FQDN

Troubleshoot Onboarding a Device to the Cloud-Delivered Firewall Management Center Using the CLI Registration Key

Error: Device Remains in Pending Setup State After Onboarding

When a device fails to register, the device's connectivity status is displayed as **Pending Setup**. In the panel located to the right, Security Cloud Control displays a **Registration Failed** message as well as a **Retry Onboarding** button to immediately allow you to reattempt onboarding the device.

If you fail to execute the `configuration manager` command in the device CLI within 3 mins after onboarding it to Security Cloud Control, the device's registration attempt expires and results in a registrationg failure. Use the following procedure to resolve the issue:

Procedure

Step 1 Log into Security Cloud Control and navigate to the **Security Devices** page. Locate the device that failed to register.

Step 2 In the panel located to the right, locate the **Registration Failed** window. Beside the device's CLI registration key, click **Copy**. This actions copies the CLI key to a local clipboard.

Step 3 Open an SSH connection to the device and log in as `admin`.

Step 4 Paste the CLI registration key into the device's CLI interface. In the CLI, enter **Y** to complete the registration. If your device was previously managed by Firewall Device Manager, enter **Yes** to confirm the submission.

Troubleshoot Onboarding a Device to Cloud-Delivered Firewall Management Center Using the Serial Number

Device is Offline or Unreachable

If the device is unreachable during the onboarding proess, or at any point post-onboarding, Security Cloud Control displays an **Unreachable** connectivity status. The device will not be able to fully onboard to Security Cloud Control until the device is able to connect. The following scenarios might be the cause:

- The device is cabled incorrectly.
- Your network may require a static IP address for the device.
- Your network uses custom DNS, or there is external DNS blocking the network.
- If your device is associated with the European region (https://defenseorchestrator.eu/), you may need to enable PPPoE authentication.For other domains, review the domain requirements.
- The device may be blocked by a firewall, or is incorrectly blocking a port for connectivity. Review the device Network Requirements, on page 22 and confirm the correct outgoing ports are enabled.

Error: Serial Number Already Claimed

The Device was Purchased From an External Vendor

If the device was purchased from an external vendor and fails to onboard with a **Serial Number Already Claimed** error, it's possible the device is still associated to the vendor's tenant. Use the following steps to claim the device and its serial number:

1. Delete the device from your Security Cloud Control tenant.
2. Install the FXOS image on the device. For more information, see the "Reimage Procedures" chapter of the Cisco FXOS Troubleshooting Guide for the Firepower 1000/21000 and Secure Firewall 3100 Firepower Threat Defense guide.
3. Connect a laptop to the device's console port.
4. Connect to the FXOS CLI and log in as **admin**.
5. In the FXOS CLI, connect to **local-mgmt** with the `firepower # connect local-mgmt` command.
6. Execute the `firepower(local-mgmt) # cloud deregister` command to deregister the device from the cloud tenancy.
7. Once the device is successfully unregistered, the CLI interface returns a success message. An example of the message:

```
Example: firepower(local-mgmt) # cloud deregister Release Image Detected RESULT=success
 MESSAGE=SUCCESS 10, X-Flow-Id: 2b3c9e8b-76c3-4764-91e4-cfd9828e73f9
```

Note If the device was never registered to another Security Cloud Control tenant, the message above states `RESULT=success MESSAGE=DEVICE_NOT_FOUND`.

8. Onboard the device to your Security Cloud Control tenant with its serial number. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24 for more information.

The Device is Claimed By a Security Cloud Control Tenant in Another Region

The device may have been previously managed by another Security Cloud Control instance in a different region and is still registered to that tenant.

If you **do** have access to the tenant the device is currently registered to, use the following procedure:

1. Delete the device from the incorrect Security Cloud Control tenant.
2. Log into the device's Firewall Device Manager UI.
3. Navigate to **System Settings** > **Cloud Services**.
4. Click **Cloud Services** and select **Unregister Cloud Services** from the drop-down list.
5. Confirm the action and click **Unregister**. This action generates a warning to indicate that the device has been removed from Security Cloud Control. This is expected behavior.
6. Log into Security Cloud Control tenant in the correct region and onboard the device. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24 for more information.
7. Navigate to **System Settings** > **Cloud Services**.
8. Click **Cloud Services** and select **Unregister Cloud Services** from the drop-down list.
9. Select the **Auto-enroll with Tenancy from Security Cloud Control** and click **Register**. The device maps to the new tenant that belongs to the new region and Security Cloud Control onboards the device.

If you **do not** have access to the tenant, use the procedure below:

1. Connect to the FXOS CLI from the console port and log in as **admin**. For information on how to log into the FXOS CLI, see Accessing the FXOS CLI.
2. In the FXOS CLI, connect to **local-mgmt** with the `firepower # connect local-mgmt` command.
3. Execute the `firepower(local-mgmt) # cloud deregister` command to deregister the device from the cloud tenancy.
4. Once the device is successfully unregistered, the CLI interface returns a success message. An example of the message:

```
Example: firepower(local-mgmt) # cloud deregister Release Image Detected RESULT=success
 MESSAGE=SUCCESS 10, X-Flow-Id: 2b3c9e8b-76c3-4764-91e4-cfd9828e73f9
```

Note If the device was never registered to another Security Cloud Control tenant, the message above states `RESULT=success MESSAGE=DEVICE_NOT_FOUND`.

5. In your Security Cloud Control tenant in the correct domain, onboard the device. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24 for more information.

6. In the device's Firewall Device Manager UI, navigate to **System Settings** > **Cloud Services**.
7. Select the **Auto-enroll with Tenancy from Security Cloud Control** and click **Register**. The device maps to the new tenant that belongs to the new region and Security Cloud Control onboards the device.

Error: Claim Error

If you enter the wrong serial number when onboarding a device, Security Cloud Control generates a **Claim Error** status.

Note Confirm that the device is claimed in the correct region within Security Cloud Control.

Resolve this issue with the provedure below:

Procedure

Step 1 Log into Security Cloud Control and navigate to the **Security Devices** page. Locate the device with the error.

Step 2 Select the device so it is highlighted and **Remove** the device from Security Cloud Control.

Step 3 Confirm the following:

- The device is online and can reach the internet.
- The device has not already been onboarded to your Security Cloud Control instance or claimed by a Security Cloud Control tenant in another region.

Step 4 Locate the device's serial number. You can use one of the following methods:

- For the 1000, 2100 and 3100 series model, locate the serial number on the physical device.
- Open an SSH connection to the device and issue the `show serial-number` command.

Step 5 In Security Cloud Control, onboard the device with the correct serial number. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24 for more information.

Error: Failed to Claim

If you see an **Error: Failed to Claim** connectivity status or error message after attempting to onboard a device, the following might be the cause:

- The Security Services Exchange platform may have temporary issues that result in no connectivity.
- The Security Cloud Control server may be down.

Follow the procedure below to resolve this issue:

Procedure

Step 1 Log into Security Cloud Control and navigate to the **Security Devices** page. Locate the device that failed to register.

Step 2 Select the device so it is highlighted and **Remove** the device from your Security Cloud Control tenant.

Step 3 Wait at least 10 minutes before attempting to onboard the device back to your Security Cloud Control tenant. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 24 for more information.

If you are still unable to claim the device, review the device's workflow to see is there is an error message. If there is,Export the Workflow and open a support case to further troubleshoot the issue.

Error: Provisional Error

Device Password Has Not Been Changed

If you did not change the default password of the device when configuring the device for remote management and selected the **No, this device has been logged into and configured for a manager** option when onboarding the device to Security Cloud Control, the device will generate an **UnProvisioned** connectivity status in the **Security Devices** page.

Use the following procedure to resolve this issue:

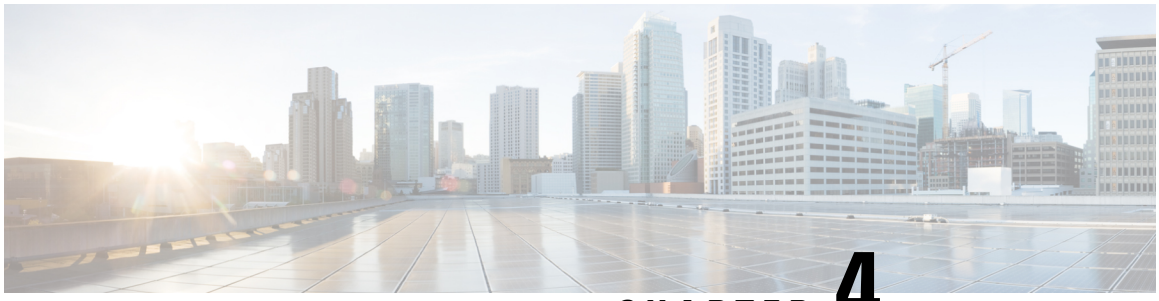
1. Log into Security Cloud Control and navigate to the **Security Devices** page.
2. Locate and select the device with the **UnProvisioned** connectivity status so it is highlighted.
3. In the pane located to the right, locate the **Change Password** window.
4. Click **Change Password** and enter a new password for your device. This overwrites the default password.

It may take a few minutes for the device to onboard and fully synchronize to Security Cloud Control.

Device Password Has Already Been Changed

If you **did** change the default password of the device when configuring the device for remote management and selected the **Is this a new device that has never been logged into or configured before?** option when onboarding the device to Security Cloud Control, Security Cloud Control generates an **UnProvisioned** connectivity status in the **Security Devices** page.

Use the following procedure to resolve this issue:



1. Log into Security Cloud Control and navigate to the **Security Devices** page.
2. Locate and select the device with the **UnProvisioned** connectivity status so it is highlighted.
3. In the pane located to the right, locate the **Confirm and Proceed** window.
4. Click **Confirm and Proceed**. This action ignores the password that was provided in the onboarding wizard and reinstates the default password for the device. Security Cloud Control then continues to onboard the device.

Other Provisional Error Scenarios

Regardless of the default password configuration of the device, it is still possible for a device to result in an **UnProvisioned** conectivity status during the onboarding process. If you confirm the password selection in the onboarding wizard is accurate for the state of the device, consider the following options to resolve the issue:

- Select the device so it is highlighted. In the window located on the right pane of the screen, click **Retry** to force Security Cloud Control to re-onboard the device with existing provisional parameters.
- Delete the device from the **Security Devices** page and attempt to re-onboard the device.
- In the device's Firewall Device Manager UI, navigate to **System Settings** > **Cloud Services**. Select the **Auto-enroll with Tenancy from Security Cloud Control** and click **Register**.

If you are still unable to claim the device, review the device's workflow to see is there is an error message. If there is,Export the Workflow and open a support case to further troubleshoot the issue.

Overview of Firewall Threat Defense to Cloud-Delivered Firewall Management Center migration

Introduction

This feature enables you to migrate Firewall Threat Defense devices from On-Premises Firewall Management Center to Cloud-Delivered Firewall Management Center through Security Cloud Control Firewall Management. Migration enables organizations to move device management from on-premises infrastructure to Cisco's cloud-based management. This migration preserves existing policies, objects, and configurations.

Customer benefits

- Preserves existing policies and configuration
- Imports device-specific configuration, including interfaces, routing, and related settings
- Handles duplicate policy and object names according to defined conflict-resolution rules
- Transfers feature licenses automatically
- Supports high availability pairs and clusters
- Provides 14-day evaluation window before permanent commit
- Allows analytics to remain on-prem or move to cloud
- Provides an intuitive troubleshooting page with status summaries and step-by-step progress to pinpoint issues.
- Provides migration reports for validation and audit

User role changes

The user roles of the On-Premises Firewall Management Center are no longer applicable in Security Cloud Control Firewall Management after migration. Your authorization to perform tasks on the migrated device is based on your user role in Security Cloud Control Firewall Management. See the Users topic to understand the On-Premises Firewall Management Center Center and Cloud-Delivered Firewall Management Center user role mapping.

How Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center Works

Security Cloud Control Firewall Management performs migration in the following sequence:

1. Onboards on-premises Firewall Management Center to Security Cloud Control Firewall Management.
2. Exports configurations from on-premises Firewall Management Center.
3. Imports shared policies, objects, and device-specific configurations to Cloud-Delivered Firewall Management Center.
4. Registers Firewall Threat Defense devices with Cloud-Delivered Firewall Management Center.
5. Starts a 14-day evaluation window to commit or revert changes.
6. Allows a commit or revert changes.

After migration:

- Cloud-Delivered Firewall Management Center manages devices and their configuration.
- Events and analytics can be handled by either the on-premises Firewall Management Center (analytics-only mode) or Security Cloud Control Firewall Management.
- Devices appear on the **Security Devices** page.

About 14-day evaluation period

When a migration job is successful, you have 14 days to test and assess migration changes using Cloud-Delivered Firewall Management Center. If you are convinced about the migration changes, we recommend that you commit the devices manually, and not wait for Secure Firewall Management Center to automatically commit the migration changes. You have a 14-day evaluation period to review and assess the migration changes that are made to the devices before Secure Firewall Management Center automatically commits them.

After successful migration:

- You have 14 days to evaluate configuration.
- You can undo the changes and continue managing the device with On-Premises Firewall Management Center.
- You can commit migration changes to Cloud-Delivered Firewall Management Center.

After 14 days evaluation period:

- Changes are automatically committed.
- Revert is no longer possible after auto-commit.

During 14 day evaluation window:

- High availability break may not be supported (depending on onboarding method).
- Performing advanced high availability or cluster operations may result in migration commit failure.
- Deleting devices is not allowed.
- Changes made in Cloud-Delivered Firewall Management Center are lost, if reverted.
- Do not create or modify domains or subdomains on the On-Premises Firewall Management Center if the domain change includes a Firewall Threat Defense device that was migrated to Cloud-Delivered Firewall Management Center. Commit the migration changes in Cloud-Delivered Firewall Management Center, or revert device management to the on-premises On-Premises Firewall Management Center, before you make domain changes that include the migrated device.

  If you create or modify a domain before the migration job is committed, deployment of the device and domain configuration can fail. You can continue to create or modify domains on the On-Premises Firewall Management Center for devices that remain managed by that On-Premises Firewall Management Center and are not part of an uncommitted migration job.

How Firewall Threat Defense licenses are handled during migration to Cloud-Delivered Firewall Management Center

- When the Firewall Threat Defense is migrated to the cloud, all feature licenses associated with the device are transferred to Security Cloud Control and released from the Firewall Management Center to the Smart License pool. The device reclaims the device-specific licenses during its registration with Security Cloud Control. You need not apply license on the device again.
- The device-specific licenses are not required if you want to keep devices in the Firewall Management Center for analytics.

End-to-End Workflow for Migrating Firewall Threat Defense to Cloud-Delivered Firewall Management Center

The following flowchart illustrates the high-level workflow for migrating Firewall Threat Defense to Cloud-Delivered Firewall Management Center.

Event and Analytics Management options during Firewall Threat Defense migration

The events and analytics management can be retained in the on-premises Firewall Management Center or transferred to Security Cloud Control Firewall Management, where the devices must be configured to send events to Security Cloud Control Firewall Management.

While initiating the migration process, you are allowed to choose the manager where the device events must be sent for analytics:

- Retain analytics on the on-premises Firewall Management Center, or
- Transfer analytics to Security Cloud Control Firewall Management.

Special requirement for FMC 1000/2500/4500

If you are migrating from an on-premises Firewall Management Center 1000/2500/4500, you **cannot** retain analytics on the on-premises Firewall Management Center due to limited availability.

In this case, devices must send events to:

- Security Analytics and Logging (On-Prem), or
- Security Analytics and Logging (SaaS).

See Cisco Security Analytics and Logging.

If you retain on-premises Firewall Management Center for analytics

- Security Cloud Control Firewall Management becomes the configuration manager.
- The devices remain on the on-premises Firewall Management Center in **analytics-only mode**.
- Devices continue sending events to the on-premises Firewall Management Center.
- Security Cloud Control Firewall Management manages configuration changes only.

Note The maximum number of supported Secure Firewall Threat Defense devices in Cloud-Delivered Firewall Management Center includes devices that are deployed for analytics on Firewall Management Center and onboarded to Cloud-Delivered Firewall Management Center for management. These devices count toward the platform device capacity limit and must be included in your capacity planning to ensure proper sizing and performance.

If you select Security Cloud Control Firewall Management for analytics

- Secure Firewall Management Center becomes both:
  - Configuration manager, and
  - Analytics manager.

- The devices are removed from the on-premises Firewall Management Center.
- You must configure the devices to send events to the Cisco cloud.
- Events can be sent using:
  - Security Services Exchange (SSE), or
  - Secure Event Connector (SEC)
- Events are processed by Cisco Secure Analytics and Logging (SAL) in the cloud.

Note If you initially select on-premises Firewall Management Center **for analytics**, you have a 14-day evaluation period during which you can change the analytics destination to Secure Firewall Management Center.

After either:

- Manually committing the migration, or
- The 14-day evaluation period expires, the analytics selection becomes permanent. Events will continue to be sent to the selected destination, and the setting cannot be changed.

To modify analytics settings after the evaluation period or after commit, refer to the migration troubleshooting procedures. see Resolving Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center Issues, on page 90

eStreamer Server Streaming

When you manage a Firewall Threat Defense device with Cloud-Delivered Firewall Management Center, the device supports sending only fully-qualified events (FQE) to eStreamer clients. If you have configured eStreamer clients in the on-premises Firewall Management Center, ensure that the clients support the detailed data formats used by FQE when you migrate the device management to Cloud-Delivered Firewall Management Center. Any legacy clients, security information and event management (SIEM) systems, or log management solutions that do not support the data format of FQE or lack the necessary storage to handle the larger volume of FQE data will not work when you migrate.

Supported features

Shared policies imported

The following policies are imported first and then followed by the device configuration:

- Access control
- IPS
- SSL
- Prefilter
- NAT

- QoS
- Identity
- Platform settings
- Flex config
- Network analysis
- DNS
- Malware & file
- Health
- Remote Access VPN
- Site-to-Site VPN

Handling duplicate names

If a policy or object name in Security Cloud Control Firewall Management matches one imported from the On-Premises Firewall Management Center, Security Cloud Control Firewall Management will take the following actions after a successful management change.

Policies, Objects	Condition	Action
Access control, SSL, IPS, Prefilter, NAT, QoS, Identity, Platform settings, Network analysis, DNS, Malware & File policies.	Name of the Cloud-Delivered Firewall Management Center policy matches the on-premises Firewall Management Center policy.	Cloud-Delivered Firewall Management Center policy is used.
RA VPN Default group policy **DfltGrpPolicy**	The default group policy**DfltGrpPolicy** from the on-premises Firewall Management Center is ignored.	Existing Cloud-Delivered Firewall Management Center default group policy **DfltGrpPolicy** is used.
Network, Port objects	Name and content of network and port objects in the Cloud-Delivered Firewall Management Center match the ones in the on-premises Firewall Management Center.	Existing Cloud-Delivered Firewall Management Center network and port objects with the same name and content are used. If the object has the same name but different content, an object override is created.
All other objects		Existing Cloud-Delivered Firewall Management Center object is used.

Note Syslog alert objects used in the access control policy are imported.

Unsupported features

Migration of a Firewall Threat Defense device registered only for analytics-only with the Firewall Management Center feature is not currently supported.

The following configuration are not imported from the Firewall Management Center to Security Cloud Control as part of migration:

- Custom Widgets, Application Detectors, Correlation, SNMP and Email Alerts, Scanners, Groups, Dynamic Access Policy, Custom AMP Configuration, Users, Domains, Scheduled Deployment Tasks, ISE configuration, Scheduled GeoDB Updates, Threat Intelligence Director configuration, Dynamic Analysis Connections.
- ISE internal certificate object is not imported as part of the migration. You must export a new system certificate or a certificate and its associated private key from ISE and import it into Security Cloud Control Firewall Management.

Secure firewall recommended rules

Migrating Firewall Threat Defense to the cloud migrates existing rule recommendations linked to intrusion policies. However, the Cloud-Delivered Firewall Management Center does not generate new rule recommendations or auto-update migrated ones post-migration, as it does not support rule recommendations. See Auto Cisco Recommended Rules.

Remove custom network analysis policies

Before migration, Custom Network Analysis policies must be removed from the On-Premises Firewall Management Center.

1. Log on to the on-premises Firewall Management Center.
2. Choose **Policies** > **Access Control**.
3. Click the edit icon on the access control policy you want to disassociate the custom NAP and then click the **Advanced** tab.
4. In the **Network Analysis and Intrusion Policies** area, click the edit icon.
5. In the **Default Network Analysis Policy** list, select a system-provided policy.
6. Click **OK**.
7. Click **Save** to save the changes and then click **Deploy** to download the changes to the device.

After migration, you can manually create the Network Analysis Policy in Security Cloud Control Firewall Management.

User Identity Migration Guidelines and Limitations for Firewall Threat Defense Devices

Before you migrate an on-premises Firewall Threat Defense to Cloud-Delivered Firewall Management Center, you must prepare and also deploy as soon as possible after the migration if any access control policies reference identity objects discussed in this topic. To confirm, click **Policies** > **Access Control heading** > **Access Control** and examine your access control policies and rules.

If none of your access control policies reference identity objects (in particular, users and groups), you can ignore these guidelines.

Before migrating

Before migrating, on the On-Prem Firewall Management Center, click **Integration** > **Other Integrations** > **Identity Sources** and see if you have any Cisco ISE/ISE-PIC or Passive Identity Agent identity sources defined.

- If you have Cisco ISE/ISE-PIC or Passive Identity Agent identity sources defined, create the Cisco ISE/ISE-PIC identity sources on Cloud-Delivered Firewall Management Center then migrate the device as discussed in the following paragraphs.
- If no Cisco ISE/ISE-PIC or Passive Identity Agent identity sources are defined, migrate the device as discussed in the following paragraphs.

Migrate the device

Migration is discussed in Overview of Firewall Threat Defense to Cloud-Delivered Firewall Management Center migration, on page 63. To avoid traffic disruption, when you migrate the device, we strongly recommend you either:

- Check the **Auto deploy to FTDs after successful migration** check box.
- Deploy policies immediately after migration is complete.

Migration guidelines and limitations for VPN configuration

Keep the following in mind when you migrate a device with VPN configuration.

Migration guidelines for Remote Access VPN

Security Cloud Control Firewall Management imports all remote access VPN policy settings, with the following exceptions:

- Object overrides are not migrated.

  If overrides are used in the address pool object, manually add them to the imported object in Security Cloud Control Firewall Management after migration.

- Local users.

If the authentication server uses a local database, the associated local realm object is imported into Security Cloud Control Firewall Management. However, you must manually add the local users to the imported local realm object after migration. See Create a Realm and Realm Directory.

- Load-balancing configuration is not migrated.
- Certificate enrollment with domain configuration.

  Perform the following after migration to enroll the certificate with domain configuration:

  1. Choose **Security Devices**.
  2. Select the migrated FTD and in the **Device Management** on the right, click **Device Overview**.
  3. Choose **Devices** > **Certificates**.

     Perform one of the following tasks:

     - If the certificates are imported in an **Error** state, click the **Refresh certificate status** icon to synchronize the certificate status with the device. The certificate status turns green.
     - If the certificates are not imported, you must manually add the certificates defined in the Remote Access VPN policy that is configured in the Firewall Management Center.

Migration guidelines for Site-to-Site VPN

- After selecting a Firewall Threat Defense device, all peers are automatically selected from various topologies, as all devices within a topology must migrate together.
- Migration wizard doesn't list the extranet devices that are associated with them, but they will still be automatically included during the migration process.

All settings will be migrated, with the following exceptions:

- Network object overrides are not migrated. They must be manually added to the imported object in Security Cloud Control Firewall Management after migration.
- If the authentication type configured as **Preshared Automatic Key** in the On-Premises Firewall Management Center:
  - Cloud-Delivered Firewall Management Center generates new pre-shared key post-deployment.
  - Existing tunnels remain active.
  - New tunnels use newly generated key.
- If devices are moved to Security Cloud Control Firewall Management but the changes are not yet committed, the associated site-to-site VPN policy can still be modified in the On-Premises Firewall Management Center, however, it those changes do not update the device configuration in Security Cloud Control Firewall Management.
- Devices configured for SASE tunnels on Cisco Umbrella are not migrated.

Supported On-Premises Firewall Management Center and Firewall Threat Defense software versions for migration

Minimum supported versions

- Minimum On-Premises Firewall Management Center: 7.2
- Minimum Firewall Threat Defense: 7.2.x (not supported for Version 7.1)

Physical On-Premises Firewall Management Center 1000/2500/4500 Model-Managed Firewall Threat Defense

- Migration is supported from **physical FMC 1000/2500/4500** models.
- *Temporary upgrade from 7.0 to 7.4* is supported for migration purposes only. The On-Premises Firewall Management Center Version 7.4 is "unsupported for general operations," but allowed as an interim step until migration completes. You can download the upgrade package here.
- After migration, do the following:
  1. Return to On-Premises Firewall Management Center to a supported version after migration.
  2. Remove re-migrated devices.
  3. Reimage back to 7.2.x.
  4. Re-register the devices.

Note Unzip (but do not untar) the upgrade package before uploading it to the On-Premises Firewall Management Center. To upgrade to Version 7.4, see Cisco Secure Firewall Management Center Upgrade Guide, Version 6.0-7.0.

We recommend upgrading the devices to Version 7.2.x before upgrading the On-Premises Firewall Management Center to Version 7.4.

Important An upgrade is necessary because Version 7.0 On-Premises Firewall Management Centers do not support cloud device migration. Only Version 7.4 is supported during the migration and evaluation process. These On-Premises Firewall Management Centers cannot run intermediate versions. Only standalone and high availability Firewall Threat Defense devices running Version 7.0.3+ (7.0.5 recommended) are eligible for migration.

Firewall Threat Defense in a High Availability Pair

- High availability pairs migrate as a single node.
- Both active and standby Firewall Threat Defense devices migrate together.

Important We highly recommend committing manager changes before performing advanced operations, like creating or breaking high availability configurations from the On-Premises Firewall Management Center on the devices being migrated. Carrying out these tasks during the evaluation period is unsupported and may lead to migration commit failure.

Firewall Management Center in a High Availability Pair

- Onboard the active On-Premises Firewall Management Center and not the standby.
- Use either the auto-onboarding method or the credentials method for onboarding the On-Premises Firewall Management Center.

Note If you have already onboarded a standalone On-Premises Firewall Management Center and later configured it as a standby, delete the standby On-Premises Firewall Management Center and onboard the active one.

Points to Remember:

- **Auto-onboarding On-Premises Firewall Management Center Method**
  - High availability break is not supported during the 14 days evaluation period.

    You can break high availability after changes are committed, manually or automatically, after the evaluation period.
  - High availability switchover is supported during the 14 days evaluation period.
- **Onboarding On-Premises Firewall Management Center Method Using Credentials**
  - High availability break and high availability switchover are not supported during the 14 days evaluation period. You can perform these operations after committing the changes manually or automatically after the evaluation period.
  - After a switchover, onboard the new active unit, which was previously in standby mode, and then start a migration job on the devices.

Note During the 14-day evaluation period after migrating a Firewall Threat Defense device, if you have performed advanced operations on the device, such as converting it to a multi-instance chassis, note that the evaluation period becomes nullified, and you will not be able to revert the device management back to the On-Premises Firewall Management Center.

If you want to manage a multi-instance chassis using Cloud-Delivered Firewall Management Center, onboard the chassis manually to Security Cloud Control.

Firewall Threat Defense cluster

Firewall Threat Defense cluster migration is supported on these platforms with minimum versions:

Platforms	Minimum Firewall Threat Defense	Minimum On-Premises Firewall Management Center Version
VMware, KVM	7.2.1	7.4.1
AWS, GCP	7.2.1	7.4.1
Azure	7.3	7.4.1
Secure Firewall 3100	7.2.1	7.4.1
Firepower 4100	7.2.x	7.4.1
Secure Firewall 4200	7.4	7.4.1
Firepower 9300	7.2.x	7.4.1

Important Before migrating the Firewall Threat Defense cluster, remember the following points:

- Do not migrate the Firewall Threat Defense cluster during clustering-related operations from the On-Premises Firewall Management Center.
- After migration, manually commit manager changes before performing advanced operations, such as adding a node, breaking a node, breaking a cluster, or converting a device from native mode to multi-instance (container) mode from the on-premises Firewall Management Center. Performing such tasks during the evaluation period may result in migration commit failure.

Migration Support for Multi-instance Firewall Threat Defense Devices

You can migrate a multi-instance Firewall Threat Defense device that is part of a chassis (Secure Firewall 3100/4200). The multi-instance device gets listed as one of the devices in the **Select Devices** page, and you can choose it to proceed with the migration. This migration is supported in Firewall Threat Defense device versions 7.6 or later.

If you decide to do such a multi-instance Firewall Threat Defense device migration, it is strongly recommended that you unregister the corresponding chassis device manually from the on-premises Firewall Management Center and onboard it to Security Cloud Control, by navigating to the **Security Devices** page.

Prerequisites for Migrating Firewall Threat Defense to Cloud-Delivered Firewall Management Center

Before you begin the process, ensure that the following prerequisites are met:

- **DNS Server Configuration**:

  The Firewall Threat Defenses must have the correct DNS server configuration to resolve Cloud-Delivered Firewall Management Center hostnames. For details about checking connectivity with Cloud-Delivered

Firewall Management Center, see Check device connectivity with Cloud-Delivered Firewall Management Center.

- **Network Access**:

  The required network access must be enabled for Firewall Threat Defenses to reach Cloud-Delivered Firewall Management Center through the TCP port 8305. Note that outbound connectivity from the Firewall Threat Defenses to Cloud-Delivered Firewall Management Center is sufficient.

- **Firewall Threat Defense Outbound Port 443**:

  The Firewall Threat Defenses must be able to access port 443 and 8305 of Cloud-Delivered Firewall Management Center.

- **On-Premises Firewall Management Center Outbound Port 443**:

  The on-premises Firewall Management Center must have access to outbound port 443 open to reach "*.cdo.cisco.com" domain.

- The on-premises Firewall Management Center is onboarded to Security Cloud Control. Onboarding the on-premises Firewall Management Center also onboards all the Firewall Threat Defense devices registered to that on-premises Firewall Management Center. See Onboard an On-Prem FMC.

Note Create a new user in the on-premises Firewall Management Center with Administrator role or a custom user role with "Devices" and "System" permissions for onboarding purposes.

Caution If you onboard an on-premises Firewall Management Center to Security Cloud Control and simultaneously sign in to that on-premises Firewall Management Center with the same user name, the onboarding fails.

- For the on-premises Firewall Management Center 1000/2500/4500 migration:
  - Run Version 7.4 (available for these models on a temporary basis). We recommend devices be running Version 7.0.5.
  - We recommend that you create a backup of on-premises Firewall Management Center.

    For versions on-premises Firewall Management Center Version 6.5 to 7.1, see the *Back up the FMC* topic in the Firepower Management Center Configuration Guide.

    For on-premises Firewall Management Center Version 7.2 and later, see the *Back up the Management Center* topic in the Cisco Secure Firewall Management Center Administration Guide.

- The Firewall Threat Defense devices must be synchronized and not have pending changes on them. The migration fails on a device if Security Cloud Control identifies pending changes on that device.
- All peer devices in a site-to-site VPN topology must be online and have no pending deployment.
- On-Premises Firewall Management Center should allow outbound HTTP/HTTPS to upload configurations to Amazon S3.

- Security Cloud Control imports Syslog alert object used in the access control policy from the on-premises Firewall Management Center. If Security Cloud Control already contains an alert object with the same name but a different type (SNMP, Email), it is reused during configuration import.

  The user must check whether the Syslog object name matches the existing SNMP or Email alert object in Security Cloud Control. If the name matches, you must rename the Syslog object in the on-premises Firewall Management Center before starting the migration process.

- If you attempt to migrate firewalls with modified system defined FlexConfig text objects from an on-premises Firewall Management Center to the Cloud-Delivered Firewall Management Center, the values of the modified system defined FlexConfig text objects are not migrated to the Cloud-Delivered Firewall Management Center, and the deployment will fail.

  To avoid this, perform these tasks before you start the migration:

  - Copy the modified system defined FlexConfig text object values from the on-premises Firewall Management Center to Cloud-Delivered Firewall Management Center before migration.
  - Initiate migration from on-premises Firewall Management Center to Cloud-Delivered Firewall Management Center after verifying the predefined FlexConfig text objects.

Points to remember

Policy and Object Name Conflicts:

If a policy in Cloud-Delivered Firewall Management Center shares the same name as one in on-premises Firewall Management Center (excluding network, port, URL, and VLAN objects), the Cloud-Delivered Firewall Management Centerversion will be retained. See Handling Shared Policies and Objects.

Policy and Object Updates:

After migration, policies and objects aren't auto-synced between on-premises Firewall Management Center and Cloud-Delivered Firewall Management Center. For phased migrations, you must update them manually.

Evaluation Period:

You can revert to on-premises Firewall Management Center within 14 days of migration. After that, changes are finalized automatically. See Revert the Threat Defense Management to On-Prem Firewall Management Center.

High availability failover link must be up

The high availability failover link should be up for a successful migration. Before initiating the migration process on Security Cloud Control, determine the health status of the failover link on the on-premises Firewall Management Center.

1. Identify the failover interfaces of all HA pairs you want to migrate to Cloud-Delivered Firewall Management Center.
   a. Choose **Devices** > **Device Management**.
   b. Next to the device high-availability pair you want to edit, click **Edit** ( ).
   c. Click the **High Availability** tab.
   d. In the **High Availability Link** area, the **Interface** field shows the failover interface used in the pair.
   e. Identify the interfaces used for failover communication if there are multiple HA pairs for migration.

2. Check the health status of the failover interfaces.
   a. Choose **Devices** > **Device Management**.
   b. Next to the device high-availability pair you want, click **Health Monitor**.
   c. In the left pane, expand the high availability pair to see the Firewall Threat Defense devices.
   d. Click the device indicated in the exclamation mark ( ).
   e. Click the **Critical** button at the top.

      The **Interface Status** shows the errors associated with interfaces.
   f. If the failover interface is down, the **Interface 'failover_interfacename' has no link** message is displayed.

Note However, you can migrate the HA pair to Cloud-Delivered Firewall Management Center if you see any other data interface issues except for the failover interface.

   g. Rectify the issue and click **Sync from onprem fmc now** to obtain the latest changes on the device.

Migrate Firewall Threat Defense to Cloud-Delivered Firewall Management Center

Procedure

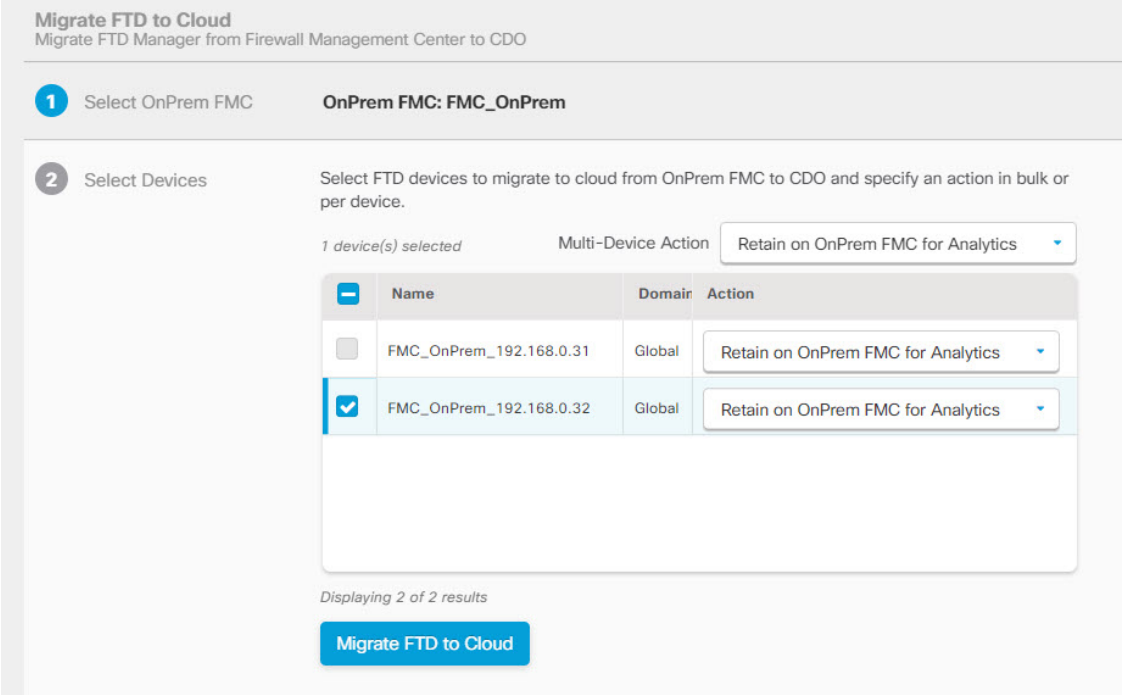
Step 1 In the navigation bar on the left, click **Administration** > **Migration** > **Migrate FTD to cdFMC**.

Step 2 Click + and choose **On-Prem FMC-managed FTD to** Cloud-Delivered Firewall Management Center.

Note
You can initiate only one migration job at one time.

Step 3 In the **Select On-Prem FMC** area, perform the following:

   a. You can click the **Onboard an FMC** link to onboard the on-premises Firewall Management Center if you have not done already. See Onboard an FMC.
   b. Select the on-premises Firewall Management Center from the available list and click **Next**.



In the **Select Devices** step, you will see the Firewall Threat Defense devices that the selected on-premises Firewall Management Center manages. If a high-availability pair is set up on the on-premise on-premises Firewall Management Center, the high availability node will be shown instead of the active and standby devices.

The **Last Synced time** field indicates the time that is elapsed since the device configuration is synchronized into the on-premises Firewall Management Center. You can click **Sync from OnPrem FMC Now** to fetch the latest device changes.

Step 4 In the **Select Devices** step, perform the following:

a) Select the devices that you want to migrate.

These devices can include standalone, high-availability pairs, or clusters. If you have a high-availability pair or a cluster, select the node that represents it. Also, you can hover your mouse pointer over the cluster to view more details about the control node.

Note

- The devices running on unsupported versions are not available for selection.
- The devices that are registered for analytics only with the on-premises Firewall Management Center or have pending changes to be deployed are not eligible for migration.
- When you select a device that is associated with a site-to-site VPN topology, Security Cloud Control automatically selects its peer devices belonging to either the same topology or a different topology, because all devices in the site-to-site VPN topology must be migrated together for a successful migration to take place. The wizard does not list the extranet devices, if any. However, Security Cloud Control migrates extranet devices.

  The **S2S VPN Topology** column indicates the number of site-to-site VPN topologies in which a selected device participates. You click the topology link to view the topologies and devices that are migrated along with the selected device. This field is not applicable to devices that are not part of the site-to-site VPN topology.
- A high availability pair is presented as a single node. You must select this node to include active and standby devices in the migration.

b) In the **Multi-Device Action** list, you can choose a common action to apply on all devices.
c) In the **Commit Action** column, you can choose one of the following actions for the selected device:

- **Retain on OnPrem FMC for Analytics**: After the migration process is completed, the analytics management for selected Firewall Threat Defense devices is retained on the on-premises Firewall Management Center.
- **Delete FTD from OnPrem FMC**: After the migration process is completed, the selected devices are removed from the on-premises Firewall Management Center and are available for Security Cloud Control to handle the analytics. You must configure the devices to send events to Security Cloud Control for managing analytics. When the devices are deleted from the on-premises Firewall Management Center, they cannot be revoked.

  Important
  For the on-premises Firewall Management Center 1000/2500/4500, when you select devices to migrate, make sure you choose **Delete FTD from OnPrem FMC**. Note that the device is not fully deleted unless you commit the changes or 14 days pass.

Note
The actions that are specified here are committed automatically after the 14 days evaluation period or after the changes are committed manually.

Step 5 (Optional) Check the **Pause migration to review imported shared policies** check box.

When you enable this option, the migration process will pause after the shared access policies like Access Control and NAT policies are staged in the Cloud-Delivered Firewall Management Center. This pause ensures that the evaluation doesn't start and that the device's current state and manager remain unaffected. It gives you ample time to review the imported configuration for accuracy. After you've assessed everything, you can resume the migration during the planned migration interval, which will then kick off the 15-day evaluation period.

Step 6 Check the **Auto deploy to FTDs after successful migration** check box to deploy the migrated configuration automatically to the device after successfully migrating and registering the device with the Cloud-Delivered Firewall Management Center.

However, if you prefer to review and manually deploy the configuration from the Cloud-Delivered Firewall Management Center after successful migration, you can uncheck this option and proceed to the next step.

Step 7 Click **Migrate FTD to cdFMC**.

Step 8 Click **View Migration to Cloud Progress** to see the progress.

What to do next

If you have paused the migration for review, you must manually click **Proceed Migration** to import the remaining configuration. See Proceed Migration Process, on page 82.

You can view the overall and individual status of migration jobs and generate a report when a job is completed successfully. See View a Firewall Threat Defense Migration Job, on page 81.

View a Firewall Threat Defense Migration Job

The migration dashboard provides the status of all migration jobs initiated from the Security Cloud Control. You can expand a specific job to see the status of individual devices associated with that tenant. This helps you keep track of the progress of your migration and identify issues, if any, that need to be addressed.

If you have set up alerts for device workflows, click the notifications icon  to see the alerts that have been triggered during the migration process. Additionally, if you have opted to receive email notifications from Security Cloud Control, you will also receive an email notification regarding alerts, if any.

When a migration job is successful, you have 14 days to test and assess migration changes. If you are convinced about the migration changes, we recommend that you commit the devices manually, and not wait for Security Cloud Control to automatically commit the migration changes. See Commit Migration Changes Manually.

Note that for the on-premises Firewall Management Center 1000/2500/4500, you would have migrated devices from Version 7.4, which is unsupported for general operations. To return the on-premises Firewall Management Center to a supported version you must remove the re-migrated devices, reimage back to Version 7.2.x, restore from backup, and re-register the devices.

Note

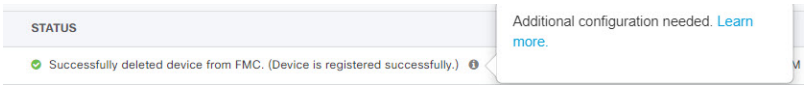
- You cannot revoke the actions that are specified in the migration commit window after committing the changes.
- You can cancel the migration during the evaluation period and return the device to the on-premises Firewall Management Center.
- You cannot delete a device from either the on-premises Firewall Management Center or Cloud-Delivered Firewall Management Center during the evaluation period.

Important Changes can be made and deployed to the device using Security Cloud Control during the evaluation period. If you switch device management back to the on-premises Firewall Management Center, Security Cloud Control-specific changes made during the evaluation period is not saved on the device once it is reverted to the source Security Cloud Control tenant. You must deploy the changes from the on-premises Firewall Management Center to the device after reverting the device's manager.

- **Name**: Represents the job name that shows the on-premises Firewall Management Center name and the date and time when the job was initiated.
- **Number of FTDs**: Shows the total number of devices that are being migrated to the cloud.
- **Status**: Shows the status of the job. Expand the job to see the status of individual devices.

  When a job is completed successfully, the **FTD Migration job is successful message** appears in the **Status** column. You can click the tooltip to see the number of days remaining for evaluating the manager.

  You can click Commit Migration Changes to commit the changes manually before the 14 days evaluation period ends.
- **Last Update**: Shows the date and time that are updated only when a change is made to the device.



- **Actions**: Click to execute the following actions:
  - **Workflows**: Takes you to the **Workflows** to monitor the job.
  - **Download Report**: Allows you to generate and download a report of every job that is completed successfully. See Generate a Firewall Threat Defense Migration Report, on page 86.
  - **Commit Manager Changes**: Allows you to apply the changes manually to devices before the evaluation period ends. See Commit Migration Changes Manually to Cloud-Delivered Firewall Management Center, on page 83.
  - **Remove Migration Job**: Allows you to remove a completed job. Link is available only for completed jobs. See Delete a Migration Job, on page 86.

After a successful migration, Security Cloud Control deploys the configuration to the device. If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors. If the deployment fails, see the *Best Practices for Deploying Configuration Changes* section of Firepower Management Center Device Configuration Guide X.Y.

Configure Relam Sequence for Identity Policy

If the device contains an identity policy with a Realm or ISE configuration, configure your device as a proxy for Security Cloud Control to communicate with the identity source. The identity policies don't function if Security Cloud Control fails to connect to the Identity Realms.

A tooltip appears in the **Status** column for a device that requires additional configuration.

1. Click the tooltip icon and then click **Learn more**.
2. In the **Configure Proxy** window, click **Configure my realms**.

   To add a proxy sequence, see the *Create a Proxy Sequence* section in the Firepower Management Center Device Configuration Guide, 7.2.

Proceed Migration Process

If the **Pause migration to review imported shared policies** option was checked during the migration setup, the migration process will pause after the shared access policies were staged in the Cloud-Delivered Firewall Management Center. After you've reviewed the staged configurations, you must manually instruct Security Cloud Control to resume the migration, which will then import device-specific configurations such as routing and interfaces, as well as register the Firewall Threat Defense with the Cloud-Delivered Firewall Management Center. Completion of the migration triggers a 14-day evaluation period.

To proceed, go to the migration job page and click **Proceed with migration** for the relevant job.

Remember that deployment from the Cloud-Delivered Firewall Management Center must be done after a successful migration.

Commit Migration Changes Manually to Cloud-Delivered Firewall Management Center

We recommend that you commit migration changes manually if you are convinced with your changes and not waiting for Security Cloud Control to auto commit changes. The **Commit Migration Changes** window shows the remaining days to commit the migration to Cloud-Delivered Firewall Management Center or revert the device to on-premises Firewall Management Center. During the evaluation period, you can modify the actions for selected threat defense devices before committing the changes. Once the changes are committed, you can't revoke the actions.

Note The commit manager changes actions are disabled in the following conditions:

- The 14-day evaluation period has passed.
- The Firewall Threat Defense devices have either been reverted to the on-premises Firewall Management Center or deleted from on-premises Firewall Management Center, in which case, no further actions can be taken.

Procedure

Step 1 In the migration jobs page, click the ... under the **Actions** column of a completed job.

Step 2 Click **Commit Migration Changes**. (This link is available only after a job is completed successfully.)

Step 3 Select a device and in the **Commit Actions** list, choose one of the following actions:

- **Retain on OnPrem FMC for Analytics**: After committing the changes, analytics management for selected Firewall Threat Defense devices is retained on the management center.
- **Delete Firewall Threat Defense from OnPrem FMC**: After committing the changes, the selected devices are removed from the on-premises Firewall Management Center and are available for Security Cloud Control to handle the analytics. You must configure the Firewall Threat Defense to send events to Security Cloud Control for managing analytics. After the Firewall Threat Defense devices are deleted from the on-premises Firewall Management Center, they cannot be revoked.

Note
If you want to revert the device management to on-premises Firewall Management Center, refer to Revert the Firewall Threat Defense Management to On-Premises Firewall Management Center, on page 84.

Step 4 Click **Commit** executes your specified actions immediately without further confirmation.

On the migration jobs screen, you can expand the job to check the progress of the actions specified.

The migrated devices appear on Security Cloud Control's **Security Devices** page. These devices can be managed using the Cloud-Delivered Firewall Management Center portal that is linked to Security Cloud Control. Ensure you deploy the changes to the devices from Cloud-Delivered Firewall Management Center.

Revert the Firewall Threat Defense Management to On-Premises Firewall Management Center

You can revert the device management to the on-premises Firewall Management Center during the evaluation period. This means that the devices will no longer be managed through the Security Cloud Control platform. However, it is important to note that any changes made during the migration process in the Security Cloud Control will not be reflected in the on-premises Firewall Management Center after reverting Firewall Threat Defense management.

Note When the Firewall Threat Defense management has been returned to the on-premises Firewall Management Center , you can begin the migration job again to switch the Firewall Threat Defense management to Security Cloud Control.

Procedure

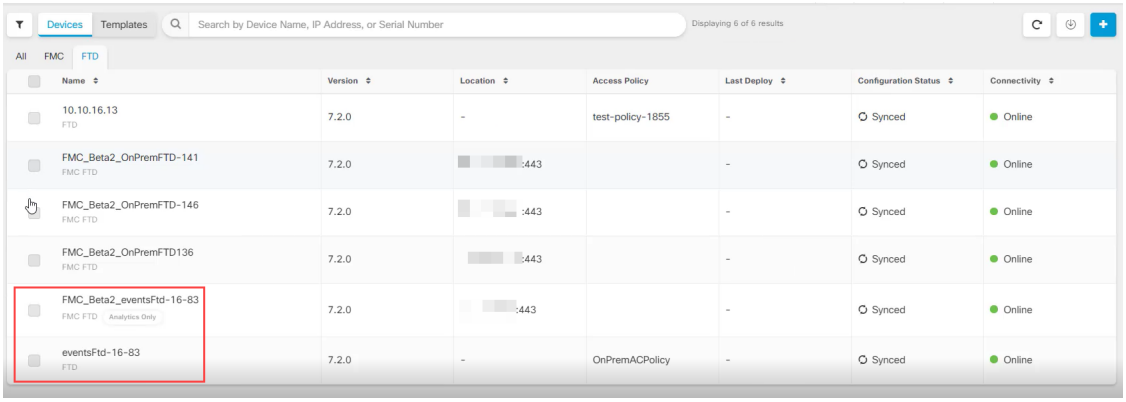
Step 1 In the migration jobs page, click the ... under the **Actions** column of a completed job.

Step 2 Click **Commit Migration Changes**. (This link is available only after a job is completed successfully.)

Step 3 Select a device and in the **Commit Actions** list, choose **Revert Manager to OnPrem FMC**.

Step 4 Click **Commit** executes your specified actions immediately without further confirmation.

Step 5 Deploy the changes to the device from the on-premises Firewall Management Center.

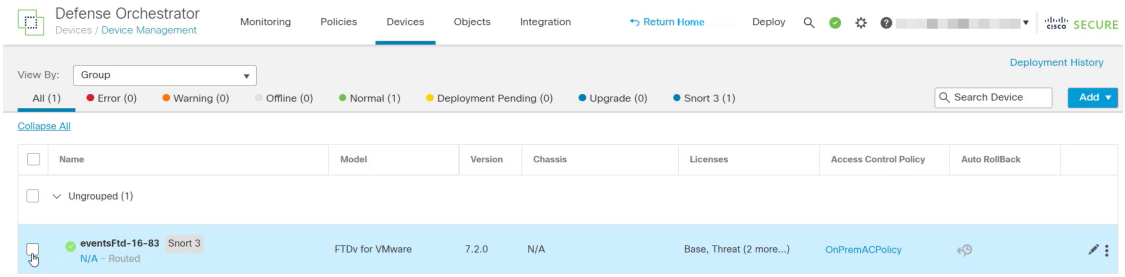


View Migrated Devices

The migrated devices appear on the **Security Devices** page in Security Cloud Control. You can cross-launch and configure the required feature on the Cloud-Delivered Firewall Management Center.

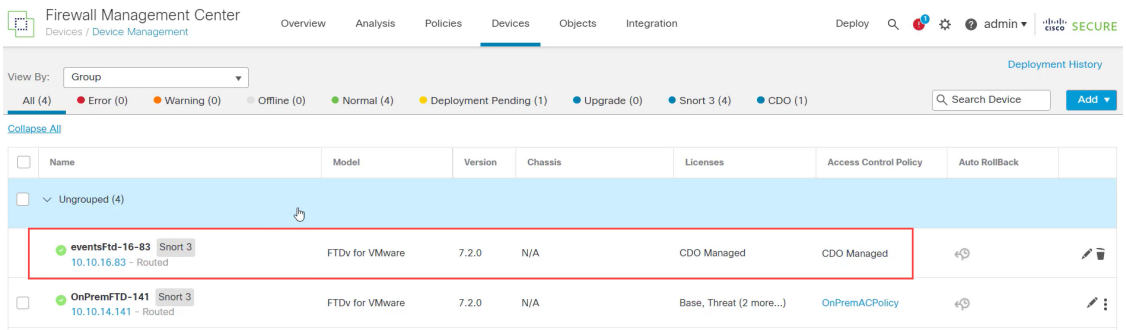
Note The devices on the Cloud-Delivered Firewall Management Center device listing page may show `No-IP` instead of the device's management IP address. Because the device registration uses the NAT ID, the device initiates the process, and therefore, the management IPs aren't discovered or used for the connection. Note that this applies to newly onboarded devices and devices migrated from the on-premises Firewall Management Center.

Analytics Only Firewall Threat Defense Device Example



Security Cloud Control creates two instances of the same device that is configured to retain on the Firewall Management Center for analytics.

The device instance with **FMC FTD** and **Analytics Only** labels shows that the Firewall Management Center handles the analytics. The device instance with the **FTD** label indicates that Security Cloud Control manages its configuration.



You can manage the configuration of the device using Security Cloud Control. To see the device in the Cloud-Delivered Firewall Management Center, do the following:

Select the device having **FTD** label and in the **Management** pane on the right, click **Device Summary**.

You can view the events from the device in the Firewall Management Center. To see the events, do the following:

1. Select the device having **FMC FTD** and **Analytics Only** labels and on the right, click the **Manage Devices** link.
2. Log on to the on premise Firewall Management Center.
3. Choose **Device** > **Device Management**.

You can't select this device as Security Cloud Control manages the configuration. The Firewall Management Center shows the **Security Cloud Control Managed** label for this device.

To see the live events in the Firewall Management Center, click **Analysis** > **Events**.

Generate a Firewall Threat Defense Migration Report

When a migration job is successful, you can generate and download a report in PDF format to analyze every parameter imported from the on-premises Firewall Management Center to Cloud-Delivered Firewall Management Center. The report provides details of each device associated with the job. Details include information about devices, values of shared policies, objects, routing details, interfaces, network settings, and more.

On the migration jobs page, click the ... under the **Actions** column of a completed job and then click **Download Report.**. You must download a report within a year of the job being triggered.

Delete a Migration Job

If you have completed a migration job and no longer need it to be displayed on the migration page, you can easily remove it by deleting it. This cleans up the migration page and make it easier to navigate.

Attention If you want to delete a migration job during the evaluation period, you must first commit the migration changes or revert the manager to the on-prem management center. Failing to do so may result in an inconsistent state of the on-prem management center, which could be unrecoverable. See Commit Migration Changes Manually.

If you don't have access to your on-premises Firewall Management Center or if it is no longer available and you are blocked from performing a commit or revert, you can delete the job.

Procedure

Step 1 Click **Administration** > **Migration** > **Migrate FTD to cdFMC**.

Step 2 Click the ... under the **Actions** column and then click **Remove Migration Job**.

Step 3 Click **Delete** to confirm your action.

Enable Notification Settings

You can subscribe to get email notifications from Security Cloud Control whenever a device associated with your tenant experiences a specific action when migrating a Firewall Threat Defense device to Security Cloud Control.

Security Cloud Control sends an email if you enable to receive a notification for the following states during migration:

- **Failed**: When a migration job fails.
- **Started**: When a migration job is initiated.
- **Succeeded**: When a migration job is completed successfully.
- **Commit Pending**: When the manager changes have to be committed.

To enable notification settings, see Notification Settings.

Verify Firewall Threat Defense Connectivity with Cloud-Delivered Firewall Management Center

This section provides the commands to determine the Firewall Threat Defense connectivity with the Cloud-Delivered Firewall Management Center.

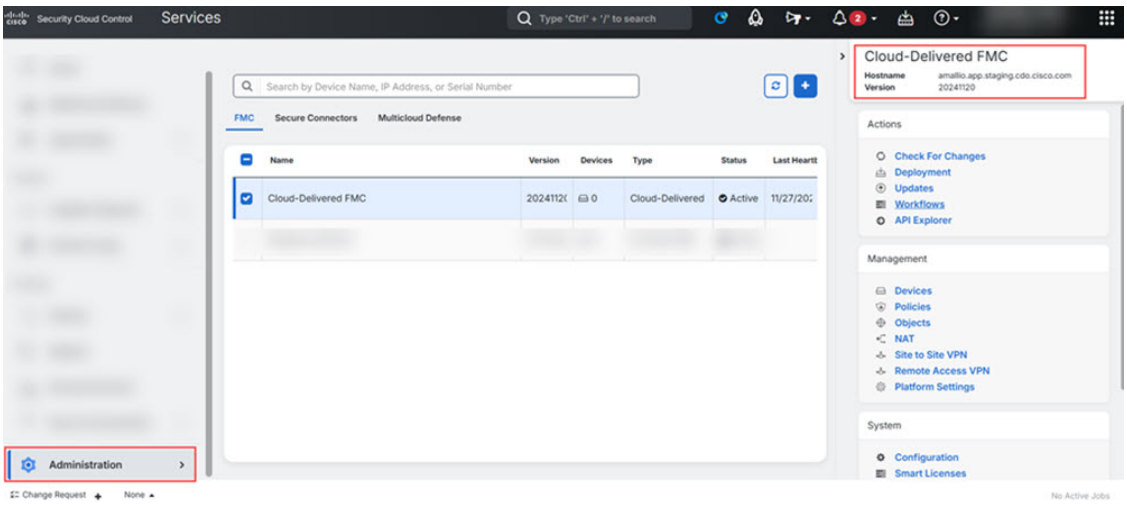
Check internet connectivity on the device

Execute the **ping system** <*any OpenDNS server address*> command to check whether the device can reach the internet.

1. Connect to the CLI of the device, either from the console port or using SSH.
2. Log in with the Admin username and password.
3. Enter **ping system** <*OpenDNS IPAddress*>.

```
ping system 208.67.222.222
PING 208.67.222.222 (208.67.222.222) 56(84) bytes of data.
64 bytes from 208.67.222.222: icmp_seq=1 ttl=48 time=22.10 ms
64 bytes from 208.67.222.222: icmp_seq=2 ttl=48 time=22.10 ms
64 bytes from 208.67.222.222: icmp_seq=3 ttl=48 time=22.8 ms
64 bytes from 208.67.222.222: icmp_seq=4 ttl=48 time=22.6 ms
^C
--- 208.67.222.222 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 7ms
rtt min/avg/max/mdev = 22.588/22.841/22.995/0.223 ms
```

The above example shows that the device can connect to the internet using the OpenDNS Server IP address. Also, the number of packets transmitted is the same as received, indicating that internet connectivity is available on the device. This shows that the device can reach the internet.



Note If your results don't match, check the internet connection manually.

Check device connectivity with Cloud-Delivered Firewall Management Center

1. Obtain the host name of the Cloud-Delivered Firewall Management Center.
   a. In the Security Cloud Control left pane, click **Administration** > **Integrations** > **Firewall Management Center**.

b. Choose **Cloud-Delivered FMC** to see the Cloud-Delivered Firewall Management Center details on the right pane.

c. In the **Hostname** field, copy only the hostname shown in the following example image.

In the above figure, the highlighted text is the hostname (*Security Cloud Control-acc10.app.us.Security Cloud Control.cisco.com*) of the FMC to be copied.

2. Connect to the CLI of the device, either from the console port or using SSH.

3. Enter **ping system** <*hostname of the FMC*>.

```
ping system cdo-acc10.app.us.cdo.cisco.com
PING cdo-acc10.app.us.cdo.cisco.com (54.187.125.161) 56(84) bytes of data.
^C
--- cdo-acc10.app.us.cdo.cisco.com ping statistics ---
2 packets transmitted, 0 received, 100% packet loss, time 64ms
```

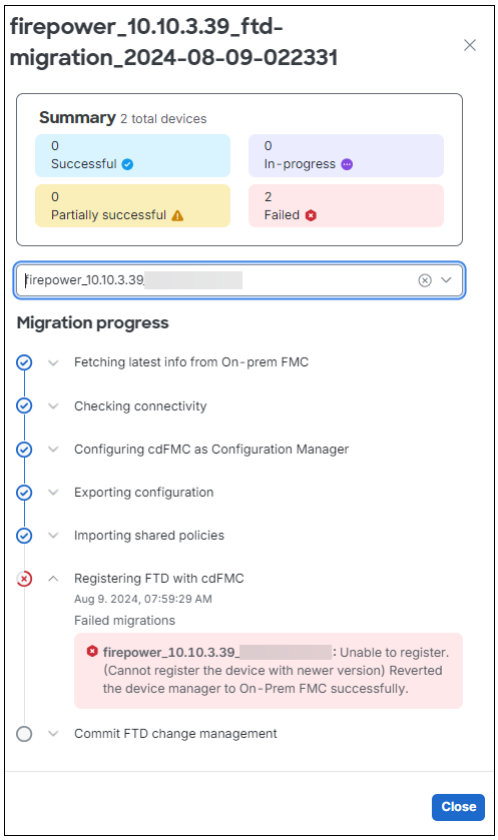
In the above example, the hostname is resolved with the IP address, indicating your connection is successful. Ignore the "100% packet loss" message shown in the response.

Note If you can't connect to the host, you can rectify the DNS configuration in the CLI using **configure network dns** <*address*>.

Use the Troubleshoot Feature for Failed Migrations

Before you begin

There might be a few instances where, owing to some issues, the migration fails or is not thoroughly successful. To help resolve issues around such failed or partially successful migrations, you can use the inbuilt **Troubleshoot** feature.



Procedure

Step 1 On the migration jobs page, click the ... under the **Actions** column of a failed or a partially migrated job.

Step 2 Click **Troubleshoot**.

This opens up a sliding window that contains the following information:

- A **Summary** containing additional details about the status of the migration.
- A detailed **Migration progess** listing all the steps in the migration and also indicating the step at which the migration has failed.

Step 3 Based on the stage at which the migration seems to have failed, refer Troubleshoot Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center for information on how to troubleshoot.

Resolving Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center Issues

This section details how to troubleshoot specific errors that may occur when migrating Firewall Threat Defense devices to Cloud-Delivered Firewall Management Center.

Migration of Firewall Threat Defense cluster fails

The migration of a Firewall Threat Defense cluster to the Cloud-Delivered Firewall Management Center fails during the migration process. When the failure occurs, Cloud-Delivered Firewall Management Center automatically performs a rollback, returning device management to the original On-Premises Firewall Management Center to maintain configuration integrity and service continuity.

Cause:

The migration failure may occur due to temporary service latency, transient connectivity issues, or other temporary conditions that interrupt the migration process.

Workaround:

- **Retry migration**: Wait for some time and then initiate the migration again from the Secure Firewall Management Center.
- **Contact support**: If the migration continues to fail after multiple attempts, contact Cisco Technical Support and provide the relevant error messages and migration details to assist with troubleshooting.

Configuration export from On-Premises Firewall Management Center failed

Cause:

- Disk space is full or nearly full, preventing the export process from being completed.
- Concurrent operations such as device upgrade, upgrade revert, moving a device between domains, device import and export, device template import and export, or policy analysis are running in on-premises Firewall Management Center.
- Connectivity issues exist between the on-premises Firewall Management Center and Security Cloud Control.

Workaround:

1. Perform these actions according to your requirements:
    - Ensure that at least 10% of disk space is available to accommodate the creation of necessary export files.
    - Ensure that no parallel operations are running during the migration.
    - Ensure that the network connection between on-premises Firewall Management Center and Security Cloud Control is stable and reliable.
2. Retry the migration.
3. If the issue persists, contact Cisco TAC.

Failed to initiate import in Security Cloud Control

Cause:

Import can fail if:

- Disk space is full or nearly full, preventing the import process from being completed.
- Concurrent operations such as device upgrade, upgrade revert, moving a device between domains, device import and export, device template import and export, or policy analysis are running in Cloud-Delivered Firewall Management Center.

Workaround:

1. Ensure that no other operations are running during import and retry migration.
2. If the issue persists, contact Cisco TAC.

Failed to retrieve the most recent device information from On-Premises Firewall Management Center

Cause:

- Network connectivity issues.
- DNS settings.
- Device synchronization issues.

Workaround:

1. Perform these actions according to your requirements:
    - Ensure that the network connection between Security Cloud Control and on-premises Firewall Management Center is stable.
    - Ensure that DNS settings for resolving Firewall Management Center hostnames are correct.
    - Ensure network access for Firewall Threat Defense devices through TCP ports 8305 and 443.
    - Ensure outbound connectivity to port 443 to Security Cloud Control and Cloud-Delivered Firewall Management Center hosts.
    - Ensure that the devices are synchronized without any pending changes.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to select Security Cloud Control as the manager for events and analytics

Cause:

Selected on-premises Firewall Management Center for analytics during Firewall Threat Defense migration and committed it or the Security Cloud Control automatically committed it after the 14-day evaluation period.

Workaround:

1. Log in to the on-premises Firewall Management Center and remove the Firewall Threat Defense device from the on-premises Firewall Management Center.

2. Enable the Firewall Threat Defense device to send events to Security Analytics and Logging (SaaS) directly. For more information, see Send Cloud-delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection.
3. Verify if the SSE Connector is running in the Firewall Threat Defense device. To verify, access Firewall Threat DefenseCLI and do the following:

```
# more /ngfw/etc/sf/connector.properties

registration_interval=180

connector_port=8989

connector_fqdn=api-sse.cisco.com
```

4. Verify the connectivity between Firewall Threat Defense and the SSE portal. The following URLs need to be allowed as IPs can change:
   - api.apj.sse.itd.cisco.com (primary SSE cloud API endpoint)
   - est.sco.cisco.com (common endpoint across geographies)
   - mx.apj.sse.itd.cisco.com
   - dex.apj.sse.itd.cisco.com (for customer success services)
   - eventing-ingest.apj.sse.itd.cisco.com (for Cisco XDR and Security Cloud Control services)
   - registration.apj.sse.itd.cisco.com (enables Firewall Threat Defense device registration to the regional Cisco cloud)
5. access Firewall Threat Defense CLI and perform a CURL request to validate tenant details using the following command:

```
root@firepower:/home/admin# curl localhost:8989/v1/contexts/default/tenant
```

6. Verify that the event logs are appearing in Security Cloud Control.

Failed to import configuration from On-Premises Firewall Management Center

Cause:

The On-Premises Firewall Management Center configuration may include policies or object configurations that are unsupported or are conflicting, leading to migration failure.

Workaround:

1. Check the On-Premises Firewall Management Center configuration for unsupported policies or object configurations to ensure compatibility.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to complete device discovery

Cause:

Conflicts or unhandled scenarios exist in the device configuration or within Security Cloud Control's internal operations, such as incompatible settings or unsupported conditions that Security Cloud Control does not support.

Workaround:

1. Perform these actions according to your requirements:
    - Inspect the device configuration in On-Premises Firewall Management Center for incompatible settings or unsupported scenarios that Security Cloud Control does not support and make necessary updates.
    - Check system logs for errors and confirm that both the On-Premises Firewall Management Center and the device are functioning properly.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to connect the device to Security Cloud Control

Cause:

Possible causes include the device being powered off, network connectivity issues, or a firewall blocking the necessary ports.

Workaround:

1. Perform these actions according to your requirements:
    - Confirm that the device is powered on, and network connection is stable. Look for Firewall issues, blocked ports, and incorrect cabling.
    - Ensure that your device has the correct DNS server configuration for resolving Security Cloud Control hostnames.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to register the device, causing the manager to revert to On-Premises Firewall Management Center

Cause:

The device failed to register with Cloud-Delivered Firewall Management Center during migration, causing the system to revert the device manager to On-Premises Firewall Management Center. This may be because of connectivity issues.

Workaround:

1. Perform these actions according to your requirements:
    - Verify DNS settings for resolving Security Cloud Control hostnames.
    - Ensure that network access is enabled for TCP port 8305, allowing the Firewall Threat Defense devices to connect to the Cloud-Delivered Firewall Management Center.

- Allow outbound HTTPS connections on Firewall Threat Defense devices to reach the Cloud-Delivered Firewall Management Center and upload configurations to Security Cloud Control.

2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to unregister the device due to an ongoing deployment

Cause:

Migration failed because a deployment is in progress on the device.

Workaround:

1. Perform these actions according to your requirements:
   - Wait for the ongoing deployment to finish.
   - Confirm that the device is stable, with no pending tasks.
2. Retry migration.
3. If the issue persists, contact Cisco TAC for support.

Report generation failed after successful FTD migration to Cloud-Delivered Firewall Management Center

Cause:

The report generation failure may be because of temporary system glitches.

Workaround:

- Generate the report after some time to overcome the temporary system issues that might have caused the initial failure.
- If the issue persists, contact Cisco TAC.

Failed to initiate FTD migration to Cloud-Delivered Firewall Management Center

Cause:

- Ongoing migration in the source manager.
- Unsupported device version.
- Incorrect DNS and network configuration.

Workaround:

1. Perform these actions according to your requirements:
   - Confirm that no other migration jobs are active in the same source manager.
   - Verify that the devices are on supported versions, have no pending changes to be deployed, and are active.

- Ensure that the DNS settings are correct, and network access is available to communicate with Cloud-Delivered Firewall Management Center.

2. If the issue persists, contact Cisco TAC.

Failed to deploy changes from Security Cloud Control

Cause:

Device migration to Cloud-Delivered Firewall Management Center failed during deployment.

Workaround:

1. Perform these actions according to your requirements:
   - Attempt the deployment again from the **Deployment** page on Cloud-Delivered Firewall Management Center.
   - Check for out-of-band changes, which are changes made directly in the device, and not through Security Cloud Control. If out-of-band changes exist, they may interfere with the deployment. Use Security Cloud Control's **Check for changes** functionality to identify and address out-of-band changes.
   - Ensure that all the configurations are supported and do not conflict with the current device settings.
   - Verify that the device is onboarded and reachable by both the Security Cloud Control and management center, with the necessary internet access and communication capabilities.
2. If the issue persists, contact Cisco TAC.

Failed to commit FTD migration to Cloud-Delivered Firewall Management Center

Cause:

- The 14-day evaluation period has expired.
- Firewall Threat Defense devices have been reverted to or deleted from the On-Premises Firewall Management Center, preventing further actions.

Workaround:

1. Try committing again to address any transient network or device issues.
2. If the issue persists, contact Cisco TAC.

Failed to retain device on On-Premises Firewall Management Center for Analytics

Cause:

If your source manager is an On-Premises Firewall Management Center 1000/2500/4500, it cannot support retaining for Analytics because of the limited resources.

Workaround:

1. Ensure that the **Retain on On-Prem FMC for Analytics** option is selected during the migration process.
2. If the issue persists, contact Cisco TAC.

Failed to revert the device manager to On-Premises Firewall Management Center

Cause:

- The device cannot be reverted if the 14-day evaluation period has expired.
- Firewall Threat Defense devices have been reverted to or deleted from the On-Premises Firewall Management Center, preventing further actions.

Workaround:

1. Perform these actions according to your requirements:
   - Try committing the changes again to address the temporary server or network issues.
   - If changes have occurred in the high availability configuration after migration, reset the devices to their original migration state before attempting to commit.
2. If the issue persists, contact Cisco TAC.

Failed to configure Security Cloud Control as the configuration manager

Cause:

The device already has a configuration manager.

Workaround:

1. If another configuration manager is present, remove it manually and retry the migration.
2. If the issue persists, contact Cisco TAC.

Failed to commit migration; the device is ineligible

Cause:

- The device has pending changes that have to be deployed.
- The device to be migrated is part of FTD high availability (HA), but the current state is invalid, for example, it is in Active/Active state.
- The device to be migrated is connected in Analytics-only mode.
- Cluster migration is supported only for FTDs version 7.4 and above.
- Migration for chassis and MI FTDs on models 3100/4200 is currently not supported.

Workaround:

1. Perform these actions according to your requirements:
   - Verify that the device is up to date with On-Premises Firewall Management Center, then retry migration.
   - Ensure all pending changes on the devices are deployed.
   - Confirm that the Firewall Threat Defense device is in a valid state, such as Active/Standby. If the status isn't correctly reflected in On-Premises Firewall Management Center, use the **Force refresh node status** option on the device listing page to update the correct status on management center.

2. If the issue persists, contact Cisco TAC.

Failed to import site-to-site VPN policies from On-Premises Firewall Management Center

Cause:

The failure may be due to various factors, such as VPN policy configuration or network connectivity issues.

Workaround:

1. Perform these actions according to your requirements:
    - Verify your site-to-site VPN policies in On-Premises Firewall Management Center to ensure there are no configuration errors. If object overrides are used within network objects, manually add these overrides to Security Cloud Control after migration.
    - Ensure that both the On-Premises Firewall Management Center and the targeted device have stable and reliable network connections to Security Cloud Control.
    - If the authentication type is set as **Pre-shared Automatic Key** in On-Premises Firewall Management Center, Security Cloud Control generates a new pre-shared key for the VPN post-migration deployment without disrupting existing tunnels.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

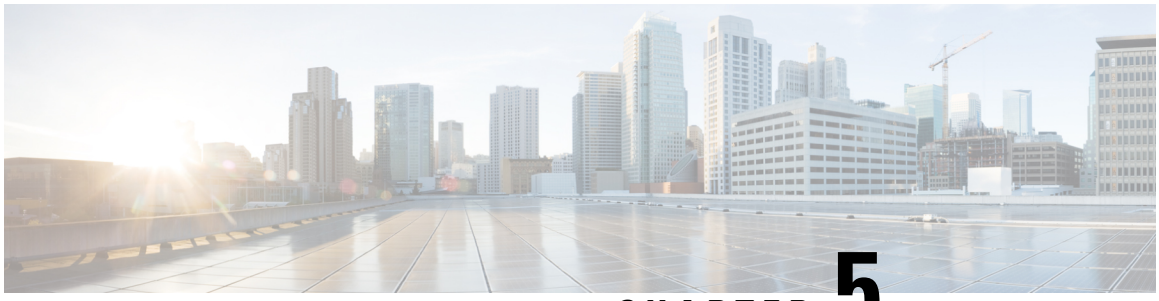
Failed to migrate as all devices within the topology need to be migrated simultaneously

Cause:

Migrating multiple devices, particularly those within the same network topology, requires synchronizing their migrations to avoid inconsistencies and potential errors. All devices should be migrated within the same timeframe.

Workaround:

1. Perform these actions according to your requirements:
    - Devices registered for Analytics -only with the On-Premises Firewall Management Center or those with pending changes are not eligible for migration.
    - When selecting a device associated with a site-to-site VPN topology, Security Cloud Control automatically selects peer devices from the same or different topology, as all devices in the topology must be migrated together for success. Extranet devices, if any, are not listed by the wizard.
    - The **S2S VPN Topology** column shows the number of site-to-site VPN topologies a device is part of. Click the topology link to view the topologies and devices migrating with the selected device. This field does not apply to devices outside the site-to-site VPN topology.
    - A high-availability pair is shown as a single node. Select this node to include both active and standby devices in the migration.
2. If the issue persists, contact Cisco TAC.



HTTP status code 201 (created) found in On-Premises Firewall Management Center response

Cause:

The Secure Device Connector (SDC) version is not compatible.

Workaround:

1. Ensure that the SDC is upgraded to version **202205191350** or later.
    - In the left pane, click **Administration** > **Integrations** > **Secure ConnectorsAdministration** > **Secure Connectors**.
    - Click the SDC to view the existing version in the **Details** pane on the right.
    - Update your Secure Device Connector.

CHAPTER 5

Device Registration

You canmanage devices in the Cloud-Delivered Firewall Management Center.

- Log into the Command-Line Interface on the device, on page 99
- Device registration management, on page 101

Log into the Command-Line Interface on the device

You can log directly into the command-line interface on Firewall Threat Defense devices. If this is your first time logging in, complete the initial setup process using the default **admin** user; see Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI, on page 51 .

For zero-touch provisioning , if you must access the Firewall Threat Defense CLI and run through the setup script, answer **n** when prompted: `Do you want to configure IPv4? (y/n) [y]:` and `Do you want to configure IPv6? (y/n) [y]:` . You also must accept the default local manager: `Manage the device locally? (yes/no) [yes]:` . These settings will preserve zero-touch provisioning capability.

For the Secure Firewall 200 , the device only supports up to three concurrent CLI sessions. For example, you can have one console session and two SSH sessions to the Management interface (this limitation is separate from SSH to a data interface). If you already have three active SSH sessions and then connect to the console, the console connection is allowed because console access will never be blocked.

Note If a user makes three consecutive failed attempts to log in to the CLI via SSH, the system terminates the SSH connection.

Before you begin

- Create additional user accounts that can log in to the CLI using the **configure user add** command.
- If you get unreadable characters when connecting to the console port, verify the port settings. If they are correct, try the cable with another device using the same settings. If the cable is good, you might need to replace the hardware for the console port. Also consider trying a different workstation to make the connection.

Procedure

Step 1 Connect to the Firewall Threat Defense CLI, either from the console port or using SSH.

You can SSH to the management interface of the Firewall Threat Defense device. You can also connect to the address on a data interface if you open the interface for SSH connections. SSH access to data interfaces is disabled by default. See Configure Secure Shell (SSH) access, on page 1262 to allow SSH connections to specific data interfaces.

For physical devices, you can directly connect to the console port on the device. See the hardware guide for your device for more information about the console cable. Use the following serial settings:

- 9600 baud
- 8 data bits
- No parity
- 1 stop bit

The CLI on the console port is FXOS (with the exception of the ISA 3000, where it is the regular Firewall Threat Defense CLI) . Use the Firewall Threat Defense CLI for basic configuration, monitoring, and normal system troubleshooting. See the FXOS documentation for information on FXOS commands.

Step 2 Log in with the **admin** username and password.

Example:

```
firepower login: admin
Password:
Last login: Thu May 16 14:01:03 UTC 2019 on ttyS0
Successful login attempts for user 'admin' : 1
firepower#
```

Step 3 If you used the console port, access the Firewall Threat Defense CLI.

connect ftd

Note
This step does not apply to the ISA 3000.

Example:

```
firepower# connect ftd
>
```

Step 4 At the CLI prompt (>), use any of the commands allowed by your level of command line access.

To return to FXOS on the console port, enter **exit** .

Step 5 (Optional) If you used SSH, you can connect to FXOS.

connect fxos

To return to the Firewall Threat Defense CLI, enter **exit** .

Step 6 (Optional) Access the diagnostic CLI:

system support diagnostic-cli

Use this CLI for advanced troubleshooting. This CLI includes additional **show** and other commands.

This CLI has submodes: user EXEC mode, privileged EXEC mode , and recovery-config mode . More commands are available in privileged EXEC mode than user EXEC mode. To enter privileged EXEC mode, enter the **enable** command; press enter without entering a password when prompted.

Example:

```
> system support diagnostic-cli
firepower> enable
Password:
firepower#
```

To use recovery-config mode, see Access recovery-config mode in the diagnostic CLI, on page 1146 .

To return to the regular CLI, type **Ctrl-a** , **d** .

Device registration management

Register and unregister devices to the Cloud-Delivered Firewall Management Center.

About the device management page

The **Devices** > **Device Management** page provides you with range of information and options.

You can enable or disable the **New device management UI** toggle button to switch between the legacy and enhanced view in the **Device Management** page.

Figure 8: Toggle button to switch between legacy and enhanced view

- **View By**—View devices based on group, licenses, model, version, or access control policy.
- **Device State**—View devices based on state (**Error**, **Warning**, etc.). You can click on a state icon to view the devices belonging to it. The number of devices belonging to the states are provided within brackets.
- **Search Device**—Search for a device by device name, host name, or IP address.
- **Add**—Add devices and other manageable components.
- Columns—Click the column head to sort by that column.
  - **Name**
  - **Model**
  - **Version**
  - **Chassis**—For supported models, click **Manage** to bring up the integrated Chassis Manager. For the Firepower 4100/9300, the link cross-launches the Firewall Chassis Manager.

- **Licenses**
- **Access Control Policy**—Click on the link in the Access Control Policy column to view the policy that is deployed to the device.
- **Auto-Rollback**—Shows whether auto-rollback of the configuration is enabled ( ) or disabled ( ) if the deployment causes the management connection to go down. See Edit deployment settings, on page 1192.

- **Edit**—For each device, use the **Edit** ( ) icon to edit the device settings.

  You can also just click on the device name or IP address.

- **More**—For each device, click the **More** ( ) icon to execute other actions:
  - **Packet Tracer**—To navigate to the packet tracer page for examining policy configuration on the device by injecting a model packet into the system.
  - **Packet Capture**—To navigate to the packet capture page, where, you can view the verdicts and actions the system takes while processing a packet.
  - **Revert Upgrade**—To revert the upgrade and configuration changes that were made after the last upgrade. This action results in restoring the device to the version that was before the upgrade.
  - **Health Monitor**—To navigate to the device's health monitoring page.
  - **Troubleshoot Files**—Generate troubleshooting files, where you can choose the type of data to be included in the report.
  - **Generate Template from Device**—Generate a new device template from a registered device. The new template has the same configuration as the device from which it is generated. You can generate a new device template from standalone and HA devices. However, if you generate a template from HA devices, the new template will not contain the failover configurations.

Add a Device Group

The Cloud-Delivered Firewall Management Center allows you to group devices so you can easily deploy policies and install updates on multiple devices. You can expand and collapse the list of devices in the group.

If you add the primary device in a high-availability pair to a group, both devices are added to the group. If you break the high-availability pair, both devices remain in that group.

Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 From the **Add** drop-down menu, choose **Add Group** .

To edit an existing group, click **Edit** ( ) for the group you want to edit.

Step 3 Enter a **Name** .

Step 4 Under **Available Devices** , choose one or more devices to add to the device group. Use Ctrl or Shift while clicking to choose multiple devices.

Step 5 Click **Add** to include the devices you chose in the device group.

Step 6 Optionally, to remove a device from the device group, click **Delete** ( ) next to the device you want to remove.

Step 7 Click **OK** to add the device group.

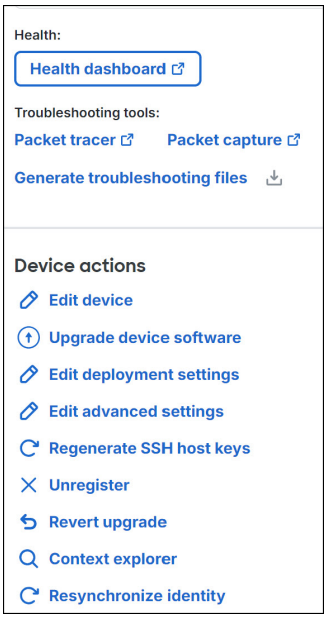
Device management page enhancements

Device management page is enhanced to a new user interface that can be toggled with the legacy version. User interface improvements offer enhanced features including improved search functionality, device status monitoring, and centralized troubleshooting tools.

Device management page enhancement features

Navigation: **Devices** > **Device Management**

Enable the **New device management UI** toggle button to switch between the legacy and the enhanced **Device Management** page.



Note The enhanced user interface is in a preliminary stage and does not include all the legacy user interface features. You can switch back to the legacy **Device Management** user interface by clicking the same toggle button to access the features that are not yet supported in the new user interface.

Key enhancements in the new user interface:

- **Improved search functionality**: Provides a more powerful and granular search experience. Unlike the legacy user interface, which was limited to searching by device name, host name, or IP address, you can now use multiple device-related criteria, to achieve highly refined results.
- **Device status banner**: A status banner at the top of the **Device Management** page displays the number of devices in various states (**Normal**, **Error**, **Offline**). A color-coded legend dynamically reflects these statuses for at-a-glance monitoring.
- **Performance improvements**: The enhanced user interface page loads faster than the legacy version. Pagination has been introduced at the bottom of the page, with each page supporting up to 1,000 devices by default.
- **Device actions and bulk operations**: Details of selected devices are displayed on a side panel in a more user-friendly format. Multiple devices can be selected simultaneously enabling device bulk actions from a centralized location.
- **Centralized troubleshooting panel**: Troubleshooting information has been consolidated into a single pane under Troubleshooting tools, making it easier to access diagnostic tools such as **Packet Tracer** and **Packet Capture**.

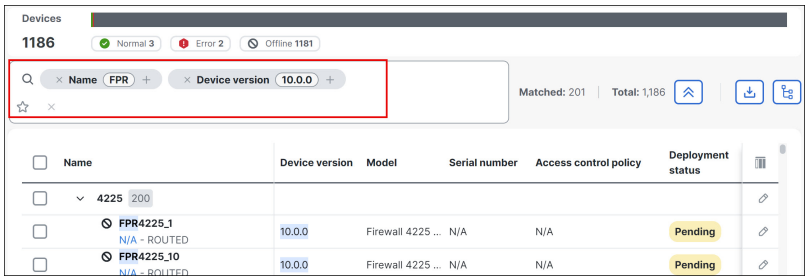
Device settings

In the new device management page view, select the device to open the side pane. Click the option you want:

- Under **Health and troubleshooting**, click **Health dashboard** to navigate to the device's health monitoring page.
- Under **Troubleshooting tools**, click:
  - **Packet Tracer**—To navigate to the packet tracer page for examining policy configuration on the device by injecting a model packet into the system.
  - **Packet Capture**—To navigate to the packet capture page, where, you can view the verdicts and actions the system takes while processing a packet.
  - **Generate troubleshooting files**—To generate diagnostic files for the device. You can choose the type of data to be included in the report.
- Under **Device actions**, click:
  - **Edit**—For each device, use the **Edit** (✎) icon to edit the device settings.
  - **Upgrade device software**—Install a software update on this device.
  - **Edit deployment settings**—Configure automatic rollback if a deployment disrupts management connectivity.
  - **Edit advanced settings**—Modify advanced device configuration settings.
  - **Regenerate SSH host keys**—Generate new SSH host keys for this device.
  - **Unregister**—Remove this device from the management center.
  - **Revert upgrade**—Restore the device to the software version and configuration from before the last upgrade.
  - **Content explorer**—Open Context Explorer to investigate device data.
  - **Resynchronize identity**—Synchronize identity data for this device.

Use the enhanced filters in device management page

This task enables you to quickly find specific devices using various search criteria and save frequently used searches for future use.



You can use different criteria to instantly search for the devices you want.

Procedure

Step 1 In the **Device Management** page, click the **Type to search** field to perform one of the following actions:

- Enter the filter criteria to search the device. Suggestions are displayed as you type.
- Select a filter and then enter a value in the field. You can add multiple criteria to refine your search results further.

In the example shown in the figure, the filter searches for devices with names that contain "FPR" andare of version of "10.0.0".

Step 2 Click the **Favourite Searches** (☆) icon and do one of the following:

- To save a new search, specify a search name and click **Save as new**.
- To overwrite a saved search, click the **Edit** () icon on next to the saved search that you want to overwrite, and click **Overwrite**.

Note

You can also use the **Favourite Searches** (☆) icon to quickly retrieve the previously executed searches.

The enhanced filters display devices that match your search criteria, and saved searches are available for future use through the Favourite Searches feature.

Add a device group

Create device groups to organize and manage multiple devices efficiently, enabling streamlined policy deployment and update installation across grouped devices.

The Management Center allows you to group devices to easily deploy policies and install updates on multiple devices. You can expand and collapse the list of devices in the group. The new device management user

interface provides enhanced functionalities in the context of device groups, improving the way you organize, manage, and interact with them.

The **Manage device groups** dialog box provides two main sections:

- Ungrouped devices: This section lists all the devices that are currently not assigned to any group. A search bar, labeled **Search devices to move** enables you to quickly locate specific devices by device name or device IP address. The count that is displayed represents the number of ungrouped devices, and not the total number of devices managed by the system.
- Groups: This section displays all the existing device groups. A search bar, **Search by group or device name**, enables you to find specific groups or devices within groups.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Enable the **New Device Management UI** toggle button and click the **Manage Groups** () icon.

Step 3 Click **Create Group**.

Step 4 Enter a name and click .

The group is created.

Step 5 Select the devices that you want to add to the newly created group.

Step 6 Under **Groups** locate the newly created group.

You can use the **Search by group or device name** field to search for the group.

Step 7 Click **Add selection to group**.

The selected devices are added to the group.

Note
You can also delete a group. However, deleting a group does not remove the devices from the Management Center. Instead, all the devices assigned to the deleted group will be automatically moved back to the Ungrouped devices section.

A new device group is created with the selected devices assigned to it. The devices appear under the group in the Groups section and are removed from the Ungrouped devices section.

Move devices to another group

Moving devices to another group allows you to reorganize your device management structure and ensure devices are properly categorized for administrative purposes.

The device must first be moved to Ungrouped Devices. Next, move it to the group you want.

Procedure

Step 1 Click the **Manage Groups** icon.

Step 2 Under **Groups**, expand the group from which you want to move the device.

Step 3 Click the X button to remove the device from the group.

The device is moved to **Ungrouped Groups**.

Step 4 Select the device that you want to add.

Step 5 Under **Groups** locate the group.

You can use the **Search by group or device name** field to search for the group.

Step 6 Click **Add selection to group**.

The selected device is added to the group.

Managed device list download

A managed device list download is a data export feature that enables administrators to obtain device inventory information in multiple file formats for offline analysis and reporting purposes.

Download process

Click  to download the device list in CSV or PDF format. Click **Download CSV** or **Download PDF** to download the report in the corresponding format.

Shut down or restart the device

It's important that you shut down your system properly. Simply unplugging the power or pressing the power switch can cause serious file system damage. Remember that there are many processes running in the background all the time, and unplugging or shutting off the power does not allow the graceful shutdown of your firewall.

See the following task to shut down or restart your system properly.

Note After restarting your device, you may see an error that the management connection could not be reestablished. In some cases, the connection is attempted before the Management interface on the device is ready. The connection will be retried automatically and should come up within 15 minutes.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device that you want to restart, click **Edit** ( ) .

Step 3 Click **Device**.

Step 4 To restart the device:

a) Under **System**, click **Restart Device** ( ) .
b) When prompted, confirm that you want to restart the device.

Step 5 To shut down the device:

a) Under **System**, click **Shut Down Device** ( ) in the **System** section.
b) When prompted, confirm that you want to shut down the device.
c) If you have a console connection to the firewall, monitor the system prompts as the firewall shuts down. You will see the following prompt:

```
System is stopped.
It is safe to power off now.
Do you want to reboot instead? [y/N]
```

If you do not have a console connection, wait approximately 3 minutes to ensure the system has shut down.

For the ISA 3000, when shutdown is complete, the System LED will turn off. Wait at least 10 seconds before you remove the power.

Download the managed device list

You can download a report of all the managed devices.

Before you begin

To perform the following task, you must be an Admin user.

Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 Click the **Download Device List Report** link.

Step 3 You can download the device list in CSV or PDF format. Choose **Download CSV** or **Download PDF** to download the report.

Migrate Firewall Threat Defense devices

The Secure Firewall Threat Defense model migration wizard enables you to migrate configurations from an earlier Firewall Threat Defense model. After the migration, all routing and interface configurations from the source Firewall Threat Defense device are available in the target Firewall Threat Defense.

Supported devices and capabilities

The wizard supports multiple models as source and target devices, for more information see Supported Devices for Migration, on page 109.

When you migrate Firepower 4100 and 9300 Series devices to the supported models, you can now configure interface attributes according to your requirements. You can map the source device interfaces to the target device interfaces. The migration locks the source and target devices.

Supported Devices for Migration

Documents the supported migration paths and device compatibility for Cisco Firepower and Secure Firewall models.

Supported Migration Paths

The following table lists the supported target Firewall Threat Defense models that you can migrate to from your source Firewall Threat Defense model.

Source Devices	Source Device Version	Target Devices	Target Device Version
Cisco Firepower 1010 Series: 1010, 1010E	7.3.x and later	Cisco Secure Firewall 1200 Series:1210CE, 1210CP, 1210CX	7.6 and later
Cisco Firepower 1010 Series: 1010, 1010E	7.3.x and later	Cisco Firewall 200 Series: 220	10.0 and later
Cisco Firepower 1100 Series: 1120, 1140, 1150	7.3.x and later	Cisco Secure Firewall 3100 Series: 3105, 3110, 3120, 3130, 3140	7.4.1 and later
Cisco Firepower 2100 Series: 2110, 2120, 2130, 2140	7.3.x and later	Cisco Secure Firewall 3100 Series: 3105, 3110, 3120, 3130, 3140	7.4.1 and later
Cisco Firepower 4100 Series: 4112, 4115, 4125, 4145	7.3.x and later	Cisco Secure Firewall 3100 Series: 3105, 3110, 3120, 3130, 3140	7.4.1 and later
		Cisco Secure Firewall 4200 Series: 4215, 4225, 4245	7.4.1 and later
		Cisco Secure Firewall 6100 Series: 6160, 6170	10.0 and later

Source Devices	Source Device Version	Target Devices	Target Device Version
Cisco Firepower 9300 Series: SM-40, SM-48, SM-56	7.3.x and later	Cisco Secure Firewall 3100 Series: 3105, 3110, 3120, 3130, 3140	7.4.1 and later
		Cisco Secure Firewall 4200 Series: 4215, 4225, 4245	7.4.1 and later
		Cisco Secure Firewall 6100 Series: 6160, 6170	10.0 and later
Cisco ASA 5500 Series: 5508, 5516	7.0.x	Cisco Secure Firewall 1200 Series:1210CE, 1210CP, 1210CX	7.6 and later
Cisco Firepower 1100 Series: 1120, 1140, 1150	7.3.x and later	Cisco Secure Firewall 1200 Series:1210CE, 1210CP, 1210CX	7.6 and later
Cisco Firepower 1100 Series: 1120, 1140, 1150	7.3.x and later	Cisco Secure Firewall 1200 Series: 1230, 1240, 1250	7.7.x and later
Cisco Firepower 2100 Series: 2110, 2120, 2130, 2140	7.4.x	Cisco Secure Firewall 1200 Series:1210CE, 1210CP, 1210CX	7.6 and later
Cisco Firepower 2100 Series: 2110, 2120, 2130, 2140	7.4.x	Cisco Secure Firewall 1200 Series: 1230, 1240, 1250	7.7.x and later

License for Firewall Threat Defense migration

You must meet licensing requirements for Firewall Threat Defense migration.

- Your Smart Licensing account must have the license entitlements for the target device.
- You must register and enroll the device with the Smart Licensing account. The migration copies the source device licenses to the target device.

Prerequisites for migration

This reference provides comprehensive prerequisites that must be satisfied to successfully migrate configurations from a source device to a target device in Secure Firewall Management Center environments.

General device prerequisites

- Register the source and the target devices to the Cloud-Delivered Firewall Management Center.
- Ensure that the target device is a newly registered device without any configurations.
- Source and target devices must be in the same state and modes:

- Firewall mode: Routed or Transparent
- Compliance mode (CC or UCAPL)
- Management state

  Devices must have the same type of manager access interfaces (management interface or data interface).
- Multi-instance mode or appliance mode

- Ensure that you have permission for modifications on the devices.
- Ensure that the configurations on the source device are valid and have no errors.
- Deployment, import, or export tasks must not run on either of the devices during the migration. The source device can have pending deployments.

Prerequisites for change management

- Ensure that source and target devices are not locked by a change management ticket.
- Ensure that shared policies assigned to the source device are not locked by a change management ticket.

Prerequisites for devices in multi-instance mode

- Ensure that the source and target devices are in multi-instance mode.
- Manually migrate the chassis configurations. Create instances before migrating the instance configuration to the target instances. The target device must have compatible interfaces. For example, on the target device, you must create EtherChannel interfaces, and also create tagged, untagged, dedicated, or shared interfaces for these interfaces on the target device.

Prerequisite for devices with out-of-band configurations

- Ensure that you acknowledge out-of-band changes and match the configurations within the Cloud-Delivered Firewall Management Center. You cannot migrate devices with these configurations. To view out-of-band configurations:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon next to the device and click the **Interfaces** tab.

  or

  1. Click the edit icon next to the device and click the **Devices** tab.
  2. Verify the **Out-of-band configuration status** in the **Health** tile.

Prerequisites for devices with manager access interfaces

Ensure that the devices are not in Data Transit or Management Transit states. You cannot migrate if devices are in these states.

- Data Transit state: Device state when the manager access interface changes from data interface to management interface without deploying the changes on the device.
- Management Transit state: Device state when the manager access interface changes from management interface to data interface without deploying the changes on the device.

Prerequisite for devices with merged management and diagnostic interfaces

Ensure that the target device is always in merged mode.

Configurations that the wizard migrates

The migration wizard copies configurations from the source device to the target device, including licenses, interfaces, policies, routing settings, and other essential device configurations.

General configurations

The migration wizard copies these configurations from the source device to the target device:

- Licenses
- Interface configurations
- Inline sets configurations
- Routing configurations
- DHCP and DDNS configurations
- Policies
- Associated objects and object overrides
- Platform settings
- Remote branch deployment configurations

Policy configurations

The migration wizard copies these policy configurations from the source device to the target device:

- Health policy
- NAT and QoS policy
- Remote access VPN policy
- FlexConfig policy
- Access control and prefilter policy
- IPS and DNS policy
- Malware and File policy
- SSL and Identity policy
- Shared policy

Routing configurations

The migration wizard copies these routing configurations from the source device to the target device:

- ECMP
- BFD
- OSPFv2/v3
- EIGRP
- RIP
- BGP
- Policy Based Routing
- Static and Multicast Route
- Virtual Router

Interface configurations

The migration wizard copies these interfaces from the source device to the target device:

- Physical interfaces
- Sub-interfaces
- EtherChannel interfaces
  - On a standalone device, the wizard copies the EtherChannels from the source device to the target device.
  - For devices in multi-instance mode, you must create EtherChannels on the chassis and assign them to the instance.
- Bridge group interfaces
- VTI interfaces
- VNI interfaces
- Loopback interfaces
- VXLAN tunnel endpoint (VTEP) interfaces

The migration wizard retains the device group of the target device.

Guidelines and limitations for migration

Follow these guidelines to ensure successful migration of secure firewall threat defense models:

- **For devices in multi-instance mode**:

  During migration, ensure that you map the interfaces according to the table below:

Source Device	Target Device
Physical interface	Physical interface
EtherChannel interface	EtherChannel interface
Supervisor-provisioned subinterface	Supervisor-provisioned subinterface
Tagged interface	Tagged interface
Untagged interface	Untagged interface
Shared interface	Shared and dedicated interface
Dedicated interface	Dedicated interface

You cannot map a supervisor-provisioned subinterface to a subinterface created by an instance.

- **For HA devices**, you can migrate:
  - Source HA device to target HA device.
  - Source HA device to target standalone device.
- **For devices in remote branch deployment**:
  - Map the source manager access interface to the target manager access interface.
  - Ensure that the manager access interfaces of the source and target Cloud-Delivered Firewall Management Centers are of the same IP address type (static or DHCP).
  - Both manager access interfaces must have IPv4 or IPv6 addresses.
  - If the manager access interfaces have static IP addresses, ensure that they are in the same subnet.
- **For Snort**:

  By default, after migration, the target device will use Snort 3, even if the source device uses Snort 2.
- **For devices using diagnostic interfaces**:

  Only merged management interfaces are available on the target devices after migration.

Limitations

Be aware of these limitations when using the migration wizard:

- The migration wizard does not migrate:
  - Site-to-site VPN policies
  - SNMP device configurations for Firepower 2100 Series

    After the migration, you can configure SNMP using the platform settings for the device.
- You can perform only one migration at a time.
- Remote access VPN trustpoint certificates are not enrolled after migration.

- For HA devices:
  - Target device: You cannot migrate a standalone device to an HA device.
- Clustering is not supported.
- For devices in remote branch deployment:
  - The wizard does not migrate a single WAN manager access data interface to a dual WAN manager access data interface.

Migrate a secure Firewall Threat Defense

Migrate a Secure Firewall Threat Defense device from a source to a target Firewall, preserving configurations and minimizing disruptions.

Before you begin

Ensure you review Prerequisites for migration, on page 110 and Guidelines and limitations for migration, on page 113 .

Procedure

Step 1 Choose **Devices** > **Device Management** .

Step 2 Click **Migrate** in the top right corner of the page.

Step 3 In **Select source and target devices** :

a) From the **Source device** drop-down list, choose a device.

b) From the **Target device** drop-down list, choose a device.

The source and target devices can have these tags:

- Routed: Devices in routed firewall mode.
- Transparent: Devices in transparent firewall mode.
- Container: Devices in multi-instance mode.
- High Availability: Devices in high availability mode.
- Analytics Only: Devices managed by Security Cloud Control and the Cloud-Delivered Firewall Management Center only recieves and displays the events (analytics-only Cloud-Delivered Firewall Management Center).

If the device is part of an HA pair, only the HA pair name appears.

Step 4 Click **Next** .

Step 5 (Only for Firepower 4100 and 9300 Series devices in appliance mode) In **Chassis manager details** :

a) Check the **Skip chassis manager** check box, if required.

b) In the **Chassis hostname or IP address** field, enter the values.

Note

- Verify that the Secure Firewall Chassis Manager is reachable from the Cloud-Delivered Firewall Management Center .

- Ensure you select the correct chassis manager for the source device, as Cloud-Delivered Firewall Management Center does not validate your choice.

c) Click **Verify certificate** to verify the chassis manager's certificate.
d) In the **Username** and **Password** fields, enter the credentials of the chassis manager.

Step 6 Click **Next** .

Step 7 In **Configure interfaces** :

By default, the source and target interfaces are mapped using the interface hardware name. You must map named interfaces, logical interfaces, and interfaces that are part of other interfaces. Mapping of all other interfaces is not mandatory. The wizard creates the logical interfaces according to the interface mapping that you provide.

You cannot map interfaces that are part of an HA failover configuration. These interfaces are disabled in the wizard.

Only data interfaces are available for interface mapping. Management, eventing, and diagnostic interfaces are not available for the interface mapping.

Firepower 4100 and 9300 Series devices in appliance mode :

For these devices, the Cloud-Delivered Firewall Management Center fetches interface attributes such as speed, duplex, and auto-negotiation from the chassis manager.

a) Click one of the following options to configure these interface attributes on the target device:

- **Retain target device values** : (Default) Retains the interface attributes configured on the target device.
- **Copy from source device** : Copies the interface attributes from the source device.

  This option is enabled only when Cloud-Delivered Firewall Management Center successfully connects to the chassis manager. We recommend that you use this option. The speed, duplex, and auto-negotiation values of physical interfaces are set to default values if they are incompatible in the target device.
- **Customize device values** —Allows you to configure the values of the required interface attributes on the target device.

b) To change the interface mapping from the default ones, choose an interface from the **Mapped interface** drop-down list.
c) For EtherChannels, you can configure interface attributes and click **Add member interface** to add member interfaces.

   Interface attributes of an EtherChannel is configured based on the first member interface's interface attributes.You can add up to 16 member interfaces.

Firepower 1100 and 2100 Series devices, and Firepower 4100 and 9300 Series devices in multi-instance mode :

For these devices, you must map the source device interfaces to target device interfaces.

For Firepower 4100 and 9300 Series devices in multi-instance mode, you can only perform the interface mapping and you cannot configure the interface attributes such as speed, duplex, auto-negotiation, and FEC mode.

If you want to change the interface mapping from the default ones, choose an interface from the **Mapped interface** drop-down list.

Click **Reset** to configure the default interface mappings. For example, the wizard maps Ethernet1/1 in the source device to Ethernet1/1 in the target device.

The interfaces can have the following tags:

- Tagged: Physical interfaces on the chassis.
- Untagged: Physical interfaces on the chassis that have sub-interfaces.
- Dedicated: Interfaces that are assigned to specific instances and are not shared across multiple instances.
- Shared: Interfaces that are shared by multiple instances.
- Manager access: Data interface is the manager access interface.

Check the **Ignore warning** check box, if required.

Step 8 Click **Next** .

Step 9 Click **Submit** to start the migration.

To view the migration status, click **Notifications** (Message Center), and then click the **Tasks** tab.

A **Device Model Migration** report is generated after the migration is completed. You will see a link to this report in the **Notifications** > **Tasks** page.

What to do next

After a successful migration, you must complete these tasks:

- Review the recommendations in Best practices for Threat Defense device migration, on page 117 .
- Validate the configurations.
- Deploy the configurations on the device.

In case of a migration failure, the target device is rolled back to the initial state.

Best practices for Threat Defense device migration

After a successful migration, perform these actions before deployment to ensure proper device configuration and functionality.

- IP addresses of the interfaces are copied to the target device from the source device. Change the IP addresses of the target device interfaces if the source device is live
- Ensure that you update your NAT policies with the modified IP addresses.
- Configure the interface speeds if they are set to default values after migration.
- Re-enroll the device certificates, if any, on the target device.
- (Optional) Configure SNMP for Firepower 1100 and 2100 using the platform settings for the device.
- (Optional) Configure remote branch deployments.

If the source or target device had manager access through a data interface, after the migration, the manager access will be lost. Update the manager access configuration on the target device. For more information, see the *Change the Manager Access Interface from Management to Data* topic in the Cisco Secure Firewall Management Center Device Configuration Guide or the Online Help.

- Configure site-to-site VPN, if required. These configurations are not migrated from the source device.
- View the deployment preview before the deployment. From the **Deploy** drop-down menu, click **Advanced Deploy**, and then click the **Preview** ( ) icon for the device.
- Monitor the health of the device in the health monitor (choose **System** ( ) > **Health** > **Monitor**). After migration, the health policy of the source device becomes the health policy of the target device. You can also configure a new health policy for the device.

  After migration, the device monitoring dashboard may temporarily display redundant colored lines because the device has different UUIDs before and after migration. This redundancy appears only during the migration time. An hour after migration, the dashboard will show a single line per metric.

Use the Security Cloud Control command line interface tool

You can use the command line interface (CLI) to troubleshoot Firewall Threat Defense and other supported device types within Security Cloud Control.

Additional information

For more information, see the Security Cloud Control configuration guide.

CHAPTER 6

Device Registration Using Device Templates

You can add devices to the Cloud-Delivered Firewall Management Center using device templates.

- Device registration using device templates, on page 119
- Prerequisites for device registration using device templates, on page 121
- Licenses for device registration using device templates, on page 122
- Guidelines for device registration using device templates, on page 123
- Configure device templates, on page 126
- Use templates with devices, on page 145
- Monitor device templates, on page 147
- Troubleshoot device templates, on page 149

Device registration using device templates

You can use device templates to apply configuration changes to multiple devices with different interface configurations, and clone configuration parameters from existing devices.

Configuration capabilities

Device templates let you pre-configure settings and apply them at the time of registration. When you register a device using basic initial configuration, you can apply limited configurations such as the access control policy and licenses. You must then configure other device settings such as interfaces, routing, and site-to-site VPN configurations individually after device registration. Values that need to be unique per device, such as IP addresses, can be defined using variables and network object overrides that you define at registration.

You can also configure site-to-site VPN connections in a device template. These configurations define the site-to-site VPN topologies that a device should be a part of. The VPN configurations along with the other device template policies and configurations enable easy deployment of the branch device to your network. Device templates support the configuration of a device only as a spoke. A device can be part of multiple hub and spoke site-to-site VPN topologies.

After the configured device template is applied to a device, the variables are resolved, the protected network overrides are configured, and the device is added as a spoke in the specified VPN topology.

Variables and network object overrides

You can parameterize template configurations using variables and network object overrides.

Variables

A variable is an object type that is supported for template configurations. A variable in a template defines specific configuration values for a device. You can define values for these variables during application of the template on the device. You can see the variable icon (x) for the fields that use a variable. The variables are displayed with a $ prefix to distinguish these values from the other values.

For information on supported variable types and creating variables, see Supported Variables and Add a Variable.

Network object overrides

Network object overrides are similar to variables. But, these are used to provide override values for a network object. You can declare a list of network objects in the template and create network object overrides for these objects. You can then provide values for these network object overrides during the application of the template on the device. For example, if you define a host network object in a template, you can add a network object override before the application of the template on the device and then provide a relevant value during the application of the template on the device.

For more information on supported network objects and adding a network object override, see Supported Network Object Overrides and Add a Network Object Override.

Model mapping

Model mapping lets you map template-defined interfaces to the interfaces of the Firewall Threat Defense model you require.

Model mapping requirements

Create model mappings in the template before applying the template to the device. During template application, the variables in the interface configurations are replaced with the values that you provide, then the resulting configurations are copied to the mapped interfaces on the device.

Interface configurations differ for each device model, so you must copy interface configurations from the template to the device's target interfaces.

During template application, the variables in the interface configurations are replaced with the values that you provide, then the resulting configurations are copied to the mapped interfaces on the device.

For more information on setting up model mapping, see Add Model Mapping.

Templates and high availability

You can apply device templates on Firewall Threat Defense high availability devices after device registration. High availability-specific configurations are not supported in device templates. Any high availability configurations and monitored interfaces that are already part of the target high availability device pair configurations are not modified. You cannot map any template interfaces to failover interfaces.

You can generate a device template from a high-availability device pair. Template operations such as application of the template on a device, template generation, importing, and exporting of a template, can be performed only on the active unit. You cannot perform these operations on the standby unit.

Validating template configurations before and after application on devices

Summary

The key components involved in the template configuration validation process are:

- System validator: Performs automated checks to ensure device compatibility and configuration integrity
- Target device: The network device receiving the template configuration
- Template configuration: The configuration settings being applied to the device
- Rollback mechanism: System capability to restore original device state if validation fails

Workflow

These stages describe how template configuration validation works:

1. The system performs pre-application validation checks before deploying the template on the target device.
   - Ensure that the target device model and version are supported.
   - Cluster and container checks -The device must not be part of a cluster or multi-instance.
   - Model mapping validation - Model mapping for the target device model exists and is valid.
   - Sanity check of template parameter values. For example, two variables used as IP addresses of interfaces must not have the same value.
2. The system applies the template configuration to the target device after successful pre-application validation.
3. The system performs post-application validation checks to ensure the applied configurations are valid.
   - Interface configuration validation. For example, variables used for the IP address fields of two or more interfaces must not have the same IP address values.
   - Routing policy validation. For example, the IPv4 address in BGP neighbor configurations must not overlap with the IP address of any interface.

   If the validation checks that are done at the end of the task to apply the template on the device fail, any applied configurations are rolled back and the device is restored to it's original state.

Prerequisites for device registration using device templates

This reference provides the prerequisites for device registration using device templates, including supported models and VPN configuration requirements.

Model support

Device templates are supported on On-Prem Cloud-Delivered Firewall Management Center, Cloud-Delivered Firewall Management Center(cdFMC), with these models running Secure Firewall version 7.4.1 and later versions:

- Secure Firewall 200

- Firepower 1010
- Firepower 1100
- Secure Firewall 1200
- Firepower 2100 (7.4.x only)
- Secure Firewall 3100

Prerequisites for VPN connections in device templates

- Configure site-to-site VPN topologies that must be used in the device template.
- Ensure that you have configured all hub and VPN topology-related configurations such as authentication methods, IKE and IPsec policies.
- Supported types of VPN hub and spoke topologies are:
  - Policy-based
  - Route-based
  - SD-WAN
- Assign appropriate logical names and IP addresses to the interfaces of the Firewall Threat Defense devices. For example, use *inside* for the interface connected to the LAN, and *outside* for the interface connected to the internet or WAN.
- Spoke devices must be version 7.4.1 and later.

Licenses for device registration using device templates

This reference provides license requirements and conditions for device registration using device templates, including Smart Licensing account requirements and Secure Client license behavior during template application.

- Device templates do not have any specific license requirements.
- License entitlements for the target device must be present in the Smart Licensing account.
- To configure VPN connections in the template, the Essentials license must allow export-controlled functionality. Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this functionality in the Cloud-Delivered Firewall Management Center.
- When you apply a template on a device, note these conditions for Secure Client licensing:

Device with Secure Client License	Template with Secure Client License	Secure Client License after Device Template Application
Yes	Yes	Template License
Yes	No	Device License
No	Yes	Template License

Guidelines for device registration using device templates

General guidelines

Follow these general guidelines when using device templates for device registration and configuration management.

- All device configurations other than VNI and VTEP are supported.
- You can attach shared policies and S2S VPN policies to a template. These policies are assigned during template application.
- Templates can be applied on HA devices. However, application of device templates during HA device pair registration is not supported. You also cannot manage HA-related configurations such as failover links, standby IP addresses, and so on. For more information, see Device Template Operations on Threat Defense HA Devices.
- Device template operations are supported only on the active Cloud-Delivered Firewall Management Center. The standby peer does not support device template operations.
- Ensure that the template names and device display names are not the same.
- Ensure that you do not create or delete a template during device backup or restore operations.
- After application of the template on the device, if the manager access is changed from management to data interface or vice-versa, you must re-establish the management connection with the device. Note that you cannot change the manager access interface during template application.
- You can add a maximum of 250 device templates to the Cloud-Delivered Firewall Management Center.
- Templates that are created and configured for devices that are managed through the data interface cannot be used to register and apply to devices that are managed through the management interface.
- Device registration and application of template does not come under the Change Management workflow. Only approved data, such as access policies, templates, template variables, network overrides declared in template, and template configurations used in the template application operation are used.
- Device registration with serial number and access control policy is supported for only one device at a time.
- When you apply a template to a device that is already registered, the configuration in the template is only copied to the target device. You can then choose to manually deploy the configuration on the device or let the copied configuration stay on the device and deploy later. However, if you apply the template during device onboarding, the configuration in the template is copied to the target device and, as per existing behavior, automatically deployed on the device after device registration.
- Any change in model mapping causes the device to be marked as 'Out of Sync'. Consider reapplying the template to the devices if you have made changes to the interface mapping in the corresponding model mapping or if you have made any configuration changes after the previous application of the template.
- Device templates are only supported on merged management and diagnostic interfaces. For more information, see Merge the Management and Diagnostic Interfaces.
- Template configuration updates are supported by change management. Creation and application of device templates is not supported by change management.

- You cannot sync configuration changes from a device to the template. A few sample scenarios during which you may want to make changes to the device configuration using a template along with recommended solutions are given below:
  - If you want to test the new configuration changes on one device before propagating the changes to multiple devices, we recommend that you make the changes in the template and apply the template to one device. Validate the changes on that device and then apply the template to the other devices.
  - If you want to make a large number of changes resulting in a signification deviation from the current configuration on a device, and then propagate those changes to other devices, you may choose one of these options:
    - Export the current template to get a copy of the template. You can then make the required changes in the template and apply to a single device. Validate the changes on that device and then apply the template to the other devices.
    - You can also make the required changes on the device and create a template from that device. You can then apply and validate the changes on the other devices. However, we do not recommend this as template parameters such as variables and network object overrides will not be present in the created template.
  - If the configuration on a particular device starts to differ significantly from the configuration in the template, you may also choose to not use the template for this device and delete the device-template association from the **Associated Devices** window.

Guidelines for VPN connections

Follow these guidelines when configuring VPN connections in device templates.

- Supported interfaces for VPN topologies are:

Topology Type	Interface Type

Policy-Based and SD-WAN	• Physical interfaces
	  • Non-management
	  • Interface Mode must be either Routed or None
	• Subinterfaces
	• Redundant interfaces
	• Etherchannel interfaces
	• VLAN interfaces

Route-Based	Static Virtual Tunnel Interfaces

- When you apply a template on a device that is part of a VPN topology, you must ensure that the template includes interface configurations for all interfaces used in the topology.

- When you apply a template with VPN connections to multiple devices, note that a template is applied to multiple devices in the order in which you have selected the devices. If the template has VPN connections, the corresponding VPN topology is locked.
- For SD-WAN topology VPN connections: Ensure that IP address subnet of the interface does not conflict with the subnet of the IP address pool of the SD-WAN hub.
- Change management: Before you apply a device template to a device, ensure that the VPN topology is not locked by a Change management ticket.

Unsupported configurations

The following features and configurations are not supported using device templates.

- Multi-instance mode
- Clustering
- Non-converged management interface
- Transparent mode
- HA failover configurations
- Chassis configurations
- Logical devices
- Variables for nested objects
- Override support for network groups and other object types

Limitations for VPN connections

Be aware of these limitations when working with VPN connections in device templates.

- When you create a template from a device that is part of a VPN topology (**Devices** > **Device Management** **More** (⋮) **> Generate Template from Device**), VPN configurations are not part of the template. You must reconfigure the VPN configurations on the template.
- When you export a device template with one or more VPN connections (**Template Settings > General > General** pane > **Export**), the VPN connections are not exported. You must reconfigure the VPN connections on the imported template.
- Certificate-based authentication:
  - Device templates do not support automatic certificate enrolment of a device.
  - When you onboard a device using a template with VPN configurations, if the VPN topology uses certificate-based authentication, the first deployment to the device will fail. Ensure that you manually enroll the device certificate after the device registration and deploy the configurations on the device again.

Configure device templates

Add a template and then configure settings in the template.

Add a device template

You can add a new device template with the required configuration or generate a device template from an existing device.

Create a new device template

Create a device template to establish standardized configurations that can be applied to multiple devices, ensuring consistent security policies and routing modes across your network.

You can specify the device template name, description, access control policy, and routing mode. You can add more configurations after the template has been created.

Follow these steps to create a device template:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click **Add Device Template**.

Step 3 In the **Add Device Template** window, enter a **Name** for the template.

Step 4 (Optional) Enter a **Description** for the template.

Step 5 Choose an **Access Control Policy** from the drop-down list.

Step 6 Choose a **Mode** from the drop-down list.

Step 7 Click **OK**.

Generate a new device template from an existing device

The new template has the same configuration as the device from which it is generated. You can generate a new device template from standalone and HA devices. However, if you generate a template from HA devices, the new template will not contain the failover configurations.

You can generate a new device template from a device that is registered with the Cloud-Delivered Firewall Management Center.

Follow these steps to generate a new device template from an existing device:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the **More** (⋮) icon, and click **Generate Template from Device**.

In the new device management view, select the device, and then select **Generate template from device** in the **Device actions** pane.

Step 3 In the **Generate template from device** window, enter a **Name** for the template.

Step 4 (Optional) Enter a **Description** for the template.

Step 5 Choose an **Access Control Policy** from the drop-down list.

Step 6 Click **OK**. To view the status of template creation, go to **Notifications**, and then click the **Tasks**tab.

Step 7 Choose **Devices** > **Template Management** to view the newly created template.

Import a device template

The device template import feature allows you to transfer templates between different Cloud-Delivered Firewall Management Center systems or domains for replication, modification, and deployment purposes.

You can import a template into the Cloud-Delivered Firewall Management Center or export a template to your local system. This feature is useful in the following scenarios:

- Generate a copy of the template from a device, export it, and import that template into another Cloud-Delivered Firewall Management Center or Cloud-Delivered Firewall Management Center.
- Generate a copy of the template, export it, modify as required to create a variation of the existing template, and import the template into the Cloud-Delivered Firewall Management Center.
- Generate a copy of the template, export it, and import that template into another domain in which the source template is not visible.

Follow these steps to import a device template into the Cloud-Delivered Firewall Management Center from your local system:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **More** (⋮) icon for the template that you want to replace with an imported template.

Step 3 Click **Import** and click **Import** again.

If you want to export a template, click **Export** and click **OK**.

Step 4 To view the status of the import task, click **Notifications**, and then click the **Tasks** tab.

Step 5 Choose the template SFO file on your local system and click **Open**. This template SFO file that you import can be newly created, generated from a device, or cloned from an existing template.

Step 6 To view the status of the import task, click **Notifications**, and then click the **Tasks** tab. You will see a notification informing you that the import or export task is successfully completed. If you are exporting a template, click **Notifications** and click the **Tasks**tab. In the tab page, click **Download Export Package** to download the template configuration as an SFO file.

Note

Alternatively, you can also go to the **Template Management** window and click the **Edit** (✎) icon of the template. Then, go to **Template Settings**, and click **General**. Click **Import** or **Export** in the **General** tile to import or export the template.

Configure device settings in the template

After creating the template, you can set up device configurations and adjust the settings by editing the template.

Add a physical interface

A physical interface allows you to expand network connectivity in a device template beyond the default interfaces provided.

By default, a device template will enable the device to come up with the following physical interfaces:

- Management interface
- Inside interface
- Outside interface

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon of the template in which you want to add the physical interface.

Step 3 In the **Interfaces** tab, click **Add Physical Interface**.

Step 4 Choose a **Slot** and **Port Index** number from the drop-down list.

Step 5 Click **Create Interface**.

Add a logical interface

Create a logical interface in a template to define network connectivity and traffic handling for your firewall deployment.

You can create a logical interface in the same way as you do on the Cloud-Delivered Firewall Management Center without using the template. Perform the procedure given below to create a logical interface.

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon of the template in which you want to add the logical interface.

Step 3 In the **Interfaces** tab, click **Add Interface**, and choose the type of interface that you want to create from the drop-down list. You can create the following types of interfaces:

- Sub-interface
- Ether channel interface
- Bridge group interface
- VLAN interface
- Virtual tunnel interface
- Loopback interface

For more information, see Interface overview and Regular Firewall Interfaces.

Edit an interface

Edit interface configurations on Firepower 1000,Secure Firewall 1200, Firepower 2100, and Secure Firewall 3100 Firewall Threat Defense devices using device templates.

You can edit an interface in the same way as you do on the Cloud-Delivered Firewall Management Center without using the template. Use template variables to set up the IPv4 and IPv6 addresses. The device template supports the configurations that are supported on Firepower 1000,Secure Firewall 1200, Firepower 2100, and Secure Firewall 3100 Firewall Threat Defense devices.

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon of the template in which you want to edit the physical interface.

Step 3 In the **Interfaces** tab, click the **Edit** icon for the interface that you want to edit.

Step 4 In the **Edit Physical Interface** window, you can edit any of the following settings:

- General
- PoE
- IPv4
- IPv6
- Path Monitoring
- Hardware Configuration
- Manager Access
- Advanced

Note
Use variables to configure IPv4 and IPv6 addresses. For more information on templatizing variables, see Configure Template Parameters.

For more information on editing the settings mentioned above, see Interface overview and Regular Firewall Interfaces.

Configure other device settings

Configure additional device settings within templates to maintain consistent configuration across multiple devices.

Configure the other device settings in the same way as you do on the Cloud-Delivered Firewall Management Center without using the template.

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon for the template in which you want to configure the settings.

Step 3 Click the tabs at the top of the window to configure any of these settings:

- Inline Sets
- Routing
- DHCP
- VPN
- Template Settings

Template settings

When you apply a template to a device, the template-specific settings are copied to the device.

Available template settings

you can configure these template settings in the **Template Settings** window.

- General
  - General
  - License
  - Applied Policies
  - Advanced Settings
  - Deployment Settings
- Template Parameters

- Variables
- Network object overrides

- Model Mapping

Edit general settings

Edit the name of the device template and enable or disable packet transfer to customize the device configuration according to your requirements.

In the **General** tile, you see the following fields:

- **Template Name** – The name of the template.
- **Transfer Packets** – Displays whether or not the managed device sends packet data with the events to the management center.
- **Mode** – Displays the mode of the management interface for the device: routed.
- **Configuration** – Click **Export** to export the template configurations as an SFO file. Click **Import** to import an SFO file that has the template configurations that you require.
- **Manage device by Data Interface** – Toggle the button to enable or disable management of the device using the data interface.

Follow these steps to edit the name of the device and to enable or disable packet transfer:

Procedure

Step 1 Click the **Edit** (✎) icon in the **General** tile.

Step 2 Change the **Template Name** as per your requirement.

Step 3 Check the **Transfer Packets** checkbox to allow packet data to be stored with events on the Cloud-Delivered Firewall Management Center.

Step 4 Click **Save**.

Edit licenses

Edit license types to match your requirements for template configurations.

In the **License** tile, you can see the **License types** that are required based on the configurations used in the template. Choosing a license here does not consume that license on the device. The license is consumed only when you apply the template to a device.

Procedure

Step 1 Click the **Edit** (✎) icon in the **License** tile.

Step 2 Check or clear the check box next to the license you want to enable or disable for the managed device.

Step 3 Click **Save**.

Edit applied policies

Edit applied policies to modify the access control policy assignments for a template according to your requirements.

In the **Applied Policies** tile, you can see the access control policies that are associated with the template.

For policies with links, you can click the link to view the policy.

Procedure

Step 1 Click the **Edit** (✎) icon in the **Applied Policies** tile.

Step 2 For each policy type, choose a policy from the drop-down list. Only existing policies are listed.

Step 3 Click **Save**.

Edit advanced settings

Edit advanced configuration settings to optimize device performance and memory usage according to your network requirements.

The **Advanced Settings** tile displays the advanced configuration settings, as described below. You can edit any of these settings.

Table 2: Advanced section table fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.
Object Group Search	The state of object group search on the device. While operating, the Firewall Threat Defense device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in the Cloud-Delivered Firewall Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules. **Note** By default, the **Object Group Search** is enabled when you add Firewall Threat Defense for the first time in the Cloud-Delivered Firewall Management Center.

Field	Description
Interface Object Optimization	The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

Procedure

Step 1 Click the **Edit** (✎) icon in the **Advanced Settings** tile.

Step 2 Change the settings as per your requirement.

- Configure Automatic Application Bypass
- Configure Object Group Search
- Configure Interface Object Optimization

Step 3 Click **Save**.

Edit deployment settings

Edit deployment settings to configure auto rollback functionality when management connection fails due to misconfiguration and to set the time interval for connectivity monitoring.

The **Deployment Settings** tile displays the information described in the table below.

Table 3: Deployment settings

Field	Description
Auto Rollback Deployment if Connectivity Fails	Enabled or Disabled. You can enable auto rollback if the management connection fails as a result of the deployment; specifically if you use data for Cloud-Delivered Firewall Management Center access, and then you misconfigure the data interface.
Connectivity Monitor Interval (in Minutes)	Shows the amount of time to wait before rolling back the configuration.

Deployment settings include enabling auto rollback of the deployment if the management connection fails as a result of the deployment; specifically if you use data for Cloud-Delivered Firewall Management Center access, and then you misconfigure the data interface. Alternatively, manually roll back the configuration using the **configure policy rollback** command.

Procedure

Step 1 Click the **Edit** icon in the **Deployment Settings** tile.

Step 2 Set the **Connectivity Monitor Interval (in Minutes)** to set the amount of time to wait before rolling back the configuration. The default is 20 minutes.

Step 3 If a rollback occurs, see the following for next steps.

- If the auto rollback was successful, you see a success message instructing you to do a full deployment.
- You can also click **Deploy** and then go to the **Advanced Deploy** screen and click the **Preview** icon to view the parts of the configuration that were rolled back (see Deploy Configuration Changes). Click **Show Rollback Changes** to view the changes, and **Hide Rollback Changes** to hide the changes.
- In the Deployment History Preview, you can view the rollback changes.

Step 4 Check that the management connection was reestablished.

In Cloud-Delivered Firewall Management Center, check the management connection status on the Connection Status page. Navigate to **Devices** > **Device Management** page and then navigate to **Management** area under the **Device** tab. Then in the **FMC Access Details** screen, click **Connection Status**.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface.

Configure template parameters

You can templatize configurations using template parameters such as variables and network object overrides.

Supported variables

The variable types are supported in device templates.

Variable Name	Description	Type
AS Number	Defines the unique Autonomous System (AS) number.	Integer Example: 2
FQDN	Defines a single Fully Qualified Domain Name (FQDN).	String Example: abc.example.com
IPv4 Host	Defines the IPv4 address of the host.	String Example: 209.165.201.8
IPv4 Network	Defines the IPv4 network address block.	String Example: 209.165.200.224/27

Variable Name	Description	Type
IPv4 Range	Defines the range of IPv4 addresses.	String Example: 209.165.200.225-209.165.200.250
IPv6 Host	Defines the IPv6 address of the host.	String Example: 2001:DB8::1
IPv6 Network	Defines the IPv6 network address block.	String Example: 2001:DB8:0:CD30::/60
Password	Defines a password string.	String Example: E28@2OiUrhx!
Router ID	Defines an identifier for the router.	Integer Example: 21
String	Defines a custom string.	String Example: testvalue2

Add a variable

Add variables to create reusable configuration elements that can be applied across multiple device templates, enabling consistent and efficient policy management.

Variables provide a way to standardize configuration elements across your deployment. You can create variables for network objects, ports, or other configurable elements that need to be consistent across multiple devices or policies.

Follow these steps to add a variable:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Variable** from the list of object types.

Step 3 Click **Add Variable**.

Step 4 Enter a **Name**.

Step 5 Choose a **Variable Type** from the drop-down list.

Step 6 (Optional) Enter a **Description**.

Step 7 Click **Save**.

Supported network object overrides

This reference provides information about the network objects that are supported for override configurations, including their descriptions and data types with examples.

Network Object Name	Description	Type
Network	An address block, also known as a subnet.	String Example: IPv4 - 209.165.200.224/27 IPv6 - 2001:DB8::/48
Host	The IP address of the host.	String Example: IPv4 - 209.165.200.225 IPv6 - 2001:DB8:1::1
Range	A range of IP addresses.	String Example: IPv4 - 209.165.200.225-209.165.200.250 IPv6 - 2001:DB8::1 - 2001:DB8:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF
FQDN	A single fully-qualified domain name (FQDN).	String Example: abc.example.com

Add a network object override

Network object overrides allow you to customize network objects within templates for specific deployments without modifying the base template.

Use this procedure to add network object overrides to a template when you need to customize network objects for specific deployment scenarios.

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon of the template in which you want to add the network object override.

Step 3 Choose **Template Settings** > **Template Parameters**.

Step 4 In the **Network Object Overrides** section, click **Add or Remove Network Object Overrides**.

Step 5 In the **Add or Remove Network Object Overrides** window, choose the network objects for which you want to create network object overrides from the **Available Networks** window and click the > button.

Step 6 Click **Save**.

Add model mapping

Model mapping allows you to map a template to one or more models as long as the interface configurations are valid for all mapped models.

For each model, you can specify which template interface corresponds with which model interface. For example, if the template includes switch ports and VLAN interfaces, then that template can only be applied to a Firepower 1010 or Secure Firewall 1210/1220.

Follow these steps to add model mapping:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click **Add Model Mapping** for the template in which you want to create the model mapping. Alternatively, you can click the **Edit** (✎) icon of the template and choose **Template Settings** > **Model Mapping**.

Step 3 Click **Add Model Mapping**.

Step 4 Choose the **Device Model** from the drop-down list.

Step 5 Map the template interfaces to the device model interfaces by choosing the interface from the **Model Interface** drop-down list.

Note
You can click **Clear Mapping** to remove the defined model mapping. Click **Reset Mappings** for default interface mapping in which the mapping is done based on the slot and port index order of the interface names.

Step 6 Click **Save**. The interface mappings are listed along with the device model and mapping status on the **Model Mapping** window.

Note
Some configurations in the template may not be supported on all device models. Unsupported configurations, if any, are not applied to the device. The device Template Apply Report provides details about such configurations.

Invalid model mappings

Some configurations in the template may not be supported on all device models. Unsupported configurations, if any, are not applied to the device. Valid model mappings can become invalid when you modify template configurations. For example, if you add a new interface on the template and assign a name to it, you must map the new interface to the appropriate device model interface.

Causes of invalid model mappings

Model mapping can be invalidated due to any of these reasons:

- Number of configured VRF instances exceeds the limit for a specific model.
- Interfaces mapped to incompatible models, versions, or interfaces. See Requirements and Prerequisites for more information.
- Number of interfaces exceeds the model limit.

- Deleted an interface that was mapped.
- Newly added physical interfaces are not mapped to a compatible model interface.
- Model mapping is not done for a named interface.
- Model mapping is not done for an interface related to other logical interfaces, such as sub-interfaces, PC interfaces, and so on.
- Policy or configuration changes that are unsupported on some device models, such as enabling switch port configuration on interfaces.

You can also save a template with invalid model mappings. However, you must review and fix the model mapping before initiating application of the template on the device.

You can hover over **Invalid** under **Mapping Status** to view the errors that caused the invalid mapping status. Fix the errors before initiating application of the template on the device.

Configure Site-to-Site VPN connections in a device template

This reference provides the configuration parameters and settings required to establish Site-to-Site VPN connections using device templates.

Configure an SD-WAN VPN connection

This task allows you to add spokes to SD-WAN topologies by configuring an SD-WAN VPN connection through the device template.

You can configure an SD-WAN VPN connection to add spokes to SD-WAN topologies using the device template.

Before you begin

- Configure a minimum of one SD-WAN topology (**Devices** > **VPN** > **Site to Site**).
- Review Prerequisites for Configuring Device Templates and Guidelines and Limitations for Device Templates.

Follow these steps to configure an SD-WAN VPN connection:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the edit icon adjacent to the device template that you want to edit.

Step 3 Click the **VPN** tab.

Step 4 Click **Add VPN Connection**.

Step 5 Choose an SD-WAN topology from the **VPN Topology** drop-down list.

The **Add VPN Connection** dialog box expands and you can configure the following parameters:

a) From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

This list contains all the interfaces configured on the device template.

b) **Use IP Address from the VPN Interface**—This drop-down list is auto populated with the IP address variable. For IPv6 addresses, choose an IPv6 address from the drop-down list.
c) Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from the spoke to a remote peer.
d) **Identity Type**—Key ID is the only supported identity type. Choose a key ID variable from the drop-down list or click (+) to create a new key ID variable.
e) Click **OK**.

You can view the VPN connection in the **Site-to-Site VPN Connections** table.

Step 6 Click **Save**.

What to do next

1. Configure the routing policy for the spoke in the device template.
2. Map the device interfaces to the template interfaces (Model Mapping).
3. Apply the template to a device.

Configure a route-based Site-to-Site VPN connection

This task allows you to add spokes to existing route-based site-to-site VPN topologies by configuring VPN connections through the device template interface.

You can configure a route-based site-to-site VPN connection to add spokes to route-based site-to-site VPN topologies using the device template.

Before you begin

- Configure a minimum of one route-based site-to-site VPN topology (**Devices** > **VPN** > **Site to Site**).
- Review Prerequisites for Configuring Device Templates and Guidelines and Limitations for Device Templates.

Follow these steps to configure a route-based site-to-site VPN connection:

Procedure

Step 1 Choose **Devices** > **Template Management**.
Step 2 Click the edit icon adjacent to the device template that you want to edit.
Step 3 Click the **VPN** tab.
Step 4 Click **Add VPN Connection**.
Step 5 Choose a route-based site-to-site VPN topology from the **VPN Topology** drop-down list.

The **Add VPN Connection** dialog box expands and you can configure the following parameters:

a) From the **Virtual Tunnel Interface (VTI)** drop-down list, choose a VTI interface or click (+) to create a new VTI.

VTI is a virtual interface used to establish a route-based VPN tunnel. You must configure routing policies for a VTI to set up a VPN tunnel. This list contains all the VTIs configured on the device template. For more information on creating a VTI, see Add a VTI interface, on page 1752.

b) Check the **Use Public IP Address** check box to override the tunnel source IP address and configure a public IP address variable for the VTI. Click (+) to create a new public IP address variable.

This IP address is the source IP address for the VPN tunnel. By default, this is the IP address of the VPN interface. However, if the device is behind NAT, the VPN interface has a private address, but the post-NAT public IP address should be configured.

c) Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from the spoke to a remote peer.

d) **Identity Type**: Key ID is the only supported identity type. Choose a key ID variable from the drop-down list or click (+) to create a new key ID variable.

e) (Optional) Check the **Enable Secondary VPN Tunnel** check box to configure the parameters for the secondary VPN tunnel.

f) Click **OK**.

You can view the VPN connection in the **Site-to-Site VPN Connections** table.

Step 6 Click **Save**.

What to do next

1. Configure the routing policy for the spoke in the device template.
2. Map the device interfaces to the template interfaces (Model Mapping).
3. Apply the template to a device.

Configure a policy-based Site-to-Site VPN connection

This task enables you to add spokes to policy-based site-to-site VPN topologies using the device template.

You can configure a policy-based site-to-site VPN connection to add spokes to policy-based site-to-site VPN topologies using the device template.

Before you begin

- Configure a minimum of one policy-based site-to-site VPN (**Devices** > **VPN** > **Site to Site**).
- Review Prerequisites for Configuring Device Templates and Guidelines and Limitations for Device Templates.

Follow these steps to configure a policy-based site-to-site VPN connection:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the edit icon adjacent to the device template that you want to edit.

Step 3 Click the **VPN** tab.

Step 4 Click **Add VPN Connection**.

Step 5 Choose a policy-based site-to-site VPN topology from the **VPN Topology** drop-down list.

The **Add VPN Connection** dialog box expands and you can configure these parameters:

a) From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

This list contains all the interfaces configured on the device template.

Do one of these to configure the IP address of the VPN interface:

- Click the **Use IP Address from the VPN Interface** radio button to use the IP address of the VPN interface.

  This IP address is auto populated. For IPv6 addresses, choose an IPv6 address from the drop-down list.

- Click the **Use Public IP Address** radio button to configure a public IP address for the VPN interface.

  Choose an IP address variable from the drop-down list or click (+) to add an IP address variable.

b) Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from the spoke to a remote peer.

c) **Identity Type**: Key ID is the only supported identity type. Choose a key ID variable from the drop-down list or click (+) to add a new key ID variable.

d) **Protected Networks**: Click (+) to configure a protected network for the VPN connection.

Do one of these:

- Choose a protected network and click **OK**.
- Click **Add** to configure a network object and click **Save**.

  When you create a protected network object, note this:

  - Click either the **Host** or the **Network** radio button.
  - Check the **Allow Overrides** check box.

e) Click **OK**.

You can view the VPN connection in the **Site-to-Site VPN Connections** table.

Step 6 Click **Save**.

What to do next

1. Before you apply a template to a device, to configure device-specific values for the protected networks, add these objects in **Template Settings** > **Template Parameters** > **Add Network Objects Overrides**.
2. Map the device interfaces to the template interfaces (model mapping).
3. Apply the template to a device.

Add a device to an SD-WAN topology in a dual ISP deployment

This task enables you to add a device to an SD-WAN topology in a dual ISP deployment using a device template.

Use this procedure to integrate a device into an existing SD-WAN topology that utilizes dual ISP connections for redundancy and load balancing.

Before you begin

Ensure that you have two SD-WAN VPN topologies with the same hub. For more information about configuring SD-WAN topologies, see Configure an SD-WAN topology using the SD-WAN wizard, on page 1792.

Follow these steps to add a device to an SD-WAN topology in a dual ISP deployment:

Procedure

Step 1 Create a device template.

Navigate to **Devices** > **Template Management**.

For detailed instructions, see Create a new device template, on page 126.

Step 2 Add a physical interface in the template.

By default, a template has only one outside interface. Rename the outside interfaces, for example, ISP1, ISP2.

Navigate to **Devices** > **Template Management**, and click **Interfaces > Add Physical Interface** .

For detailed instructions, see Add a physical interface, on page 128.

Step 3 Configure an SD-WAN VPN connection using ISP1 interface.

Navigate to **Devices** > **Template Management**, and click **VPN > Add VPN Connection**.

For detailed instructions, see Configure an SD-WAN VPN connection, on page 138.

Step 4 Configure an SD-WAN VPN connection using ISP2 interface.

Navigate to **Devices** > **Template Management**, and click **VPN > Add VPN Connection**.

For detailed instructions, see Configure an SD-WAN VPN connection, on page 138.

Step 5 Add static routes from ISP1 and ISP2 interfaces to the SD-WAN hub network.

Navigate to **Devices** > **Template Management**, and click **Routing > Static Route**.

Step 6 Add the ISP1 and ISP2 interfaces to an ECMP zone.

Navigate to **Devices** > **Template Management**, and click **Routing > ECMP**.

Step 7 Configure the network object overrides.

Navigate to **Devices** > **Template Management**, and click **Template Settings > Template Parameters > Add Network Objects Overrides**.

For detailed instructions, see Add a network object override, on page 136.

Step 8 Map the template interfaces to the device model interfaces (Model Mapping).

Navigate to **Devices** > **Template Management**, and click **Template Settings > Model Mapping**.

For detailed instructions, see Add model mapping, on page 137.

Step 9 Apply template to the device.

Navigate to **Devices** > **Template Management**.

For detailed instructions, see Apply a template, on page 145.

The device is successfully added to the SD-WAN topology in a dual ISP deployment. For more information about dual ISP deployment using the SD-WAN wizard, see Sample configurations for dual-ISP deployment using SD-WAN wizard, on page 1797.

What to do next

Click **Deploy** deploy the configurations on the device and the hubs of the SD-WAN topologies.

Configure a Template for Firewall Threat Defense Devices Managed Using the Data Interface

This task configures a template for Firewall Threat Defense devices that are managed using a data interface, ensuring proper connectivity parameters match between the device and template to maintain Cloud-Delivered Firewall Management Center connectivity after template deployment.

To configure a template for a Firewall Threat Defense device that is managed using a data interface for Cloud-Delivered Firewall Management Center connectivity, ensure that the connectivity parameters of the device match the template. This ensures that the Threat Defense device does not lose connectivity with the Cloud-Delivered Firewall Management Center after application of the template. A template that you configure for Firewall Threat Defense devices managed using the data interface cannot be applied on devices that are not managed by the data interface.

These are the connectivity parameters:

- Data interface used to the manage the Firewall Threat Defense device. For example, **Ethernet1/1**.
- Name of the interface. For example, **outside**.
- IP address configured on the data interface. For example, DHCP or static IP.
- Route configured for the data interface. This can be a default or specific route defined on the data interface used for connectivity between the Firewall Threat Defense device and the Cloud-Delivered Firewall Management Center.
- DDNS hostname configuration on the data interface.

If the template connectivity parameters do not match those on the device, validation fails and the template is not applied on the device. Validation does not require an exact match for some parameters, such as IP address or DDNS hostname. However, configure these parameters appropriately to maintain connectivity between the Firewall Threat Defense device and the Cloud-Delivered Firewall Management Center after deployment.

These template validation checks are done to ensure sanity of configurations that are required to manage the Firewall Threat Defense device using the data interface:

- You cannot apply a template in which manager access to the device is configured with the management interface to a device in which manager access to the device is configured with the data interface.
- You cannot apply a template in which manager access to the device is configured with the data interface to a device in which manager access to the device is configured with the management interface.
- You cannot apply a template in which manager access to the device is configured with the single WAN data interface to a device in which manager access to the device is configured with the dual WAN data interface.
- If any of the connectivity parameters do not match, you cannot apply a template in which manager access to the device is configured with the data interface to a device in which manager access to the device is configured with the data interface.

Before you begin

Follow these steps to configure a template for Firewall Threat Defense devices managed using the data interface:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon of the template that you want to configure to manage Firewall Threat Defense devices using the data interface.

Step 3 Click the **Template Settings** tab.

a) In the **General** tile, toggle the **Manage device by Data Interface** button.
b) You will see a popup asking you to pick a data interface for manager access. Click **OK**.

Step 4 Click the **Interfaces** tab.

a) Click the **Edit** icon of the data interface that you want to use for manager access. The first data interface – Ethernet1/1 (outside interface), is the data interface that is most commonly used for manager access.
b) In the **Edit Physical Interface** window, click the **Manager Access** tab.
c) Check the **Enable management access** checkbox.
d) Click **OK**. You will see that the interface that you selected for manager access has been marked with **Manager Access**.

Step 5 Click the **DHCP** tab.

Step 6 Click the **DDNS Update Methods** tab.

a) Click **+Add** to add a DDNS update method.
b) In the **Add DDNS Update Method** window, enter a **Method Name** and choose **FMC only**.
c) Set the **Update Interval** as per your requirement.
d) Click **OK**. You will see the method that you created in the **DDNS Update Methods** table.

Step 7 Click the **DDNS Interface Settings** tab.

a) Click **+Add** to add dynamic DNS configuration.

b) In the **Add Dynamic DNS** configuration window, choose values for these fields:

- **Interface** – Choose the interface enabled for manager access
- **Method Name** – Choose the method that you created.
- **Host Name** – Choose a variable for the hostname.

Do not edit the rest of the fields in this window.

c) Click **OK**. The **DDNS Interface Settings** table is populated with the entry that you created.

Step 8 To configure the model mapping to ensure that the data interface set for manager access in the template matches the data interface selected for manager access on the device, click the **Template Settings** tab and click **Model Mapping**.

a) Click **Add Model Mapping**.

b) Choose the **Device Model** from the drop-down list.

c) Map the date interface that is set for manager access in the template to the appropriate data interface on the device by choosing the interface from the **Model Interface** drop-down list.

d) Click **Save**. The interface mappings are listed along with the device model and mapping status on the **Model Mapping** window. You can now apply the template on a device that is managed using the data interface.

Use templates with devices

You can apply templates in these scenarios:

- During device registration: Choose a compatible template for the initial configuration when registering a device with the Cloud-Delivered Firewall Management Center.
- After device registration: Apply templates to devices that are already registered with the Cloud-Delivered Firewall Management Center.

Apply templates to existing devices

You can apply or reapply a template to existing devices.

Apply a template

Template application clears existing configurations and applies configurations from the template to devices already registered with the Cloud-Delivered Firewall Management Center.

You can apply a template to devices that are already registered with the Cloud-Delivered Firewall Management Center. Application of a template on a device clears existing configurations and applies configurations from the template. However, the Firewall Threat Defense HA failover configurations are not cleared.

Application of a template changes device configurations only on the Cloud-Delivered Firewall Management Center. You must explicitly deploy these device configuration changes to the Firewall Threat Defense device.

You cannot roll back the applied configuration changes. However, you can apply another template with the required configurations.

Note Any change management tickets related to template configurations must be approved for the corresponding changes to be incorporated into the template application workflow. Only approved template configurations are used during template application.

Follow these steps to apply a template to existing devices:

Procedure

Step 1 To apply the template from the **Template Management** window, choose **Devices** > **Template Management**.

a) Click the **More** (⋮) icon next to the template that you want to apply, and click **Apply**.
b) From the **Device** dropdown list, choose the **Device** on which you want to apply the template.
c) Click **Confirm** to initiate application of template on the device.

Step 2 (Optional) To apply the template from the **Associated Devices** window, choose **Devices > Template Management**.

a) Click the **Edit** (✎) icon of the template that you want to apply to a device.
b) Click **Associated Devices**.
c) In the **Associated Devices** window, click **Apply Template**.
d) From the **Device** drop-down list, choose the **Device** on which you want to apply the template.
e) Enter values for the **Variables** and **Network object overrides** fields.
f) Click **Apply** to initiate application of template on the device.

Reapply a template

Reapply a template to synchronize the device configuration with the template configuration when changes result in an out-of-sync state.

If you make any changes to the device or template that results in the configuration being out-of-sync, you can reapply the template to make the configuration in sync with the template.

Follow these steps to reapply a template on a device:

Procedure

Step 1 Choose **Devices** > **Template Management**.

Step 2 Click the **Edit** (✎) icon of the template that you want to reapply to a device.

Step 3 Click **Associated Devices**.

Step 4 In the **Associated Devices** window, click **Reapply Template** for the device on which you want to reapply the template.

Note
If you want to reapply the template on all the associated devices in the template, click **Bulk Reapply** and click **Confirm**.

Step 5 On the **Reapply template** window, you can reuse the autopopulated **Variables** and **Network object overrides** values or enter new values.

Step 6 Click **Confirm** to initiate reapplication of the template on the device.

Monitor device templates

You can monitor and verify the application of templates by viewing the devices listed in the **Associated Devices** window and by viewing the **Template Apply Report**.

View associated devices

The devices that are associated with the templates are listed in the **Associated Devices** window. Each device row displays the **Device Name, Sync Status, Template Application Status**, and **Applied Date**. You can also click **Reapply template** to reapply the template. Click the **Variable Summary** icon to display a summary of the variables in the template and the **Report** ( ) icon to download the Device Template Apply report.

Click the **Delete** ( ) icon to remove the template from the device.

Click **Apply Template** if you want to apply a template on a device from the **Associated Devices** window. If you want to reapply the template on all the associated devices in the template, click **Bulk Reapply** and click **Confirm**.

The **Sync Status** can be either **Sync** or **Out-of-Sync**. **Sync** indicates that the template and device configurations are the identical. **Out-of-Sync** indicates that the configuration has changed on either the device or the template since the template was last applied.

These conditions do not affect the association of the device with the template:

- Pending configuration changes on the device—The **Sync Status** does not change if there are pending configuration changes that have to applied on the device.
- Deployment of pending configuration changes on the device—The **Sync Status** does not change after deployment of pending configuration changes on the device.

This table shows the **Sync** and **Out-of-Sync** scenarios that may occur.

Device Configurations Modified After Application of Template on Device	Template Configurations Modified After Application of Template on Device	Association Status
No	No	In Sync
Yes	No	Out of Sync
No	Yes	Out of Sync
Yes	Yes	Out of Sync

Template Apply reports

A **Template Apply Report** PDF is generated after the task to apply the template is completed. This report is generated on both successful and unsuccessful application of the template on the device. To access the link to this report, click **Notifications**, and then click the **Tasks** tab.

Template apply report details

The **Template Apply Report** contains these details:

- Template name
- Device model name
- Start and end time
- Status of the application of the template on the device
- Interface mapping information
- Variable values

Some configurations on the template may not be applied to the device if the device model or version is incompatible. The report includes details about these configurations and any errors encountered when the application of the template fails. Application of a template on a device may fail due to any of these reasons:

- Model mapping does not exist for the device model that is used.
- Values used for variables and network object overrides do not conform to routing policy or interface configuration rules. For example, the same IPv4 address has been used for two IPv4 address interface variables.
- The device or template is locked because another task, such as applying or modifying the template, is in progress.

Audit logs

View logs related to application of device templates, configuration updates, device template creation, and deletion activities that are recorded under audit logs.

Logs related to application of the device template, configuration updates, device template creation, and deletion, are logged under audit logs. The device template audit logs are added to the log both at the start and at the end of the task to apply the template on the device.

An audit diff file is also generated. This file contains the configuration changes that have been done during application of the template on the device.

Procedure

Step 1 Choose **System** (⚙) > **Monitoring** > **Audit**.

Step 2 The device template logs are logged under the subsystem **Devices** > **Template Management**. Click the **diff** icon to open a new window that displays the configuration changes that have been done during the application of the template on the device.

Troubleshoot device templates

This reference provides comprehensive troubleshooting information for device templates. For initial troubleshooting, we recommend looking at the information in the Template Apply Report and notifications that come up on the Cloud-Delivered Firewall Management Center UI when you run into an error. The Cloud-Delivered Firewall Management Center log files also contain detailed debugging and troubleshooting info.

Initial troubleshooting

Follow this procedure for initial troubleshooting.

1. Check the errors mentioned in the **Template Apply Report**. For more information, see Template Apply Report.
2. Review variable values and check for overlaps and incompatibilities.
3. Check model mappings to ensure if the correct model mappings exist. Delete or add mappings accordingly.
4. See the Cloud-Delivered Firewall Management Center audit logs to find any other issues and resolve them.

Consider this error scenario. In a device template, the inside interface is configured with a static IPv4 variable - *$insideIPv4*.

The BGP IPv4 address is configured with an IPv4 BGP neighbor.

An overlapping IPv4 address is configured for the BGP neighbor and an interface.

Due to these issues, the application of the device template fails and an error is displayed.

To troubleshoot this error, identify the error from the notification displayed on the UI.

```
IP Address 192.168.10.1 same as ip address of interface - 'inside'(Ethernet1/1)
```

Check the **Template Apply Report** for more information.

Enter correct values for the variables and apply the template again to ensure successful application of the template on the device.

Troubleshoot device registration

- Issue: Admin Password is incorrect or not provided during registration

  Scenario: If the admin password is not set on the device and if you have not provided the admin password during registration, the Firewall Threat Defense device provisioning will fail. In such a scenario, a *Provision Error* along with an **Enter Password** link is displayed.

  Workaround: Click **Enter Password** to enter a new password and click **Save**. Click **Confirm and Proceed** to trigger the onboarding again.

- If the admin password is already set on the device and you provide another admin password during registration, device provisioning will fail.
- Issue: Device registration in Cloud-Delivered Firewall Management Center fails

  Workaround: Follow existing device registration troubleshooting steps. For more information, see Configure, Verify, and Troubleshoot Firepower Device Registration.
- Issue: Bulk Registration Request Fails in Cloud-Delivered Firewall Management Center

  Scenario: The bulk registration request can fail due to a few scenarios:
  - You do not have the required permissions to perform template-related operations
  - Invalid CSV file provided

  Workaround: You can see logs for these errors in the VMS Shared and USM Shared log files. Fix the errors and initiate registration again.
- Issue: Device provisioning fails in Security Cloud Control due to some generic errors, such as communication with the device fails

  Workaround: Click Retry in the Provision Error to trigger the onboarding in Security Cloud Control again. You can also see the Security Cloud Control workflows for more information on the error and troubleshooting information.

Troubleshoot Cisco Security Cloud integration

Issue: Cisco Security cloud integration not successful

Workaround: Follow Cisco Security Cloud integration troubleshooting steps. For more information, see Cisco Security Cloud Integration.

Troubleshoot device template configuration issues

Issue: Device template misconfigurations causing deployment failures after registration

Workaround: Follow these steps for initial troubleshooting.

1. Check the errors mentioned in the Template Apply Report.
2. Review variable values and check for overlaps and incompatibilities.
3. Check model mappings to ensure if the correct model mappings exist. Delete or add mappings accordingly.
4. See the Cloud-Delivered Firewall Management Center audit logs to find any other issues and resolve them.

Troubleshoot Security Cloud Control Issues

- Issue: Device with serial number already claimed

  Workaround: Verify serial number and reinitiate onboarding.
- Issue: Security Cloud Control fails to claim devices

  Workaround: Select the device in the Security Cloud Control **Security Devices** window for more details on the error. You can see logs related to device claim issues in the VMS Shared and USM Shared log files. Click **Retry** to initiate registration again.

- Issue: Communication failures between Cloud-Delivered Firewall Management Center and Security Cloud Control

  Scenario: Communication failures between Cloud-Delivered Firewall Management Center and Security Cloud Control can cause failures during the Zero-Touch Provisioning (ZTP) device registration request.

  Workaround: Refresh the ZTP device status, retry ZTP registration, and delete the ZTP device. You can see logs regarding communication failure between the Cloud-Delivered Firewall Management Center and Security Cloud Control in the Auth Daemon logs. For operational failures related to ZTP, you can see the logs in the VMS Shared and USM Shared log files.

CHAPTER 7

Transparent or Routed Firewall Mode

This chapter describes how to set the firewall mode to routed or transparent, as well as how the firewall works in each firewall mode.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes. See Inline Sets and Passive Interfaces, on page 1119 for more information about IPS-only interfaces. Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode described in this chapter or the firewall-type interfaces.

Caution

- Use FTD CLI commands to set "Firewall Mode."

- Firewall mode, on page 153
- Default settings, on page 163
- Guidelines for firewall mode, on page 163
- Set the firewall mode, on page 164

Firewall mode

A Firewall Threat Defense device supports two firewall modes for regular firewall interfaces:

- Routed Firewall mode
- Transparent Firewall mode

Routed firewall mode

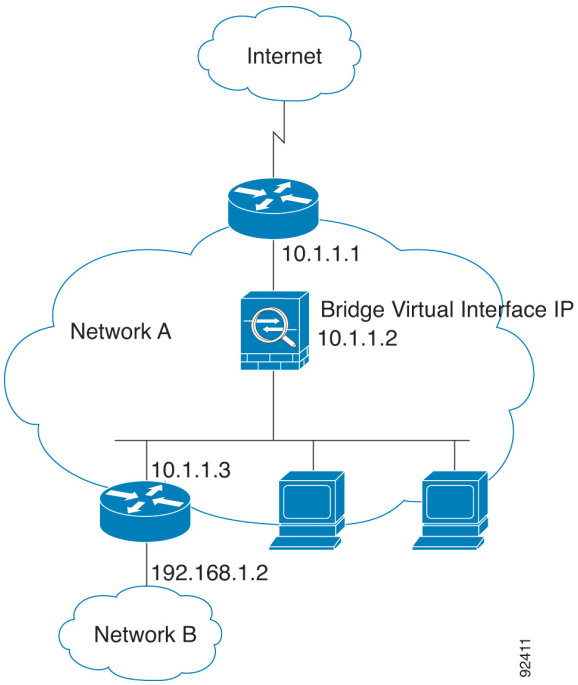
In routed mode, the Firewall Threat Defense device is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet.

Integrated routing and bridging features

With Integrated Routing and Bridging, you can use a "bridge group" where you group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. The Firewall Threat Defense device routes between BVIs and regular routed interfaces. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead of transparent mode. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

Transparent firewall mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. However, like any other firewall, access control between interfaces is controlled, and all of the usual firewall checks are in place.



Layer 2 connectivity is achieved by using a "bridge group" where you group together the inside and outside interfaces for a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. You can have multiple bridge groups for multiple networks. In transparent mode, these bridge groups cannot communicate with each other.

Transparent firewall network usage

The Firewall Threat Defense device connects the same network between its interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

The figure shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

Figure 9: Transparent firewall network

Passing traffic for routed-mode features

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality.

Supported traffic types

For example, by using an access rule, you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or multicast traffic such as that created by IP/TV. You can also establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an access rule. Likewise, protocols like HSRP or VRRP can pass through the Firewall Threat Defense device.

Bridge groups

A bridge group is a group of interfaces that the Firewall Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. Like any other firewall interfaces, access control between interfaces is controlled, and all of the usual firewall checks are in place.

Bridge virtual interfaces

Each bridge group includes a Bridge Virtual Interface (BVI). The Firewall Threat Defense device uses the BVI IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the bridge group member interfaces. The BVI does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

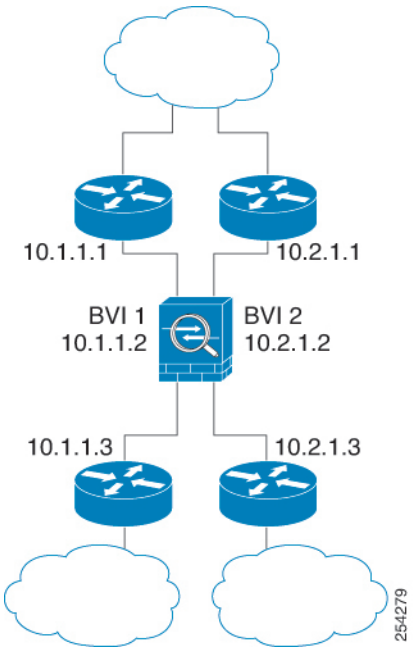
BVI functionality by mode

In transparent mode: Only bridge group member interfaces are named and can be used with interface-based features.

In routed mode: The BVI acts as the gateway between the bridge group and other routed interfaces. To route between bridge groups/routed interfaces, you must name the BVI. For some interface-based features, you can use the BVI itself:

- DHCPv4 server—Only the BVI supports the DHCPv4 server configuration.
- Static routes—You can configure static routes for the BVI; you cannot configure static routes for the member interfaces.
- Syslog server and other traffic sourced from the Firewall Threat Defense device—When specifying a syslog server (or SNMP server, or other service where the traffic is sourced from the Firewall Threat Defense device), you can specify either the BVI or a member interface.

If you do not name the BVI in routed mode, then the Firewall Threat Defense device does not route bridge group traffic. This configuration replicates transparent firewall mode for the bridge group. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.



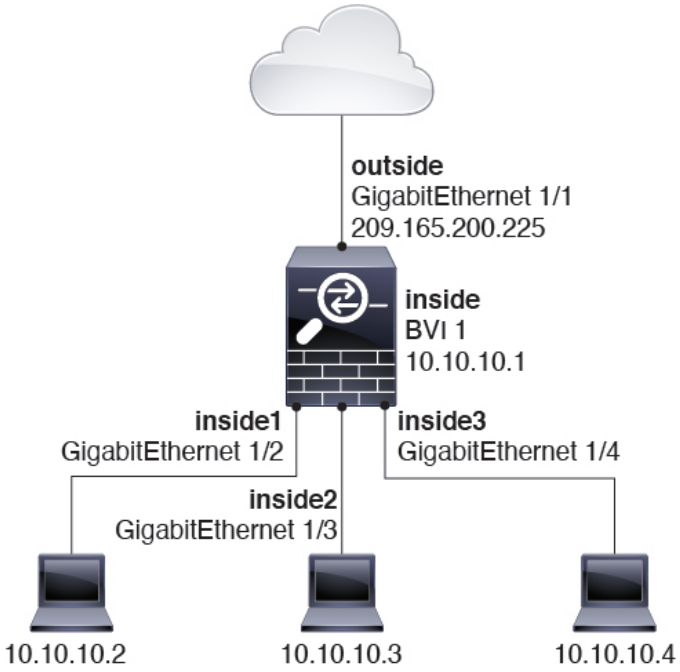
Bridge groups in transparent firewall mode

Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the Firewall Threat Defense device , and traffic must exit the Firewall Threat Defense device before it is routed by an external router back to another bridge group in the Firewall Threat Defense device. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration.

You can include multiple interfaces per bridge group. See Guidelines for firewall mode, on page 163 for the exact number of bridge groups and interfaces supported. If you use more than 2 interfaces per bridge group, you can control communication between multiple segments on the same network, and not just between inside and outside. For example, if you have three inside segments that you do not want to communicate with each other, you can put each segment on a separate interface, and only allow them to communicate with the outside interface. Or you can customize the access rules between interfaces to allow only as much access as desired.

This figure shows two networks connected to the Firewall Threat Defense device, which has two bridge groups.

Figure 10: Transparent firewall network with two bridge groups



Bridge groups in routed firewall mode

Bridge group traffic can be routed to other bridge groups or routed interfaces. You can choose to isolate bridge group traffic by not assigning a name to the BVI interface for the bridge group. If you name the BVI, then the BVI participates in routing like any other regular interface.

Bridge group usage and configuration

One use for a bridge group in routed mode is to use extra interfaces on the Firewall Threat Defense instead of an external switch. For example, the default configuration for some devices include an outside interface as a regular interface, and then all other interfaces assigned to the inside bridge group. Because the purpose of this bridge group is to replace an external switch, you need to configure an access policy so all bridge group interfaces can freely communicate.

Figure 11: Routed firewall network with an inside bridge group and an outside routed interface

Allow layer 3 traffic

This topic describes how different types of Layer 3 traffic are handled through bridge groups and the access rule requirements for each traffic type.

- Unicast IPv4 and IPv6 traffic requires an access rule to be allowed through the bridge group.
- ARPs are allowed through the bridge group in both directions without an access rule. ARP traffic can be controlled by ARP inspection.
- IPv6 neighbor discovery and router solicitation packets can be passed using access rules.
- Broadcast and multicast traffic can be passed using access rules.

Allowed MAC addresses

These destination MAC addresses are allowed through the bridge group if allowed by your access policy (For more information, refer to Allow layer 3 traffic, on page 158). Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD

BPDUs handling

To prevent loops using the Spanning Tree Protocol, BPDUs are passed by default.

By default BPDUs are also forwarded for advanced inspection, which is unnecessary for this type of packet, and which can cause problems if they are blocked due to an inspection restart, for example. We recommend that you always exempt BPDUs from advanced inspection. To do so, use FlexConfig to configure an EtherType ACL that trusts BPDUs and exempts them from advanced inspection on each member interface.

The FlexConfig object should deploy the following commands, where you replace <if-name> with an interface name. Add as many access-group commands as needed to cover each bridge group member interface on the device. You can also choose a different name for the ACL.

```
access-list permit-bpdu ethertype trust bpdu
access-group permit-bpdu in interface <if-name>
```

MAC address and route lookups

For traffic within a bridge group, the outgoing interface of a packet is determined by performing a destination MAC address lookup instead of a route lookup.

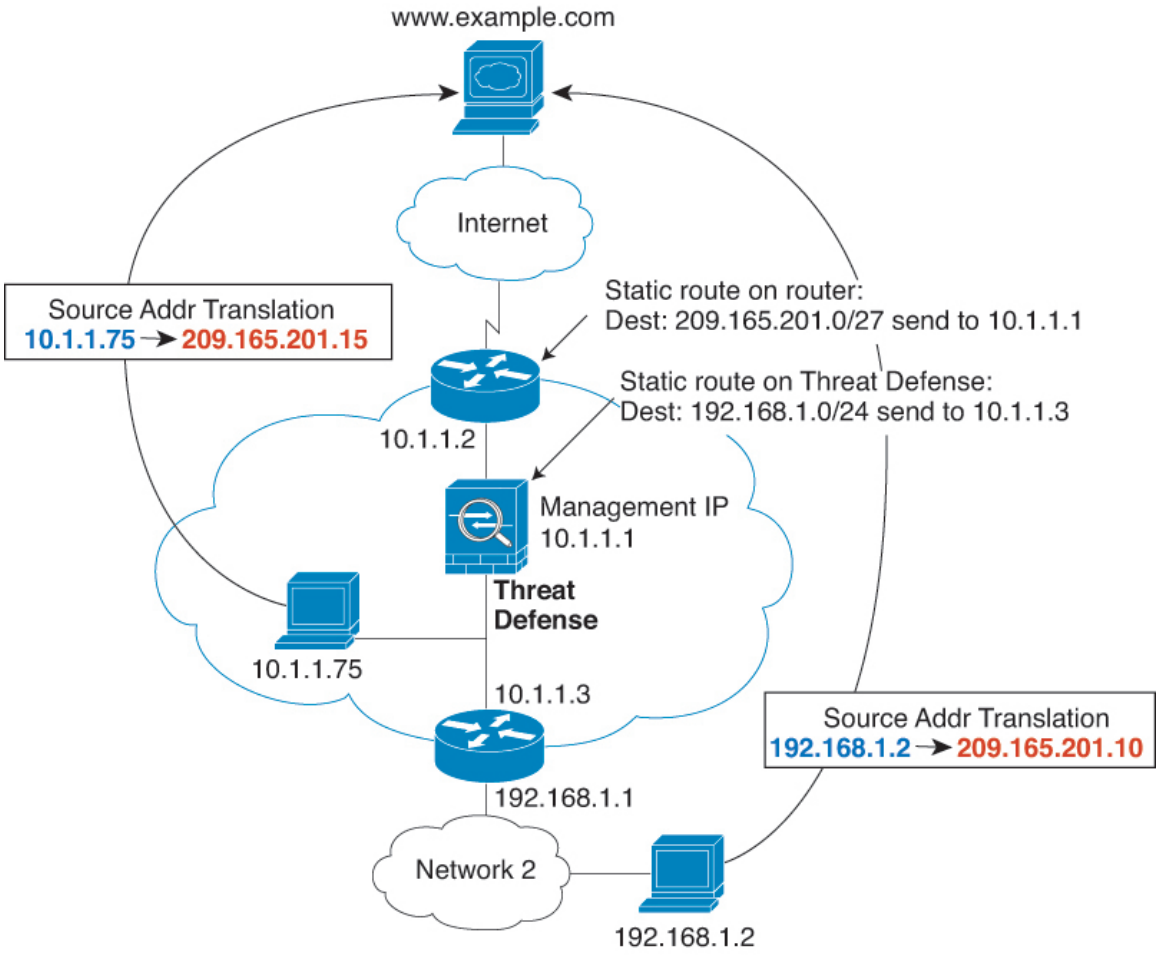
Route lookups, however, are necessary for these situations:

- Traffic originating on the Firewall Threat Defense device—Add a default/static route on the Firewall Threat Defense device for traffic destined for a remote network where a syslog server, for example, is located.
- SSL policy enabled in transparent firewall mode—
  - TLS 1.3 traffic passes through the Firewall Threat Defense device device.
  - Firewall Threat Defense device acts as a TCP proxy. It terminates the client-side TCP connection and initiates a separate server-side connection. The Firewall Threat Defense device TCP stack owns the session state.
  - For idle proxied sessions, Firewall Threat Defense device generates TCP ACK keepalive probes to preserve the connection state. These are not passthrough packets—the firewall originates them and sends them toward the client or server depending on the state of the TLS transit connection.
  - Because the Firewall Threat Defense device originates these keepalives, it must perform an adjacency table lookup (next-hop or egress MAC resolution) even in transparent mode.
  - If the adjacency lookup fails for one of these proxy-generated packets, the Firewall Threat Defense device logs syslog 110003.

    To prevent these syslog messages, configure routes on the Firewall Threat Defense device for the transit connection endpoints (client and server IP addresses). Proper routing enables successful adjacency lookups for keepalive packets.

    If the Firewall Threat Defense device successfully sends a TCP keepalive and receives a reply, it keeps the transit connection active. If the device cannot send the keepalives, or receives no reply, it removes the transit connection after approximately 240 seconds.
- Voice over IP (VoIP) and TFTP traffic, and the endpoint is at least one hop away—Add a static route on the Firewall Threat Defense device for traffic destined for the remote endpoint so that secondary connections are successful. The Firewall Threat Defense device creates a temporary "pinhole" in the access control policy to allow the secondary connection; and because the connection might use a different set of IP addresses than the primary connection, the Firewall Threat Defense device needs to perform a route lookup to install the pinhole on the correct interface.

Affected applications include:



- H.323
- RTSP
- SIP and Skinny (SCCP)
- SQL*Net
- SunRPC
- TFTP

- Traffic at least one hop away for which the Firewall Threat Defense device performs NAT—Configure a static route on the Firewall Threat Defense device for traffic destined for the remote network. You also need a static route on the upstream router for traffic destined for the mapped addresses to be sent to the Firewall Threat Defense device.

  This routing requirement is also true for embedded IP addresses for VoIP and DNS with NAT enabled, and the embedded IP addresses are at least one hop away. The Firewall Threat Defense device needs to identify the correct egress interface so it can perform the translation.

NAT within a bridge group

Figure 12: NAT example: NAT within a bridge group

Unsupported features for bridge groups in transparent mode

This table lists the features that are not supported in bridge groups in transparent mode.

Table 4: Unsupported features in transparent mode

Feature	Description
Dynamic DNS	—
DHCPv6 stateless server	Only the DHCPv4 server is supported on bridge group member interfaces.

Feature	Description
DHCP relay	The transparent firewall can act as a DHCPv4 server, but it does not support DHCP relay. DHCP relay is not required because you can allow DHCP traffic to pass through using two access rules: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.
Dynamic routing protocols	You can, however, add static routes for traffic originating on the Firewall Threat Defense device for bridge group member interfaces. You can also allow dynamic routing protocols through the Firewall Threat Defense device using an access rule.
Multicast IP routing	You can allow multicast traffic through the Firewall Threat Defense device by allowing it in an access rule.
QoS	—
VPN termination for through traffic	The transparent firewall supports site-to-site VPN tunnels for management connections only on bridge group member interfaces. It does not terminate VPN connections for traffic through the Firewall Threat Defense device. You can pass VPN traffic through the Firewall Threat Defense device using an access rule, but it does not terminate non-management connections.

Unsupported features for bridge groups in routed mode

This table lists the features are not supported in bridge groups in routed mode.

Table 5: Unsupported features in routed mode

Feature	Description
EtherChannel member interfaces	Only physical interfaces, redundant interfaces, and subinterfaces are supported as bridge group member interfaces. Management interfaces are also not supported.
Clustering	Bridge groups are not supported in clustering.
Dynamic DNS	—
DHCPv6 stateless server	Only the DHCPv4 server is supported on BVIs.
DHCP relay	The routed firewall can act as a DHCPv4 server, but it does not support DHCP relay on BVIs or bridge group member interfaces.
Dynamic routing protocols	You can, however, add static routes for BVIs. You can also allow dynamic routing protocols through the Firewall Threat Defense device using an access rule. Non-bridge group interfaces support dynamic routing.
Multicast IP routing	You can allow multicast traffic through the Firewall Threat Defense device by allowing it in an access rule. Non-bridge group interfaces support multicast routing.

Feature	Description
QoS	Non-bridge group interfaces support QoS.
VPN termination for through traffic	You cannot terminate a VPN connection on the BVI. Non-bridge group interfaces support VPN. Bridge group member interfaces support site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the Firewall Threat Defense device. You can pass VPN traffic through the bridge group using an access rule, but it does not terminate non-management connections.

Default settings

Lists the default settings for firewall mode.

Bridge group defaults

By default, all ARP packets are passed within the bridge group.

Guidelines for firewall mode

Review these guidelines for firewall mode.

Bridge group limits and network requirements

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The Firewall Threat Defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

BVI IP address requirements

- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the Firewall Threat Defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).

Unsupported bridge group members

- Management interfaces are not supported as bridge group members.

- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
-
- For the 200/ 1010/ 1210// 1220, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.

Transparent mode requirements and limitations

- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the Firewall Threat Defense as the default gateway.
- In transparent mode, the default route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.

Routed mode requirements and limitations

- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, Firewall Threat Defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

Traffic handling limitation

- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using bridge group members. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Set the firewall mode

You can set the firewall mode when you perform the initial system setup at the CLI. We recommend setting the firewall mode during setup because changing the firewall mode erases your configuration to ensure you do not have incompatible settings. If you need to change the firewall mode later, you must do so from the CLI.

Procedure

Step 1 Unregister the Firewall Threat Defense device from the Cloud-Delivered Firewall Management Center.

You cannot change the mode until you unregister the device.

a) Performance profiles are retained across firewall mode changes and can't be changed after you re-register. You must set the performance profile to Default. See the **Performance Profile** page in your platform settings policy (choose **Devices** > **Platform Settings**, and then click **Edit** (✎) for your policy).

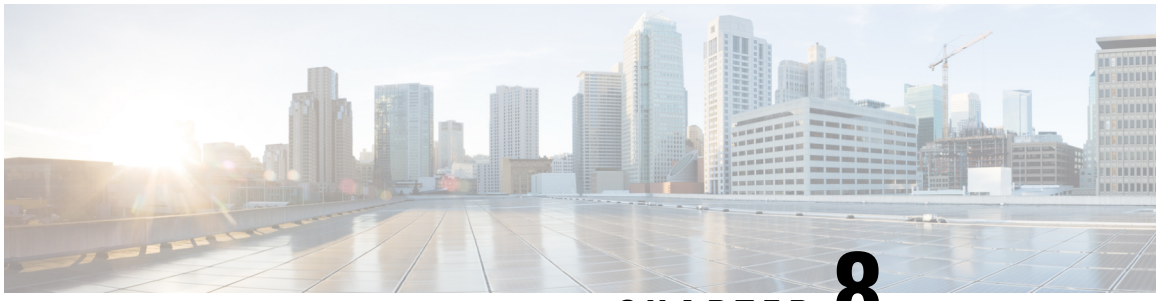
Deploy the configuration to make these changes.

b) Choose **Devices** > **Device Management**.

c) Next to the device you want to unregister, click **More** (⋮), and then click **Delete**.

d) If you have switched to the new device management page, select the device to open the side pane, and under **Device actions**, click **Delete**.

Step 2 Access the Firewall Threat Defense device CLI, preferably from the console port.



Step 3 Change the firewall mode:

configure firewall [**routed** | **transparent**]

Example:

```
> configure firewall transparent
This will destroy the current interface configurations, are you sure that you want to
proceed? [y/N] y
The firewall mode was changed successfully.
```

Step 4 Re-register with the Cloud-Delivered Firewall Management Center.

CHAPTER 8

Change Management

You can enable change management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed.

- Change management, on page 167
- Requirements and prerequisites for change management, on page 171
- Guidelines and limitations for change management, on page 172
- Enabling or disabling change management, on page 172
- Manage tickets, on page 173

Change management

Change management is a formal process that

- enforces an official approval process before configuration changes can be made to a device,
- requires administrators to open tickets before they can make configuration changes, and
- ensures that the right employees make the final decisions through submission and approval of tickets.

Change management characteristics

When using change management, the system implements these controls:

- Administrators can see their own changes within a ticket, but they cannot see changes anyone else has made within a ticket
- A policy is locked once a user makes a change within a ticket, preventing interfering changes
- Users cannot make changes while another user has made a change that is pending approval

Administrators can create multiple tickets so that a single ticket contains only logically-related policy changes. Tickets with a more limited scope are also easier to evaluate and approve quickly.

Make configuration changes in the change management workflow

This task enables configuration specialists to make configuration changes to supported policies and objects when change management is enabled.

When you enable change management, users who configure devices and shared policies need to change their approach slightly. Configuration specialists need to take the following approach when making configuration changes to supported policies and objects.

Procedure

Step 1 Create a ticket.

Step 2 Open the ticket.

Step 3 Make the configuration changes.

Note that the procedures explained in the online help and user guides assume that change management is not active, and omit any steps for creating, opening, or submitting tickets.

Step 4 Optionally, preview and validate the ticket to ensure the changes are complete and correct.

Step 5 Submit the ticket. At this point, the approver can either approve or reject the ticket.

- If the ticket is approved, deploy the changes.
- If the ticket is rejected, address the issues, and resubmit the ticket.

The configuration changes are successfully implemented through the change management workflow with proper approval and deployment processes.

Create separate approver and configuration roles

Separate approver and configuration roles are system-defined and custom roles that

- have permissions to modify (create/open/discard) and review (approve/reject/take over) tickets,
- provide granular access control to separate ticket approval from configuration changes, and
- ensure that ticket approval is assigned only to users who have organizational authority to approve changes.

System-defined roles and permissions

Some system-defined roles have permissions to modify (create/open/discard) and review (approve/reject) tickets:

- To both modify and review tickets:
  - Admin
- To modify tickets only:
  - Edit Only
- To review tickets only:
  - Deploy Only

The **Deploy Only** role can approve or reject change management tickets. Approving a ticket makes the ticketed changes available for deployment, but does not deploy the changes to the device. You must deploy approved changes separately.

Note A Read Only user cannot use the change management feature.

If you need more granular roles to separate these activities due to your organizational requirements, you can create separate roles to ensure that ticket approval is assigned only to those users who have the organizational authority to approve changes. To create a new user, navigate back to Security Cloud Control and from the Security Cloud Control navigation bar, choose **Settings** > **User Management**.

The approach you take depends on your precise requirements. For example:

- If your approvers should also be allowed to make configuration changes, you can simply assign them the system-defined roles, such as Administrator. Then, create custom configuration-only roles that include the same permissions but not the Review Tickets permission.
- If you need complete separation between approvers and those who make configuration changes, create custom roles for both, limiting the roles to either the Modify Tickets or the Review Tickets permission plus all other needed permissions for viewing or changing the supported policies and objects.

Policies and objects that support change management

If a policy or object supports the change management workflow, then creating, editing, or deleting the policy or object, including assigning a policy to a device, must be done in an open ticket.

Any action, policy, or object that does not support the change management workflow can be created, edited, or deleted, and so forth, without an open ticket. Even if a ticket is open, the changes made to unsupported policies are not included in the ticketed changes and are available for deployment immediately.

This information includes the policies and objects that are supported. Anything not listed is unsupported.

Supported policies

- Access control, including rules, references to other policies, and inheritance settings. Cloning access control policies is not included within a ticket. The clone is immediately accepted and available to all users.
- Device configuration policies:
  - Interfaces
  - Inline sets
  - DHCP
  - VTEP
  - All routing
- Decryption policy

- DNS policy
- FlexConfig
- Intrusion policy and network analysis policy (NAP), Snort 3 only.
- Malware and file policy
- Network address translation (NAT)
- Network discovery policy
- Platform settings
- Prefilter policy
- QoS
- Splunk integration
- Umbrella SASE topology
- VPN policies, both site-to-site and remote access
- Zero trust access

Supported objects

- AAA server
- Access list
- Address pools
- AS path
- Cipher suit lists
- Community list
- Distinguished name objects
- DHCP IPv6 pools
- DNS server group
- FlexConfig objects
- Group policy
- Interface
- Key chain
- Network
- PKI certificates, all objects
- Policy list
- Port

- Prefix list
- PKI certificates, all objects
- Route map
- Sinkhole
- SLA monitor
- Time range
- Time zone
- Tunnel zone
- URL
- Variable set
- VLAN tag
- VPN objects (IKEv1, IKEv2 IPSec and policy, PKI enrollment, certificate map)

Requirements and prerequisites for change management

This reference provides the requirements and prerequisites necessary to configure change management functionality.

Model support

Management center

User roles

- To enable or disable change management: Admin.
- To both modify and review tickets:
  - Admin
- To modify tickets only:
  - Edit Only
- To review tickets only:
  - Deploy Only

    The **Deploy Only** role can approve or reject change management tickets. Approving a ticket makes the ticketed changes available for deployment, but does not deploy the changes to the device. You must deploy approved changes separately.

Guidelines and limitations for change management

When operating in change management mode, users can make changes to supported policies, but they cannot save the changes. For example, you could go through the dialog box to create a new platform settings policy without an open ticket, but when you click OK to actually create the policy, you will get an error and the policy will not be created.

The following activities require that all tickets be in a terminal state, that is, approved or discarded: backup/restore.

Deleting a device from the inventory requires that all tickets involving that device be approved or discarded.

Some system processes prevent you from enabling or disabling change management. Wait until the following processes complete before you enable or disable change management:

- critical management center processes, including SRU updates, LSP updates, VDB updates, and management center upgrades
- pending or running background activities, including device registration; cluster auto-registration; Firewall Threat Defense high availability operations; high availability auto-registration; FlexConfig migration; cluster creation, break, edit, reconcile, or node changes; device-template creation or application; device-model migration; and EPM join or breakout
- system jobs, including backup or restore, device import or export, general import, and domain movement.

Your ability to create objects while configuring a feature is constrained based on whether the feature and objects are all supported by change management. For example, importing a configuration is not supported by change management. Therefore, you cannot create security zone objects, which are supported, during the import. On the other hand, you can create new objects while configuring access control rules, because both are supported.

When you create an object from Security Cloud Control, the system automatically creates a ticket internally and allows the object to be associated with the Cloud-Delivered Firewall Management Center. You do not have to create or have an open ticket to do this. However, when you want to create an object from the Cloud-Delivered Firewall Management Center, you need an existing ticket or create one. The object is synchronized to Security Cloud Control only after the ticket is approved.

When using Cloud-Delivered Firewall Management Center, a user defined in Security Cloud Control is available to be assigned tickets only after the user cross-launches cdFMC at least once. Until the first cross-launch, the user does not exist in cdFMC.

Enabling or disabling change management

Enable or disable change management to control whether users must open tickets and get approval when making configuration changes to the system.

The default is that the change management workflow is disabled. Users do not need to open tickets and get approval when making configuration changes. If you want to enforce the change management workflow, you must enable it globally for the system.

Before you begin

There are several system processes that prevent you from enabling/disabling change management. If any of the following are in process, you need to wait for them to complete before changing these settings: backup/restore; import/export; domain movement; upgrade; Flexconfig migration; device registration; high-availability registration, creation, break, or switch; cluster create, registration, break, edit, add or remove nodes; EPM break out or join.

An access control policy cannot be locked when you change these settings. If a policy is locked, you must wait for the lock to be released before enabling/disabling this feature.

Follow these steps to enable or disable change management:

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Change Management**.

Step 3 Select **Enable Change Management**.

To disable the feature, deselect the option. All tickets must be approved or discarded to disable change management. You cannot disable change management if any ticket is in the In Progress, On Hold, Rejected, or Pending Approval state.

Step 4 Select the **Number of approvals required**, which is how many administrators must approve the change for the ticket to be approved and deployable. The default is 1, but you can require up to 5 approvers per ticket. Users can override this number when creating tickets.

Step 5 Select the **Ticket Purge Duration**, which is the number of days to keep approved tickets, from 1-100 days. The default is 5 days.

Step 6 (Optional.) Enter the **Reply to Address** and the email addresses for the **List of Approver Addresses**. You must also configure the email notification system settings for email to work.

Step 7 Click **Save**.

The system adds the **Ticket** (📄) shortcut to the menu bar, and the **System** (⚙) > **Change Management Workflow** command. Users can manage tickets using these methods.

Change management is enabled or disabled according to your configuration. If enabled, the system adds ticket management shortcuts to the interface, and users must follow the change management workflow when making configuration changes.

Manage tickets

This task enables you to manage change management tickets for configuration changes to supported policies that require approval workflow.

When you enable change management, configuration changes for supported policies must be done within the context of a ticket. You open a ticket, make your changes, then submit the ticket for approval.

You can see a list of tickets, and create new ones, either on the change management page or through the ticket quick-access menu. All ticket changes are synchronized in each menu, so you can switch back and forth at your convenience and use whichever method you prefer.

Note When you open a ticket and make a change to a supported policy, that policy is locked from changes by other users or through other tickets. The policy remains locked until the ticket is approved or discarded.

Procedure

Step 1 Do any of these actions:

- Choose **System** (⚙) > **Change Management Workflow** to open a page showing existing tickets.
- Click the **Ticket** (📋) quick-access menu. The icon can either be named Select a Ticket (if no ticket is opened), the ticket name if a ticket is opened, or unnamed if no tickets exist.

Both pages are organized the same. The **Ticket** tab lists all tickets, whereas the **Review** tab lists tickets that have been submitted for approval. The default view shows your tickets only.

Step 2 On the **Ticket** tab, take any of these actions:

- To create a new ticket, click **Add Ticket**.
- To view the details of a ticket, click the > next to the ticket name. The Details page includes UUID, name, description, user, last modified date, and comments. The History page includes the status changes for the ticket. The image at the top shows where the ticket stands in the overall workflow.
- To preview the configuration changes for an open ticket, click **Preview** (📄).
- To validate the configuration changes in an open ticket, click **Validate** (📋) or **More** (⋮) > **Validate**. A dialog box opens showing error, warning, and informational messages, if there are any validation errors.
- To open a ticket, click **Open** (📂) or **More** (⋮) > **Open**. To close an open ticket, click **Put Ticket on Hold (X)** or **More** (⋮) > **Put Ticket on Hold**. Closing a ticket does not submit it for review, nor does it release any locks placed on edited policies.
- To submit an open ticket for review and approval, click **Submit for Approval** (⬆) or **More** (⋮) > **Submit for Approval**. The ticket must be open to be submitted.
- To discard a ticket, click **Discard** (🗑) or **More** (⋮) > **Discard**.
- To take over or reassign a ticket, click **More** (⋮) > **Take Over Ticket** when viewing all tickets in the system.
- To search for a ticket, type a string in the search box. The search looks at ticket name, description, and responsible user. To filter the list by ticket status (on the change management workflow page), click the status above the list: **New**, **Open**, **On Hold** (ticket was closed), **Rejected**, **Pending Approval**, **Approved**. Each status has a count of the number of tickets in that state. Click **All** under **My Tickets** to return to the default of showing all of your tickets, or **All** under **Tickets in System** to see everyone's tickets.

Step 3 On the **Reviews** tab, take any of these actions on submitted tickets.

The list is empty if there are no submitted tickets. In addition, only users with Review Ticket permissions can see this tab.

- To preview the configuration changes for a ticket, click **Preview** ( ).
- To validate the configuration changes in an open ticket, click **Validate** ( ) or **More** ( ) > **Validate**.
- To approve the ticket, click **Approve** ( ) or **More** ( ) > **Approve**.
- To disapprove the ticket, click **Reject** ( ) or **More** ( ) > **Reject**.

You have successfully managed your change management tickets. Approved tickets can proceed with configuration changes, while rejected tickets require revision before resubmission.

Create change management tickets

Create change management tickets to ensure all configuration changes are performed within the context of an approved workflow ticket.

When using the change management workflow, you must do all configuration changes within the context of an open ticket. If you do not already have a ticket, you must create a new one.

Procedure

Step 1 Choose **System** ( ) > **Change Management Workflow**, or click the **Ticket** ( ) shortcut menu.

Step 2 Click **Add Ticket**.

Step 3 Configure the ticket options:

- **Name**—The name of the ticket. The name can include letters, numbers, spaces, and the following special characters: #-_!
- **Description**—An optional description of what you intend to configure using this ticket. For example, if you have a case number related to what you intend to fix using this ticket, that would be useful information in a description.
- **Number of Approvers**—How many administrators must approve the change for the ticket to be approved and deployable. You can specify 1-5.
- **Assign to**—Select the user who will own the ticket and be responsible for implementing the changes. Choose **self** to assign it to yourself.

Step 4 Click one of the following:

- **Create**—The ticket is added to the list of tickets, but it is not opened. You need to open it before you can work within the context of the ticket.
- **Create and Open**—The ticket is added to the list of tickets and also opened.

The change management ticket is created and available for use in the workflow. If you selected Create and Open, the ticket is immediately opened for configuration changes.

Opening a ticket for configuration changes

Open a ticket to enable configuration changes within the ticket management system.

Before you can make changes within a ticket, you must open the ticket.

If you have another ticket open, the system puts it on hold (closes it) for you before opening the new one.

Procedure

Step 1 Choose **System** ( ) > **Change Management Workflow**, or click the **Ticket** ( ) shortcut menu.

Step 2 On the **Tickets** tab, click **Open** ( ) or **More** ( ) > **Open** for the ticket.

Step 3 Optionally, enter a comment for the action.

Step 4 Click **Open**.

You can now start your configuration changes. The name of the ticket icon changes to the name of the open ticket.

The ticket is now open and ready for configuration changes. The ticket icon displays the name of the open ticket.

Preview a ticket

Preview a ticket to view all configuration changes made within the context of the ticket.

You can preview a ticket while making your configuration changes, or before approving it. The preview shows all configuration changes made within the context of the ticket.

Procedure

Step 1 Choose **System** ( ) > **Change Management Workflow**, or click the **Ticket** ( ) shortcut menu.

Step 2 Click **Preview** ( ) for the ticket.

The Preview dialog box opens. Changes are color coded according to the legend at the top of the dialog box.

Step 3 Select the policy whose changes you want to view in the Changed Policies list.

You are shown both the current version of the policy as it is defined in Cloud-Delivered Firewall Management Center (on the left) and the proposed changes defined within the ticket.

For policies that contain pages, such as platform settings, you can select the overall policy to see all changes, or specific pages within the policy, in the Changed Policies list.

You cannot alter the changes from within the preview. If you need to change something, you must close the preview and return to the policy you want to change.

Step 4 Optionally, click **Download as PDF** to save the preview to a PDF file for offline viewing or archival purposes.

Step 5 Click **OK**.

The ticket preview displays all configuration changes, allowing you to review them before approval or while making modifications.

Submit a ticket

Submit a ticket to apply changes made within the ticket after validation and review.

After you have completed the changes needed for a ticket, you can preview and validate the changes. Then, when you are satisfied with the changes, submit the ticket for review and approval.

Changes made within the ticket are not applied until you submit the ticket and the ticket is approved. Until approval happens, all policies modified within a ticket are locked to that ticket and cannot be changed by anyone else.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📋) shortcut menu.

Step 2 Click **Submit for Approval** (⬆) or **More** (⋮) > **Submit for Approval** for the open ticket.

Step 3 Optionally, enter a comment for your action.

Step 4 Click **Submit**.

The ticket is submitted for review and approval. Once approved, the changes made within the ticket are applied and the policies are unlocked.

Discard a ticket

Discard a ticket to remove any changes that were made within the ticket when you no longer need to proceed with those changes.

You cannot undo this action and retrieve a ticket with its changes. If you need them, you must create a new ticket and start over.

You cannot discard a ticket after you submit it. However, if the approver rejects the ticket, you can then discard it.

Note If you have permission to modify tickets, you can discard tickets that belong to another user. This makes it possible to deal with situations where an admin is on vacation or otherwise unavailable to manage an in-process ticket. If you have Review Ticket permission, you can alternatively reassign or take over the ticket rather than discard it.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📋) shortcut menu.

Step 2 Click **Discard** (🗑) or **More** (⋮) > **Discard** for the ticket.

Step 3 Optionally, enter a comment for your action.

Step 4 Click **Discard**.

The ticket is discarded and any changes made within the ticket are removed.

Approving or rejecting a ticket

Approve or reject tickets to control which configuration changes become active and available for deployment in your network.

When a user submits a ticket, it must be approved for the changes made within the ticket to become active and available for deployment.

Whether you can approve your own tickets, or there is a separate approver, depends on your workplace policies and how user roles are assigned, not on the management software.

The Details view includes a summary of how many approvers are required for the ticket, and who has approved the ticket.

If the changes are inadequate or undesirable, you can reject the ticket. Rejected tickets go back to the submitter, who can then make additional changes and resubmit the ticket, or simply discard the ticket and the configuration changes it contains.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📋) shortcut menu.

Step 2 On the **Review** tab, click **Preview** (🔍) for the ticket and evaluate the proposed changes.

You can also click **Validate** (🔍) or **More** (⋮) > **Validate** to check for errors.

Step 3 After completing your evaluation, do one of the following:

- To approve the ticket, click **Approve** (✓) or **More** (⋮) > **Approve**.
- To disapprove the ticket, click **Reject** (✗) or **More** (⋮) > **Reject**.

Step 4 Optionally, enter a comment for your action.

Step 5 Click **Approve** or **Reject**, as appropriate.

The ticket is approved or rejected based on your selection. Approved tickets become active and available for deployment. Rejected tickets return to the submitter for revision or disposal.

Take over or reassign tickets

Take over or reassign tickets to ensure continuous workflow management when the original ticket owner is unavailable or when ticket ownership needs to be transferred for deployment purposes.

Sometimes it might be necessary to take over a ticket that someone else created. For example, the ticket owner might be on vacation or is otherwise unavailable, and the ticket is blocking updates that need to be deployed.

You can also use this procedure to reassign your own ticket to another person.

Before you begin

Following are the permissions required to take over tickets:

- Admin user—You can assign tickets to yourself or other users.
- Modify or Review ticket + System > User Management > Users (custom role)—You can assign tickets to yourself or other users.

However, you can assign a user only if the user has the same role as the current ticket owner, or the Admin role. This ensures that the new user has the permissions required to configure the features currently modified within the ticket.

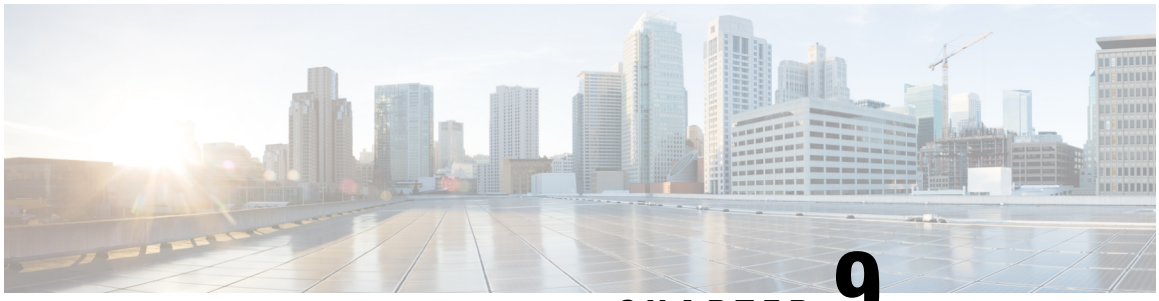
You cannot reassign a ticket that has been submitted for approval.

Follow these steps to take over or reassign tickets:

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**.

Step 2 Click on **All** under **Tickets in System**.



Step 3 Click **More** (⋮) > **Take Over Ticket**.

Step 4 Select the user who should now own the ticket.

The list of users is restricted to those who have the permissions required to edit the policies already changed within the ticket. For example, if a ticket contains changes to the access control policy, the list of users contains only those users who are allowed to modify the access control policy.

Step 5 Enter an optional comment and click **Takeover**.

The ticket ownership is transferred to the selected user, and the new owner can now manage and modify the ticket according to their permissions.

CHAPTER 9

CLI Users

Managed devices include a default **admin** account for CLI access. This chapter discusses how to create custom user accounts.

- CLI users, on page 181
- Guidelines for CLI users, on page 183
- Add an internal user at the CLI, on page 183
- Troubleshoot LDAP authentication connections, on page 186

CLI users

A CLI user is a user account that

- can be added as internal users or as external users on a LDAP or RADIUS server,
- is maintained separately on each managed device, and
- requires separate configuration for access to the Cloud-Delivered Firewall Management Center versus managed devices.

User account separation

When you add a user to the Cloud-Delivered Firewall Management Center, that user only has access to the Cloud-Delivered Firewall Management Center; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and external users

Managed devices support two categories of users—internal and external—for user access control.

Internal users authenticate through a local database on the device. External users authenticate through LDAP or RADIUS servers when they are not found in the local database. Both user types enable secure access management for network devices.

User authentication types

Managed devices support these user authentication methods:

- Internal user: The device checks a local database for user authentication.

- External user: If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

CLI access

CLI access is a command-line interface capability that

- provides a Firepower CLI running on top of Linux for device administration
- enables creation of internal users on devices using the CLI, and
- supports establishment of external users on Firewall Threat Defense devices using the Cloud-Delivered Firewall Management Center.

Security considerations for CLI access

Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk.

Caution Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firepower user documentation.
- Make sure that you restrict the list of users with CLI access appropriately.
- When granting CLI access privileges, restrict the list of users with Config level access.
- Do not add users directly in the Linux shell; only use the procedures in this chapter.
- Do not access Firepower devices using CLI expert mode unless directed by Cisco TAC or by explicit instructions in the Firepower user documentation.

CLI user roles

A CLI user role is an access control mechanism that

- determines the level of command access a user has on managed devices,
- controls whether users can execute configuration or non-configuration commands, and
- provides security by restricting unauthorized access to critical system functions.

Role types and permissions

On managed devices, user access to commands in the CLI depends on the role you assign.

- **None**: The user cannot log into the device on the command line.

- **Config**: The user can access all commands, including configuration commands. Exercise caution in assigning this level of access to users.
- **Basic**: The user can access non-configuration commands only. Allowed commands are dig, ping, and traceroute. Only internal users and Firewall Threat Defense external RADIUS users support the Basic role.

Guidelines for CLI users

This reference provides essential guidelines for CLI users, including username requirements, default account information, and user account limits for different device models.

Usernames

- You cannot add the same username for both internal and external users. If the external server uses a duplicate username, the deployment to the device fails.
- The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Defaults

All devices include an **admin** user as a local user account; you cannot delete the **admin** user. The default initial password is **Admin123**; the system forces you to change this during the initialization process. The agent stores the modified credentials in the Windows registry and uses the same encryption as the Cloud-Delivered Firewall Management Center, which is Cipher Block Chaining (CBC). See the getting started guide for your model for more information about system initialization.

Number of user accounts

You can create a maximum of 43 user accounts for the Firepower 1000.

Add an internal user at the CLI

Create internal users to provide authorized access to the Firewall Threat Defense system with appropriate privilege levels.

Use the CLI to create internal users on the Firewall Threat Defense.

Procedure

Step 1 Log into the device CLI using an account with Config privileges.

The **admin** user account has the required privileges, but any account with Config privileges will work. You can use an SSH session or the Console port.

For certain Firewall Threat Defense models, the Console port puts you into the FXOS CLI. Use the **connect ftd** command to get to the Firewall Threat Defense CLI.

Step 2 Create the user account.

configure user add *username* {**basic** | **config**}

- *username*—Sets the username. The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)
- **basic**—Gives the user basic access. This role does not allow the user to enter configuration commands. Allowed commands are dig, ping, and traceroute.
- **config**—Gives the user configuration access. This role gives the user full administrator rights to all commands.

Example:

This example adds a user account named johncrichton with Config access rights. The password is not shown as you type it.

```
> configure user add johncrichton config
Enter new password for user johncrichton: newpassword
Confirm new password for user johncrichton: newpassword
> show user
Login              UID   Auth Access  Enabled Reset    Exp Warn  Str Lock Max
admin             1000  Local Config  Enabled    No  Never  N/A  Dis   No N/A
johncrichton      1001  Local Config  Enabled    No  Never  N/A  Dis   No   5
```

Note
Tell users they can change their own passwords using the **configure password** command.

Step 3 (Optional) Adjust the characteristics of the account to meet your security requirements.

You can use these commands to change the default account behavior.

- **configure user aging** *username max_days warn_days*

  Sets an expiration date for the user's password. Specify the maximum number of days for the password to be valid followed by the number of days before expiration the user will be warned about the upcoming expiration. Both values are 1 to 9999, but the warning days must be less than the maximum days. When you create the account, there is no expiration date for the password.

- **configure user forcereset** *username*

  Forces the user to change the password on the next login.

- **configure user maxfailedlogins** *username number*

Sets the maximum number of consecutive failed logins you will allow before locking the account, from 1 to 9999. Use the **configure user unlock** command to unlock accounts. The default for new accounts is 5 consecutive failed logins. The admin account is exempt from being locked out after a maximum number of failed logins unless you enable security certification compliance.

- **configure user minpasswdlen** *username number*

  Sets a minimum password length, which can be from 1 to 127.

- **configure user strengthcheck** *username* {**enable** | **disable**}

  Enables or disables password strength checking, which requires a user to meet specific password criteria when changing their password. When a user's password expires or if the **configure user forcereset** command is used, this requirement is automatically enabled the next time the user logs in.

Step 4 Manage user accounts as necessary.

Users can get locked out of their accounts, or you might need to remove accounts or fix other issues. Use these commands to manage the user accounts on the system.

- **configure user access** *username* {**basic** | **config**}

  Changes the privileges for a user account.

- **configure user delete** *username*

  Deletes the specified account.

- **configure user disable** *username*

  Disables the specified account without deleting it. The user cannot log in until you enable the account.

- **configure user enable** *username*

  Enables the specified account.

- **configure user password** *username*

  Changes the password for the specified user. Users should normally change their own password using the **configure password** command.

  Caution
  Do not use the Linux **passwd** command in Expert Mode to change the admin user password. This command can cause file system corruption. Only use the regular Firewall Threat Defense CLI **configure user password admin** command (if you are not admin) or **configure password** command (if you are admin). If you do not know the password and can't log in at all, refer to the password recovery procedure.

- **configure user unlock** *username*

  Unlocks a user account that was locked due to exceeding the maximum number of consecutive failed login attempts.

Note
Firewall Threat Defense uses the Pluggable Authentication Module (PAM) framework for user authentication. Within this framework, the pam_unix.so module handles password hashing and verification using the SHA-512 algorithm

Passwords are hashed using the SHA-512 algorithm.

Troubleshoot LDAP authentication connections

This reference provides troubleshooting information for resolving LDAP authentication connection problems in your system configuration.

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the web interface screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
  - Check that you have the rights to browse to the directory indicated in your base-distinguished name by connecting to the LDAP server using a third-party LDAP browser.
  - Check that the user name is unique to the directory information tree for the LDAP server.
  - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.
  - When configuring LDAP authentication, avoid using a backslash ("\") in the binding password. The presence of a backslash in the password causes the LDAP binding process to fail, resulting in unsuccessful external authentication.
- Check that you have correctly identified the server:
  - Check that the server IP address or host name is correct.
  - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.
  - Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
  - If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.
  - Check that you have not used an IPv6 address for the server connection if you are authenticating CLI access.
  - If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.
- If you typed in your base-distinguished name, click **Fetch DNs** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.

- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a CLI access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator (maximum 450 characters, including the enclosing parentheses).
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.
- If you are using an encrypted connection:
  - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
  - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query that you are using by connecting to the LDAP server and using this syntax:

```
ldapsearch -x -b 'base_distinguished_name'
-h LDAPserver_ip_address -p port -v -D
'user_distinguished_name' -W 'base_filter'
```

  For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of (`cn=*`), you could test the connection using this statement:

```
ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
-h myrtle.example.com -p 389 -v -D
'domainadmin@myrtle.example.com' -W '(cn=*)'
```

If you can test your connection successfully but authentication does not work after you deploy a platform settings policy, check that authentication and the object you want to use are both enabled in the platform settings policy that is applied to the device.

If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or CLI access filter or use a more restrictive or less restrictive base DN.

While authenticating a connection to Active Directory (AD) server, rarely the connection event log indicates blocked LDAP traffic although the connection to AD server is successful. This incorrect connection log occurs when the AD server sends a duplicate reset packet. The Firewall Threat Defense device identifies the second reset packet as part of a new connection request and logs the connection with Block action.

CHAPTER 10

Configuration Deployment

This chapter describes how to download configuration changes to one or more managed devices.

- Configuration deployment, on page 189
- Requirements and prerequisites for deployment management, on page 200
- Best practices for deploying configuration changes, on page 200
- Configuration deployment, on page 201
- Deployment management, on page 209

Configuration deployment

Configuration deployment is a management process that enables centralized control and distribution of device settings from Cloud-Delivered Firewall Management Center to managed devices.

Configuration changes that require deployment

Cloud-Delivered Firewall Management Center marks out-of-date policies with red status text that indicates how many of its targeted devices need a policy update. Redeploy the policy to the devices to clear this status.

Deployment required

You must deploy changes after these configuration updates:

- Modifying an access control policy: any changes to access control rules, the default action, policy targets, Security Intelligence filtering, advanced options including preprocessing, and so on.
- Modifying any of the policies that the access control policy invokes: the SSL policy, network analysis policies, intrusion policies, file policies, identity policies, or DNS policies.
- Changing any reusable object or configuration used in an access control policy or policies it invokes:
  - network, port, VLAN tag, URL, and geolocation objects
  - Security Intelligence lists and feeds
  - application filters or detectors
  - intrusion policy variable sets
  - file lists

    - decryption-related objects and security zones

- Updating intrusion rules (SRU/LSP) or the vulnerability database (VDB).
- Upgrading managed devices.

You can change some of these configurations from multiple places in the web interface. For example, you can modify security zones using the object manager (**Objects** > **Object Management**), but modifying an interface type in a device configuration (**Devices** > **Device Management**) can also change a zone and require a deployment.

Deployment not required

These updates do not require a deployment:

- Security Intelligence updates to feeds and the global Block or Do Not Block lists.
- URL filtering data updates.
- Geolocation database (GeoDB) updates.

Deployment preview

A deployment preview is a snapshot that provides all the policy and object changes to be deployed on the device.

The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. The unused object changes are not displayed because they are not deployed on the device.

- **Comparison View**: Displays a side-by-side comparison of all the device configuration changes made since your last deployment.
- **Advanced View**: Displays the pending CLI commands to be applied to the device.

For more information about viewing the deployment preview, refer to Deploy configuration changes, on page 202.

The preview shows all the default values, even when they are not altered, along with the other configured settings when an interface or a platform settings policy is added for the first time. Similarly, the high availability-related policies and default values for settings are shown, even when they are not altered, in the first preview after a high availability pair is configured or disrupted.

To view changes due to an auto rollback, refer to Edit deployment settings, on page 1192.

Unsupported features:

- Object additions and attribute changes are displayed in the preview only if the objects are associated with any device or interface. Object deletions are not displayed.
- Preview is not supported for the policies:
    - High availability
    - Network discovery
    - Network analysis

- Device settings

- User information at the rule level is not available for intrusion policies.
- The preview does not show the reordering of rules across policies.

  For DNS policies, reordered rules appear in the preview list as rule additions and deletions. For example, moving a rule from position 1 to position 3 in the rule order is displayed as if the rule was deleted from position 1 and added as a new rule in position 3. Similarly, when a rule is deleted, the rules under it are listed as edited rules as they have changed their positions. The changes are displayed in the final order in which they appear in the policy.
- Preview is not supported in these HA scenarios:
  - If a device was in standalone mode and if a chain is made, then an auto-deployment is triggered. For that particular job, preview is not supported. On hover over the **Preview** (), a message is displayed that it is a HA bootstrap deployment, and no preview is supported.
  - **Configuration groups** - Consider a flow in which a device was initially standalone. Subsequently, three deployments took place. In the fourth deployment, the device was a HA bootstrap deployment. After these, the user deploys devices 5, 6, and 7. The deployment 7 is an HA break deployment, and the user deploys devices 8, 9, and 10.

    In this flow, the preview between 3 and 5 is not supported because 4 was a HA deployment. Similarly, the preview between 8 and 3 is also not supported. Preview is supported only from 3 to 1, 7,6, 5, 4, and 10, 9, and 8.
  - If a device is broken (HA is broken) then the new device is considered as a fresh device.

Guidelines for selective policy deployment

The Cloud-Delivered Firewall Management Center allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy.

This table describes the policies that suppot selective deployment.

Table 6: Policies that support selective deployment

Type	Policy
Access control	• Access control policies • Prefilter policies • QoS policies
Threat prevention and inspection	• Intrusion policies • Malware and file policies • DNS policies

Type	Policy
Identity and discovery	• SSL / decryption policies • Identity policies • Network discovery
Device or network connectivity	• NAT policies • Routing policies • VPN policies

Use the this table to understand the constraints and conditions for applying selective policy deployment.

Table 7: Limitations for selective deployment

Type	Description	Scenarios
Full deployment	Full deployment is necessary for specific deploy scenarios, and the Firewall Management Center does not support selective deployment in such scenarios. If you encounter an error in such scenarios, you may choose to proceed by selecting all the changes for deployment on the device.	Full deployment is required for: • The first deployment after you upgrade devices. • The first deployment after you restore a device. • The first deployment after modifications to a device's interface settings. • The first deployment after modifications in the virtual router settings.
Associated policy deployment	The Cloud-Delivered Firewall Management Center identifies interdependent policies which are interlinked. When one of the interlinked policies is selected, the remaining interlinked policies are automatically selected.	Scenarios wherein an associated policy is automatically selected: • When a new object is associated with an existing policy. • When an existing policy's object is modified. Scenarios wherein multiple policies are automatically selected: • When a new object is associated with an existing policy, and the same object is already associated with other policies, all the associated policies are automatically selected. • When a shared object is modified, all the associated policies are automatically selected.

Type	Description	Scenarios
Interdependent policy changes (shown using color-coded tags)	The Cloud-Delivered Firewall Management Center dynamically detects dependencies in-between policies, and between the shared objects and the policies. The interdependency of the objects or policies is shown using color-coded tags.	Scenarios wherein color-coded interdependent policies or objects are automatically selected: • When all the out-of-date policies have interdependent changes. For example, when an access control policy, an intrusion policy, and a NAT policy are out-of-date. Since access control policy and NAT policy share an object, all policies are selected together for deployment. • When all out-of-date policies share an object, and the object is modified.
Access Policy Group specifications	Access Policy Group policies are listed together in the preview window under **Access Policy Group** when you click **View** ( ).	The scenarios and the expected behavior for Access Policy Group policies are: • If the access control policy is out-of-date, all other out-of-date policies under this group, except file policy and intrusion policy, are selected when the access control policy is selected for deployment. However, if the access control policy is out-of-date, intrusion and file policies can be individually selected or deselected irrespective of whether the access control policy is selected or not, unless there are any dependent changes. For example, if a new intrusion policy is assigned to an access control rule, it indicates that there are dependent changes, then both the access control policy and the intrusion policy will be automatically selected when either of them is selected. • If no access control policy is out-of-date, other out-of-date policies in this group can be selected and deployed individually.

System username

The Cloud-Delivered Firewall Management Center displays the username as **system** for specific management operations. This allows administrators to distinguish system-initiated actions from those performed by users.

The **system** username is applied to these operations:

- Rollback
- Upgrade
- Firewall Threat Defense backup and restore

- SRU update
- LSP update
- VDB update

Auto-enabling of application detectors

When you perform application control but disable required detectors, the Cloud-Delivered Firewall Management Center automatically enables the appropriate system-provided detectors upon policy deployment. If no system-provided detector exists for the application, the Cloud-Delivered Firewall Management Center enables the most recently modified user-defined detector.

Asset rediscovery with network discovery policy changes

When you deploy changes to a network discovery policy, the system deletes and then rediscovers MAC address, TTL, and hops information from the network map for the hosts in your monitored networks. Also, the affected managed devices discard any discovery data that has not yet been sent to the Cloud-Delivered Firewall Management Center.

Snort restart scenarios

A Snort restart scenario is a situation that

- causes the traffic inspection engine, referred to as the `Snort process`, on a managed device to restart,
- interrupts inspection until the process resumesWhether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196., and
- may result in resource demands that cause a small number of packets to drop without inspection when you deploy.

Common snort restart triggers

Any of these scenarios cause the Snort process to restart:

- You deploy a specific configuration that requires the Snort process to restart. For more information, refer to Configurations that restart the snort process when deployed or activated, on page 198.
- You make a change that immediately restarts the Snort process. For more information, refer to Actions that immediately restart the snort process, on page 199.
- Traffic activates the currently deployed Automatic Application Bypass (AAB) configuration. For more information, refer Configure automatic application bypass, on page 1189.
- Enabling or disabling **Logging connection events to RAM disk** feature. For more information, refer the section **Log to Ramdisk** in Troubleshoot Drain of FMC Unprocessed Events.

Inspection interruption warnings during deployment

When you deploy configurations, the **Inspect Interruption** column in the deploy page indicates if a deployed configuration will restart the Snort process on the Firewall Threat Defense device. When the traffic inspection engine referred to as the `Snort process` restarts, inspection is interrupted until the process resumes. Whether traffic is interrupted or passes without inspection during the interruption depends on how the traffic is handled by the device. You can proceed with the deployment, cancel the deployment and modify the configuration, or delay the deployment until a time when deploying would have the least impact on your network.

During deployment, when the **Inspect Interruption** column indicates **Yes** and you expand the device configuration listing, an icon will highlight any configuration type that may restart the Snort process. Moving your pointer over the icon displays a message saying that deployment may interrupt traffic.

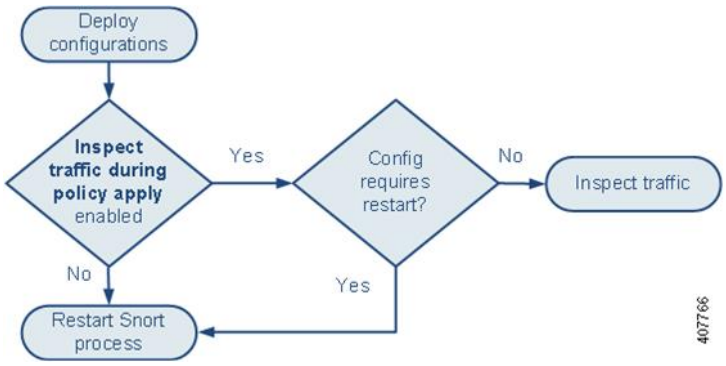
This table summarizes how the deploy page displays inspection interruption warnings.

Table 8: Inspection interruption indicators

Type	Inspect interruption	Description
Firewall Threat Defense	**Inspect Interruption** ( )Yes	At least one configuration would interrupt inspection on the device if deployed, and might interrupt traffic depending on how the device handles traffic. You can expand the device configuration listing for more information.
	--	Deployed configurations will not interrupt traffic on the device.
	Undetermined	The system cannot determine if a deployed configuration may interrupt traffic on the device. Undetermined status is displayed before the first deployment after a software upgrade, or in some cases during a Support call.
	Errors ( )	The system cannot determine the status due to an internal error. Cancel the operation and click **Deploy** again to allow the system to redetermine the **Inspect Interruption** status. If the problem persists, contact Support.
sensor	--	The device identified as *sensor* is not the Firewall Threat Defense device; the system does not determine if a deployed configuration may interrupt traffic on this device.

For information on all configurations that restart the Snort process for all device types, see Configurations that restart the snort process when deployed or activated, on page 198.

Inspect traffic during policy apply



Inspect traffic during policy apply is an advanced access control policy general setting that enables managed devices to inspect traffic while configuration changes are applied, and allows inspection unless a deployed configuration requires the Snort process to restart.

Configuration options

You can configure this setting as follows:

- Enabled — Traffic is inspected during the deployment unless certain configurations require the Snort process to restart. When a Snort restart is not needed, the system first uses the currently deployed access control policy to inspect traffic, then switches to the policy being deployed.
- Disabled — Traffic is not inspected during the deployment. The Snort process always restarts when you deploy.

This graphic illustrates how Snort restarts can occur when you enable or disable **Inspect traffic during policy apply**.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 196 and Configurations that restart the snort process when deployed or activated, on page 198.

Snort restart traffic behavior

This reference explains how different devices handle traffic when the Snort process restarts.

Table 9: The Firewall Threat Defense and the Firewall Threat Defense Virtual Restart Traffic Effects

Interface configuration	Restart traffic behavior
inline: **Snort Fail Open: Down**: disabled	dropped

Interface configuration	Restart traffic behavior
inline: **Snort Fail Open: Down**: enabled	passed without inspection Some packets can be delayed in buffer for several seconds before the system recognizes that Snort is down. This delay can vary depending upon the load distribution. However, the buffered packets are eventually passed.
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** enabled (**configure snort preserve-connection enable**; default) For more information, see *Cisco Secure Firewall Threat Defense Command Reference*.	existing TCP/UDP flows: passed without inspection so long as at least one packet arrives while Snort is down new TCP/UDP flows and all non-TCP/UDP flows: dropped Note that traffic drops even when **preserve-connection** is enabled for: • plaintext, passthrough prefilter tunnel traffic that matches an **Analyze** rule action or an **Analyze all tunnel traffic** default policy action • connections that do not match an access control rule and are instead handled by the default action • decrypted TLS/SSL traffic • a safe search flow • a captive portal flow
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** disabled (**configure snort preserve-connection disable**)	dropped
inline: tap mode	egress packet immediately, copy bypasses Snort
passive	uninterrupted, not inspected

Note In addition to traffic handling when the Snort process is down while it restarts, traffic can also pass without inspection or drop when the Snort process is busy, depending on the configuration of the Snort Fail Open **Busy** option (see Configure Inline Sets, on page 1128). A device supports either the Failsafe option or the Snort Fail Open option, but not both.

Note When the Snort process is busy but not down during configuration deployment, some packets may drop on routed, switched, or transparent interfaces if the total CPU load exceeds 60 percent.

Warning Do not reboot the system while the Snort Rule Update is in progress.

Snort-busy drops happen when snort is not able to process the packets fast enough. Lina does not know whether Snort is busy due to processing delay, or if is stuck or due to call blocking. When transmission queue is full, snort-busy drops occur. Based on Transmission queue utilization, Lina will try to access if the queue is being serviced smoothly.

Configurations that restart the snort process when deployed or activated

Deploying any of these configurations except AAB restarts the Snort process as described. Deploying AAB does not cause a restart, but excessive packet latency activates the currently deployed AAB configuration, causing a partial restart of the Snort process.

Access control policy advanced settings

- Deploy when **Inspect Traffic During Policy Apply** is disabled.
- Add or remove an SSL policy.

File policy

Deploy the first or last of any one of these configurations; note that while otherwise deploying these file policy configurations does not cause a restart, deploying non-file-policy configurations can cause restarts.

- Take either of these actions:
  - Enable or disable **Inspect Archives** when the deployed access control policy includes at least one file policy.
  - Add the first or remove the last file policy rule when **Inspect Archives** is enabled (note that at least one rule is required for **Inspect Archives** to be meaningful).
- Enable or disable **Store files** in a **Detect Files** or **Block Files** rule.
- Add the first or remove the last active file rule that combines the **Malware Cloud Lookup** or **Block Malware** rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**).

Note that access control rules that deploy these file policy configurations to security zones or tunnel zones cause a restart only when your configuration meets these conditions:

- Source or destination security zones in your access control rule must match the security zones associated with interfaces on the target devices.
- Unless the destination zone in you access control rule is *any*, a source tunnel zone in the rule must match a tunnel zone assigned to a tunnel rule in the prefilter policy.

Identity policy

- When SSL decryption is disabled (that is, when the access control policy does not include an SSL policy), add the first or remove the last active authentication rule.

An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Network discovery

- Enable or disable non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy.

Device management

- MTU: Change the highest MTU value among all non-management interfaces on a device.
- Automatic Application Bypass (AAB): The currently deployed AAB configuration activates when a malfunction of the Snort process or a device misconfiguration causes a single packet to use an excessive amount of processing time. The result is a partial restart of the Snort process to alleviate extremely high latency or prevent a complete traffic stall. This partial restart causes a few packets to pass without inspection, or drop, depending on how the device handles traffic.

TLS server identity discovery

Enabling or disabling **TLS Server Identity Discovery** will result in a Snort 2 restart.

Note Snort 3 does not restart when **TLS Server Identity Discovery** is enabled or disabled.

Updates

- System update: Deploy configurations the first time after a software update that includes a new version of the Snort binary or data acquisition library (DAQ).
- For managed devices running Snort 3, deploying configurations the first time after installing a vulnerability database (VDB) update may temporarily interrupt application detection, but there will be no traffic interruptions.

Actions that immediately restart the snort process

These actions immediately restart the Snort process without requiring deployment. How the restart affects traffic depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Applications or application detectors

- Activate or deactivate a system or custom application detector.
- Delete an activated custom detector.
- **Save and Reactivate** an activated custom detector.
- Create a user-defined application.

When you perform any of these actions, a message warns you that continuing will restart the Snort process. The message allows you to cancel. The system restarts Snort on all managed devices in the current domain and any child domain.

High availability configuration

Create or break a Firewall Threat Defense high availability pair.

When you create or break a high availability pair, a message warns you that creating or breaking a high availability pair restarts the Snort process on the primary and secondary devices. The message allows you to cancel.

Requirements and prerequisites for deployment management

Before using the configuration deployment feature in the Cloud-Delivered Firewall Management Center, ensure you meet these requirements.

- You must have **Administrator**, **Network Admin**, or **Security Approver** privileges to access the deployment features.
- Before deploying policy changes, you can compare the differences between the current device configuration and the pending policy, ensuring accuracy before you finalize the deployment. To use this feature, you must have the appropriate access rights, valid licenses for the specific policy, and be in the correct domain context.
- You must enable REST API access to preview the changes before a deployment. To enable the REST API access, follow the steps in *Enabling REST API Access* in the *Cisco Secure Firewall Management Center Administration Guide*.

Best practices for deploying configuration changes

Reliable management connection

The management connection between the Cloud-Delivered Firewall Management Center and the device is a secure, TLS-1.3-encrypted communication channel between itself and the device.

To ensure reliable management connection, use a direct management path instead of routing management traffic through an additional encrypted tunnel, such as a Site-to-Site VPN. If the tunnel fails, you could lose management connectivity.

To maintain a reliable management connection, exclude management traffic from the VPN tunnel if it exits a VPN-terminating interface.

Caution Avoid routing a device's management connection through a VPN tunnel that terminates on the device itself. If a configuration update causes the tunnel to drop, you will lose the management connection and cannot recover the device configuration unless you connect directly to the device.

Maximum concurrent deployments

Avoid deploying to more than 25 percent of the maximum devices allowed for a Cloud-Delivered Firewall Management Center in the same deployment task. For example, for the FMCv300, the maximum deployment task size is 75 devices (25 percent of 300). Deploying concurrently to more devices can cause performance issues.

Deployment of shared policies

For best performance, deploy to devices that use the same policies. Create a separate deployment task for each group of devices that share policies.

Time to deploy and memory limitations

Deployment time depends on multiple factors, including:

- The configurations you send to the device. For example, if you dramatically increase the number of Security Intelligence entries you block, deployment can take longer.
- Device model and memory. On devices with less memory, deployment can take longer.

Keep your configurations within the capability of your devices. If you exceed the maximum number of rules or policies supported by a target device, Cloud-Delivered Firewall Management Center displays a warning. The maximum depends on a number of factors—not only memory and the number of processors on the device, but also on policy and rule complexity. For information on optimizing policies and rules, refer to Best practices for access control rules, on page 2058.

Use a maintenance window to lessen the impact of traffic interruptions

We *strongly* recommend you deploy in a maintenance window or at a time when interruptions will have the least impact.

- When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 196 and Configurations that restart the snort process when deployed or activated, on page 198.
- For the Firewall Threat Defense devices, the **Inspect Interruption** column in the **Deploy** dialog warns you when deploying might interrupt traffic flow or inspection. You can proceed with, cancel, or delay deployment. For more information, refer to Inspection interruption warnings during deployment, on page 195.

Configuration deployment

Configuration deployment is the process of deploying configuration and policy updates to your Fireall Threat Defense devices after you make changes. This process allows you to apply changes to multiple components including device configurations, security policies, and network discovery settings.

Deployment components

Deploying updates applies to these components:

- Device and interface configurations
- Device-related policies, such as NAT, VPN, QoS, and platform settings policy

- Access control and related policies: DNS, file, identity, intrusion, network analysis, prefilter, SSL
- Network discovery policy
- Intrusion rule updates
- Configurations and objects associated with any of these elements

You can configure the system for automatic deployment by scheduling a deploy task or by setting the system to deploy when importing intrusion rule updates. Automating policy deployment is especially useful if you allow intrusion rule updates to modify system-provided base policies for intrusion and network analysis. Intrusion rule updates can also modify default values for the advanced preprocessing and performance options in your access control policies.

You can view deployment status in the **Notifications** pane.

Deploy configuration changes

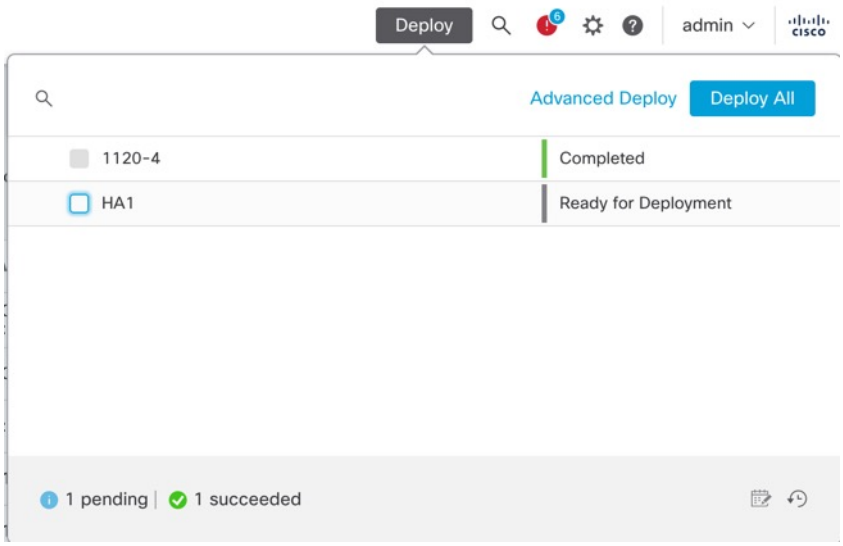
Apply new or updated device configurations to managed devices.

After you change a device configuration, you must deploy the changes for them to take effect. Deploy during a maintenance window or off-peak hours to minimize potential traffic and inspection disruption.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 196 and Configurations that restart the snort process when deployed or activated, on page 198.

Before you begin

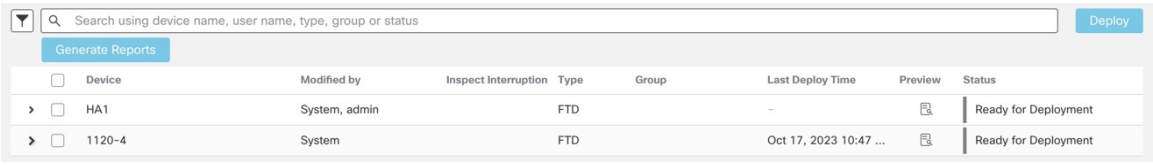
- Confirm that all managed devices use the same revision of the Security Zones object. If you have edited security zone objects: Do not deploy configuration changes to any device until you edit the zone setting for interfaces on *all* devices you want to sync. You must deploy to all managed devices at the same time.
- To preview the deployment changes, enable REST API access. To enable the REST API access, follow the steps in *Enabling REST API Access* in the *Cisco Secure Firewall Management Center Administration Guide* .



Note The deployment process fails if the device configuration is being read at the device CLI during deployment. Do not execute commands such as **show running-config** during the deployment.

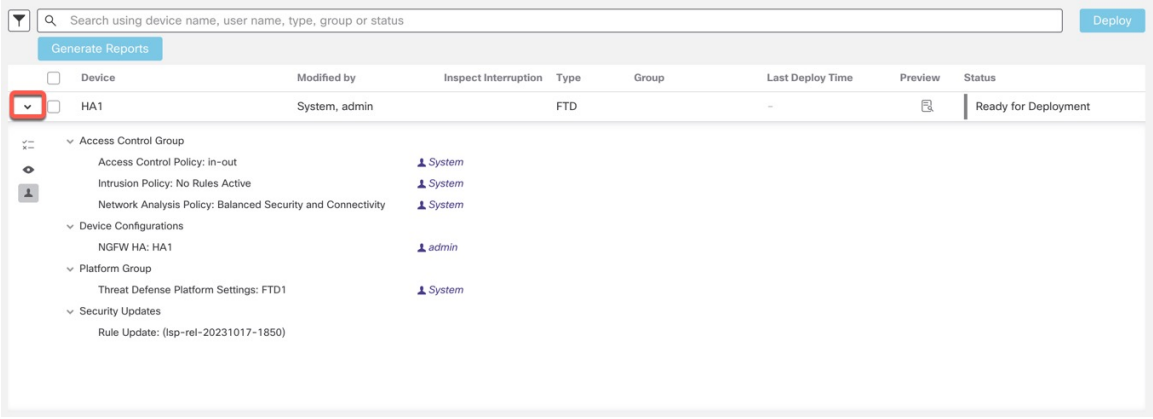
Procedure

Step 1 On the Cloud-Delivered Firewall Management Center menu bar, click **Deploy**.



Step 2 For a quick deployment, check specific devices and then click **Deploy**, or click **Deploy All** to deploy to all devices. For additional deployment options, click **Advanced Deploy**.

Figure 13: Quick Deploy



The rest of this procedure applies to the **Advanced Deploy** screen.

Figure 14: Advanced Deploy

Step 3 Click **Expand Arrow** (›) to view device-specific configuration changes to be deployed.

Figure 15: Expand

- The **Modified By** column lists the users who have modified the policies or objects. On expanding the device listing, you can view the users who have modified the policies against each policy listing. For

information about when the **System** user is shown (instead of the logged-in user), refer to System username, on page 193.

Note
Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption may be caused in the device during deployment.

  When the status indicates (Yes) that deploying will interrupt inspection, and perhaps traffic, on the Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).

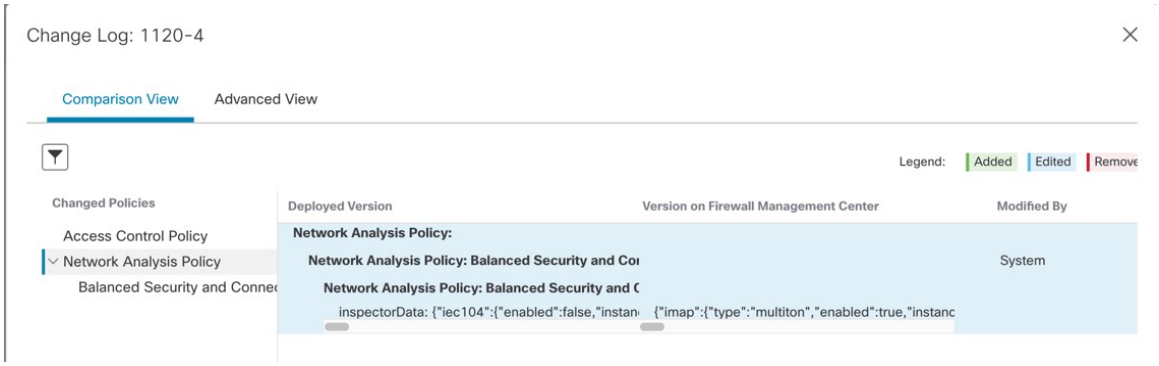
  If the entry is blank in this column for a device, then it indicates that there will be no traffic inspection interruptions on that device during deployment.

  For information about identifying configurations that interrupt traffic inspection and might interrupt traffic when deployed to the Firewall Threat Defense devices, refer to Inspection interruption warnings during deployment, on page 195.

- The **Last Modified Time** column specifies when you last made the configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment. For more information, see Deployment status, on page 209.

Step 4 In the **Preview** column, click **Preview** ( ) to see the configuration changes that you can deploy.

Figure 16: Preview



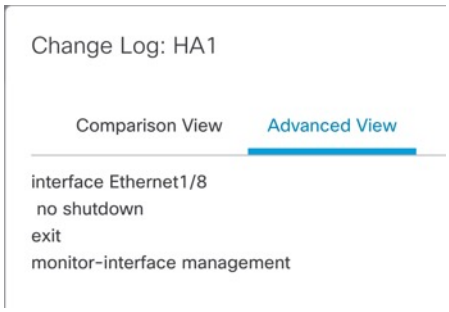
Note
If you change the Cloud-Delivered Firewall Management Center name in **System** ( ) > **Configuration** > **Information** , the deployment preview does not specify this change, yet it requires a deployment.

For unsupported features for Preview, see Deployment preview, on page 190.

The **Comparison View** tab lists all the policy and object changes. The left pane lists all the different policy types that have changed on the device, organized in a tree structure.

Figure 17: Comparison View

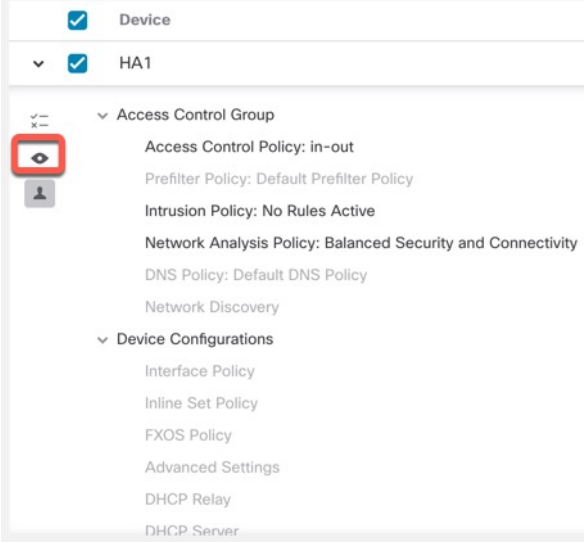
The **Filter**(lets you filter the policies at the user level and policy level.



The right pane lists all the additions, changes, or deletions in the policy, or the object selected in the left pane. The two columns on the right pane provide the last deployed configuration settings (in the **Deployed Version** column) versus the changes that are due for deployment (in the **Version on Firewall Management Center** column). The last-deployed configuration settings are derived from a snapshot of the last saved deployment in the Cloud-Delivered Firewall Management Center and not from the device. The background colors of the settings are color-coded as per the legend available on the top-right of the page.

The **Modified By** column lists the users who have modified, or added the configuration settings. At the policy level, the Cloud-Delivered Firewall Management Center displays all the users who have modified the policy, and at the rule level, the Cloud-Delivered Firewall Management Center displays only the last user who has modified the rule.

You can download a copy of the change log by clicking the **Download Report** button.



The **Advanced View** tab shows the CLI commands that will be applied. This view is useful if you are familiar with ASA CLI, which is used on the back end of the Firewall Threat Defense.

Figure 18: Advanced View

Step 5 Use **Show or Hide Policy** ( ) to selectively view or hide the associated unmodified policies.

Figure 19: Show or Hide Policy

Step 6 Check the box next to the device name to deploy all configuration changes, or click **Policy selection** ( ) to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.

You can also view the interdependent changes for a certain policy or configuration using this option. The Cloud-Delivered Firewall Management Center dynamically detects dependencies between policies (for example, between an access control policy and an intrusion policy), and between the shared objects and the policies. Interdependent changes are indicated using color-coded tags to identify a set of interdependent deployment changes. When one of the deployment changes is selected, the interdependent changes are automatically selected.

For more information, refer to Guidelines for selective policy deployment, on page 191.

Note

- When the changes in shared objects are deployed, the impacted policies should also be deployed along with them. When you select a shared object during deployment, the impacted policies are automatically selected.
- Selective deployment is not supported for scheduled deployments and deployments using REST APIs. You can only opt for complete deployment of all the changes in these cases.
- The pre-deployment checks for warnings and errors are performed not only on the selected policies, but on all the policies that are out-of-date. Therefore, the warnings or errors list shows the deselected policies as well.
- Similarly, the **Inspect Interruption** column indication on the Deployment page considers all out-of-date policies and not just the selected policies. For information on the **Inspect Interruption** column, refer to Inspection interruption warnings during deployment, on page 195.

Step 7 After you select the devices or policies to deploy, click **Estimate** to get a rough estimate of the deployment duration .

Figure 20: Estimate

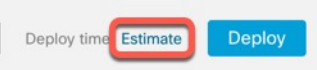


Figure 21: Deploy Time

The time duration is a rough estimate (having around 70% accuracy), and the actual time taken for deployment may vary for a few scenarios. The estimate is dependable for deployments of up to 20 devices.

When an estimate is not available, it indicates that the data is not available, since the first successful deployment on the selected device is pending. This situation could occur after the Cloud-Delivered Firewall Management Center reimage, version upgrade, or after a high availability failover.

Note
The estimate is incorrect and unreliable for bulk policy changes (in case of bulk policy migrations), and selective deployments because the estimate is based on the heuristic technique.

Step 8 For more details about the Pre-readiness assessment states, refer to .

Step 9 Click **Deploy**.

Configuration changes are deployed to the selected devices. You receive confirmation messages regarding success, warnings, or errors.

What to do next

If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. Check the **Ignore warnings** checkbox, to ignore warnings and deploy the changes. You cannot proceed if the system identifies errors.
- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.
- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the *Cisco Secure Firewall Management Center Administration Guide* .
- If the deployment fails, refer to Best practices for deploying configuration changes, on page 200 .
- During deployment, if there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For example, in a cluster environment, an erroneous configuration of an IP address that is not in the same subnet as the Site IPs is configured on the interface. Due to this error, deployment fails and the device attempts to clear the configuration while the rollback operation is being processed. These events collectively lead to a deployment failure that interrupts the traffic.

  See the following table to know what configuration changes may cause traffic interruption when deployment fails.

Table 10: Traffic interruption scenarios

Configuration Changes	Exists?	Traffic Impacted?
Threat Defense Service changes in an access control policy	Yes	Yes
VRF	Yes	Yes
Interface	Yes	Yes
QoS	Yes	Yes

Note The configuration changes interrupting traffic during deployment is valid only if both the Cloud-Delivered Firewall Management Center and the Firewall Threat Defense are of version 6.2.3 or later.

Redeploy existing configurations to a device

Force-deploying existing configurations to a managed device ensures that its policy rules are fully regenerated and applied. This procedure is recommended during maintenance windows or when disruption to network traffic is minimal. Force-deploy takes longer than regular deployment because it generates all policy rules for the device.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 196 and Configurations that restart the snort process when deployed or activated, on page 198.

Before you begin

- Review the guidelines described in Best practices for deploying configuration changes, on page 200.
- Plan to perform the redeployment during a maintenance window or low-impact period.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** (✎) next to the device where you want to force deployment.

Step 3 Click **Device**.

Step 4 Click **Edit** (✎) next to the **General** section heading.

Step 5 Click **Force Deploy** ( ).

Step 6 Click **Deploy**.

The system identifies any errors or warnings with the configurations you are deploying. You can click **Proceed** to continue without resolving warning conditions. However, you cannot proceed if the system identifies an error.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.
- If deploy fails, see Best practices for deploying configuration changes, on page 200.

Deployment management

Cloud-Delivered Firewall Management Center provides a set of deployement management options to oversee configuration changes across your Firewall Threat Defense devices. These options enable you to monitor real-time deployment status, track historical records, and ensure configuration integrity through rollback capabilities. Additionally, you can utilize built-in reporting and policy comparison features to audit changes, verify compliance, and troubleshoot issues.

Deployment status

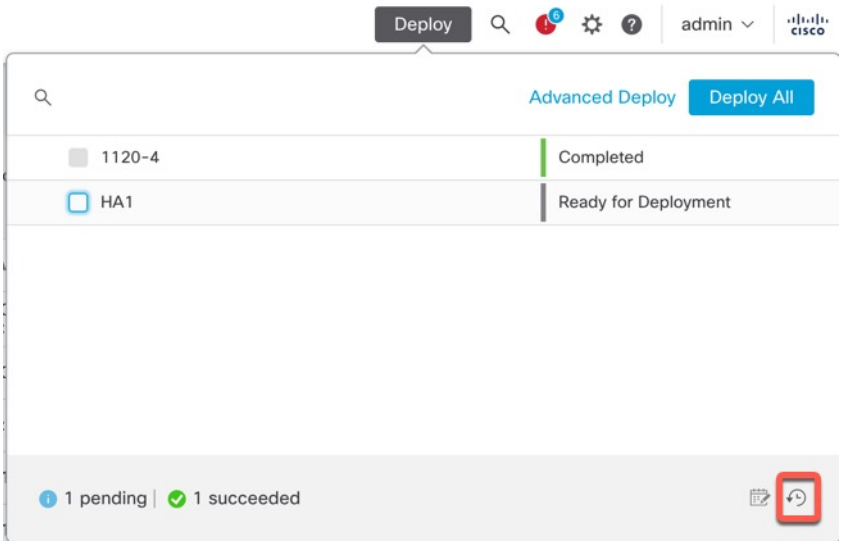
On the **Deployment** page, the **Status** column provides the deployment status for each device. If a deployment is in progress, a live progress indicator is displayed; otherwise, one of these deployment status values appears:

- **Pending**: Indicates that there are changes in the device that need be deployed.
- **Warnings or errors**: Indicates that the pre-deployment checks have identified warnings or errors for the deployment. You may continue deployment if there are warnings, but not if there are errors.

Note The status column provides the warning or error status only for a single user session on the **Deployment** page. If you navigate away or refresh the page, the status changes to **Pending**.

- **Failed**: Indicates that the previous deployment attempt failed. Click the status to view the details.
- **In queue**: Indicates that deployment is initiated, and the system is yet to start the deployment process.
- **Completed**: Indicates that deployment has completed successfully.

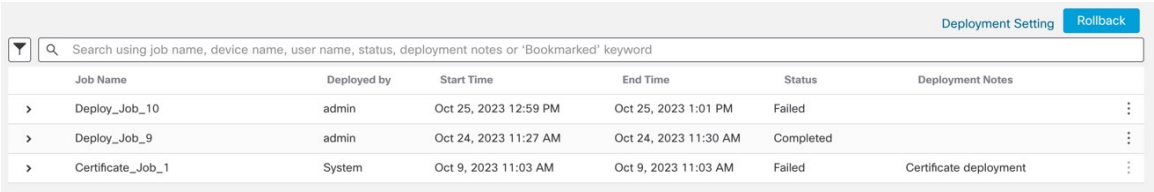
View deployment history



View deployment history to track and analyze past deployment activities, including successful deployments, failed deployments, and rollback operations.

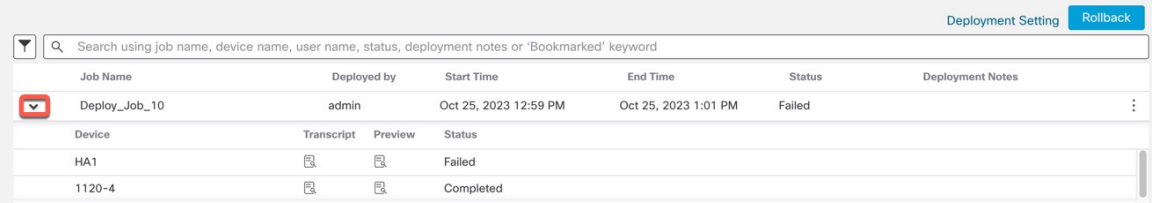
In the deployment history, the last 10 successful deployments, the last 5 failed deployments, and last 5 rollback deployments are captured.

Procedure



Step 1 On the Cloud-Delivered Firewall Management Center menu bar, click **Deploy** and then click **Deployment History** ( ).

Figure 22: Deployment history icon



A list of all the previous deployment and rollback jobs is displayed in reverse chronological order.

Figure 23: Deployment history page

Step 2 Click **Expand Arrow** ( ) next to the required deployment job to view the devices included in the job and their deployment statuses.

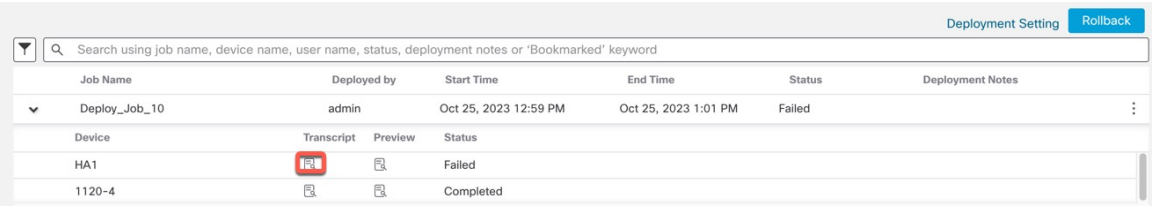
Figure 24: Expand

- View notes in the **Deployment Notes** column.

  Deployment notes are custom notes that a user can add as part of the deployment, and these notes are optional.

Step 3 (Optional) Click **Transcript Details** ( ) to view the commands sent to the device, and the responses received.

Figure 25: Transcript details icon



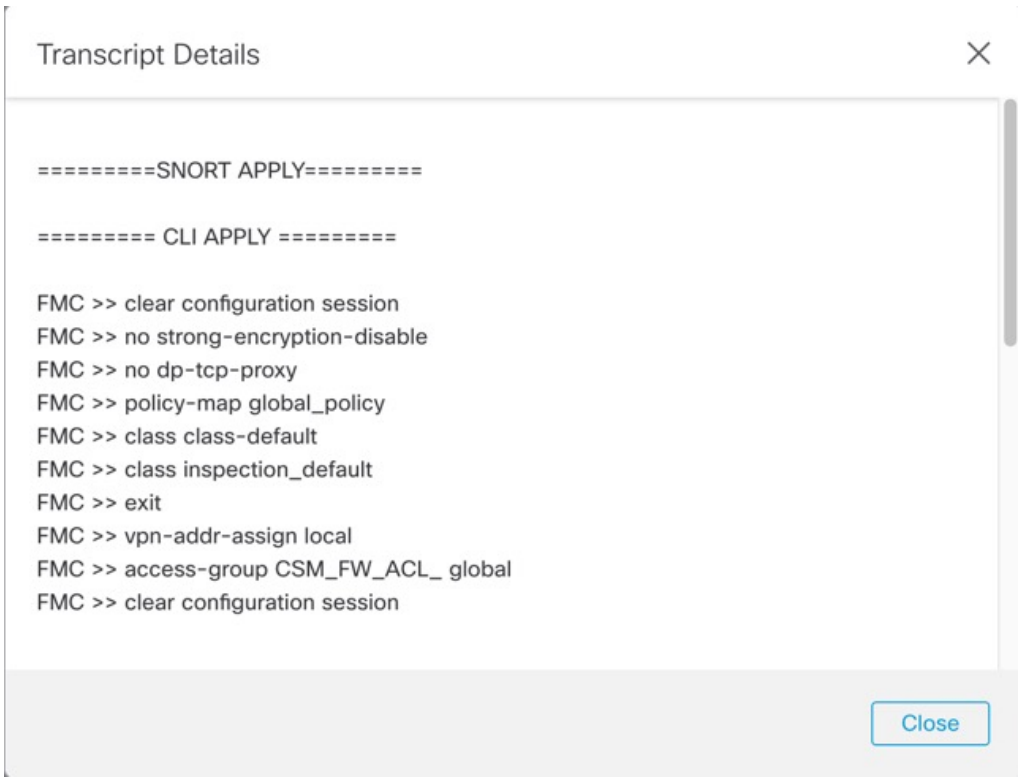


Figure 26: Transcript details

The transcript includes the following sections:

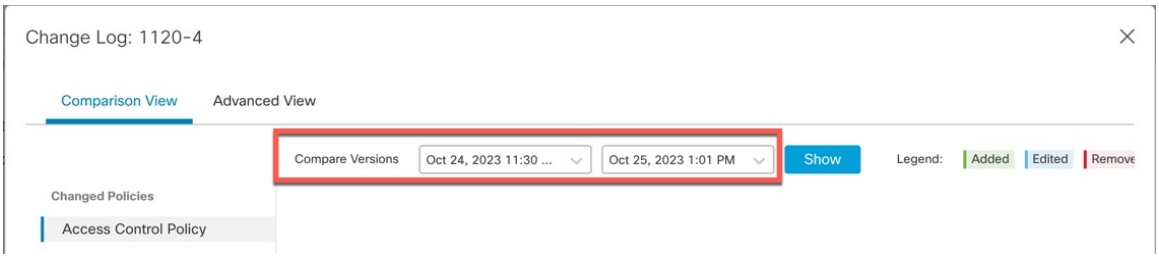
- **Snort Apply**—If there are any failures or responses from Snort-related policies, then the messages are displayed in this section. Normally, the section is empty.
- **CLI Apply**—This section covers features that are configured using commands that are sent to the device.
- **Infrastructure Messages**—This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript includes commands that are sent to the device, and any responses returned from the device. These responses can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands. Examining these errors can be particularly helpful if you are using FlexConfig policies to configure customized features. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note
There is no distinction that is made in the transcript between commands that are sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that Cloud-Delivered Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name **outside**. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything.

```
========= CLI APPLY =========



FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

Step 4 (Optional) Click **Preview** () to view the policy and object changes deployed on the device versus the previously deployed version.

Figure 27: Preview icon

a. To compare any two versions and view the change log, choose the required versions in the drop-down boxes and click the **Show** button. The drop-down boxes show the deployment job name and the end time of the deployment.

Figure 28: Compare versions

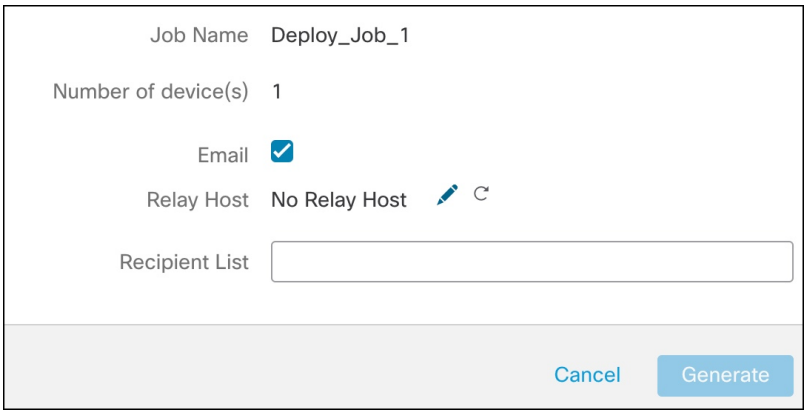
Note
The drop-down boxes also show failed deployments.

b. The **Modified By** column lists the users who have modified the policies or objects.

1. At the policy level, Cloud-Delivered Firewall Management Center displays all the user names who have modified the policy.
2. At the rule level, Cloud-Delivered Firewall Management Center displays the last user who has modified the rule.

c. You can also download a copy of the change log by clicking **Download Report**.

Note



- Deployment history preview is not supported for certificate enrollments, HA operations, and failed deployments.
- When a device is registered, preview is not supported for the job history record that is created.

Step 5 (Optional) Against each deployment job, click the **More** (⋮) icon and execute other actions:

- **Bookmark**—To bookmark the deployment job.
- **Edit Deployment Notes**—To edit your custom deployment notes that you added for a deployment job.
- **Generate Report**—To generate a deployment report, which can be used for auditing. This report includes job properties with preview and transcript information, and the report can be downloaded as a PDF file.

a. Click **Generate Report** to generate a deployment report.

Figure 29: Generate report

b. In the **Generate Report** popup window, check the **Email** checkbox.

c. In the **Recipient List**, you can enter multiple email adddresses, separated by semicolons.

d. Click **Generate** to generate the report, and this report is emailed to the recipients.

e. In the Notifications task tab, you can track the progress. After the report generation is complete, click the link in the notification task tab to download the PDF report.

Deployment rollback

Deployment rollback is the process of reverting a device to a previously saved configuration state. This operation allows you to restore the device to its earlier state if a recent policy deployment results in unintended traffic behavior.

Note Rollback is a disruptive operation. Executing a rollback terminates all existing connections and resets routing tables, which will cause a temporary interruption of traffic.

Identifying the disruptive configuration

When a deployment has caused unintended traffic interruption, identify the specific change responsible for the condition. To compare current and previous deployments:

Before a rollback

1. Choose **Deploy** > **Deployment History**, expand the last deployed job that caused the traffic disruption, and click the **Preview** ().

   The preview page lets you compare deployments to identify specific changes from previous configurations.

2. After identifying the change causing the problem, rectify the configuration and redeploy it on the device.

After a rollback

1. After a successful rollback, choose **Deploy** > **Deployment**, and click the **Preview** icon next to the rolled back device.
2. View the changes between the rolled back configuration and the current changes in the Cloud-Delivered Firewall Management Center that are pending deployment.
3. After identifying the change causing the problem, rectify the configuration, and redeploy it on the device.

Rollback reverts most configurations, but some exceptions apply. Refer the table below for details.

Rollback guidelines

Follow these guidelines to ensure successful configuration rollbacks.

- You have to perform a deployment before you can roll back again.
- After you perform a rollback, the rolled back devices are marked as out-of-date on the Cloud-Delivered Firewall Management Center. The changes you made to the configuration are still pending for the next deployment. To see the pending changes, choose **Deploy** > **Deployment**, and click the **Preview** icon next to the rolled back device.

- For devices with very large access lists, if the **Object Group Search** setting is disabled, then the rollback operation may take a longer duration to complete. To verify the **Object Group Search** setting, choose **Devices** > **Device Management**, and then select the device and click **Edit Advanced Settings**.
- For the Firepower 4100/9300, make sure your current Firewall Chassis Manager interface configuration is the same for any rollback versions. Otherwise, the rollback interface configuration may not match your actual interfaces.
- Independent certificate enrollments are also listed as deployment jobs in the Deployment History page. However, you cannot roll back to these versions. A rollback from a deployment version created after certificate enrollments reverts the certificate associations as well. In the next deployment after a rollback, manually associate the certificates before proceeding with the deployment.
- If a deployment for a device with a FlexConfig object configured with a deployment frequency set to **Once** is rolled back, then you will not be able to redeploy the object even though it is displayed as out-of-date on the Preview page. After a rollback, you will have to manually unassign and then reassign the FlexConfig object to the device before the next deployment.

Rollback limitations

Observe these limitations that restrict the use of rollback functionality.

- You can roll back to any one of the last 10 versions before the currently deployed version. Rollback to versions prior to these are not supported. The rollback icon is greyed out for unsupported versions.
- Rollback is not supported if the manager access interface (Manager or data interface) is different between the rollback version and the current version.
- If you upgrade the Cloud-Delivered Firewall Management Center, all rollback versions from the previous software release will no longer be available for devices, even if you did not upgrade the devices.
- If you upgrade the device, you can only roll back to versions on the current software release.
- For High Availability, rollback is not supported in these scenarios:
  - When the version you want to roll back to contains the high-availability bootstrap configuration. In other words, the deployment when you first formed high availability for the standalone devices.
  - When a device that is currently in standalone mode was part of a high availability pair in the previous deployment version.
- For clustering:
  - Rollback is not supported when a device that is currently in standalone mode was part of a cluster in the previous deployment version.
  - (Secure Firewall 3100/4200 and Firewall Threat Defense Virtual in a private cloud) If you change the clustering bootstrap configuration or add or delete nodes, you cannot roll back to a version prior to those changes.

Table 11: Configurations reverted and not reverted during rollback

Configurations that are reverted during a rollback	Configurations that are not reverted during a rollback
• All policy configurations • Interface configurations • SRU configurations • VDB configurations • LSP configurations • VPN configurations • FXOS configurations	• Snort binaries • Geo DB

Perform a rollback

Use rollback to revert a device to a previously deployed configuration when the traffic through the device is affected in an unintended way after a policy deployment.

You can roll back a device to a previously deployed configuration. After a policy deployment, if the traffic through the device is affected in an unintended way, rollback provides an option to revert the device to the earlier state, which existed before the faulty deployment.

Rollback reverts the configuration only on the selected devices.

Procedure

Step 1 Choose **Deploy >Deployment History** ( ).

A list of all the previous deployment jobs is displayed in reverse chronological order.

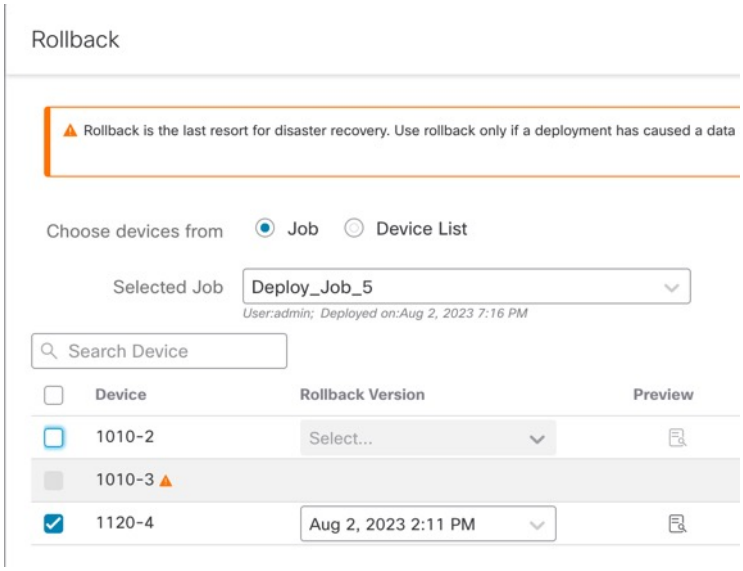
Step 2 Click **Rollback**.

Step 3 Filter the list of devices displayed by either clicking **Job** and choosing a job from the **Selected Job** drop-down list, or by clicking **Device List**.

Step 4 (Optional) Enter the device name in the **Search Device** search box to filter the device list.

Step 5 Check the box next to the devices you want to roll back and choose the version for each device from the **Rollback Version** drop-down list.

Figure 30: Selected job list



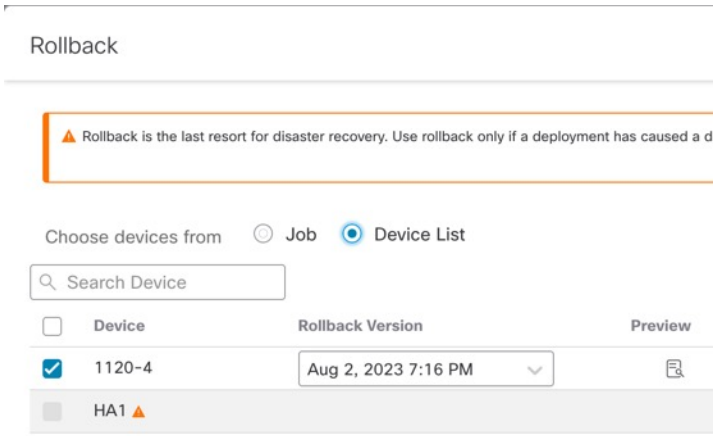


Figure 31: Device list

The job names and associated deployment notes are also listed for a particular rollback version.

Step 6 (Optional) Click the **Preview** ( ) to view the changes deployed in the selected version.

Step 7 Click **Rollback** to restore the selected devices to the chosen configuration version.

What to do next

To verify rollback status, go to **Deploy** > **Deployment** and check the rollback status next to the device name.

View the deployment rollback transcript

View the CLI commands that were executed during a successful rollback operation to understand what changes were made to the device configuration.

Rollback transcript is a written version of the commands that are sent to the device, along with the responses returned from the device. If a rollback operation has failed, the reason for the failure can be viewed by clicking **Deploy**, and then click the **Deployment History** (). However, to know the CLI commands executed for a successful rollback operation, follow the steps given below after a rollback operation has completed.

Note

- The CLI command information is available after a rollback is complete and is available only until the next deployment. The first deployment after a rollback operation erases all the rollback-related information.
- For any rollback deployment, the deployment notes are updated automatically as rollback job. In the **Deployment History** page, the user can filter the rollback jobs easily using the search option.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center menu bar, choose **System** () > **Health** > **Monitor**.
Step 2 Select the device, which was rolled back, from the left pane.
Step 3 Click **View System & Troubleshooting Details** link.
Step 4 Click **Advanced Troubleshooting**.
Step 5 Click **Threat Defense CLI**.
Step 6 Select **show** from the **Command** drop-down box.
Step 7 Enter `running` in the **Parameter** field.
Step 8 Click **Execute**.

Download policy changes report for multiple devices

Download reports on the policy and object changes made since your last deployment for multiple Firewall Threat Defense devices. Reports help you review pending changes before completing deployment. The reports are provided as a zip file containing:

- A pending changes report for each device, previewing modifications to policy or objects that are to be deployed on the device. For more information, refer to Deploy configuration changes, on page 202 and Deployment Preview.
- A consolidated report categorizing each device by report status.

Procedure

Step 1 Choose **Deploy** > **Advanced Deploy**.
Step 2 Check the check box next to the devices for which you want to generate a pending policy changes report, and then click **Pending Changes Reports**.
Step 3 Click **Pending Changes Reports**. Reports are generated in the background.

Step 4 On the Cloud-Delivered Firewall Management Center menu bar, choose **Notifications** > **Tasks** to view the report generation task.

When the report request task is complete, the download link appears within the task notification.

Step 5 Click the **Download Report(s)** link to download the reports.

Compare policies

Policy comparison allows you to examine the differences between two policies or between a saved policy and the running configuration to review policy changes for compliance with your organization's standards or to optimize system performance.

You can compare these policy types:

- DNS
- File
- Health
- Identity
- Network Analysis
- SSL

The comparison view displays both policies in a side-by-side format. Differences between the two policies are highlighted:

- Blue indicates that the highlighted setting is different in the two policies, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy but not the other.

Before you begin

You can compare policies only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy you want to compare:

- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**.

Note

If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **Decryption**

Step 2 Click **Compare Policies**.

Step 3 From the **Compare Against** drop-down list, choose the type of comparison you want to make:

- To compare two different policies, choose **Other Policy**.
- To compare two revisions of the same policy, choose **Other Revision**.
- To compare another policy to the currently active policy, choose **Running Configuration**.

Step 4 Depending on the comparison type you choose, you have various choices:

- If you are comparing two different policies, choose the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
- If you are comparing the running configuration to another policy, choose the second policy from the **Policy B** drop-down list.

Step 5 Click **OK**.

Step 6 Review the comparison results:

- Comparison Viewer—To use the comparison viewer to navigate individually through policy differences, click **Previous** or **Next** above the title bar.
- Comparison Report—To generate a PDF report that lists the differences between the two policies, click **Comparison Report**.

Generate current policy reports

You can generate two types of reports for most policies: a single-policy report detailing the policy's current saved configuration, and a comparison report listing differences between two policies. You can generate a single-policy report for all policy types except health.

Note Intrusion policy reports combine the settings in the base policy with the settings of the policy layers, and make no distinction between which settings originated in the base policy or policy layer.

Before you begin

- Ensure you have the required access rights and licenses for the specific policy.
- Verify you are operating within the correct domain for the policy you wish to report.

Procedure

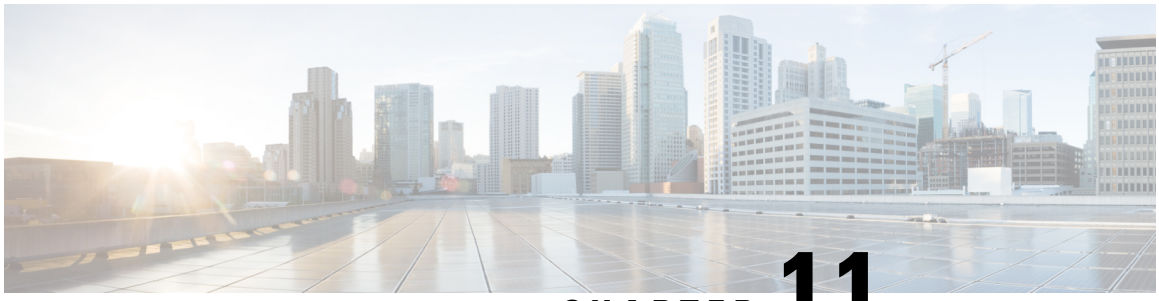
Step 1 Access the management page for the policy for which you want to generate a report:

- Access Control—**Policies** > **Access Control heading** > **Access Control**

- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Intrusion—**Policies** > **Access Control heading** > **Intrusion**
- NAT—**Devices** > **NAT**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**

  Note
  If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **Decryption**



Step 2 Click **Report** (📄) next to the policy for which you want to generate a report.

PART III

System Settings

- Users, on page 243
- Updates, on page 263
- Licenses, on page 275
- Security certifications compliance, on page 315

CHAPTER 11

System Configuration

This chapter explains how to configure system configuration settings on the Cloud-Delivered Firewall Management Center.

- Meet requirements and prerequisites for the system configuration, on page 225
- Manage the Cloud-Delivered Firewall Management Center system configuration, on page 226
- Configure access control preferences, on page 226
- Audit logs, on page 227
- Audit log certificates, on page 231
- Change reconciliation, on page 237
- Email notifications, on page 239
- Intrusion policy preferences, on page 239
- Network analysis policy preferences, on page 241

Meet requirements and prerequisites for the system configuration

This reference lists the requirements and prerequisites for the system configuration, including supported models, domains, and user roles.

Model support

User roles

Admin

Manage the Cloud-Delivered Firewall Management Center system configuration

Configure the system to establish and maintain the essential settings for the Cloud-Delivered Firewall Management Center. Ensure that these settings align with organizational requirements.

The system configuration identifies basic settings for the Cloud-Delivered Firewall Management Center. Use this task when you need to review or update the fundamental configuration options for the management center.

Before you begin

Access to the Cloud-Delivered Firewall Management Center interface may be required. Follow these steps to manage the Cloud-Delivered Firewall Management Center system configuration.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Use the navigation panel to choose configurations to change.

When you complete the steps, the basic settings for the Cloud-Delivered Firewall Management Center will update to maintain proper system operation.

What to do next

Verify that the configuration changes are applied and the system is functioning as expected.

Configure access control preferences

You can track changes to access control rules by allowing or requiring users to comment when they save. This allows you to assess why critical policies in a deployment were modified. By default, this feature is disabled.

Configure object optimization to evaluate and optimize network or host policy objects that are used in rules. The system then creates associated network object groups on the device. For more information, refer to Object-group optimization.

Procedure

Step 1 Choose **System** (⚙) > **Configuration** > **Access Control Preferences**.

Step 2 From the **Comments on rule change** list, choose an option:

- **Disabled**: Disables comments for access control rule changes.
- **Optional**: Allows users to optionally add a comment when they change an access control rule.

- **Required**: Requires users to add a comment when they change an access control rule.

Step 3 From the **Object-group optimization** list, choose an option:

- **Enabled**: Enables object-group optimization. The setting takes effect after deployment.
- **Disabled**: Disables object-group optimization.

Warning
For the first deployment to a threat defense device after you enable object-group optimization, the device can take several minutes to an hour to reevaluate the policy configuration and optimize object groups. CPU utilization on the device can also increase. Schedule the deployment during a low-traffic period or a maintenance window.

Step 4 Click **Save**.

What to do next

Deploy the access control policies for object-group optimization to take effect.

Audit logs

An audit log is a security record that

- records user activity in read-only logs,
- allows review, sorting, filtering, deletion, and reporting of audit information, and
- supports streaming audit log messages to external servers such as syslog and HTTP servers.

Audit log review and streaming options

You can review audit log data in several ways:

- Use the web interface: .

  Audit logs appear in a standard event view. In this view, you can view, sort, and filter audit log messages based on any item. You can also delete audit information, generate reports, and view detailed reports of user changes.

- Stream audit log messages to the syslog: Stream audit logs to syslog, on page 228.
- Stream audit log messages to an HTTP server: Stream audit logs to an HTTP server, on page 230.

Streaming audit log data to an external server allows you to conserve space on the Cloud-Delivered Firewall Management Center. Note that sending audit information to an external URL may affect system performance.

Optionally, you can secure the channel for audit log streaming, enable TLS and mutual authentication using TLS certificates; refer to Audit log certificates, on page 231.

Streaming to multiple syslog servers

You can stream audit log data to a maximum of five syslog servers. However, if you have enabled TLS for secured audit log streaming, you can stream only to a single syslog server.

Streaming configuration changes to syslog

You can stream configuration changes as part of audit log data to syslog by specifying the configuration data format and the hosts. The Cloud-Delivered Firewall Management Center supports backup and restore of the audit configuration log.

Stream audit logs to syslog

Configure audit log streaming to syslog servers to ensure centralized monitoring and compliance tracking for your system. Enable external logging of configuration changes and security events.

When this feature is enabled, audit log records appear in the syslog in the following format:

```
Date Time Host: [Tag] Sender: User_Name@User_IP, Subsystem, Action
```

Where the local date, time, and originating hostname precede the bracketed optional tag, and the sending device name precedes the audit log message.

For example, if you specify a tag of `FMC-AUDIT-LOG` for audit log messages from your management center, a sample audit log message from your Cloud-Delivered Firewall Management Center could appear as follows:

```
Mar 01 14:45:24 localhost: [FMC-AUDIT-LOG] Dev-MC7000: admin@10.1.1.2, Operations >
Monitoring, Page View
```

If you specify a severity and facility, these values do not appear in syslog messages; instead, they tell the system that receives the syslog messages how to categorize them.

This task is relevant when you need to send audit logs from your management center to an external syslog server for compliance or operational monitoring. Use this procedure when integrating with centralized log management solutions.

Before you begin

Make sure the Cloud-Delivered Firewall Management Center can communicate with the syslog server. When you save your configuration, the system uses ICMP/ARP and TCP SYN packets to verify syslog server connectivity. By default, the system uses port 514/UDP to stream audit logs. To secure the channel, manually configure port 1470 for TCP.

Follow these steps to stream audit logs to a syslog server:

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log**.

Step 3 Choose **Enabled** from the **Send Audit Log to Syslog** drop-down menu.

Step 4 The following fields are applicable only for audit logs sent to syslog:

Option	Description
Send Configuration Changes	To include configuration changes syslog in the audit log streaming, from the drop-down, select the relevant options: • JSON—the syslog includes detailed differences in the configuration changes. • API—the syslog includes API to retrieve the detailed differences in the configuration changes. • None—to have all other audit logs except details of the configuration changes.
Host	The IP address or the fully qualified name of the syslog server to which you will send audit logs. You can add a maximum of five syslog hosts, separated by commas. **Note** You can specify multiple syslog hosts, only when TLS is disabled for the Audit Server Certificate.
Facility	The subsystem that creates the message. Choose a facility described in SYSLOG alert facilities, on page 491. For example, choose AUDIT.
Severity	The severity of the message. Choose a severity described in Syslog severity levels, on page 492.
Tag	An optional tag to include in audit log syslog messages. Best practice: Enter a value in this field to easily differentiate audit log messages from other, similar syslog messages such as health alerts. For example, if you want all audit log records sent to the syslog to be labeled with `FMC-AUDIT-LOG`, enter `FMC-AUDIT-LOG` in the field.

Step 5 (Optional) To test whether the IP address of the syslog servers is valid, click **Test Syslog Server**.

The system sends the following packets to verify whether the syslog server is reachable:

a. ICMP echo request

b. TCP SYN on 443 and 80 ports

c. ICMP time stamp query

d. TCP SYN on random ports

Note
If the Cloud-Delivered Firewall Management Center and syslog server are in the same subnet, ARP is used instead of ICMP.

The system displays the result for each server.

Step 6 Click **Save**.

After you complete this task, audit logs are sent from the management center to the specified syslog server, allowing you to monitor and review system activity externally.

What to do next

Verify that the syslog server is receiving audit log messages as expected. Check for log entries corresponding to configuration changes or security events.

Stream audit logs to an HTTP server

Stream audit logs from the device to an HTTP server to centralize log management and support compliance requirements.

Use this task to forward audit logs from your device to an external HTTP server for monitoring, analysis, or compliance.

When this feature is enabled, the appliance sends audit log records to an HTTP server in the following format:

```
Date Time Host [Tag] Sender: User_Name@User_IP, Subsystem, Action
```

Where the local date, time, and originating hostname precede the bracketed optional tag, and the sending appliance name precedes the audit log message.

For example, if you specify a tag of `FROMMC`, a sample audit log message could appear as follows:

```
Mar 01 14:45:24 localhost [FROMMC] Dev-MC7000: admin@10.1.1.2, Operations > Monitoring,
Page View
```

Before you begin

Make sure the device can communicate with the HTTP server.

Follow these steps to stream audit logs to an HTTP server.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log**.

Step 3 Optionally, in the **Tag** field, enter the tag name that you want to appear with the message. For example, if you want all audit log records to be preceded with `FROMMC`, enter `FROMMC` in the field.

Step 4 Choose **Enabled** from the **Send Audit Log to HTTP Server** drop-down list.

Step 5 In the **URL to Post Audit** field, designate the URL where you want to send the audit information. Enter a URL that corresponds to a Listener program that expects the HTTP POST variables as listed:

- `subsystem`
- `actor`
- `event_type`
- `message`
- `action_source_ip`
- `action_destination_ip`

- `result`
- `time`
- `tag` (if defined; see Step 3)

Caution
To allow encrypted posts, use an HTTPS URL. Sending audit information to an external URL may affect system performance.

Step 6 Click **Save**.

When you complete this task, the device sends audit logs to the specified HTTP server. Centralized monitoring and record-keeping become possible.

Audit log certificates

An audit log certificate is a security credential that

- secures communications between the Cloud-Delivered Firewall Management Center and a trusted audit log server,
- enables authentication and encryption using Transport Layer Security (TLS), and
- supports mutual authentication and certificate revocation checks for enhanced security.

Client certificates

Client certificates are required to secure communications between the Cloud-Delivered Firewall Management Center and the audit log server.

- Generate a certificate signing request (CSR). Submit it to a Certificate Authority (CA) for signing. Import the signed certificate onto the Cloud-Delivered Firewall Management Center.
- Use the local system configuration: Obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center, on page 233 and Import an audit log client certificate into the Cloud-Delivered Firewall Management Center, on page 234.

Server certificates

Server certificates are optional and provide additional security through mutual authentication.

- Require mutual authentication between the Cloud-Delivered Firewall Management Center and the audit log server by loading one or more certificate revocation lists (CRLs).
- You cannot stream audit logs to servers with revoked certificates listed in those CRLs.
- Secure Firewall supports CRLs encoded in Distinguished Encoding Rules (DER) format. These are the same CRLs used to validate HTTPS client certificates for the Cloud-Delivered Firewall Management Center web interface.
- Use the local system configuration: Require valid audit log server certificates, on page 235.

Audit log certificate example

For example, a signed client certificate imported onto the Cloud-Delivered Firewall Management Center enables secure TLS communication with an audit log server, ensuring log integrity and confidentiality.

Non-compliant audit log certificate

A certificate that is not signed by a trusted Certificate Authority or is listed in a certificate revocation list (CRL) cannot be used to stream audit logs securely.

Audit log certificate analogy

An audit log certificate is like a passport for secure communication, verifying identity and granting access between the management center and the audit log server.

Secure audit log streaming

Configure secure audit log streaming to ensure that audit logs are transmitted safely between the Cloud-Delivered Firewall Management Center and a trusted server.

When you stream the audit log to a trusted HTTP server or syslog server, use Transport Layer Security (TLS) certificates to secure the channel between the Cloud-Delivered Firewall Management Center and the server.

You must generate a unique client certificate for each appliance you want to audit. Mutual authentication requires the client certificate to be signed by the same CA as the server certificate. For more considerations on client and server certificate requirements, refer to Audit log certificates, on page 231.

Before you begin

Refer to ramifications of requiring client and server certificates at Audit log certificates, on page 231. Ensure you have access to a recognized certificate authority (CA) for signing client certificates.

Follow these steps to secure audit log streaming.

Procedure

Step 1 Obtain and install a signed client certificate on the Cloud-Delivered Firewall Management Center.

a) Obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center, on page 233:

Generate a Certificate Signing Request (CSR) from the Cloud-Delivered Firewall Management Center based on your system information and the identification information you supply.

- Submit the CSR to a recognized, trusted certificate authority (CA) to request a signed client certificate.
- If you will require mutual authentication between the Cloud-Delivered Firewall Management Center and the audit log server, ensure the client certificate is signed by the same CA that signed the server certificate.

b) After you receive the signed certificate from the certificate authority, import it into the Cloud-Delivered Firewall Management Center. Refer to Import an audit log client certificate into the Cloud-Delivered Firewall Management Center, on page 234.

Step 2 Configure the communication channel with the server to use Transport Layer Security (TLS) and enable mutual authentication.

Step 3 If you have not yet configured audit log streaming, do so now.

Refer to Stream audit logs to syslog, on page 228 or Stream audit logs to an HTTP server, on page 230.

Audit logs are securely streamed to the trusted server using TLS, with mutual authentication enabled. The Cloud-Delivered Firewall Management Center and the server verify each other's certificates, ensuring secure transmission and integrity of audit log data.

What to do next

Monitor the audit log streaming status and verify certificate validity periodically. Renew client and server certificates before expiration to maintain secure log streaming.

Obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center

Obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center. This certificate enables secure communication between the appliance and the audit log server. It ensures that the server can authenticate audit log data and that the data is transmitted securely.

The system generates certificate request keys in Base-64 encoded PEM format.

Perform this task on the active appliance to generate a certificate signing request for audit log client authentication. Do not perform this task on a standby appliance in a high availability setup.

Before you begin

Keep this in mind:

- To ensure security, use a globally recognized and trusted certificate authority (CA) to sign your certificate.
- If you will require mutual authentication between the appliance and the audit log server, the same certificate authority must sign both the client certificate and the server certificate.

Follow these steps to obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center:

Procedure

Step 1 Choose **System** (⚙) > **Configuration** and click **Audit Log Certificate**.

Step 2 Click **Generate New CSR**.

Step 3 Enter a country code in the **Country Name (two-letter code)** field.

Step 4 Enter a state or province postal abbreviation in the **State or Province** field.

Step 5 Enter a **Locality or City**, an **Organization** name, and an **Organizational Unit (Department)** name.

Step 6 Enter the fully qualified domain name of the server for which you want to request a certificate in the **Common Name** field.

Note
If the common name and the DNS hostname do not match, audit log streaming will fail.

Step 7 Click **Generate** and then open a new blank file with a text editor.

Step 8 Copy the block of text from the certificate request, including the `BEGIN CERTIFICATE REQUEST` and `END CERTIFICATE REQUEST` lines. Paste this information into a blank text file.

Step 9 Save the file as *`clientname`*`.CSR`. Replace *`clientname`* with the appliance name where you plan to use the certificate. Click **Close**.

After completing these steps, you will have a certificate signing request (CSR) file that can be submitted to a trusted certificate authority. After it is signed, you can import the certificate to the appliance for secure audit log streaming.

What to do next

- Submit the certificate signing request to the certificate authority you selected, according to the guidelines in the 'Before You Begin' section.
- When you receive the signed certificate, import it to the appliance; refer to Import an audit log client certificate into the Cloud-Delivered Firewall Management Center, on page 234.

Import an audit log client certificate into the Cloud-Delivered Firewall Management Center

Importing an audit log client certificate enables secure communication between the Secure Firewall Management Center and external systems during audit log transmission. This task verifies that you import the correct signed certificate and any necessary intermediate certificates for secure operations.

In a Secure Firewall Management Center high availability setup, you must use the active peer when importing the audit log client certificate. This procedure is relevant when configuring audit log security or after obtaining a new signed client certificate.

Before you begin

- Obtain a signed audit log client certificate for the Cloud-Delivered Firewall Management Center, on page 233.
- Make sure you are importing the signed certificate for the correct Cloud-Delivered Firewall Management Center.
- If the signing authority requires an intermediate CA, ensure you provide the certificate chain. The same CA must sign both the client certificate and the intermediate certificates.

Follow these steps to import an audit log client certificate into the Secure Firewall Management Center.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log Certificate**.

Step 3 Click **Import Audit Client Certificate**.

Step 4 Open the client certificate in a text editor, copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Paste this text into the **Client Certificate** field.

Step 5 To upload a private key, open the private key file and copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Paste this text into the **PRIVATE KEY** field.

Step 6 Open any required intermediate certificates, copy the entire block of text for each, and paste it into the **Certificate Chain** field.

Step 7 Click **Save**.

The audit log client certificate and any required intermediate certificates are successfully imported into the Secure Firewall Management Center.

Require valid audit log server certificates

The system supports validating audit log server certificates using imported CRLs in Distinguished Encoding Rules (DER) format.

Note If you choose to verify certificates using CRLs, the system uses the same CRLs to validate both audit log server certificates and certificates used to secure the HTTP connection between an appliance and a web browser.

Before you begin

- Understand the ramifications of requiring mutual authentication and of using certificate revocation lists (CRLs) to ensure that certificates are still valid. Refer to Audit log certificates, on page 231.
- Obtain and import the client certificate following the steps in Secure audit log streaming, on page 232 and the topics referenced in that procedure.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center , choose **System** (⚙) > **Configuration** .

Step 2 Click **Audit Log Certificate** .

Step 3 To use Transport Layer Security to securely stream the audit log to an external server, select **Enable TLS** .

When TLS is enabled, the syslog client (Cloud-Delivered Firewall Management Center) verifies the certificate received from the server. The connection between the client and the server succeeds only if server certificate verification is successful. For this verification process, these conditions must be met:

- Configure the syslog server to send the certificate to the client.
- Add (import) a CA certificate to the client to verify the server certificate:
  - You must import the CA certificate during the import of the client certificate.
  - If the issuing CA is a subordinate CA, add the issuing CA before adding the signing CA from the subordinate CA (Root CA).

Step 4 If you do not want the client to authenticate itself against the server, but wish to accept the server certificate when the certificate is issued by the same CA (not recommended), complete these steps.

a) Deselect **Enable Mutual Authentication** .

Important
Ensure that the server is configured to trust the client without verifying any client certificates.

b) Click **Save** and skip the remainder of this procedure.

Step 5 (Optional) To enable client certificate verification by the audit log server, select **Enable Mutual Authentication**.

Important
The **Enable Mutual Authentication** option is applicable only when TLS is enabled.

When mutual authentication is enabled, the syslog client (Cloud-Delivered Firewall Management Center) sends a client certificate to the syslog server for verification. The client uses the same CA certificate of the CA who signed the server certificate of the syslog server. The connection succeeds only if client certificate verification is successful. For this verification process, these conditions must be met:

- Configure the syslog server to verify the certificate received from the client.
- Add a client certificate to be sent to the syslog server. This certificate must be signed by the same CA who signed the server certificate of the syslog server.

Note
To use mutual authentication for streaming Audit Log to the Syslog server, use PKCS#8 format for the private key instead of PKCS#1 format. Use this command line to convert PKCS#1 keys to PKCS#8 format:

```
openssl pkcs8 -topk8 -inform PEM -outform PEM
-nocrypt -in

 PKCS1 key file name

-out

 PKCS8 key filename
```

Step 6 (Optional) To automatically recognize server certificates that are no longer valid:

a) Select **Enable Fetching of CRL** .

Important
This option is displayed only when you select the **Enable Mutual Authentication** check box. However, the **Enable Fetching of CRL** option is applicable only when the TLS option is enabled. The use of CRL

is for server certification verification, and it is not dependent on the use of Mutual Authentication which is for enabling client certificate verification.

When you enable fetching of the CRL, the client creates a scheduled task to regularly update (download) the CRL or CRLs. The CRLs are used for server certificate verification. Verification fails if a CRL from the CA specifies that the server certificate has been revoked.

b) Enter a valid URL to an existing CRL file and click **Add CRL**.

Repeat to add up to 25 CRLs.

c) Click **Refresh CRL** to load the current CRL or CRLs from the specified URL or URLs.

Step 7 Verify that you have a valid server certificate generated by the same certificate authority that created the client certificate.

Step 8 Click **Save**.

What to do next

(Optional) Set the frequency of CRL updates. Refer to Schedule certificate revocation list (CRL) updates.

View the audit log client certificate on the Cloud-Delivered Firewall Management Center

View the audit log client certificate to confirm its presence and details on the appliance you are logged in to. This helps ensure that audit log operations are secured with the correct certificate.

You can view the audit log client certificate only for the appliance that you are logged in to.

Before you begin

Follow these steps to view the audit log client certificate on the appliance:

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log Certificate**.

The appliance you are logged in to displays the audit log client certificate details. For high availability pairs, only the active peer shows the certificate.

Change reconciliation

A change reconciliation report is a configuration monitoring tool that

- captures snapshots whenever a user saves changes to the system configuration,
- combines information from these snapshots to present a clear summary of recent system changes, and

- provides a detailed report of changes made over the past 24 hours through email.

User change summaries

The change reconciliation report displays both the previous value for each configuration and the value after changes.

Users can view summaries of each distinct change in chronological order, beginning with the most recent.

- Lists both previous and updated values for each configuration.
- Summarizes multiple changes to the same configuration.
- Orders changes chronologically, starting with the most recent.

Change reconciliation report example

An example change reconciliation report includes a User section that lists configuration changes, showing both the previous and updated values for each item.

Non-reconciled changes

Changes made without reconciliation are not summarized or tracked in a report, making it difficult to monitor user activity.

Change reconciliation as a transaction log

Change reconciliation is similar to a transaction log, where each modification is recorded and summarized for review.

Configure change reconciliation

Configure change reconciliation to enable the system to generate and send daily reports of configuration changes, supporting audit and compliance requirements. This helps administrators monitor and review all changes made to the system within a 24-hour period.

Use this task when you need to track and review configuration changes made to your system for security, compliance, or operational awareness.

Change reconciliation is especially useful in environments where multiple administrators make changes or where audit trails are required for regulatory purposes. Perform this configuration after setting up your email server to ensure reports are delivered successfully.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Change Reconciliation**.

Step 3 Check the **Enable** check box.

Step 4 Choose the time of day you want the system to send out the change reconciliation report from the **Time to Run** drop-down lists.

Step 5 Enter email addresses in the **Email to** field.

Tip
Once you have added email addresses, click **Resend Last Report** to send recipients another copy of the most recent change reconciliation report.

Step 6 If you want to include policy changes, check the **Include Policy Configuration** check box.

Step 7 If you want to include all changes over the past 24 hours, check the **Show Full Change History** check box.

Step 8 Click **Save**.

After you complete this task, the system will automatically generate and email daily reports of all configuration changes, allowing you to monitor and review system modifications for compliance and troubleshooting.

Change reconciliation options

The change reconciliation options control whether the system includes records of policy changes and the full change history in the change reconciliation report. These options determine the scope and detail of reported changes.

The **Include Policy Configuration** option controls whether the system includes records of policy changes in the change reconciliation report. It includes changes to access control, intrusion, system, health, and network discovery policies. If you do not select this option, the report will not show changes to any policies. This option is available only on Cloud-Delivered Firewall Management Centers.

The **Show Full Change History** option controls whether the system includes records of all changes over the past 24 hours in the change reconciliation report. If you do not select this option, the report includes only a consolidated view of changes for each category.

Note The change reconciliation report does not include changes to Firewall Threat Defense interfaces and routing settings.

Email notifications

An email notification is a system alert mechanism that enables automated emailing of event-based, status, change reconciliation, and data-pruning reports.

Email notification restrictions for static mail relay hosts

You cannot configure a mail host. TThe mail relay host is hardcoded to a static host. It is set to email-smtp.us-west-2.amazonaws.com with authorization. For notifications, the email sender is set to cdo-alert@cisco.com.

Intrusion policy preferences

An intrusion policy preference is a configuration option that

- enables monitoring of critical policies,
- tracks changes to those policies, and
- supports management of policy settings in a deployment.

Set intrusion policy preferences

Configure intrusion policy preferences to manage how policy changes are tracked, logged, and monitored for security intelligence. You can enable or disable comments on policy changes, audit logging, user overrides for deleted Snort 3 rules, and Talos Threat Hunting Telemetry.

This task is relevant when you need to control how intrusion policy changes are documented, audited, and monitored for advanced threat detection and compliance.

Use this configuration to ensure that policy modifications are properly tracked and that security events are sent to Cisco Talos for analysis when required. Perform this task during initial setup or when updating security and compliance requirements for your deployment.

Before you begin

Follow these steps to set intrusion policy preferences:

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Intrusion Policy Preferences**.

Step 3 You have these options:

- **Comments on policy change**: Check this check box to track policy-related changes using the comment functionality when users modify intrusion policies. With policy change comments enabled, administrators can quickly assess why critical policies in a deployment were modified.

  If you enable comments on policy changes, you can make the comment optional or mandatory. The Cloud-Delivered Firewall Management Center prompts the user for a comment when each new change to a policy is saved.

- **Write changes in Intrusion Policy to audit log**: Check this check box to record the changes to the intrusion policies to the audit logs. This option is enabled by default.

- **Retain user overrides for deleted Snort 3 rules**: Check this check box to get notifications for changes to any *overridden* system-defined rules during LSP updates. When you enable this feature, the system retains the rule overrides in the new replacement rules that are added as part of the LSP update. On the Cloud-Delivered Firewall Management Center menu bar, click **Notifications** (message center). Then click **Tasks** to view the notifications. This option is enabled by default.

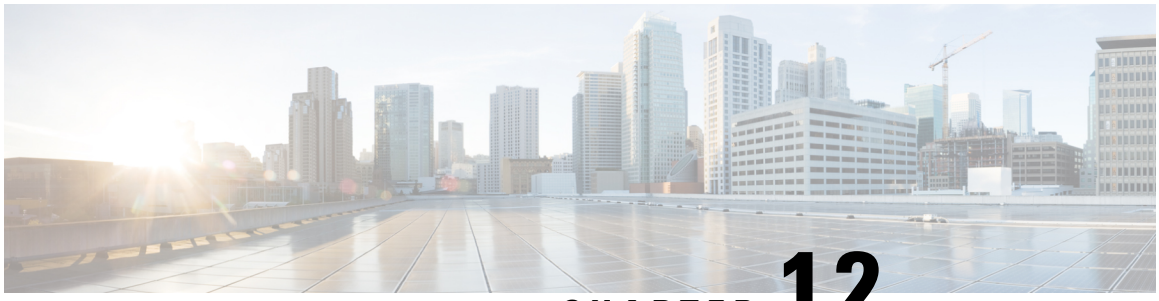
- **Talos Threat Hunting Telemetry**: Check this check box to allow Cisco Talos to conduct threat hunting and to gather critical security intelligence. When enabled, a special set of threat-hunting rules is added to the global intrusion policy. Although the threat-hunting rules are processed like regular IPS rules, events generated by these rules do not appear in the Cloud-Delivered Firewall Management Center's event tables. These events are sent to Talos as telemetry for analysis. This option is enabled by default.

  Note

- If you send firewall events to the Cisco Security Cloud via a direct connection by registering your Cloud-Delivered Firewall Management Center to the cloud tenancy using your Security Cloud Control account, your Security Cloud Control account must have a Security Analytics and Logging license in order to forward threat-hunting rule events to Talos.

After completing this task, your intrusion policy preferences are set according to your selections. Policy changes are tracked, logged, and, if enabled, threat-hunting telemetry is sent to Cisco Talos for analysis.

Network analysis policy preferences



Network analysis policy preferences are configuration settings that enable tracking and documentation of policy modifications within the system.

Policy Change Tracking Options

You can configure the system to track policy-related changes using the comment functionality when users modify network analysis policies. With policy change comments enabled, administrators can quickly assess why critical policies in a deployment were modified.

If you enable comments on policy changes, you can make the comment optional or mandatory. The system prompts the user for a comment when each new change to a policy is saved.

Optionally, you can have changes to network analysis policies written to the audit log.

CHAPTER 12

Users

The Cloud-Delivered Firewall Management Center includes default **admin** accounts for web and CLI access. This chapter discusses how to create custom user accounts.

- CLI users, on page 243
- Create a User Record with Your Security Cloud Control Username, on page 246
- External authentication configuration for Cloud-Delivered Firewall Management Center, on page 247
- Troubleshoot LDAP authentication connections, on page 261
- Configure User Preferences, on page 261

CLI users

A CLI user is a user account that

- can be added as internal users or as external users on a LDAP or RADIUS server,
- is maintained separately on each managed device, and
- requires separate configuration for access to the Cloud-Delivered Firewall Management Center versus managed devices.

User account separation

When you add a user to the Cloud-Delivered Firewall Management Center, that user only has access to the Cloud-Delivered Firewall Management Center; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and external users

Managed devices support two categories of users—internal and external—for user access control.

Internal users authenticate through a local database on the device. External users authenticate through LDAP or RADIUS servers when they are not found in the local database. Both user types enable secure access management for network devices.

User authentication types

Managed devices support these user authentication methods:

- Internal user: The device checks a local database for user authentication.
- External user: If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

User roles

Web Interface User Roles

There are a variety of user roles in Security Cloud Control (Security Cloud Control): Read-Only, Edit-Only, Deploy-only, Admin, and Super Admin. User roles are configured for each user on each tenant. If a Security Cloud Control user has access to more than one tenant, they may have the same user ID but different roles on different tenants. A user may have a read-only role on one tenant and a Super Admin role on another. When the interface or the documentation refers to a Read-only user, Deploy Only, Edit Only, an Admin user, or a Super Admin user we are describing that user's permission level on a particular tenant. Note that you cannot create user roles in the Cloud-Delivered Firewall Management Center because it uses Security Cloud Control user roles.

Read Only

Read Only users can view all device configurations but cannot change them.

Deploy Only

Deploy Only users can audit queued changes made to device configurations and deploy them but cannot change them.

Edit Only

Edit Only users can make changes to all device configurations but cannot deploy them to devices.

Super Admin and Admin

Super Admin and Admin users can access everything in the product. As a Super Admin, you can create accounts for other users on a tenant and modify existing user roles. As an Admin, you cannot create accounts or modify user roles.

For more information about user roles in Security Cloud Control, refer to User Roles.

This table shows the mapping of user roles in On-Premises Firewall Management Center to their equivalent roles in the cloud-delivered Firewall Management Center in Security Cloud Control.

Tip We recommend that you read through the table only if you are familiar with the user roles in On-Premises Firewall Management Center.

Table 12: Secure Firewall Management Center and Cloud-Delivered Firewall Management Center User Role Mapping

On-Premises Firewall Management Center User Role	Equivalent Cloud-Delivered Firewall Management Center User Role	Capabilities
Access Admin, Discovery Admin, Intrusion Admin, Maintenance User	Edit Only	You can search, filter, or view these: • Access control policies and associated features • Intrusion policies • Intrusion rules • Network discovery rules • Custom detectors • Correlation policies • Objects • Rulesets • Interfaces • VPN configurations • Monitoring- and maintenance-related settings You can back up or restore a device but cannot deploy policies to the devices.
Administrator	Super Admin	You can access all features of the Cloud-Delivered Firewall Management Center and perform tasks, including create, read, modify, or delete policies or objects and deploy those changes to the devices. You can also edit user roles or create user records in Security Cloud Control.
Network Admin	Admin	You can access all features of the cloud-delivered Firewall Management Center and perform tasks, including create, read, modify, or delete policies or objects and deploy those changes to the devices. However, you cannot edit user roles or create user records in Security Cloud Control.

On-Premises Firewall Management Center User Role	Equivalent Cloud-Delivered Firewall Management Center User Role	Capabilities
Security Analyst, Security Analyst (Read Only)	Read Only	You can view device information, policies, objects, and their related settings but cannot do these: • Create or edit objects • Create or edit policies • Modify device configurations • Backup or restore devices
Security Approver	Deploy Only	You can view most settings and deploy staged changes to devices but cannot create or modify objects or policies.

Create a User Record with Your Security Cloud Control Username

Only a Security Cloud Control user with **Super Admin** privileges can create the Security Cloud Control user record. The **Super Admin** must create the user record with the same email address that was specified in the **Create Your Security Cloud Control Username** task above.

Use the following procedure to create a user record with an appropriate user role:

Procedure

Step 1 Login to Security Cloud Control.

Step 2 In the left pane, choose **Settings** > **User Management**.

Step 3 Click  to add a new user to your tenant.

Step 4 Provide the email address of the user.

Note
The user's email address must correspond to the email address of the Cisco Secure Log-On account.

Step 5 From the **Role** drop-down list, select the user's role.

Step 6 Click **OK**.

External authentication configuration for Cloud-Delivered Firewall Management Center

An external authentication configuration is a security setup that

- adds one or more external authentication objects,
- enables users to authenticate through external identity providers, and
- replaces local credential authentication with external authentication.

External authentication objects for Cloud-Delivered Firewall Management Center

An external authentication object is a security configuration element that

- enables the Cloud-Delivered Firewall Management Center to verify user credentials with LDAP or RADIUS servers,
- supports multiple objects for web interface access, allowing users from any configured object to authenticate, and
- restricts CLI access to a single external authentication object, permitting authentication only through the first object in the list.

External authentication objects can be used by the Cloud-Delivered Firewall Management Center and Firewall Threat Defense devices. You can either share the same object across different devices or create distinct objects for each device type.

For the Cloud-Delivered Firewall Management Center, enable the external authentication objects directly on the **System** (⚙) > **Users** > **External Authentication** tab. This setting affects only Cloud-Delivered Firewall Management Center usage. You do not need to enable it on this tab for managed device usage. For Firewall Threat Defense devices, enable the external authentication object in the platform settings that you deploy to the devices.

Define web interface users and CLI users separately in the external authentication object. For RADIUS, pre-configure the list of CLI usernames in the object. For LDAP, set up a filter on the LDAP server to match CLI users.

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges. This access creates a security risk. Make sure you:

- Restrict the list of users with CLI or Linux shell access.
- Do not create Linux shell users.

If you have five external authentication objects configured for web interface access, users from any of them can be authenticated to access the web interface. For CLI access, only the first external authentication object in the list is used for authentication.

You cannot use an LDAP object for CLI access if it is also configured for CAC authentication.

An external authentication object functions as a control point, permitting access only to users with valid credentials from specified sources.

LDAP

The Lightweight Directory Access Protocol (LDAP) is a directory service protocol that allows you to set up a directory on your network that organizes objects, such as user credentials, in a centralized location. Multiple applications can then access those credentials and the information used to describe them. If you ever need to change a user's credentials, you can change them in one place.

LDAP binding information

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, refer to 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

If you have not done so already, we recommend you start using TLS/SSL encryption to authenticate with an Active Directory server.

RADIUS

RADIUS is a network authentication protocol that

- provides centralized authentication and authorization for network access,
- operates using client-server architecture for user credential verification, and
- supports accounting functions to track user sessions and network usage.

Remote Authentication Dial In User Service (RADIUS) is an authentication protocol used to authenticate, authorize, and account for user access to network resources. You can create an authentication object for any RADIUS server that conforms to RFC 2865.

Secure Firewall devices support the use of SecurID tokens. When you configure authentication by a server using SecurID, users authenticated against that server append the SecurID token to the end of their SecurID PIN and use that as their password when they log in. You do not need to configure anything extra on the Secure Firewall device to support SecurID.

By default, RADIUS uses port 1812 for authentication and port 1813 for accounting.

If you change the RADIUS authentication port, the RADIUS accounting port changes accordingly. Ensure that the Cloud-Delivered Firewall Management Center can connect to the RADIUS server on the new accounting port; otherwise, authentication delays may occur.

Although you cannot configure RADIUS accounting parameters, the Firewall Threat Defense uses port 1813 for RADIUS accounting on the same server used for authentication. If the RADIUS server is unreachable on port 1813, it can cause delays in logging in.

Add an LDAP external authentication object for the Security Cloud Control

Add an LDAP server to support external users for device management.

Before you begin

- You must specify DNS server(s) for domain name lookup on your device. Even if you specify an IP address for the LDAP server during this procedure, the server may return a URI for authentication that includes a hostname. A DNS lookup is required to resolve the hostname.
- If you are configuring an LDAP authentication object for use with CAC authentication, do not remove the CAC from your computer. You must have a CAC inserted at all times after enabling user certificates.

Procedure

Step 1 Choose a **Server Type** from the drop-down list.

Tip
If you click **Set Defaults** , the device populates the **User Name Template** , **UI Access Attribute** , **CLI Access Attribute** , **Group Member Attribute** , and **Group Member URL Attribute** fields with default values for the server type.

Step 2 For the **Primary Server**, enter a **Host Name/IP Address**. If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections. Now, change the **Port** from the default and enter the **Backup Server** parameters and **LDAP-Specific Parameters**.

a) Enter the **Base DN** for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com` . Alternatively click **Fetch DNs** , and choose the appropriate base distinguished name from the drop-down list.

b) (Optional) Enter the **Base Filter** . For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)` .

If you are using CAC authentication, to filter only active user accounts (excluding the disabled user accounts), enter `(!(userAccountControl:1.2.840.113556.1.4.803:=2))` . This criteria retrieves user accounts within AD belonging to `ldpgrp` group and with `userAccountControl` attribute value that is not `2` (disabled).

c) Enter a **User Name** for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at your example company has a `uid` value of `NetworkAdmin` , you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com.`

d) Enter the user password in the **Password** and the **Confirm Password** fields.

e) (Optional) Click **Show Advanced Options** to configure these advanced options.

- **Encryption** —Click **None** , **TLS** , or **SSL** .

  If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS** , the port resets to the default value of 389

  - **None** — LDAP communication is unencrypted.

- **TLS** — LDAP communication is upgraded to TLS using the STARTTLS operation on default port 389
- **SSL** — LDAP communication is encrypted using TLS immediately upon connection (LDAPS) on default port 636.

- **SSL Certificate Upload Path** —For SSL or TLS encryption, click **Choose File** and choose the complete CA chain certificate.

  Note
  Do not choose a binary certificate (PKCS12, DER, and alike) file because Firewall Threat Defense does not support them.

  To remove the uploaded certificate, check the **Clear loaded certificate** check box. This option only appears when you have uploaded a certificate, and when you are in the Edit mode of the external authentication object.

  If you had previously uploaded a certificate and want to replace it, reupload the new certificate (complete CA chain), and redeploy the configuration to your devices to copy over the new certificate.

  Note
  TLS encryption requires a certificate on all platforms. We recommend that you **always** upload a certificate for SSL to prevent adversary-in-the-middle attacks.

- **User Name Template** —Provide a template that corresponds with your **UI Access Attribute** . For example, to authenticate all users who work in the Security organization of the Example company by connecting to an OpenLDAP server where the UI access attribute is `uid` , you might enter `uid=%s,ou=security,dc=example,dc=com` in the **User Name Template** field. For a Microsoft Active Directory server, you could enter `%s@security.example.com` .

  This field is required for CAC authentication.

- **Shell User Name Template** —Provide a template that corresponds with your **CLI Access Attribute** to authenticate CLI users. For example, to authenticate all users who work in the Security organization by connecting to an OpenLDAP server where the CLI access attribute is `sAMAccountName` , you might enter `%s` in the **Shell User Name Template** field.

- **Timeout (Seconds)** —Enter the number of seconds before rolling over to the backup connection, between 1 and 1024. The default is 30.

  Note
  The timeout range is different for Firewall Threat Defense and the Cloud-Delivered Firewall Management Center , so if you share an object, be sure not to exceed the Firewall Threat Defense 's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the Firewall Threat Defense LDAP configuration will not work.

Step 3 Configure **Attribute Mapping** to retrieve users based on an attribute.

- Enter a **UI Access Attribute** , or click **Fetch Attrs** to retrieve a list of available attributes. For example, on a Microsoft Active Directory Server, you may want to use the UI access attribute to retrieve users, because there may not be a `uid` attribute on Active Directory Server user objects. Instead, you can search the `userPrincipalName` attribute by typing `userPrincipalName` in the **UI Access Attribute** field.

- Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` CLI access attribute to retrieve CLI access users by typing `sAMAccountName` .

Step 4 (Optional) Configure **Group Controlled Access Roles**.

If you do not configure a user's privileges using group-controlled access roles, a user has only the privileges granted by default in the external authentication policy.

a) (Optional) In the fields that correspond to user roles, enter the distinguished name for the LDAP groups that contain users who should be assigned to those roles.

Any group you reference must exist on the LDAP server. You can reference static LDAP groups or dynamic LDAP groups. Static LDAP groups are groups where membership is determined by group object attributes that point to specific users, and dynamic LDAP groups are groups where membership is determined by creating an LDAP search that retrieves group users based on user object attributes. Group access rights for a role only affect users who are members of the group.

If you use a dynamic group, the LDAP query runs exactly as it is configured on the LDAP server. To prevent infinite loops caused by search syntax errors, the device limits recursions of a search to four.

Example:

Enter this in the **Administrator** field to authenticate names in the information technology organization at the Example company:

```
cn=itgroup,ou=groups, dc=example,dc=com
```

b) Choose a **Default User Role** for users that do not belong to any of the specified groups.

c) If you use static groups, enter a **Group Member Attribute** .

Example:

If the `member` attribute is used to indicate membership in the static group for default Security Analyst access, enter `member` .

d) If you use dynamic groups, enter a **Group Member URL Attribute** .

Example:

If the `memberURL` attribute contains the LDAP search that retrieves members for the dynamic group you specified for default Admin access, enter `memberURL` .

Step 5 (Optional) Set the **CLI Access Filter** to allow CLI users.

To prevent LDAP authentication of CLI access, leave this field blank. To specify CLI users, choose one of these methods:

- To use the same filter you specified when configuring authentication settings, check the check box of **Same as Base Filter** .
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell` , you can set a base filter of `(manager=shell)` .

The usernames must be Linux-valid:

- Maximum 32 alphanumeric characters, plus period (.), hyphen (-), and underscore (_)

- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include at sign (@) or slash (/)

Note
Users with CLI access can gain Linux shell access with the **expert** command. "Linux shell users can obtain root privileges, which presents a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note
Do not create any internal users that have the same user name as users included in the **CLI Access Filter**. The only internal Cloud-Delivered Firewall Management Center user should be **admin** ; do not include an **admin** user in the **CLI Access Filter**.

Step 6 (Optional) Click **Test** to test connectivity to the LDAP server.

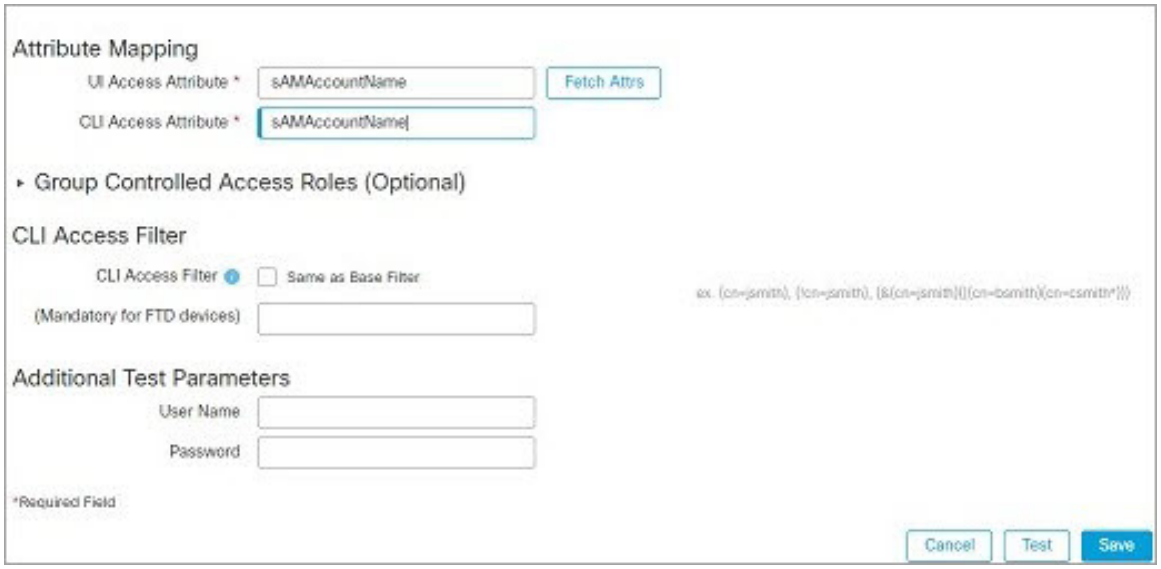
The test output lists valid and invalid user names. Valid user names are unique, and can include underscores (_), periods (.), hyphens (-), and alphanumeric characters. Note that testing the connection to servers with more than 1000 users only returns 1000 users because of UI page size limitations. If the test fails, refer to Troubleshoot LDAP authentication connections, on page 261 .

Step 7 (Optional) You can also enter **Additional Test Parameters** to test user credentials for a user who should be able to authenticate: enter a **User Name** `uid` and **Password** , and then click **Test**. Click **Save**. Enable use of this server. Refer to Enable external authentication for users on the CDO.

If you are connecting to a Microsoft Active Directory Server and supplied a UI access attribute in place of `uid` , use the value for that attribute as the user name. You can also specify a fully qualified distinguished name for the user.

Tip
If you mistype the name or password of the test user, the test fails even if the server configuration is correct. To verify that the server configuration is correct, click **Test** without entering user information in the **Additional Test Parameters** field first. If that succeeds, supply a user name and password to test with the specific user.

Example:



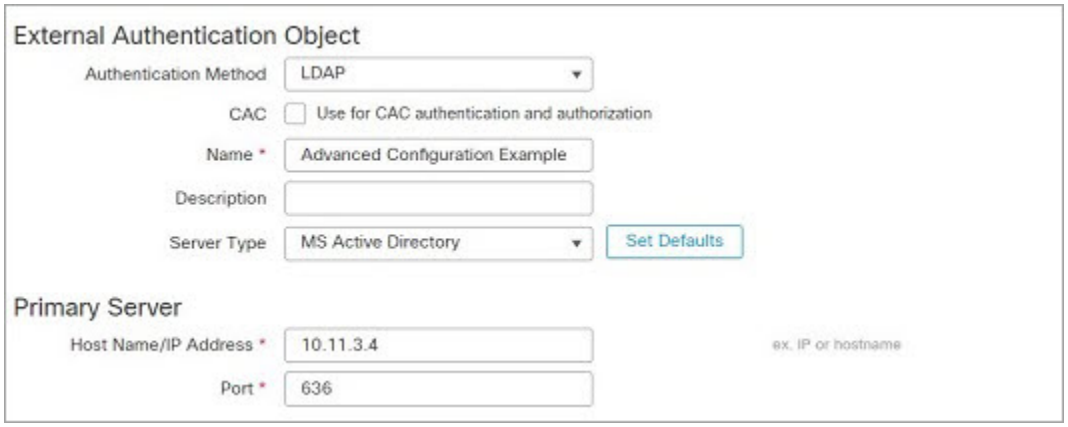
To test if you can retrieve the `JSmith` user credentials at the Example company, enter `JSmith` and the correct password.

Examples

Basic Example

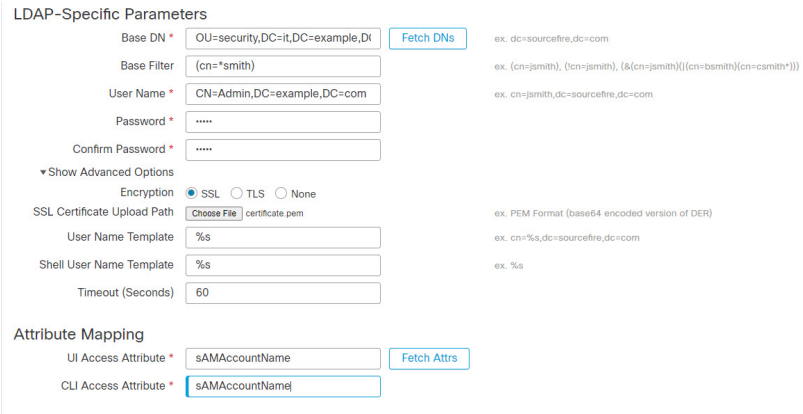
This figures illustrate a basic configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 389 for access.

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company.



However, because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute. Choosing the MS Active Directory server type and clicking **Set Defaults** sets the UI Access Attribute to `sAMAccountName` . As a result, the system checks the `sAMAccountName` attribute for each object for matching user names when a user attempts to log into the system.

In addition, a **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into a CLI account on the appliance.

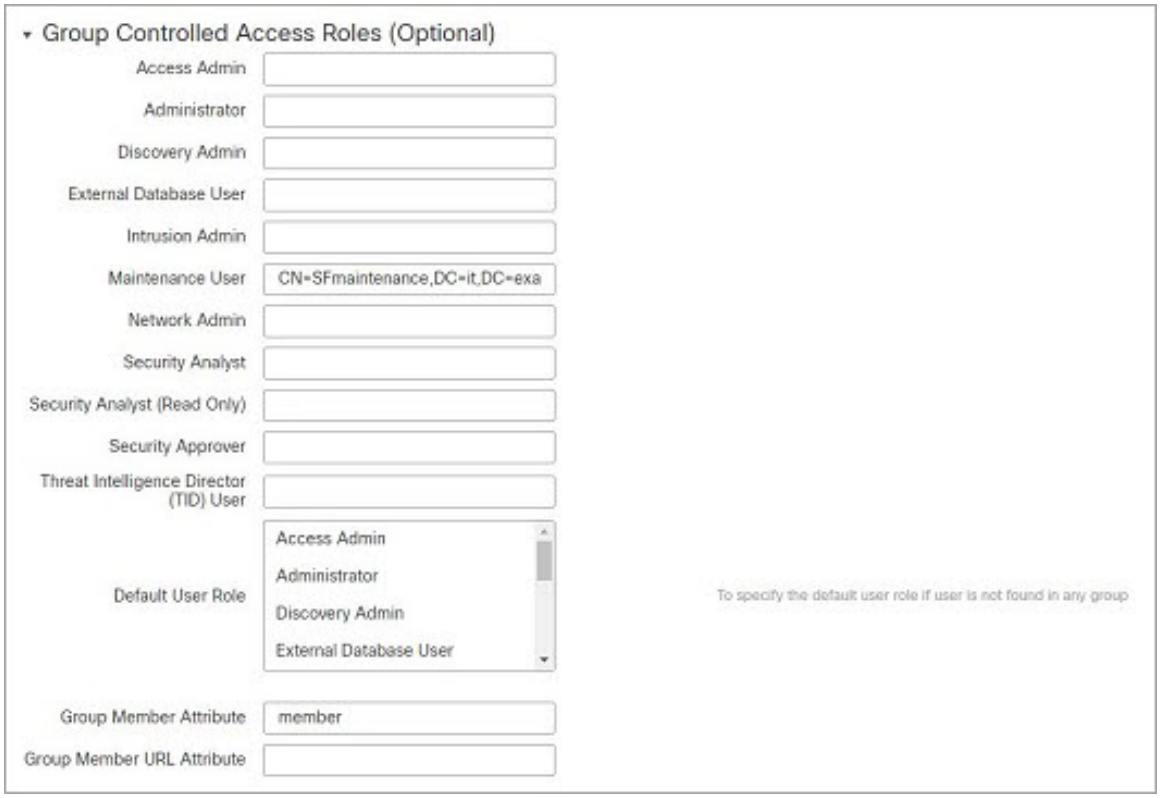


Note that because no base filter is applied to this server, the system checks attributes for all objects in the directory indicated by the base distinguished name. Connections to the server time out after the default time period (or the timeout period set on the LDAP server).

Advanced Example

This example illustrates an advanced configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 636 for access.

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company. However, note that this server has a base filter of `(cn=*smith)` . The filter restricts the users retrieved from the server to those with a common name ending in `smith` .



The connection to the server is encrypted using SSL and a certificate named `certificate.pem` is used for the connection. In addition, connections to the server time out after 60 seconds because of the **Timeout (Seconds)** setting.

Because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute. Note that the configuration includes a **UI Access Attribute** of `sAMAccountName` . As a result, the system checks the `sAMAccountName` attribute for each object for matching user names when a user attempts to log into the system.

In addition, a **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into a CLI account on the appliance.

This example also has group settings in place. The Maintenance User role is automatically assigned to all members of the group with a `member` group attribute and the base domain name of `CN=SFmaintenance,DC=it,DC=example,DC=com` .

The **CLI Access Filter** is set to be the same as the base filter, so the same users can access the appliance through the CLI as through the web interface.

Add a RADIUS external authentication object for Security Cloud Control

Add a RADIUS server to support external users for device management.

Note that supports only these six attributes in the access request of the RADIUS authentication:

- `NAS-IP-Address` : Used in UI and CLI authentication
- `NAS-Identifier` : Used in CLI authentication
- `NAS-Port` : Used in UI and CLI authentication

- `NAS-Port-Type` : Used in CLI authentication
- `Service-Type` : Used in UI and CLI authentication
- `Calling-Station-Id` : Used in CLI authentication

Note

- `NAS-Port` attribute: The attribute value is dynamically generated and cannot be configured.
- `NAS-Port-Type` attribute: The server always sets the attribute value to `Virtual`, regardless of whether the device is virtual or physical. of whether the is virtual or physical.
- `NAS-Identifier` attribute: The attribute value is always `sshd`.
- `Service-Type` attribute: supports only `Login` and `Authenticate Only` service types

Procedure

Step 1 Choose **System** (⚙) > **Users** and click **External Authentication**.

Step 2 Click **Add icon** (+). In the **Add External Authentication Object** window, set the **Authentication Method** to **RADIUS**, and enter a unique **Name** and optional **Description**.

Step 3 Check the **RADIUS Server-Enabled Message Authenticator** check box. This requires the Message-Authenticator attribute in all RADIUS responses and ensures that every response from the RADIUS server is securely verified by the Firewall Threat Defense.

The feature is enabled by default for new RADIUS servers. Enable it for existing servers after the upgrade. Enable message authenticators to protect your firewalls from potential attacks. Ensure that your RADIUS server has the Message-Authenticator configuration.

Note
The Message-Authenticator attribute persists whether the feature is enabled or disabled. The server always requires this attribute. When the check box is enabled in the configuration, it also becomes a requirement from the Cloud-Delivered Firewall Management Center.

Step 4 For the **Primary Server**, enter a **Host Name/IP Address**. Then, change the **Port** from the default and then enter the **RADIUS Secret Key**.

Step 5 (Optional) Enter the **Backup Server** parameters, then provide the **RADIUS-Specific Parameters**.

a) Enter the **Timeout** in seconds before retrying the primary server, between 1 and 1024. The default is 30.
b) Enter the **Retries** before rolling over to the backup server. The default is 3.
c) In the fields that correspond to user roles, enter the name of each user or identifying attribute-value pair that should be assigned to those roles.

Separate usernames and attribute-value pairs with commas.

Example:

If you know all users who should be Security Analysts have the value `Analyst` for their `User-Category` attribute, you can enter `User-Category=Analyst` in the **Security Analyst** field to grant that role to those users.

Example:

To grant the Administrator role to the users `jsmith` and `jdoe`, enter `jsmith, jdoe` in the **Administrator** field.

Example:

To grant the Maintenance User role to all users with a `User-Category` value of `Maintenance`, enter `User-Category=Maintenance` in the **Maintenance User** field.

d) Select the **Default User Role** for users that do not belong to any of the specified groups.

After you change a user's role, save and deploy the updated external authentication object. Remove the user from the **Users** screen. The system adds the user when they log in again.

Step 6 (Optional) **Define Custom RADIUS Attributes**.

If your RADIUS server returns values for attributes not included in the `dictionary` file in `/etc/radiusclient/`, define those attributes. You must define them if you plan to use the attributes to set roles for users.You can locate the attributes returned for a user by looking at the user's profile on your RADIUS server.

Note
Before you configure custom RADIUS attributes, obtain the Attribute ID and Type from the RADIUS server administrator. If there is a mismatch, the RADIUS packet capture displays the custom RADIUS attribute as `Unassigned Attribute`.

a) Enter an **Attribute Name**.

Enter an attribute name using alphanumeric characters. Separate words in an attribute name with dashes instead of spaces.

b) Enter the **Attribute ID** as an integer.

Enter an integer for the attribute ID. Make sure the attribute ID does not conflict with any existing IDs in the `etc/radiusclient/dictionary` file.

c) Choose the **Attribute Type** from the drop-down list.

You also specify the type of attribute: string, IP address, integer, or date.

d) Click **Add** to add the custom attribute.

When you create a RADIUS authentication object, a new dictionary file for that object is created on the device in the `/var/sf/userauth` directory. Any custom attributes you add are added to the dictionary file.

Example:

If a RADIUS server is used on a network with a Cisco router, you might want to use the `Ascend-Assign-IP-Pool` attribute to grant a specific role to all users logging in from a specific IP address pool. `Ascend-Assign-IP-Pool` is an integer attribute that defines the address pool where the user is allowed to log in, with the integer indicating the number of the assigned IP address pool.

To declare that custom attribute, you create a custom attribute with an attribute name of `Ascend-IP-Pool-Definition`, an attribute ID of `218`, and an attribute type of `integer`.

You could then enter `Ascend-Assign-IP-Pool=2` in the **Security Analyst (Read Only)** field to grant read-only security analyst rights to all users with an `Ascend-IP-Pool-Definition` attribute value of `2`.

Step 7 (Optional) In the **CLI Access Filter** area **Administrator CLI Access User List** field, enter the usernames that should have CLI access, separated by commas.

Enter usernames that match those on the RADIUS server. Usernames must be valid Linux usernames:

- Maximum of 32 alphanumeric characters, plus period (.), hyphen (-), and underscore (_).

  (_)

- All letters must be lowercase.
- "The username cannot start with a hyphen (-), cannot be composed entirely of numbers, and cannot include an at sign (@) or a slash (/).

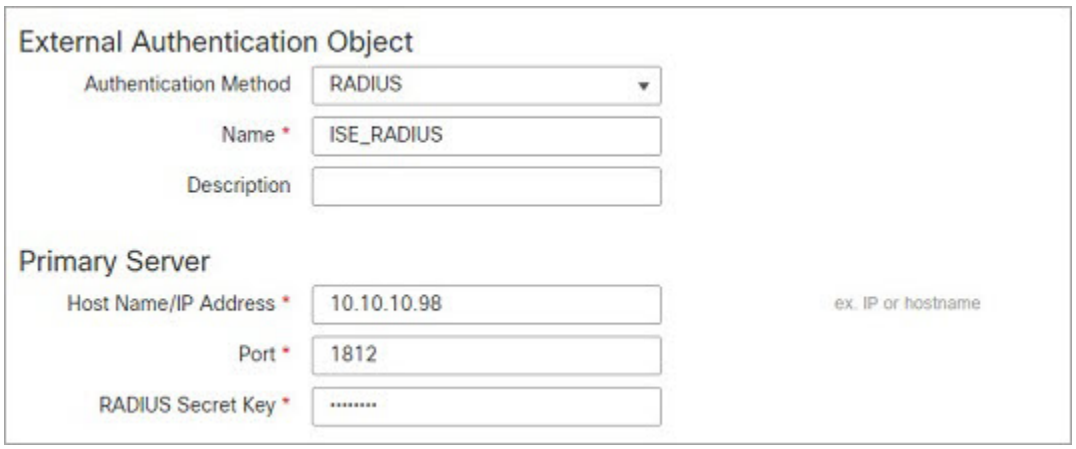
Leave the field blank to disable RADIUS authentication for CLI access.

Note
Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note
Remove any internal users that have the same user name as users included in the shell access filter. For the Cloud-Delivered Firewall Management Center, the only internal CLI user is **admin**, so do not also create an **admin** external user.

Step 8 (Optional) Click **Test** to test Cloud-Delivered Firewall Management Center connectivity to the RADIUS server.

Step 9 (Optional) You can also enter **Additional Test Parameters** to test user credentials for a user who should be able to authenticate: enter a **User Name** and **Password**, and then click **Test**. Click **Save**. For more information, refer to Enable external authentication for users on the CDO.



Tip
If you mistype the name or password of the test user, the test fails even if the server configuration is correct. To verify that the server configuration is correct, click **Test** without entering user information in the **Additional Test Parameters** field first. If that succeeds, supply a user name and password to test with the specific user.

Example:

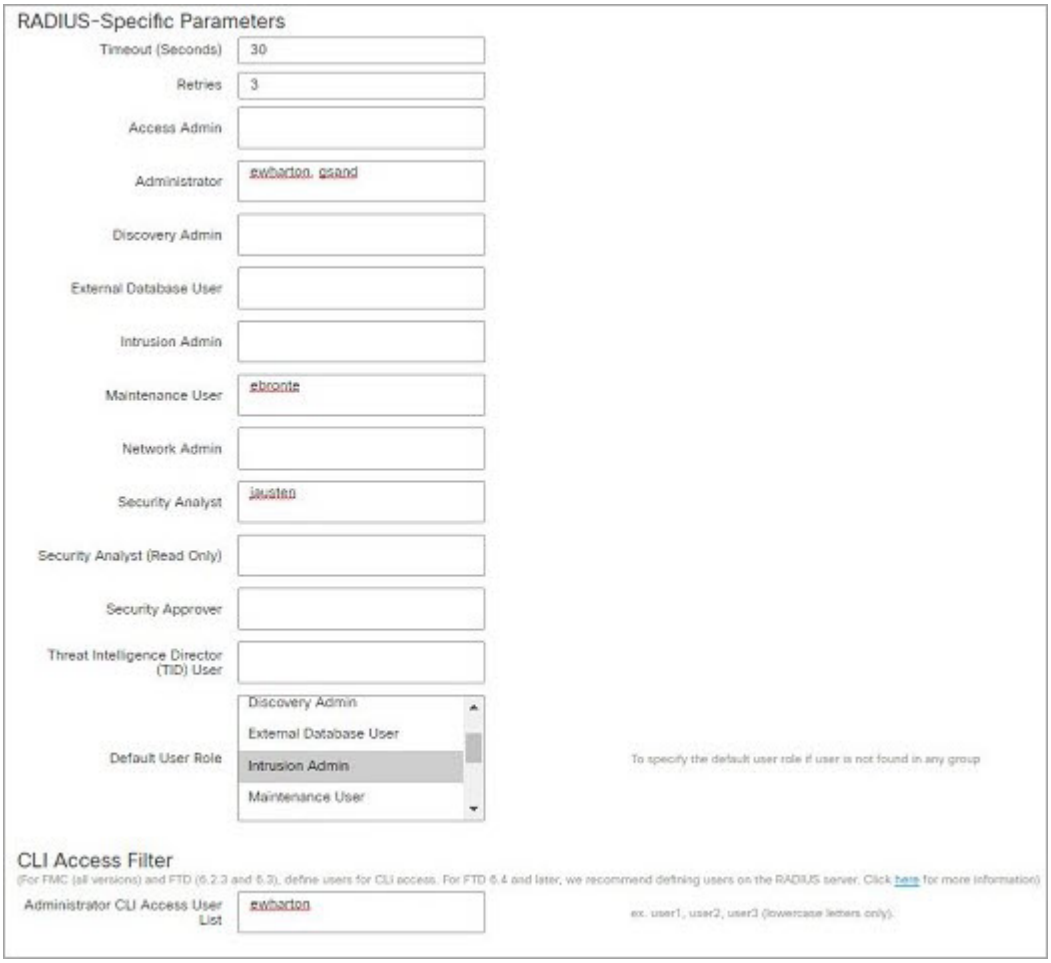
To test if you can retrieve the `JSmith` user credentials at the Example company, enter `JSmith` and the correct password.

Simple user role assignments

This figure illustrates a sample RADIUS login authentication object for a server running Cisco Identity Services Engine (ISE) with an IP address of 10.10.10.98 on port 1812. No backup server is defined.

This example shows RADIUS-specific parameters, including the timeout (30 seconds) and number of failed retries before the Secure Firewall System attempts to contact the backup server, if any.

This example illustrates important aspects of RADIUS user role configuration:



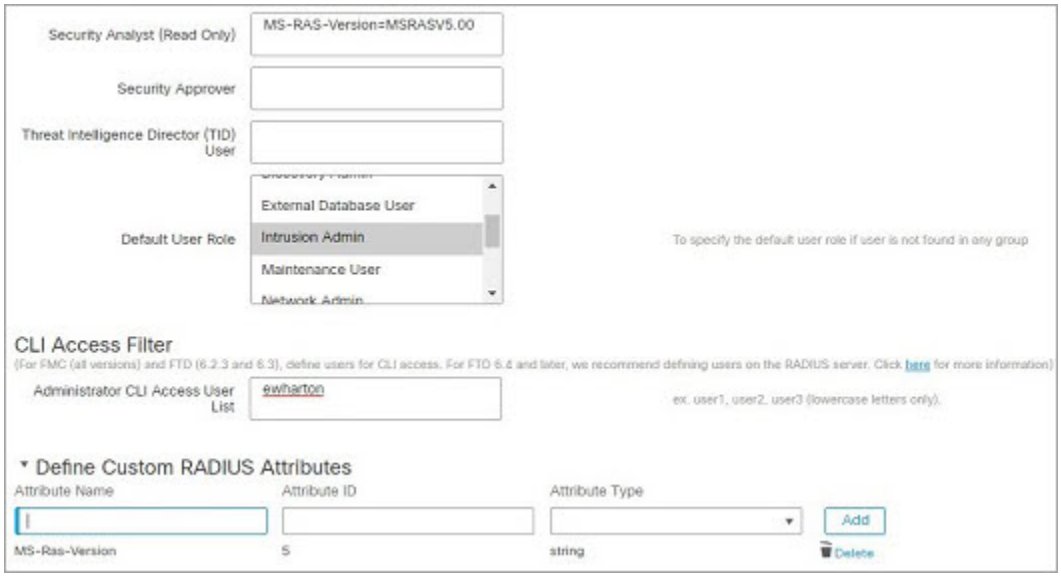
Users `ewharton` and `gsand` are granted web interface Administrative access.

The user `cbronte` is granted web interface Maintenance User access.

The user `jausten` is granted web interface Security Analyst access.

The user `ewharton` can log into the device using a CLI account.

This graphic depicts the role configuration for the example:



Roles for users matching an attribute-value pair

You can use an attribute-value pair to identify users who should receive a particular user role. If the attribute you use is a custom attribute, you must define the custom attribute.

This figure illustrates the role configuration and custom attribute definition in a sample RADIUS login authentication object for the same ISE server as in the previous example.

In this example, however, the `MS-RAS-Version` custom attribute is returned for one or more of the users because a Microsoft remote access server is in use. Note the `MS-RAS-Version` custom attribute is a string. In this example, all users logging in to RADIUS through a Microsoft version 5.00 remote access server should receive the Security Analyst (Read Only) role, so you enter the attribute-value pair of `MS-RAS-Version=MSRASV5.00` in the **Security Analyst (Read Only)** field.

Troubleshoot LDAP authentication connections

This reference explains how to troubleshoot LDAP authentication connection issues, identify common failure causes, and apply solutions to restore communication between Cisco devices and LDAP servers.

Configure User Preferences

Depending on your user role, you can specify certain preferences for your user account.

Change the web interface appearance

Change the web interface appearance by choosing from available themes or enable new design options for the light theme variant.

You can change the way the web interface appears when you are using the light theme. Theme options and design toggles may vary based on your system version and available features.

Before you begin

Follow these steps to change the web interface appearance:

Procedure

Step 1 From the drop-down list under your username, choose **User Preference**.

Step 2 Under **Light theme variant**, click the **Use new design** toggle button to enable or disable the new design.

Enable the toggle to use the left navigation menu and disable it to use the top navigation menu.

Note
This toggle works only if you are using the light theme. If you want to switch between dark theme and light theme, you must do this from the **General Preference** page in Security Cloud Control. For more information, refer to Change the Security Cloud Control Web Interface Appearance.

The web interface appearance changes according to your selected theme or design preference, providing a personalized and comfortable user experience.

Set your default time zone

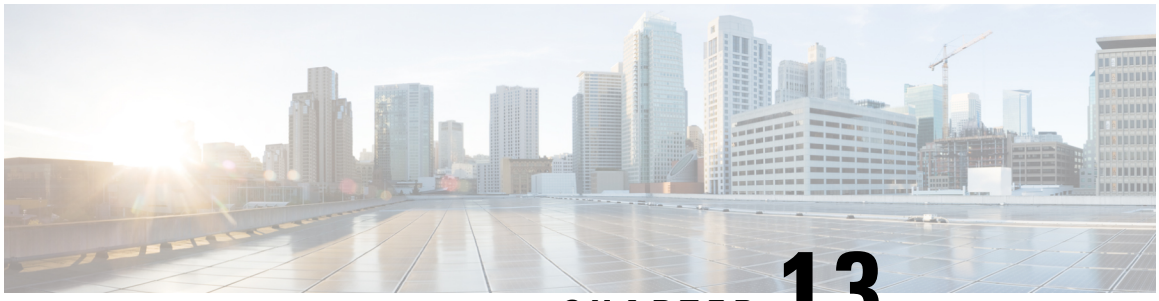
Set your default time zone so that all times shown in the web interface for your user account reflect your local time preferences. This helps you view scheduled tasks and dashboards in your preferred time zone.

This setting determines the times displayed in the web interface for your user account, such as for task scheduling and dashboard viewing. It does not change the system time, affect other users, or modify data stored in the system, which generally uses UTC.

- The Time Zone function in User Preferences assumes that the system clock is set to UTC. Do not change the system time. Changing the system time from UTC is not supported and will require reimaging the device to recover from an unsupported state.
- This feature does not affect the time zone used for time-based policy application. Set the time zone for a device in **Devices** > **Platform Settings**.

Before you begin

Follow these steps to set your default time zone:



Procedure

Step 1 From the drop-down list under your user name, choose **User Preferences**.

Step 2 Click the **TIME Zone** drop-down list.

Step 3 Choose the continent or country and the state name that corresponds with the time zone you want to use.

After completing these steps, your user account will display times in the web interface according to your selected time zone. System time and other users are not affected.

CHAPTER 13

Updates

- Content updates, on page 263
- Product upgrades, on page 264
- Guidelines for content updates, on page 264
- Vulnerability database (VDB) updates, on page 264
- Geolocation database (GeoDB) updates, on page 266
- Intrusion rule updates, on page 268

Content updates

Content updates keep your deployment current with changing security and contextual information. The system uses this information to evaluate network activity and respond to changes in the threat landscape. Automatic content updates are often enabled by initial configuration or when you enable the related feature.

Types of content updates

Cloud-Delivered Firewall Management Center uses these types of content updates:

- Vulnerability database (VDB): A database of known vulnerabilities to which hosts may be susceptible, as well as fingerprints for operating systems, clients, and applications. The system uses the VDB to help determine whether a particular host increases your risk of compromise.

  Refer to Vulnerability database (VDB) updates, on page 264.

- Geolocation database (GeoDB): Maps IP addresses to countries and continents.

  Refer to Geolocation database (GeoDB) updates, on page 266.

- Intrusion rules (LSP/SRU): Intrusion rule updates provide new and updated intrusion and preprocessor rules and can modify rule states, categories, variables, and default policy settings.

  Refer to Intrusion rule updates, on page 268.

- Security Intelligence feeds: Collections of IP addresses, domain names, and URLs used to filter matching traffic.

  Refer to List and feed updates for security intelligence feeds, on page 3025.

- URL categories and reputations: Classification and risk information used to control access to websites.

  Refer to Enable URL filtering using category and reputation, on page 2096.

Product upgrades

This guide does not include procedures for upgrading firewall software or chassis. Instead, refer to the Secure Firewall Threat Defense upgrade guides for Cloud-Delivered Firewall Management Center.

Guidelines for content updates

These guidelines apply to all content updates. Refer to the topics for each update type for update-specific guidance.

Release information

Read any release notes or advisory text that accompanies a content update. This information describes compatibility, prerequisites, new capabilities, behavior changes, and warnings.

When to perform content updates

Follow these guidelines when performing and scheduling content updates:

- Scheduled updates: Review scheduled updates to make sure they run at the right time for your environment.
- Traffic inspection and flow: Perform updates that might interrupt traffic during maintenance windows.

Content updates are scheduled in Coordinated Universal Time (UTC), which remains constant year-round. Scheduled updates do not adjust automatically for local time changes, such as daylight saving time or summer time. For example, an update scheduled for 2:00 a.m. during standard time runs at 3:00 a.m. after the local clock moves forward.

Vulnerability database (VDB) updates

The VDB is a database of known vulnerabilities to which hosts may be susceptible, as well as fingerprints for operating systems, clients, and applications. The system uses the VDB to help determine whether a particular host increases your risk of compromise.

VDB versions

We periodically release VDB updates. Each update replaces the previous version.

Starting with VDB 357, you can install an earlier VDB as far back as the baseline VDB for Cloud-Delivered Firewall Management Center.

VDB update duration

The time required to update the VDB and its associated mappings on the Cloud-Delivered Firewall Management Center depends on the number of hosts in your network map. Allow approximately one minute for every 1000 hosts.

Scheduled VDB updates

Initial configuration automatically downloads and installs the latest VDB as a one-time operation and creates a weekly task to download future updates. Review the schedule and adjust as needed. To update the VDB and deploy configurations automatically, create separate tasks. For more information, refer to Scheduling, on page 471.

Deployment after VDB updates

Deploy configuration changes after a VDB update for updated application detectors and operating system fingerprints to take effect. Updated vulnerability information takes effect without deploy.

Caution The first deploy after a VDB update usually restarts Snort because updated application detectors and operating system fingerprints require a restart. Restarting Snort briefly interrupts traffic flow and inspection on all devices, including those configured for high availability or scalability. Interface configurations determine whether traffic drops or passes without inspection during the interruption. When you deploy without restarting Snort, resource demands may result in a small number of packets dropping without inspection.

VDB release information

For VDB 343 and later, Cisco Secure Firewall Application Detectors provides searchable application detector information. The release notes describe changes in each VDB release.

VDB lite

For the Secure Firewall 220, the system installs a smaller VDB (also called VDB lite). This smaller VDB contains the same applications, but fewer detection patterns. Devices using the smaller VDB can miss some application identification versus devices using the full VDB.

Manually update the VDB

Perform an on-demand update to keep the VDB current or to install an older VDB.

Before you begin

If you are installing an older VDB, download it manually from https://www.cisco.com/go/firepower-software. Choose any Cloud-Delivered Firewall Management Center model, then open the Coverage and Content Updates page.

Starting with VDB 357, you can install any VDB as far back as the baseline VDB for the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **VDB Updates**.

Step 2 Choose how you want to get the VDB onto the Cloud-Delivered Firewall Management Center.

- Direct download: Click **Download Updates**.

- Manual upload: Click **Upload Update**, click **Choose File**, select the VDB, and click **Upload**.

Step 3 Install the VDB.

a) Next to the VDB update you want to install, click either the **Install** icon (for a newer VDB) or the **Rollback** icon (for an older VDB).
b) Choose the Cloud-Delivered Firewall Management Center.
c) Click **Install**.

Monitor update progress in the Message Center. Do not use mapped-vulnerability features while the VDB is updating. If the Message Center shows no progress for several minutes or reports that the update failed, do not restart it. Contact Cisco TAC.

Step 4 Verify update success.

The current version is displayed on the VDB update page.

The system uses the new vulnerability information. However, you must deploy before updated application detectors and operating system fingerprints can take effect.

What to do next

- Deploy configuration changes.
- If configurations reference vulnerabilities, application detectors, or fingerprints that are no longer available, review those configurations to confirm that they handle traffic as expected. A scheduled VDB update can undo a rollback. To retain the older VDB, change the scheduled task or delete any newer VDB packages.

Geolocation database (GeoDB) updates

The geolocation database (GeoDB) maps IP addresses to geographic locations so that you can view and filter traffic by location.

GeoDB versions

We periodically release GeoDB updates. Each update replaces the previous version.

Scheduled GeoDB updates

Initial configuration schedules weekly updates to keep geolocation information accurate. Review the schedule and adjust it as needed. Refer to Schedule GeoDB updates, on page 267.

Deployment after GeoDB updates

The Cloud-Delivered Firewall Management Center automatically updates the GeoDB on managed devices, so deploy is usually unnecessary. If an update adds a new country, which is rare, deploy configuration changes as soon as possible. This allows the new country to count as part of its continent. For example, if an update adds Country to Continent, rules that filter based on "Continent" do not match traffic through Country until you deploy.

Schedule GeoDB updates

Schedule recurring GeoDB updates to keep the installed geolocation information current.

Initial configuration creates a weekly schedule for GeoDB updates. Review the schedule and adjust the start time as needed.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Geolocation Updates**.

Step 2 Configure recurring GeoDB updates.

a) Under **Recurring Geolocation Updates**, check **Enable Recurring Weekly Updates from the Support Site**.

b) Specify the **Update Start Time**.

Step 3 Click **Save**.

Manually update the GeoDB

Perform an on-demand update to keep the GeoDB current.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Geolocation Updates**.

Step 2 Under **One-Time Geolocation Update**, choose how you want to get the GeoDB onto the Cloud-Delivered Firewall Management Center.

- Direct download: Choose **Download and install geolocation update from the Support Site**.
- Manual upload: Choose **Upload and install geolocation update**, click **Choose File**, and select the GeoDB.

Step 3 Click **Import**.

Monitor update progress in the Message Center.

Step 4 Verify update success.

The current version is displayed on the GeoDB update page.

The system uses the new geolocation information. However, you must deploy before new countries can take effect. Until you deploy, the new country does not count as part of its continent. For example, if an update adds Country to Continent, rules that filter based on "Continent" do not match traffic through Country until you deploy.

What to do next

If the update adds a new country, deploy configuration changes.

Intrusion rule updates

An intrusion rule update is a cumulative package that provides new and modified intrusion and preprocessor rules, and modifies the policies that use them.

Intrusion rule update versions

As new vulnerabilities become known, the Talos Intelligence Group releases intrusion rule updates. Keep intrusion rules up to date. Each update replaces the previous version, and you can import only an update that is newer than the currently installed version.

Contents of intrusion rule updates

An intrusion rule update can contain these types of content:

- Rules and rule states: An update can add, modify, or delete intrusion and preprocessor rules. The default state of a new rule can differ between system-provided intrusion policies. For example, a new rule can be enabled in the Security over Connectivity policy and disabled in the Connectivity over Security policy. An update can also change the default state of an existing rule.
- Rule categories: An update can contain new rule categories. Importing the update adds all new categories.
- Preprocessor and advanced settings: An update can change advanced settings in system-provided intrusion policies and preprocessor settings in system-provided network analysis policies. It can also change the default values of advanced preprocessing and performance options in access control policies.
- Variables: An update can change the default values of existing variables without overriding customized values. It also adds new variables.

Policy changes from intrusion rule updates

Intrusion rule updates can affect system-provided and custom network analysis and intrusion policies, as well as the access control policies that use them. The effects depend on the policy type.

- System-provided policies: Changes to system-provided network analysis and intrusion policies and advanced access control settings take effect after you redeploy the configuration.
- Custom policies: Every custom network analysis and intrusion policy is based directly or indirectly on a system-provided policy. For each custom policy, you can prevent rule updates from automatically applying changes from its base policy. You can then apply the base-policy changes manually on a schedule independent of rule update imports. Updates do not override customized settings.

Caution Importing an intrusion rule update discards all cached changes to network analysis and intrusion policies. Before you import an update, use the Rule Updates page to identify policies with cached changes and the users who made them.

Scheduled intrusion rule updates

Initial configuration creates a daily schedule for intrusion rule updates. Review the schedule and adjust the frequency as needed. Refer to Schedule intrusion rule updates, on page 269.

Deployment after intrusion rule updates

Deploy configuration changes after an intrusion rule update for the update's changes to take effect. You can configure an import to deploy automatically to affected devices. Automatic deployment is especially useful when you allow updates to modify system-provided base intrusion policies.

Caution Although a rule update by itself does not restart Snort when you deploy, other changes you have made may. Restarting Snort briefly interrupts traffic flow and inspection on all devices, including those configured for high availability or scalability. Interface configurations determine whether traffic drops or passes without inspection during the interruption. When you deploy without restarting Snort, resource demands may result in a small number of packets dropping without inspection.

Schedule intrusion rule updates

Schedule recurring intrusion rule updates to keep the installed intrusion rules current.

Before you begin

Make sure your process for updating intrusion rules complies with your security policies.

Initial configuration creates a daily schedule for intrusion rule updates. Review the schedule and adjust the frequency as needed. You can also configure automatic deployment after each rule update. Automatic deployment can disrupt traffic inspection and flow.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Rule Updates**.

Step 2 Configure recurring rule updates.

a) Under **Recurring Rule Update Imports**, check **Enable Recurring Rule Update Imports**.
b) Specify the **Import Frequency** and start time.
c) (Optional) Check **Deploy all policies to targeted devices after rule update completes**.

Step 3 Click **Save**.

Manually update intrusion rules

Perform an on-demand update to keep intrusion rules current.

Before you begin

Make sure your process for updating intrusion rules complies with your security policies.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Rule Updates**.

Step 2 Configure the one-time rule update.

a) Under **One-Time Rule Update/Rules Import**, choose how to update intrusion rules.

- Direct download: Choose **Download new rule update...**.
- Manual upload: Choose **Rule update or text rule file...**, click **Choose File**, and select the intrusion rule update.

b) (Optional) Check **Reapply all policies after the rule update import completes**.

Step 3 Click **Import**.

Monitor update progress in the Message Center. Even if the Message Center shows no progress for several minutes or indicates that the update has failed, do not restart the update. Instead, contact Cisco TAC.

Step 4 Verify update success.

The current version is displayed on the rule update page.

What to do next

If you did not deploy configuration changes as part of the update, deploy them now.

Guidelines for importing custom Snort 2 rules

Use these guidelines to import custom standard text rules for use in Snort 2 intrusion policies.

File and rule syntax requirements

Import rules using a rule file that meets these requirements:

- Use a plain text file encoded in ASCII or UTF-8.
- Use only alphanumeric characters, spaces, underscores (_), periods (.), and hyphens (-) in the file name.
- To import a rule in the deleted state, precede it with one number sign (#). A rule preceded by two number signs (##) is not imported.
- Do not use escape characters in rules.
- Limit each source or destination port list to 64 characters. A longer list causes the import to fail.

For more information on writing custom rules, refer to *Custom Snort 2 Intrusion Policies for Access Control* and to the Snort manual at http://www.snort.org.

SID, GID, and revision number requirements

Follow these requirements for SIDs, GIDs, and revision numbers:

- Do not specify a GID. A standard text rule receives GID 1.
- Leave the SID and revision number unspecified when importing a rule for the first time. The rule receives an available SID of 1000000 or greater and a revision number of 1.
- If you must specify a SID for a new rule, use an unassigned value from 1000000 through 2147483647 (the 32-bit limit).
- When importing an updated or previously deleted rule, include its assigned SID and a revision number greater than its current revision number.

To determine the current revision number, edit the imported rule. Deleting a custom rule moves it to the deleted rule category and increments its revision number. You can then import a later revision to reinstate the rule.

Import custom Snort 2 rules

Import custom standard text rules so you can enable them in Snort 2 intrusion policies.

This procedure applies only to custom standard text rules for Snort 2 intrusion policies. For Snort 3, refer to the rule-tuning topics in *Custom Snort 3 Intrusion Policies for Access Control*.

Before you begin

- Make sure your custom rule file follows the guidelines in Guidelines for importing custom Snort 2 rules, on page 270.
- Make sure your process for importing custom rules complies with your security policies.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Rule Updates**.

You can also click **Import Rules** in the intrusion rules editor (**Objects** > **Intrusion Rules**).

Step 2 (Optional) Delete all existing custom rules.

To replace all existing custom rules with the rules in the new file, click **Delete All Local Rules**. The deleted rules move to the deleted rule category, and their revision numbers increase.

Step 3 Import the rule file.

a) Under **One-Time Rule Update/Rules Import**, choose **Rule update or text rule file to upload and install**.
b) Click **Choose File**, select your rule file, and click **Import**.

You can monitor import progress in the Message Center. Even if the Message Center shows no progress for several minutes or indicates that the import has failed, do not restart the import. Instead, contact Cisco TAC.

- Imported rules are added to the local rule category in a disabled state.
- Imported rules receive Generator ID (GID) 1.

- New imported rules receive an available Snort ID (SID) of 1000000 or greater and a revision of 1.

What to do next

- Edit Snort 2 intrusion policies and enable the rules you imported.

  Do not enable an imported rule that uses the deprecated `threshold` keyword in an intrusion policy that also uses intrusion event thresholding. This combination causes policy validation to fail.

- Deploy configuration changes.

Intrusion rule update logs

The Rule Update Log on the Rule Updates page records each intrusion rule update and custom Snort 2 rule import, including its time, user, and status. Each log also identifies the affected rules and components. Deleting a log does not delete the imported objects.

Intrusion rule update log fields

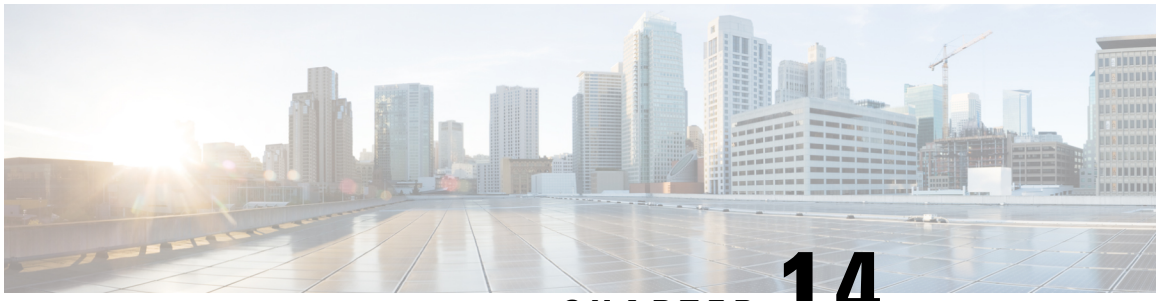
This table explains the fields in intrusion rule update logs.

Table 13: Intrusion rule update log fields

Field	Description
Action	Identifies how the import affected the object.
Default action	For a rule, the default action defined by the update is Pass, Alert, or Drop. The field is blank for other object types.
Details	Identifies the affected component or rule. For a changed rule, the field displays the GID, SID, and previous revision number in `GID:SID:Rev` format. The field is blank for a rule that has not changed.
GID	The generator ID for a rule. For example: • A GID of 1 identifies a standard text rule. • A GID of 3 identifies a shared object rule.
Name	The name of the imported object. For a rule, the name corresponds to the rule's Message field. For a rule update component, the field displays the component name.
Policy	For an imported rule, the field displays `All` when the import succeeds and the rule can be enabled in all applicable system-provided default intrusion policies. The field is blank for other object types.
Rev	The revision number for a rule.
Rule update	The rule update file name.
SID	The Snort ID for a rule.
Time	The time and date the import began.

Field	Description
Type	Identifies the imported object as a rule update component, rule, or policy apply. A policy apply record indicates that the option to reapply all policies after the import was enabled.

Action values



The Action field in intrusion rule update logs uses these values.

Table 14: Action values in intrusion rule update logs

Action	Meaning
new	The rule was stored for the first time.
changed	A rule update component was modified, or a rule was imported with a higher revision number and the same GID and SID.
collision	The import was skipped because the revision conflicts with an existing component or rule.
deleted	The rule was deleted from the rule update.
enabled	A rule, preprocessor, or other feature was enabled in a system-provided default policy.
disabled	A rule was disabled in a system-provided default policy.
drop	A rule was set to Drop and Generate Events in a system-provided default policy.
error	The update or import failed.
apply	The option to reapply all policies after the import was enabled.

Searching intrusion rule update logs

A search from the detailed log view searches the entire database, not only the selected import. Use the time range to limit the results to relevant records.

CHAPTER 14

Licenses

This chapter provides in-depth information about the different license types, service subscriptions, licensing requirements and more.

- Licenses, on page 275
- Prerequisites for licensing, on page 289
- Create a Cisco account, on page 290
- Create a smart account and add licenses, on page 291
- Configure Smart Licensing, on page 292
- Configure Legacy Cloud-Delivered Firewall Management Center PAK-Based Licenses, on page 300
- Additional information about licensing, on page 301
- Overview, on page 301
- Requirements, on page 302
- Supported Platforms and Versions, on page 302
- How to Implement Universal Permanent Licensing, on page 302
- Universal Permanent License Status, on page 308
- Maintain Your UPLR Deployment, on page 309
- Deactivate and Return a Universal Permanent License, on page 309
- Troubleshooting, on page 312
- For Assistance, on page 313

Licenses

Cisco Smart Licensing is a flexible licensing model that provides you with an easier, faster, and more consistent way to purchase and manage software across the Cisco portfolio and across your organization. And it's secure—you control what users can access. With Smart Licensing you get:

- **Easy Activation**: Smart Licensing establishes a pool of software licenses that can be used across the entire organization—no more PAKs (Product Activation Keys).
- **Unified Management**: Cisco License Central provides a complete view into all of your Cisco products and services in an easy-to-use portal, so you always know what you have and what you are using.
- **License Flexibility**: Your software is not node-locked to your hardware, so you can easily use and transfer licenses as needed.

To use Smart Licensing, you must first set up a Smart Account on Cisco License Central.

For a more detailed overview on Cisco Licensing, visit the Licensing Hub.

Smart Software Manager and accounts

When you purchase one or more licenses, you manage them in the Smart Software Manager: https://software.cisco.com/#module/SmartLicensing. The Smart Software Manager lets you create a primary account for your organization. If you do not yet have an account, click the link to set up a new account. For instructions, refer to Create a Cisco Account.

By default, your licenses are assigned to the Default Virtual Account under your primary account. As the account administrator, you can create additional virtual accounts; for example, for regions, departments, or subsidiaries. Multiple virtual accounts help you manage large numbers of licenses and devices.

You manage licenses by virtual account. Only that virtual account's devices can use the licenses assigned to the account. If you need additional licenses, you can transfer an unused license from another virtual account. You can also transfer devices between virtual accounts.

Licensing for Management Center and devices

The Cloud-Delivered Firewall Management Center registers with the Smart Software Manager, and then assigns licenses for each managed device. Devices do not register directly with the Smart Software Manager.

A physical Cloud-Delivered Firewall Management Center does not require a license for its own use.

Periodic communications with the Smart Software Manager

You use a Product Instance Registration Token to register the Cloud-Delivered Firewall Management Center with the Smart Software Manager. The Smart Software Manager issues an ID certificate for communication between the Cloud-Delivered Firewall Management Center and the Smart Software Manager. This certificate is valid for one year, although it will be renewed every six months. If an ID certificate expires (after a year with no communication), the Cloud-Delivered Firewall Management Center may be removed from your account.

The Cloud-Delivered Firewall Management Center communicates with the Smart Software Manager on a periodic basis. If you make changes in the Smart Software Manager, you can refresh the authorization on the Cloud-Delivered Firewall Management Center so the changes immediately take effect. You also can wait for the Cloud-Delivered Firewall Management Center to communicate as scheduled. Your Cloud-Delivered Firewall Management Center must either have direct internet access to the Smart Software Manager.

In non-airgapped deployments, normal license communication occurs every 30 days. With the grace period, your Cloud-Delivered Firewall Management Center will operate for up to 90 days without contacting the Smart Software Manager. Ensure that the Cloud-Delivered Firewall Management Center contacts the Smart Software Manager within 90 days, or the Cloud-Delivered Firewall Management Center will revert to an unregistered state.

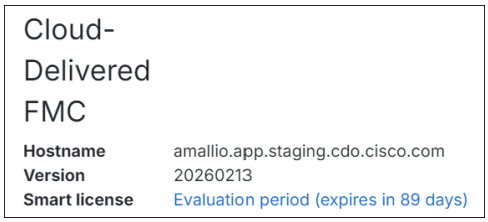
If your device is unable to communicate due to network issues, it continues working for up to 90 days. Once communication resumes and the ID certificate is validated, license entitlement is restored.

Cloud-Delivered Firewall Management Center licensing and registration

Register Cloud-Delivered Firewall Management Center with Cisco Smart Licensing the same way you would for On-Premises Firewall Management Center.

Overview

Cloud-Delivered Firewall Management Center is included with the base subscription and trial for Security Cloud Control Firewall Management. You do not need to purchase a separate license for Cloud-Delivered Firewall Management Center. The base subscription or trial covers Cloud-Delivered Firewall Management Center, enabling you to manage Firewall Threat Defense devices through the cloud.



Cloud-Delivered Firewall Management Center is provisioned with a 90-day evaluation license upon deployment.

Important We strongly recommend registering Cloud-Delivered Firewall Management Center with Cisco Smart Software Manager immediately after deployment to access all features, including those requiring export encryption such as RAVPN and SSL VPN. Early registration prevents feature limitations and deployment interruptions.

Evaluation license

- Features requiring export encryption, such as Remote Access VPN, SSL VPN, and other encryption-dependent options, remain disabled until you register Cloud-Delivered Firewall Management Center with Cisco Smart Software Manager (CSSM).
- After the 90-day evaluation period ends, you can continue onboarding Firewall Threat Defense devices, but manually triggered or scheduled deployments are blocked until registration with CSSM is completed.
- Security Cloud Control Firewall Management sends alert notifications as the evaluation license nears expiration.

Note The **Smart license** field displays a warning when the evaluation license is expiration.

When the evaluation period ends, Cloud-Delivered Firewall Management Center is unregistered. Registering Cloud-Delivered Firewall Management Center with Cisco Smart Software Manager converts from evaluation mode to a fully licensed state.

Click the evaluation warning link to open the smart licensing registration page and register Cloud-Delivered Firewall Management Center with Cisco Smart Software Manager.

Registration with Cisco Smart Software Manager (CSSM)

- Connect Cloud-Delivered Firewall Management Center to your smart licensing account, following the same process as On-Premises Firewall Management Center. The high-level procedure is provided in this section.

- No separate license purchase is needed for Cloud-Delivered Firewall Management Center; the license is automatically applied upon registration.
- Registering with smart licensing enables encryption export features.
- Registration ensures compliance and prevents deployment issues.

To learn how to get a Cloud-Delivered Firewall Management Center provisioned on your Security Cloud Control tenant, see Request a Cloud-Delivered Firewall Management Center for your Security Cloud Control Tenant.

Licensing for Firewall Threat Defense devices

- No separate license purchase is needed for Cloud-Delivered Firewall Management Center.
- Each Firewall Threat Defense device managed by Cloud-Delivered Firewall Management Center requires an individual license.
- After registering Cloud-Delivered Firewall Management Center with CSSM, an administrator may apply feature licenses to security devices.

Step-by-step registration

A high-level procedure is provided here. For detailed steps, see Register the Management Center with the Smart Software Manager.

1. Create or Access Your Smart Account:

   Ensure you have a Cisco Smart Software Manager account. If you do not have one, create it at Smart Software Manager.

2. Generate a Registration Token or Use a Registration Token:

   In the Smart Software Manager, use an existing valid registration token or generate a registration token for the virtual account to which you want to register the Cloud-Delivered Firewall Management Center.

   a. Navigate to **Inventory** > **New Token**.

   b. Enter a description and set an expiration (Cisco recommends 30 days).

   c. Create and copy the token.

3. Register Cloud-Delivered Firewall Management Center with the Token:

   a. Log in to the Cloud-Delivered Firewall Management Center interface.

   b. Navigate to **System** > **Licenses** > **Smart Licenses**.

   c. Click **Register** and paste the registration token into the **Product Instance Registration Token** field.

   d. Ensure there are no extra spaces or blank lines before or after the token.

   e. Click **Apply Changes**.

4. Verify Registration:

   After registration, verify the license status under **System** > **Licenses** > **Smart Licenses** to confirm successful registration, license application, and that “Export-Controlled Features” are enabled.

Out-of-compliance state

The Smart License Usage Authorization of Cloud-Delivered Firewall Management Center can become out of compliance in these situations:

- License expiration—When a term-based license of a managed device expires.

In an out-of-compliance state, these effects occur:

- All managed device licenses—Operation is not affected.

After you resolve the licensing problem, the Cloud-Delivered Firewall Management Center will show that it is now in compliance after its regularly scheduled authorization with the Smart Software Manager. To force an authorization, click **Re-Authorize** on the **System** (⚙) > **Licenses** > **Smart Licenses** page.

Unregistered state

The Cloud-Delivered Firewall Management Center can become unregistered in these situations:

- Evaluation mode expiration—Evaluation mode expires after 90 days.
- Manual deregistration of the Cloud-Delivered Firewall Management Center
- Lack of communication with the Smart Software Manager—The Cloud-Delivered Firewall Management Center does not communicate with the Smart Software Manager for 1 year. Note: After 90 days, the Cloud-Delivered Firewall Management Center authorization expires, but it can successfully resume communication within one year to automatically re-authorize. After a year, the ID certificate expires, and the Cloud-Delivered Firewall Management Center is removed from your account so you will have to manually re-register the Cloud-Delivered Firewall Management Center.

In an unregistered state, the Cloud-Delivered Firewall Management Center cannot deploy any configuration changes to devices *for features that require licenses*.

End-user license agreement

The Cisco end-user license agreement (EULA) and any applicable supplemental agreement (SEULA) that governs your use of this product are available from http://www.cisco.com/go/softwareterms.

License types and restrictions

This section describes the types of licenses available for Secure Firewall.

Table 15: Smart Licenses

License You Assign	Duration	Granted Capabilities
Essentials	Perpetual or Subscription **Note** Essentials subscription licenses are supported only on Firewall Threat Defense Virtual .	Except for Specific License Reservation and the Secure Firewall 1200/ 3100 /4200 , Essentials perpetual licenses are automatically assigned with all Firewall Threat Defense s. User and application control Switching and routing NAT For details, see Essentials licenses, on page 281 .
IPS	Subscription	Intrusion detection and prevention File control Security Intelligence filtering For details, see IPS licenses, on page 282
Malware defense	Subscription	Malware defense Secure Malware Analytics File storage (IPS license is a prerequisite for a Malware defense license.) For details, see Malware Defense Licenses, on page 282 and *License Requirements for File and Malware Policies* in the *Cisco Secure Firewall Management Center Device Configuration Guide* .
Carrier	Subscription for Firepower 4100/9300, Secure Firewall 3100 /4200 , and Firewall Threat Defense Virtual	Diameter, GTP/GPRS, M3UA, and SCTP inspection For details, see Carrier license, on page 283 .
URL Filtering	Subscription	Category and reputation-based URL filtering For details, see URL Filtering licenses, on page 284 . (IPS license is a prerequisite for a URL Filtering license.)
Export-Controlled Features	Perpetual	Features that are subject to national security, foreign policy, and anti-terrorism laws and regulations; see License for export-controlled functionality, on page 286 .

License You Assign	Duration	Granted Capabilities
Remote Access VPN: • Secure Client Premier • Secure Client Advantage • Secure Client VPN Only	Subscription or perpetual	Remote access VPN configuration. Your account must allow export-controlled functionality to configure remote access VPN. You select whether you meet export requirements when you register the device. The Firewall Threat Defense can use any valid Secure Client license. The available features do not differ based on license type. For more information, see Secure Client licenses, on page 285 and *VPN Licensing* in the *Cisco Secure Firewall Management Center Device Configuration Guide* .

Note Subscription licenses are term-based licenses.

Essentials licenses

The Essentials license allows you to configure and manage firewall devices with essential networking and security capabilities, including switching, routing, high availability, clustering, user control, application control, and database updates.

The Essentials license allows you to:

- Configure your devices to perform switching and routing (including DHCP relay and NAT)
- Configure devices as a high availability pair
- Configure clustering
- Implement user and application control by adding user and application conditions to access control rules
- Update the Vulnerability database (VDB) and geolocation database (GeoDB).
- Download intrusion rules such as SRU/LSP. However, you cannot deploy access control policy or rules that have intrusion policy to the device unless IPS license is enabled.

Secure Firewall 1200/3100/4200

You obtain a Essentials license when you purchase the Secure Firewall 1200/3100/4200.

Other Models

Except in deployments using Specific License Reservation, a Essentials license is automatically added to your account when you register a device to the Cloud-Delivered Firewall Management Center. For Specific License Reservation, you need to add the Essentials license to your account.

Malware Defense Licenses

A Malware defense license lets you perform Malware Defense and Secure Malware Analytics. With this feature, you can use devices to detect and block malware in files transmitted over your network.

To support this feature license, you can purchase the Malware defense (AMP) service subscription as a stand-alone subscription or in combination with IPS (TM) or IPS and URL Filtering (TMC) subscriptions. IPS license is a prerequisite for a Malware defense license.

Note Managed devices with Malware defense licenses enabled periodically attempt to connect to the Secure Malware Analytics Cloud even if you have not configured dynamic analysis. Because of this, the device's Interface Traffic dashboard widget shows transmitted traffic; this is expected behavior.

You configure Malware Defense as part of a file policy, which you then associate with one or more access control rules. File policies can detect your users uploading or downloading files of specific types over specific application protocols. Malware Defense allows you to use local malware analysis and file preclassification to inspect a restricted set of those file types for malware. You can also download and submit specific file types to the Secure Malware Analytics Cloud for dynamic and Spero analysis to determine whether they contain malware. For these files, you can view the network file trajectory, which details the path the file has taken through your network. The Malware Defense license also allows you to add specific files to a file list and enable the file list within a file policy, allowing those files to be automatically allowed or blocked on detection.

Note that a Malware defense license is required only if you deploy Malware Defense and Secure Malware Analytics. Without a Malware defense license, the Cloud-Delivered Firewall Management Center can receive Secure Endpoint malware events and indications of compromise (IOC) from the Secure Malware Analytics Cloud.

Refer to important information at *License Requirements for File and Malware Policies* in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

When you disable this license:

- The system stops querying the Secure Malware Analytics Cloud, and also stops acknowledging retrospective events sent from the Secure Malware Analytics Cloud.
- You cannot re-deploy existing access control policies if they include Malware Defense configurations.
- For a very brief time after a Malware defense license is disabled, the system can use existing cached file dispositions. After the time window expires, the system assigns a disposition of **Unavailable** to those files.

If the license expires, your entitlement for the above capabilities ceases and the Cloud-Delivered Firewall Management Center moves to the out-of-compliance state.

IPS licenses

A IPS license allows you to perform intrusion detection and prevention, file control, and Security Intelligence filtering.

License capabilities

- *Intrusion detection and prevention* allows you to analyze network traffic for intrusions and exploits and, optionally, drop offending packets.

- *File control* allows you to detect and, optionally, block users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols. *Malware defense*, which requires a Malware defense license, allows you to inspect and block a restricted set of those file types based on their dispositions.
- *Security Intelligence filtering* allows you to block —deny traffic to and from—specific IP addresses, URLs, and DNS domain names, before the traffic is subjected to analysis by access control rules. Dynamic feeds allow you to immediately block connections based on the latest intelligence. Optionally, you can use a "monitor-only" setting for Security Intelligence filtering.

License purchase options

You can purchase a IPS license as a stand-alone subscription (T) or in combination with URL Filtering (TC), Malware defense (TM), or both (TMC).

Disabled license behavior

When you disable this license:

- The Cloud-Delivered Firewall Management Center stops acknowledging intrusion and file events from the affected devices. As a consequence, correlation rules that use those events as a trigger criteria stop firing.
- The Cloud-Delivered Firewall Management Center does not contact the internet for either Cisco-provided or third-party Security Intelligence information.
- You cannot re-deploy existing intrusion policies until you re-enable IPS.

Expired license behavior

If the license expires, your entitlement for the above capabilities ceases and the Cloud-Delivered Firewall Management Center moves to the out-of-compliance state.

Carrier license

The Carrier license enables the inspection of specific protocols used in next-generation mobile and telecom networks. This license supports protocol inspection for Diameter, GTP/GPRS, M3UA, and SCTP protocols across supported devices.

Enabled protocols

- Diameter—Diameter is an Authentication, Authorization, and Accounting (AAA) protocol used in next-generation mobile and fixed telecom networks such as EPS (Evolved Packet System) for LTE (Long Term Evolution) and IMS (IP Multimedia Subsystem). It replaces RADIUS and TACACS in these networks.
- GTP/GPRS—GPRS Tunneling Protocol (GTP) is used in GSM, UMTS, and LTE networks for general packet radio service (GPRS) traffic. GTP provides a tunnel control and management protocol to provide GPRS network access for a mobile station by creating, modifying, and deleting tunnels. GTP also uses a tunneling mechanism for carrying user data packets.
- M3UA—MTP3 User Adaptation (M3UA) is a client/server protocol that provides a gateway to the Signaling System 7 (SS7) network for IP-based applications that interface with the SS7 Message Transfer

Part 3 (MTP3) layer. M3UA makes it possible to run the SS7 User Parts (such as ISUP) over an IP network.

- SCTP—Stream Control Transmission Protocol (SCTP) is a transport-layer protocol that supports the SS7 protocol over IP networks. It supports the 4G LTE mobile network architecture. SCTP can handle multiple simultaneous streams, multiplexed streams, and provides more security features.

Note After you enable this license on a device, use a FlexConfig policy to enable the protocol inspection.

The Carrier license PIDs are available per family and not per device model. You can enable this license for each device either in the evaluation mode or with a Smart License.

The Carrier license for Firepower 4100/9300, Secure Firewall 3100/4200, and Firewall Threat Defense Virtual is term-based. This license also supports Specific License Reservation.

Supported devices

- Cisco Secure Firewall 3100 Series
  - Secure Firewall 3110
  - Secure Firewall 3120
  - Secure Firewall 3130
  - Secure Firewall 3140
- Cisco Secure Firewall 4100 Series
  - Firepower 4112
  - Firepower 4115
  - Firepower 4125
  - Firepower 4145
- Cisco Secure Firewall 4200 Series
  - Secure Firewall 4215
  - Secure Firewall 4225
  - Secure Firewall 4245
- Firepower 9300
- Firewall Threat Defense Virtual

URL Filtering licenses

The URL Filtering license allows you to write access control rules that determine the traffic that can traverse your network based on URLs requested by monitored hosts, correlated with information about those URLs. To support this feature license, you can purchase the URL Filtering service subscription as a stand-alone

subscription or in combination with IPS (TC) or Threat and Malware defense (TMC) subscriptions. IPS license is a prerequisite for this license.

Tip Without a URL Filtering license, you can specify individual URLs or groups of URLs to allow or block. This option gives you granular, custom control over web traffic, but does not allow you to use URL category and reputation data to filter network traffic.

Although you can add category and reputation-based URL conditions to access control rules without a URL Filtering license, the Cloud-Delivered Firewall Management Center will not download URL information. You cannot deploy the access control policy until you first add a URL Filtering license to the Cloud-Delivered Firewall Management Center, then enable it on the devices targeted by the policy.

When you disable this license:

- You may lose access to filtering network traffic based on the URL category and reputation ACP rules. The manual URL filtering options will continue to be supported.
- Access control rules with URL conditions immediately stop filtering URLs.
- Your Cloud-Delivered Firewall Management Center can no longer download updates to URL data.
- You cannot re-deploy existing access control policies if they include rules with category and reputation-based URL conditions.

If the license expires, your entitlement for the above capabilities ceases and the Cloud-Delivered Firewall Management Center moves to the out-of-compliance state.

Secure Client licenses

You can configure remote access VPN using the Secure Client and standards-based IPSec/IKEv2.

To enable remote access VPN, you must purchase and enable one of these licenses: Secure Client Advantage, Secure Client Premier, or Secure Client VPN Only. You can select Secure Client Advantage and Secure Client Premier if you have both licenses and you want to use them both. The Secure Client VPN Onlylicense cannot be used with **Apex** or **Plus**. The Secure Client license must be shared with the Smart Account. For more instructions, refer to http://www.cisco.com/c/dam/en/us/products/collateral/security/anyconnect-og.pdf.

You cannot deploy the remote access VPN configuration to the device if the specified device does not have the entitlement for a minimum of one of the specified Secure Client license types. If the registered license moves out of compliance or entitlements expire, the system displays licensing alerts and health events.

While using remote access VPN, your Smart Account must have the export controlled features (strong encryption) enabled. The Firewall Threat Defense requires strong encryption (which is higher than DES) for successfully establishing remote access VPN connections with Secure Clients.

You cannot deploy remote access VPN if these conditions are true:

- Smart Licensing on the Cloud-Delivered Firewall Management Center is running in evaluation mode.
- Your Smart Account is not configured to use export-controlled features (strong encryption).

License for export-controlled functionality

This topic provides information about software features that are subject to export control laws and regulations, and describes how to determine and enable export-controlled functionality for your system.

Features that require export-controlled functionality

Certain software features are subject to national security, foreign policy, and anti-terrorism laws and regulations. These export-controlled features include:

- Security certifications compliance
- Remote access VPN
- Site-to-site VPN with strong encryption
- SSH platform policy with strong encryption
- SSL policy with strong encryption
- Functionality such as SNMPv3 with strong encryption

Verify export-controlled functionality in your system

To determine whether export-controlled functionality is currently enabled for your system: Choose **System** (⚙) > **Licenses** > **Smart Licenses** and see if **Export-Controlled Features** displays **Enabled**.

Enable export-controlled functionality

If **Export-Controlled Features** shows **Disabled** and you want to use features that require strong encryption, there are two ways to enable strong cryptographic features. Your organization may be eligible for one or the other (or neither), but not both.

- If there is *no* option to enable export-controlled functionality when you generate a new Product Instance Registration Token in the Smart Software Manager, contact your account representative.
- If the option "Allow export-controlled functionality on the products registered with this token" appears when you generate a new Product Instance Registration Token in the Smart Software Manager, make sure you check it before generating the token.

  If you did not enable export-controlled functionality for the Product Instance Registration Token that you used to register the Cloud-Delivered Firewall Management Center, then you must deregister and then re-register the Cloud-Delivered Firewall Management Center using a new Product Instance Registration Token with export-controlled functionality enabled.

If you registered devices to the Cloud-Delivered Firewall Management Center in evaluation mode or before you enabled strong encryption on the Cloud-Delivered Firewall Management Center, reboot each managed device to make strong encryption available. In a high availability deployment, the active and standby devices must be rebooted together to avoid an Active-Active condition.

The entitlement is perpetual and does not require a subscription.

More information

For general information about export controls, see https://www.cisco.com/c/en/us/about/legal/global-export-trade.html.

Firewall Threat Defense Virtual Licenses

Learn about the performance-tiered license entitlements for Firewall Threat Defense Virtual, including supported vCPU and memory configurations, compatible VM resource footprints, and RA VPN session limits by entitlement tier.

Any Firewall Threat Defense Virtual license can be used on any supported Firewall Threat Defense Virtual vCPU/memory configuration. This allows Firewall Threat Defense Virtual customers to run on a wide variety of VM resource footprints. This also increases the number of supported AWS and Azure instances types. When configuring the Firewall Threat Defense Virtual VM, the maximum supported number of cores (vCPUs) is 16 ; and the maximum supported memory is 32 GB RAM .

Performance Tiers for Firewall Threat Defense Virtual Smart Licensing

Session limits for RA VPNs are determined by the installed Firewall Threat Defense Virtual platform entitlement tier, and enforced via a rate limiter. The following table summarizes the session limits based on the entitlement tier and rate limiter.

Table 16: Firewall Threat Defense Virtual Licensed Feature Limits Based on Entitlement

Performance Tier	Device Specifications (Core/RAM)	Rate Limit	RA VPN Session Limit
FTDv5, 100Mbps	4 core/8 GB	100Mbps	50
FTDv10, 1Gbps	4 core/8 GB	1Gbps	250
FTDv20, 3Gbps	4 core/8 GB	3Gbps	250
FTDv30, 5Gbps	8 core/16 GB	5Gbps	250
FTDv50, 10Gbps	12 core/24 GB	10Gbps	750
FTDv100, 16Gbps	16 core/32 GB	16Gbps	10,000
FTDvU	32 core/64 GB	Not limited	20,000
FTDvU	64 core/128 GB	Not limited	32,000

Firewall Threat Defense Virtual Performance Tier Licensing Guidelines and Limitations

Review and follow these guidelines and limitations when licensing your Firewall Threat Defense Virtual device.

- The Firewall Threat Defense Virtual supports performance-tiered licensing that provides different throughput levels and VPN connection limits based on deployment requirements.
- Any Firewall Threat Defense Virtual license can be used on any supported Firewall Threat Defense Virtual core/memory configuration. This allows the Firewall Threat Defense Virtual customers to run on a wide variety of VM resource footprints.
- You can select a performance tier when you deploy the Firewall Threat Defense Virtual , whether your device is in evaluation mode or is already registered with Smart Software Manager

Note Make sure your Smart Licensing account contains the available licenses you need. It's important to choose the tier that matches the license you have in your account. If you are upgrading your Firewall Threat Defense Virtual to Version 7.0 and later, you can choose **FTDv - Variable** to maintain your current license compliance. Your Firewall Threat Defense Virtual continues to perform with session limits based on your device capabilities (number of cores/RAM).

- The default performance tier is FTDv50 when deploying a new Firewall Threat Defense Virtual device, or when provisioning the Firewall Threat Defense Virtual using the REST API.
- Essentials licenses are subscription-based and mapped to performance tiers. Your virtual account needs to have the Essentials license entitlements for the Firewall Threat Defense Virtual devices, as well as for IPS , Malware Defense , and URL Filtering licenses.
- Each HA peer consumes one entitlement, and the entitlements on each HA peer must match, including Essentials license.
- A change in performance tier for an HA pair should be applied to the primary peer.
- You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.
- Universal PLR licensing is applied to each device in an HA pair separately. The secondary device will not automatically mirror the performance tier of the primary device. It must be updated manually.

Edit performance tier of Firewall Threat Defense Virtual

The Firewall Threat Defense Virtual supports performance-tiered licensing that provides different throughput levels and VPN connection limits based on deployment requirements. You can edit the performance tier using this procedure.

Before you begin

Ensure that you review Firewall Threat Defense Virtual Performance Tier Licensing Guidelines and Limitations , on page 287.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 2 Click **Edit Performance Tier**.

Step 3 Choose a tier from the **Target Performance Tier** drop-down list.

Step 4 From the **Available Devices** list, select the required devices and click **Add**.

Step 5 Click **Apply**.

Prerequisites for licensing

This topic lists the prerequisites, supported domains, and user roles required for licensing.

General prerequisites

- Make sure NTP is configured on the Cloud-Delivered Firewall Management Center and managed devices. Time must be synchronized for registration to succeed.
- For a Firepower 4100/9300, you must configure NTP on the chassis using the same NTP server for the chassis as for the Cloud-Delivered Firewall Management Center.

Supported domains

Global, except where indicated.

User roles

Admin

Prerequisites for licensing in high availability, clustering, and multi-instance

This section describes the licensing requirements for device High Availability.

FTD Services does not support clustering or multi-instance deployments.

License requirements for Firewall Threat Defense device high availability

Both Firewall Threat Defense units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the Cloud-Delivered Firewall Management Center releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit.

For example, if the active unit has a Essentials license and a IPS license, and the standby unit has only a Essentials license, the Cloud-Delivered Firewall Management Center communicates with the Smart Software Manager to obtain an available IPS license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

License for device clusters

Device clusters require specific licensing considerations for proper operation and feature functionality.

Performance tier license requirements

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes

to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

Feature license assignment

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Cloud-Delivered Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

Note If you add the cluster before the Cloud-Delivered Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Cloud-Delivered Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Create a Cisco account

You need a Cisco account to access Smart Account functionality and license any Cisco products.

You must have a Cisco account to request a Smart Account and license any Cisco products.

Procedure

Step 1 Open the URL https://id.cisco.com/signin/register to create a new account.

Step 2 Enter all the required fields to create an account.

Step 3 Click **Register**.

An email with an activation code is sent to verify your email address.

Note
If you haven't received an email yet, send an email to the registration support team at web-help@cisco.com.

Step 4 In the **Verify with your email** page, enter the activation code to complete the registration process and click **Verify**.

After successful registration, you will be redirected to the login page.

What to do next

Enter the newly created account details on the login page to request a Smart Account. Refer to Create a smart account and add licenses, on page 291.

Create a smart account and add licenses

Create a Smart Account to centrally manage and track your Cisco software licenses across your organization.

You should set up this account before you purchase licenses. Your account representative or reseller may have set up a Smart Account on your behalf. If so, obtain the necessary information to access the account from that person instead of using this procedure, then verify that you can access the account.

Before you begin

You must create a new Cisco account if you don't already have one. For instructions, refer to Create a Cisco Account.

For general information about Smart Accounts, refer to http://www.cisco.com/go/smartaccounts.

Procedure

Step 1 Go to the Create a Smart Account page.

You are prompted to log in with your Cisco account. In the **Create a Smart Account** page, your basic account information is displayed.

Step 2 Click the **My Account** icon appearing in the top right corner and click **Manage Profile**.

Step 3 Click **Personal** and configure these parameters:

a) In the **Your Company Details** section, click **Edit**.

b) In the **Company or organization** field, type your organization name.

c) If your company information is already present in our database, it will appear in the list. You can select your company.

In the **Address** drop-down list, select the address of your company.

d) If your company is not listed in our database, you can continue to enter your company information in the **Company or organization** field.

1. In the **Address** drop-down list, click the drop-down arrow and click **Add New Address**.
2. You can select one of the following **Address Type** options:
   - **Company/Organization**: To provide your organization's address. Cisco verifies this address. If the address and company name cannot be validated with the country, you may not be able to proceed. Therefore, you must ensure that the correct address is provided.
   - **Personal**: To provide your personal address.

e) Enter all the mandatory fields associated with your company and click **Update**.

The **Your Company Details** section displays the company details you entered.

A success message appears if your company details are validated.

Step 4 Click **Update**.

A success message appears if your company details are validated.

Step 5 Open the **Create a Smart Account** page, which was opened in the previous tab. Refresh the page if changes are not reflecting.

Alternatively, you can open this page using the https://software.cisco.com/software/company/smartaccounts/home?route=module/accountcreation URL and login using your credentials.

Step 6 Click **Create Account**.

The **Account Summary** page displays your account details.

Step 7 Click **Done**.

Step 8 Wait for an email telling you that your Smart Account is ready to set up. When it arrives, click the link it contains, as directed.

Step 9 Make sure your Smart Licensing account contains the available licenses you need.

What to do next

To configure Smart License using the Smart Software Manager, refer to Configure Smart Licensing, on page 292.

Configure Smart Licensing

This section describes how to use Smart Licensing using the Smart Software Manager or the Smart Software Manager On-Prem.

Register the Cloud-Delivered Firewall Management Center for Smart Licensing

You can register the Cloud-Delivered Firewall Management Center directly to the Smart Software Manager over the internet, or when using an air-gapped network, with the Smart Software Manager On-Prem.

Register the Cloud-Delivered Firewall Management Center with the Smart Software Manager

Register the Cloud-Delivered Firewall Management Center with the Smart Software Manager to enable Smart Licensing functionality and proper license management.

Before you begin

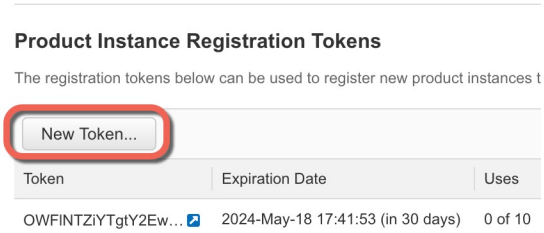
- Make sure your Smart Licensing account contains the available licenses you need.

  When you bought your device from Cisco or a reseller, your licenses should have been linked to your Smart Account. However, if you need to add licenses yourself, see Cisco Commerce Workspace.

- Ensure that the Cloud-Delivered Firewall Management Center can reach the Smart Software Manager at smartreceiver.cisco.com.
- Configure NTP. During registration, a key exchange occurs between the Smart Agent and the Smart Software Manager, so time must be in sync for proper registration.

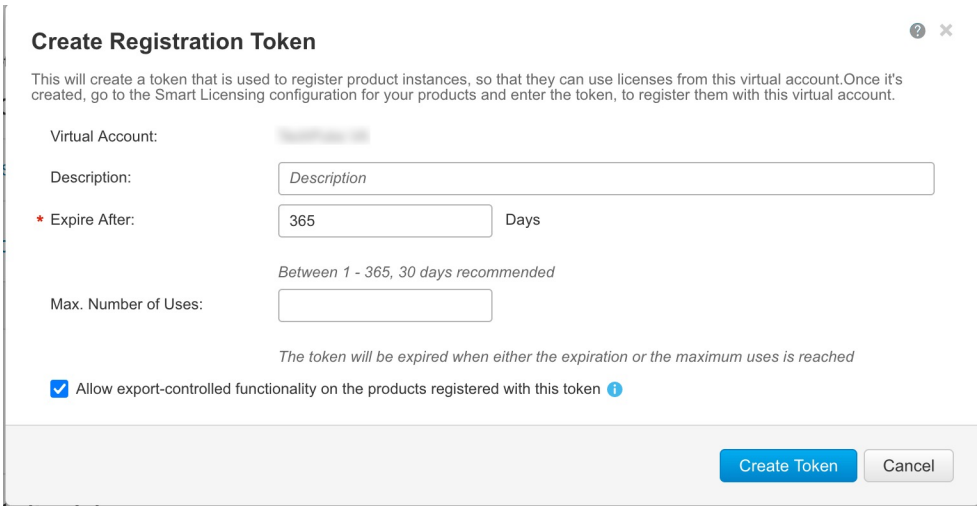
  For the Firepower 4100/9300, configure NTP on the chassis using the same NTP server as the Cloud-Delivered Firewall Management Center.

- If your organization has multiple Cloud-Delivered Firewall Management Centers, make sure each one has a unique name that clearly identifies and distinguishes it from others that may be registered to the same virtual account. This name is critical for managing your Smart License entitlements and ambiguous names will lead to problems later.



Procedure

Step 1 In the Smart Software Manager, request and copy a registration token for the virtual account to which you want to add this device.



a) Click **Inventory**.

b) On the **General** tab, click **New Token**.

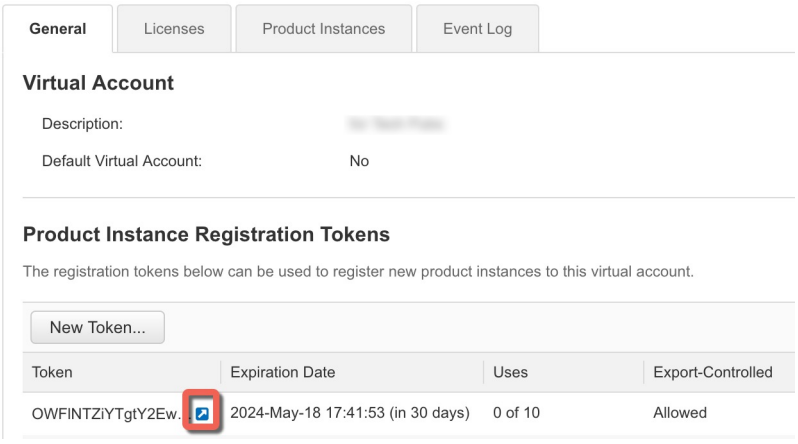
c) In the **Create Registration Token** dialog box enter these settings, and then click **Create Token**:

- **Description**
- **Expire After**—Cisco recommends 30 days.
- **Max. Number of Uses**
- **Allow export-controlled functionality on the products registered with this token**—Enables the export-compliance flag if you are in a country that allows for strong encryption. You must select this option now if you plan to use this functionality. If you enable this functionality later, you will need to re-register your device with a new product key and reload the device. If you do not see this option, your account does not support export-controlled functionality.

The token is added to your inventory.

d) Click the arrow icon to the right of the token to open the **Token** dialog box so you can copy the token ID to your clipboard. Keep this token ready for later in the procedure when you need to register the Firewall Threat Defense.

Figure 32: View token



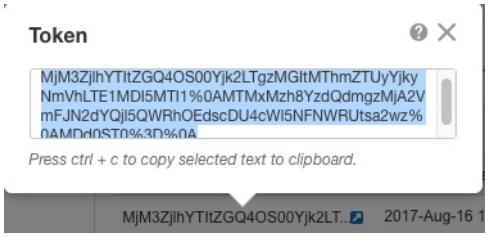


Figure 33: Copy token

Step 2 In the Cloud-Delivered Firewall Management Center, choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 3 Click **Register**.

Step 4 Paste the token you generated from Smart Software Manager into the **Product Instance Registration Token** field.

Make sure there are no empty spaces or blank lines at the beginning or end of the text.

Step 5 Click **Apply Changes**.

What to do next

- Add a device to the Cloud-Delivered Firewall Management Center; see *Add a Device to the Cloud-Delivered Firewall Management Center* in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

Assign licenses to devices

You can assign most licenses when you register a device to the Cloud-Delivered Firewall Management Center. You can also assign licenses per device, or for multiple devices.

Assign licenses to a single device

This task allows you to enable or disable specific licensed features on a managed device by assigning or removing licenses as needed.

You can enable or disable specific licensed features on a managed device by assigning or removing licenses as needed. Although there are some exceptions, you cannot use the features associated with a license if you disable it on a managed device.

Note For container instances on the same security module/engine, you apply the license to each instance; note that the security module/engine consumes only one license per feature for all instances on the security module/engine.

Note For the Firewall Threat Defense cluster, you apply the licenses to the cluster as a whole; note that each unit in the cluster consumes a separate license per feature.

Before you begin

You must have Admin or Network Admin privileges to perform this task. When operating with multiple domains, you must do this task in leaf domains.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign or disable a license, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 Next to the **License** section, click **Edit** ( ).

Step 5 Check or clear the appropriate check boxes to assign or disable licenses for the device.

Step 6 Click **Save**.

Step 7 Deploy configuration changes.

What to do next

Verify license status:

1. Choose **System** ( ) > **Licenses** > **Smart Licenses**.
2. Enter the hostname or IP address of the device into the filter at the top of the Smart Licenses table
3. Verify that only a green circle with a **Check Mark** ( ) appears for each device, for each license type.

   If you see any other icon, hover over the icon for more information.

Assign licenses to multiple managed devices

Devices managed by the Cloud-Delivered Firewall Management Center obtain their licenses via the Cloud-Delivered Firewall Management Center, not directly from the Smart Software Manager.

Note For container instances on the same security module/engine, you apply the license to each instance; note that the security module/engine consumes only one license per feature for all instances on the security module/engine.

Note For the Firewall Threat Defense cluster, you apply the licenses to the cluster as a whole; note that each unit in the cluster consumes a separate license per feature.

Use this procedure to enable licensing on multiple devices at once.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses** or **Specific Licenses**.

Step 2 Click **Edit Licenses**.

Step 3 For each type of license you want to add to a device:

a) Click the tab for that type of license.
b) Click a device in the list on the left.
c) Click **Add** to move that device to the list on the right.
d) Repeat for each device to receive that type of license.

For now, don't worry about whether you have licenses for all of the devices you want to add.

e) Repeat this subprocedure for each type of license you want to add.
f) To remove a license, click the **Delete** ( ) next to the device.
g) Click **Apply**.

You can select a cluster and assign any license to all nodes of a cluster.

What to do next

Verify that your licenses are correctly installed. Follow the procedure in Monitor Smart Licensing, on page 298.

Manage Smart Licensing

This section describes how to manage Smart Licensing.

Deregister the Cloud-Delivered Firewall Management Center

Deregister your Cloud-Delivered Firewall Management Center from the Smart Software Manager to release all of the license entitlements back to your Smart Account so they can be used for other devices.

Deregister if you need to decommission the Cloud-Delivered Firewall Management Center or reimage it.

Refer to Unregistered state, on page 279 for more information about license enforcement in an unregistered state.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 2 Click **Deregister** ( ).

Monitor Smart License status

The **Smart License Status** section of the **System** (⚙) > **Licenses** > **Smart Licenses** page provides an overview of license usage on the Cloud-Delivered Firewall Management Center.

Usage authorization

Possible status values are:

- **In-compliance** (🟢) — All licenses assigned to managed devices are in compliance and the Cloud-Delivered Firewall Management Center is communicating successfully with the Smart Software Manager.
- **License is in compliance but communication with licensing authority has failed**— Device licenses are in compliance, but the Cloud-Delivered Firewall Management Center is not able to communicate with the Cisco licensing authority.
- **Out-of-compliance icon or unable to communicate with License Authority**— One or more managed devices is using a license that is out of compliance, or the Cloud-Delivered Firewall Management Center has not communicated with the Smart Software Manager in more than 90 days.

Product registration

Specifies the last date when the Cloud-Delivered Firewall Management Center contacted the Smart Software Manager and registered.

Assigned virtual account

Specifies the Virtual Account under the Smart Account that you used to generate the Product Instance Registration Token and register the Cloud-Delivered Firewall Management Center. If this deployment is not associated with a particular virtual account within your Smart Account, this information is not displayed.

Export-Controlled features

If this option is enabled, you can deploy restricted features. For details, see License for export-controlled functionality, on page 286.

Cisco success network

Specifies whether you have enabled Cisco Success Network for the Cloud-Delivered Firewall Management Center. If this option is enabled, you provide usage information and statistics to Cisco which are essential to provide you with technical support. This information also allows Cisco to improve the product and make you aware of unused available features so that you can maximize the value of the product in your network.

Monitor Smart Licensing

To view the license status for the Cloud-Delivered Firewall Management Center and its managed devices, use the Smart Licenses page.

For each type of license in your deployment, the page lists the total number of licenses consumed, whether the license is in compliance or out of compliance, the device type, and the domain and group where the device is deployed. You can also view the Cloud-Delivered Firewall Management Center's Smart License Status. Container instances on the same security module/engine only consume one license per security module/engine.

Therefore, even though the Cloud-Delivered Firewall Management Center lists each container instance separately under each license type, the number of licenses consumed for feature license types will only be one.

Other than the **Smart Licenses** page, there are a few other ways you can view licenses:

- The **Product Licensing** dashboard widget provides an at-a-glance overview of your licenses.
- The **Device Management** page (**Devices** > **Device Management**) lists the licenses applied to each of your managed devices.
- The **Smart License Monitor** health module communicates license status when used in a health policy.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 2 In the **Smart Licenses** table, click the arrow at the left side of each **License Type** folder to expand that folder.

Step 3 In each folder, verify that each device has a green circle with a **Check Mark** (✓) in the **License Status** column.

If all devices show a green circle with a **Check Mark** (✓), your devices are properly licensed and ready to use.

If you see any License Status other than a green circle with a **Check Mark** (✓), hover over the status icon to view the message.

What to do next

- If you had any devices that did not have a green circle with a **Check Mark** (✓), you may need to purchase more licenses.

Troubleshoot Smart Licensing

This topic lists some common Smart Licensing issues and provides troubleshooting steps.

Expected licenses do not appear in my smart account

If the licenses you expect to see are not in your Smart Account, try the following:

- Make sure they are not in a different Virtual Account. Your organization's license administrator may need to assist you with this.
- Check with the person who sold you the licenses to be sure that transfer to your account is complete.

Unexpected out-of-compliance notification or other error

- If a device is already registered to a different Cloud-Delivered Firewall Management Center, you need to deregister the original Cloud-Delivered Firewall Management Center before you can license the device

under a new Cloud-Delivered Firewall Management Center. See Deregister the Cloud-Delivered Firewall Management Center, on page 297.

- Check if the term of the subscription license has expired.

Troubleshoot other issues

For solutions to other common issues, see Use FMC and FTD Smart License Registration and Common Issues to Troubleshoot.

Configure Legacy Cloud-Delivered Firewall Management Center PAK-Based Licenses

The Cloud-Delivered Firewall Management Center supports either a Smart license or a legacy PAK (Product Activation Key) license for its platform license. This procedure describes how to apply a PAK-based license.

After re-registration of your Smart Account, you must manually add the classic licenses for all classic devices.

Before you begin

- Make sure you have the product activation key (PAK) from the Software Claim Certificate that Cisco provided when you purchased the license. If you have a legacy, pre-Cisco license, contact Support.

Procedure

Step 1 Note the license key for the Cloud-Delivered Firewall Management Center.

The license key uniquely identifies the Cloud-Delivered Firewall Management Center in the Smart Software Manager. It is composed of a product code (for example, 66) and the MAC address of the management port (eth0) of the Cloud-Delivered Firewall Management Center; for example, 66:00:00:77:FF:CC:88.

a) Choose **System** (⚙) > **Licenses** > **Classic Licenses**.
b) Click **Add New license**.
c) Note the value in the **license Key** field at the top of the **Add Feature license** dialog.

Step 2 Choose **System** (⚙) > **Licenses** > **Classic Licenses**.

Step 3 Click **Add New license**.

Step 4 Continue as appropriate:

- If you have already obtained the license text, skip to Step 8.
- If you still need to obtain the license text, go to the next step.

Step 5 Click **Get license** to open the License Registration Portal.

Note
If you cannot access the Internet using your current computer, switch to a computer that can, and browse to http://cisco.com/go/license.

Step 6 Generate a license from the PAK in the License Registration Portal: https://cisco.com/go/license.

This step requires the PAK you received during the purchase process, as well as the LICENSE key for the Cloud-Delivered Firewall Management Center.

For more information on using this portal, see:

https://slexui.cloudapps.cisco.com/SWIFT/LicensingUI/Quickstart

You will need your account credentials in order to access these links.

Step 7 Copy the license text from either the License Registration Portal display, or the email the License Registration Portal sends you.

Important
The licensing text block in the portal or email message may include more than one license. Each license is bounded by a BEGIN LICENSE line and an END LICENSE line. Make sure that you copy and paste only one license at a time.

Step 8 Return to the **Add Feature License** page in the management center virtual's web interface.

Step 9 Paste the license text into the **License** field, click **Verify License**, and click **Submit License**.

If the license is invalid, make sure that you correctly copied the license text.

Additional information about licensing

For additional information to help resolve common licensing questions, see these documents:

- Licensing FAQ
- License Roadmap

Overview

Some secure deployment environments may restrict or disable access to the Internet. In such environments, the Firepower Management Center is unable to communicate with the License Authority either through the Cisco Smart Software Manager (CSSM) or Smart Software Satellite Server. These deployments can use Universal Permanent License Reservation (UPLR). Permanent licenses do not require access to the internet or the Cisco licensing authority.

The Universal Permanent License permits perpetual, unlimited use of supported Firepower products, if your account on Cisco Smart Software Manager is authorized.

Features that require access to the internet, such as URL Lookups or contextual cross-launch to public web sites, will not work.

Cisco does not collect web analytics or telemetry data for deployments that use Universal Permanent Licensing.

Note Various names are used at Cisco for this functionality, including: Universal Permanent License Reservation, Universal License Reservation, Permanent License Reservation, UPLR, ULR, and PLR. These terms may also be used at Cisco to refer to similar but not necessarily identical licensing models. In this document, PLR and UPLR both mean Universal Permanent License Reservation.

Requirements

Usage of Universal Permanent License Reservation requires approval and authorization from Cisco.

Work with your account representative to determine whether you qualify for this licensing option.

Cisco TAC cannot assist with obtaining approval for this licensing; please do not contact TAC about obtaining approval.

Supported Platforms and Versions

Product	Version	Platform/Hosting Environment
Firepower Management Center	6.3 or later	All
Firepower Management Center Virtual	6.3 or later	All
Firepower Threat Defense	6.1.0 or later	All
Classic devices: ASA with FirePOWER Services NGIPSv 7000- and 8000-Series	Not supported.	

How to Implement Universal Permanent Licensing

	Do This	More Information
Step 1	Meet the prerequisites for this feature.	Prerequisites, on page 303
Step 2	Verify that your Smart Account is ready to deploy Universal Permanent License Reservation.	Verify that your Smart Account is Ready to Deploy Universal Permanent License Reservation, on page 304
Step 3	Enable Universal Permanent License Reservation using the Firepower Management Center shell	Enable the Permanent Licensing Menu Option, on page 305

	Do This	More Information
Step 4	Generate a Reservation Request Code from the Firepower Management Center	Generate a Reservation Request Code from the Firepower Management Center, on page 306
Step 5	Use the Reservation Request Code to generate a Reservation Authorization Code from Cisco Smart Software Manager	Generate a Reservation Authorization Code from Cisco Smart Software Manager, on page 306
Step 6	Enter the Reservation Authorization Code into the Firepower Management Center	Enter the Reservation Authorization Code into the Firepower Management Center, on page 307
Step 7	Apply Permanent Licenses to managed Firepower Threat Devices	Apply Permanent Licenses to Managed Firepower Threat Devices, on page 307
Step 8	(Outside of your Firepower Management Center) Schedule reminders for ongoing maintenance tasks	See the "Maintain Your Air-Gapped Deployment" topic in the Firepower Management Center online help.

Prerequisites

Before you can begin implementing a Universal Permanent License Reservation, you must complete the following:

- If you have not already done so, create your Smart Account.

  For more information, see Create a smart account and add licenses.

- Work with your account representative to obtain approval for Universal Permanent License Reservation for your Firepower products.

- Purchase standard licenses and service subscriptions for your products, sufficient to cover all devices and features you will deploy.

  For descriptions of standard Firepower licenses and service subscriptions, see License types and restrictions.

- Arrange for export-controlled strong cryptographic functionality, if required and if your organization is eligible, and confirm that your account is enabled to use it. Your account representative can assist you with this.

- Confirm with your account representative that the Universal Permanent License is ready for use and reflected in your Smart Account.

- Make sure NTP is configured on the Firepower Management Center and managed devices. Time must be synchronized for registration to succeed. For more information, see the online help in FMC.

  If you are deploying FTD on a Firepower 4100/9300 chassis, you must configure NTP on the Firepower chassis using the same NTP server for the chassis as for the Firepower Management Center.

- If you are currently using standard Smart Licensing on your Secure Firewall Management Center, de-register the Secure Firewall Management Center to release the licenses back to your account. For information, see Deregister the Cloud-Delivered Firewall Management Center.

- (Recommended) Add managed devices to your Secure Firewall Management Center. For instructions, see Register with a new management center. (You can add managed devices at any time, but adding them

now simplifes this process.) You will need to enable the evaluation license in order to do this (under **System > Licenses > Smart Licenses**). Evaluation licensing does not require a connection to the License Authority.

- (Recommended) If you will deploy a Secure Firewall Management Center pair in a high availability configuration, configure that before you assign licenses. (FMCs in a high availability configuration require the same number of licenses as a single FMC.) If you have already deployed licenses to the secondary appliance, de-register licensing from that appliance.

Verify that your Smart Account is Ready to Deploy Universal Permanent License Reservation

In order to prevent problems with deploying your permanent license, complete this procedure before you make any changes in your Cisco Smart Software Manager.

Before you begin

- Complete all Prerequisites, on page 303.
- Make sure you have your Secure Firewall Management Center credentials.

Procedure

Step 1 Sign in to the Secure Firewall Management Center:

https://software.cisco.com/#SmartLicensing-Inventory

Step 2 If applicable, select the correct account from the top right corner of the page.

Step 3 Click **Manage licenses** under the **Smart Software Manager** tile.

Step 4 Click the **Inventory** tab.

Step 5 Click the **Licenses** tab.

Step 6 Verify the following:

- There is a **License Reservation** button.
- In the **License** column, there is a **Cisco FMC Universal License Feature** license.
- In the **Purchased** column for this Cisco FMC Universal License Feature, the number of available licenses matches the number of Secure Firewall Management Center instances (hardware or virtual) that you will deploy.
- There are enough platform and feature licenses for the devices and features you will deploy, including Base licenses and Secure Firewall Management Center Virtual entitlements for your devices.

Step 7 If any of these items is missing or incorrect, contact your account representative to resolve the problem.

Important

Do **not** continue with this process until all the problems are corrected!

Enable the Permanent Licensing Menu Option

Universal License	Supported Devices	Supported Domains	Access
Any	Secure Firewall Management Center	Global only	Admin

Procedure

Step 1 Access the Firepower Management Center console using a USB keyboard and VGA monitor, or use SSH to access the management interface.

Step 2 Log into the Firepower Management Center **admin** account.

FMC versions 6.3 and 6.4: By default, this gives you access to the Linux shell. If the Firepower Management Center CLI is enabled, this gives you access to the command line interface.

FMC versions 6.5 and later: By default, this gives you access to the command line interface.

Step 3 If you are in the command line interface, enter the **expert** command to access the Linux shell.

Step 4 Enable Universal Permanent Licensing by executing the following command:

sudo manage_plr.pl

Example:

```
admin@fmc63betaplr: ~$ sudo manage_plr.pl
Password:
*************** Configuration Utility *************

1 Show PLR Status
2 Enable PLR
3 Disable PLR
0 Exit ************************************************************
Enter choice:
```

Step 5 Enable Permanent License Reservation by selecting option 2.

Step 6 Select option 0 to exit the manage_plr utility.

Step 7 Type **exit** to exit the Linux shell.

Step 8 If applicable, exit the command line interface.

Versions 6.3 and 6.4: If the CLI is enabled, enter **exit**.

Version 6.5 and later: Enter the **exit** command.

Step 9 Verify that you can access the **Permanent License Reservation** page in the Secure Firewall Management Center web interface:

- If the **System** > **Licenses** > **Smart Licenses** page is currently displayed, refresh the page.
- Otherwise, choose **System** > **Licenses** > **Universal Licenses**.

Generate a Reservation Request Code from the Firepower Management Center

Universal License	Supported Devices	Supported Domains	Access
Any	Secure Firewall Management Center	Global only	Admin

Procedure

Step 1 If you are not already viewing the **Universal License Reservation** page in the Firepower Management Center, choose **System** > **Licenses** > **Universal Licenses**.

Step 2 Click **Generate**.

Step 3 Make a note of the **Reservation Request Code**.

Generate a Reservation Authorization Code from Cisco Smart Software Manager

Procedure

Step 1 Go to the Cisco Smart Software Manager:

https://software.cisco.com/#SmartLicensing-Inventory

Step 2 If necessary, select the correct account from the top right of the page.

Step 3 If necessary, click **Inventory**.

(This page may display automatically.)

Step 4 Click the **Licenses** tab.

Step 5 Click **License Reservation**.

Step 6 Enter the code that you generated from Firepower Management Center into the **Reservation Request Code** box.

Step 7 Click **Next**.

Step 8 Select **Cisco FMC Universal License Feature**.

Step 9 Click **Next**.

Step 10 Click **Generate Authorization Code**.

At this point, the license is now in use according to the Smart Software Manager.

Step 11 Copy, download, or note down the Authorization Code in preparation for entering it into the Secure Firewall Management Center.

Enter the Reservation Authorization Code into the Firepower Management Center

Universal License	Supported Devices	Supported Domains	Access
Any	Secure Firewall Management Center	Global only	Admin

Procedure

Step 1 If you are not already viewing the **Permanent License Reservation** page in the Firepower Management Center web interface, choose **System** > **Licenses** > **Universal Licenses**.

Step 2 Enter the generated authorization code in the **Authorization Code** text box.

Step 3 Click **Install**.

Step 4 Verify that the **Permanent License Reservation** page shows the **Usage Authorization** status as authorized.

Apply Permanent Licenses to Managed Firepower Threat Devices

Universal License	Supported Devices	Supported Domains	Access
Any	Secure Firewall Management Center	Global only	Admin

Procedure

Step 1 Choose **System** > **Licenses** > **Universal Licenses**.

Step 2 Click **Edit Licenses**.

Step 3 For each type of license you want to add to a device:

a) Click the tab for that type of license.
b) Click a device in the list on the left.
c) Click **Add** to move that device to the list on the right.
d) Repeat for each device to receive that type of license.

Ensure you have licenses for all of the devices you want to add.

e) Repeat this sub procedure for each type of license you want to add.
f) Click **Apply**.

Step 4 Verify that your licenses are assigned as you expect them, and that each feature for each managed device shows a green circle with a **Check Mark** ( ).

If necessary, see Universal Permanent License Status, on page 308 for information.

What to do next

- If you applied a license with export-controlled functionality enabled, reboot each managed device.

  If devices are configured in a high-availability pair, reboot both devices at the same time to avoid an Active-Active condition.

- Deploy configuration changes to managed devices; see the "Deploy Configuration Changes" topic in the Secure Firewall Management Center online help.

Maintain your air-gapped deployment

Manually obtain and install essential content updates when the Cloud-Delivered Firewall Management Center cannot access the internet.

Refer to:

- Manually update the VDB, on page 265
- Manually update intrusion rules, on page 269
- Manually update the GeoDB, on page 267

Universal Permanent License Status

Universal License Status (on the **System** > **Licenses** > **Universal Licenses** page) provides an overview of license usage on the Firepower Management Center, as described below.

Usage Authorization

Authorized— The product is successfully registered and in compliance after successful installation of the authorization code.

Product Registration

Specifies the date when the Authorization Code was installed for Universal Permanent License.

Export-Controlled Features

Specifies whether export-controlled functionality is enabled for your deployment. If it is not, and you expect it to be, contact Cisco TAC.

Product Instance

The Universally Unique Identifier (UUID) of this Firepower Management Center. This identifies the Firepower Management Center in Cisco Smart Software Manager.

Maintain Your UPLR Deployment

To ensure that your deployment remains effective, you must manually obtain and install updates. For more information, see Maintain your air-gapped deployment.

Deactivate and Return a Universal Permanent License

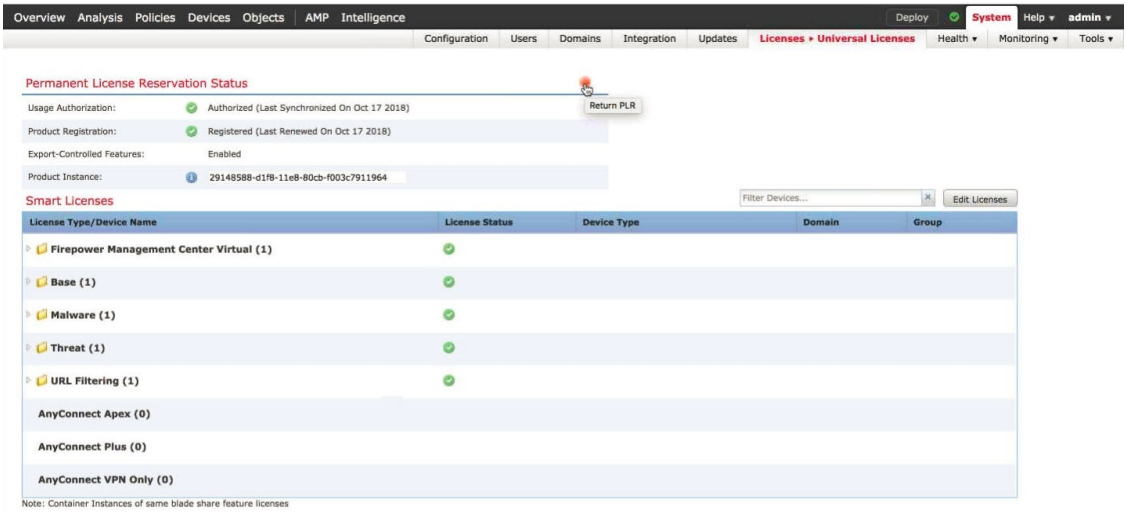
Universal License	Supported Devices	Supported Domains	Access
Any	Secure Firewall Management Center	Global only	Admin

If you no longer need a permanent license, you must return it to your Smart Account.

Important If you do not follow all of the steps in this procedure, the license remains in an in-use state in Cisco Smart Software Manager and cannot be re-used.

Procedure

Step 1 In the Secure Firewall Management Center web interface, choose **System** > **Licenses** > **Universal Licenses**.



Step 2 Make a note of the **Product Instance** identifier for this Secure Firewall Management Center.

Important
You cannot complete this procedure without this identifier.

Step 3 Generate a return code from Firepower Management Center:

a) Click the **Return PLR** button.

The following figure shows the **Return PLR** button.

Firepower Threat Defense becomes unlicensed and Firepower Management Center moves to the de-registered state.

b) Make a note of the **Return Code**.

Step 4 In Cisco Smart Software Manager, identify the Firepower Management Center appliance to deregister:

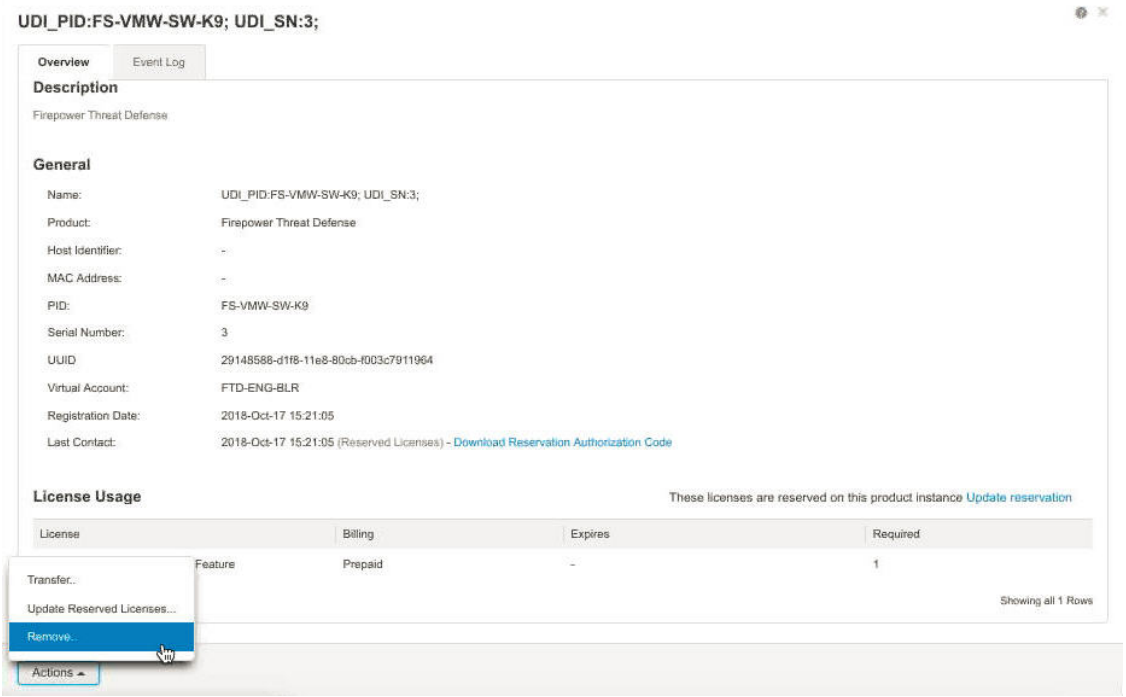
a) Go to the Cisco Smart Software Manager:

https://software.cisco.com/#SmartLicensing-Inventory

b) If necessary, click **Inventory**.

(This page may display automatically.)

c) Click **Product Instances**.



d) Look for a product instance that has **FP** in the **Type** column and a generic SKU (not a hostname) in the **Name** column. You may also be able to use the values in other table columns to help determine which Firepower Management Center is the correct Firepower Management Center. Click the name.

e) Look at the **UUID** and see if it is the UUID of the Firepower Management Center that you are trying to modify.

If not, you must repeat these steps until you find the correct Firepower Management Center.

Step 5 When you have identified the correct Firepower Management Center, return the license to your Smart Account:

a) On the device page, choose **Actions** > **Remove**.

b) Enter the reservation return code that you generated from Secure Firewall Management Center into the **Remove Product Instance** dialog box.

c) Click **Remove Product Instance**.

The Permanent License is returned to the pool of available licenses in the Smart Account.

Step 6 Disable the Universal Permanent License in the Secure Firewall Management Center CLI:

a) Access the Firepower Management Center console using a USB keyboard and VGA monitor, or use SSH to access the management interface.

b) Log in to the Firepower Management Center admin account.

FMC versions 6.3 and 6.4: By default, this gives you access to the Linux shell. If the Firepower Management Center CLI is enabled, this gives you access to the command line interface.

FMC versions 6.5 and later: By default, this gives you access to the command line interface.

c) If you are in the command line interface, enter the **expert** command to access the Linux shell.

d) Execute the following command:

sudo manage_plr.pl

Example:

```
admin@fmc63betaplr: ~$ sudo manage_plr.plnp
Password:
*************** Configuration Utility *************
1 Show PLR Status
2 Enable PLR
3 Disable PLR
0 Exit ************************************************************
Enter choice:
```

e) Select menu option 3 to disable the Universal Permanent License.

f) Select option 0 to exit the manage_plr utility.
g) Type **exit** to exit the shell.
h) If applicable, exit the command line interface:

   Versions 6.3 and 6.4: If the CLI is enabled, enter the **exit** command.

   Version 6.5 and later: Enter the **exit** command.

What to do next

(Optional) If you wish to use the system with standard, connected Smart Licensing, see information about Smart Licensing in the Secure Firewall Management Center online help.

Troubleshooting

How do I identify a particular Firepower Management Center in the Product Instance list in Cisco Smart Software Manager?

On the **Product Instances** page in Cisco Smart Software Manager, if you cannot identify the product instance based on a value in one of the columns in the table, you must click the name of each generic product instance of type **FP** to view the product instance details page. The **UUID** value on this page uniquely identifies one Firepower Management Center.

In the Firepower Management Center web interface, the UUID for a Firepower Management Center is the **Product Instance** value displayed on the **System > Licenses > Universal Licenses** page.

I have enabled Universal Permanent Licensing, but now I do not see a Smart License page.

This is the expected behavior. When you enable Universal Permanent Licensing, Smart Licensing is disabled. You can use the Universal Permanent License page to perform licensing operations.

If you want to use Smart Licensing, you must return the Universal Permanent License. For more information, see Deactivate and Return a Universal Permanent License, on page 309.

I was interrupted in the middle of the licensing process. How can I pick up where I left off?

If you have generated but not yet downloaded an Authorization code from Cisco Smart Software Manager, you can go to the Product Instance page in Cisco Smart Software Manager, click the product instance, then click **Download Reservation Authorization Code**.

I have disabled Universal Permanent Licensing, but forgot to copy the Return Code. What should I do?

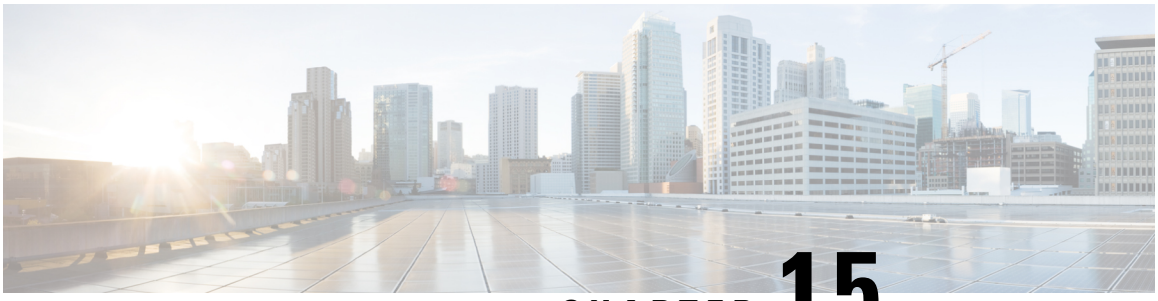
The Return Code is saved in Firepower Management Center. You must re-enable the Universal Permanent License from the shell (see Enable the Permanent Licensing Menu Option, on page 305.) Then refresh the Firepower Management Center web interface. Your Return Code will be displayed.

What do I do in case of a re-image?

Return the Permanent License, add the Return Code in Cisco Smart Software Manager to release the Permanent License, and re-image the Firepower Management Center box.

What do I do in case of a Return Materials Authorization (RMA)?

Contact Cisco TAC to release the reserved licenses.



For Assistance

If you have any questions about installing or using Firepower feature licenses, contact TAC Support:

- Visit the Cisco Support site at http://support.cisco.com/.
- Email Cisco Support at mailto:tac@cisco.com.
- Call Cisco Support at 1.408.526.7209 or 1.800.553.2447.

.

CHAPTER 15

Security certifications compliance

These topics describe how to configure your system to comply with security certifications standards:

- Security certifications compliance modes, on page 315
- Security certifications compliance characteristics, on page 316
- Security certifications compliance recommendations, on page 317

Security certifications compliance modes

A security certifications compliance mode refers to a set of security standards established by the U.S. Department of Defense and global certification organizations. Organizations must use only equipment and software that comply with these standards.

Security certification standards

Secure Firewall supports compliance with these security certifications standards:

- **Common Criteria (CC)**: A global standard established by the international Common Criteria Recognition Arrangement, defining properties for security products.
- **Unified Capabilities Approved Products List (UCAPL)**: A list of products meeting security requirements established by the U.S. Defense Information Systems Agency (DISA).

Note The U.S. Government has changed the name of the Unified Capabilities Approved Products List (UCAPL) to the Department of Defense Information Network Approved Products List (DODIN APL). References to UCAPL in this documentation and the Cloud-Delivered Firewall Management Center web interface can be interpreted as references to DODIN APL.

- **Federal Information Processing Standards (FIPS) 140**: A requirements specification for encryption modules used in secure systems.

Organizations can enable security certifications compliance in CC mode or UCAPL mode. Enabling these modes does not guarantee compliance with every requirement of the selected security mode. For more information on hardening procedures, refer to the product guidelines provided by the certifying entity.

Caution After you enable a security certifications compliance mode, you cannot disable it. To remove an appliance from CC or UCAPL mode, you must reimage the appliance.

Security certifications compliance characteristics

This table describes changes to system behaviors and compliance characteristics when CC (Common Criteria) or UCAPL (Unified Capabilities Approved Product List) mode is enabled. Restrictions on login accounts apply to command line access. These restrictions do not apply to web interface access.

System Change	Cloud-Delivered Firewall Management Center		Classic Managed Devices		Secure Firewall Threat Defense	
	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode
FIPS compliance is enabled.	Yes	Yes	Yes	Yes	Yes	Yes
The system does not allow remote storage for backups or reports.	Yes	Yes	—	—	—	—
The system starts an additional system audit daemon.	No	Yes	No	Yes	No	No
The system boot loader is secured.	No	Yes	No	Yes	No	No
The system applies additional security to login accounts.	No	Yes	No	Yes	No	No
The system disables the reboot key sequence Ctrl+Alt+Del.	No	Yes	No	Yes	No	No
The system enforces a maximum of ten simultaneous login sessions.	No	Yes	No	Yes	No	No
Passwords must be at least 15 characters long, and must consist of alphanumeric characters of mixed case and must include at least one numeric character.	No	Yes	No	Yes	No	No
The minimum required password length for the local `admin` user can be configured using the local device CLI.	No	No	No	No	Yes	Yes
Passwords cannot be a word that appears in a dictionary or include consecutive repeating characters.	No	Yes	No	Yes	No	No
The system locks out users other than `admin` after three failed login attempts in a row. In this case, the password must be reset by an administrator.	No	Yes	No	Yes	No	No
The system stores password history by default.	No	Yes	No	Yes	No	No

System Change	Cloud-Delivered Firewall Management Center		Classic Managed Devices		Secure Firewall Threat Defense	
	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode
The `admin` user can be locked out after a maximum number of failed login attempts configurable through the web interface.	Yes	Yes	Yes	Yes	—	—
The `admin` user can be locked out after a maximum number of failed login attempts configurable through the local appliance CLI.	No	No	Yes, regardless of security certifications compliance enablement.	Yes, regardless of security certifications compliance enablement.	Yes	Yes
The system automatically rekeys an SSH session with an appliance: • After a key has been in use for one hour of session activity • After a key has been used to transmit 1 GB of data over the connection	Yes	Yes	Yes	Yes	Yes	Yes
The system performs a file system integrity check (FSIC) at boot-time. If the FSIC fails, Secure Firewall software does not start, remote SSH access is disabled, and you can access the appliance only via local console. If this happens, contact Cisco TAC.	Yes	Yes	Yes	Yes	Yes	Yes

Security certifications compliance recommendations

Cisco recommends that you observe the following best practices when using a system with security certifications compliance enabled:

- Enable security certifications compliance first on the Cloud-Delivered Firewall Management Center, then enable it in the same mode on all managed devices.
- The Cloud-Delivered Firewall Management Center will not receive event data from a managed device unless both are operating in the same security certifications compliance mode.
- For all users, enable password strength checking and set the minimum password length to the value required by the certifying agency.
- To use Cloud-Delivered Firewall Management Centers in a high-availability configuration, configure them both to use the same security certifications compliance mode before forming the high availability pair.

- When you configure Firewall Threat Defense on a Firepower 4100/9300 to operate in CC or UCAPL mode, you should also configure the Firepower 4100/9300 to operate in CC mode. For more information, see the *Cisco Firepower 4100/9300 FXOS Chassis Manager Configuration Guide*.

Do not configure the system to use any features:

- Email reports, alerts, or data pruning notifications.
- Nmap Scan, Cisco IOS Null Route, Set Attribute Value, or ISE EPS remediations.
- Third-party client access to the system database.
- External notifications or alerts transmitted via email (SMTP), SNMP trap, or syslog.
- Audit log messages transmitted to an HTTP server or to a syslog server without using SSL certificates to secure the channel between the appliance and the server.

Configure authentication and access settings appropriately for your security certifications compliance mode.

- Do not enable external authentication using LDAP or RADIUS in deployments using CC mode.
- Do not enable CACs in deployments using CC mode.
- Disable access to the Cloud-Delivered Firewall Management Center and managed devices via the Secure Firewall REST API in deployments using CC or UCAPL mode.
- Enable CACs in deployments using UCAPL mode.
- Do not configure SSO in deployments using CC mode.

The system does not support CC or UCAPL mode for:

- Firewall Threat Defense devices in clusters
- Firewall Threat Defense container instances on the Firepower 4100/9300
- Exporting event data to an external client using eStreamer.

Appliance hardening

To further harden your system, see the latest versions of the *Cisco Secure Firewall Management Center Hardening Guide* and the *Cisco Secure Firewall Threat Defense Hardening Guide*.

Refer to these topics for configuration steps:

Identity and access management

PART IV

Optimize Firewall Performance with AgenticOps

- Introduction to AgenticOps insights, on page 323

CHAPTER 16

Introduction to AgenticOps insights

AgenticOps brings AI-driven intelligence to firewall management, helping you proactively identify issues, optimize configurations, plan software upgrades, analyze policy health, track feature adoption, and assess capacity requirements. Use AgenticOps capabilities to gain operational visibility, prioritize remediation efforts, and improve the performance, security, and reliability of your firewall deployment.

About AgenticOps insights

Firewalls are a critical component of any organization's network security architecture. As organizations expand and the threat landscape evolves, managing these firewalls becomes complex. Organizations must continuously update rules and configurations to adapt to new threats, network changes, and compliance requirements, which presents significant challenges. Improper management can lead to security gaps and vulnerabilities. These issues pose risks to an organization's network security.

To effectively address these challenges, a new approach to firewall management is required. This is where AgenticOps becomes essential. AgenticOps leverages artificial intelligence (AI) and machine learning (ML) to streamline and enhance firewall management and network security.

Note Currently, AgenticOps supports:

- Firewall Threat Defense devices that are managed by Cloud-Delivered Firewall Management Center.
- Firewall Threat Defense devices managed by On-Premises Firewall Management Center integrated with Cisco Security Cloud.

  For information on supported versions, see AgenticOps Support for On-Premises Firewall Management Centers.

Key functionalities

- **Traffic and capacity monitoring**: Monitors network traffic and system capacity in real-time, and detects anomalies such as elephant flows. This ensures resources are optimized for peak performance.
- **Policy anomaly detection**: Analyzes firewall policies and detects misconfigurations or anomalies before they impact performance or security.
- **Feature adoption insights and best practice recommendations**: Provides insights into the level of feature adoption and suggests best practices to optimize security configurations.
- **Predictive forecasting for network issues**: Predicts potential future network issues, allowing you to address them proactively and minimize downtime.
- **Operational insights:** Evaluates device readiness for software upgrades, suggests compatible versions, and helps plan upgrades to maintain consistency, stability, and compliance across deployments.
- **Critical alerts**: Filters and prioritizes the most urgent security events, helping you focus on critical issues.

Key features

- **Policy Analyzer and Optimizer**: Analyzes security policies, detects anomalies, and provides recommendations on remediations that can be performed to optimize the policies, thereby improving the firewall performance.
- **Policy Change Impact Analyzer**: Provides visibility into pending access control policy rule changes across devices, analyzes affected rules and traffic segments, and assesses potential traffic impacts to help you make informed deployment decisions.
- **Best Practices and Recommendations**: Generates detailed assessment reports that highlight failed checks against Cisco Secure Firewall best practices and provides actionable recommendations to resolve issues, ensuring optimal firewall performance.
- **Feature Adoption**: Provides insights into the features that are adopted and the percentage of adoption to modify the usage pattern and achieve optimal security. Analyze the adoption rate of different features to improve usage patterns and enhance security measures.
- **Software Upgrade Planner**: Provides upgrade suggestions for your devices through a centralized dashboard. The dashboard displays the current and suggested versions and details about security vulnerabilities and bug fixes.

- **Application Outage Insights**: Detects application outages that may impact users, sites, and business-critical services. The feature correlates outage telemetry, operational insights, and affected resources to help you reduce troubleshooting time.
- **Capacity and Trend Analyzer**: Analyzes firewall capacity utilization and traffic trends to identify abnormal spikes, sustained resource consumption, and emerging performance risks. The feature provides operational visibility into throughput, connection behavior, and traffic patterns to optimize firewall performance.
- **Compliance Posture**: Assess firewall compliance posture against supported security standards. The feature evaluates firewall configurations, identifies compliance gaps, and provides actionable remediation insights to improve security posture
- **Configuration Settings**: Provides the ability to configure thresholds for AgenticOps features and enable or disable insight preferences. You can customize these settings to suit your specific needs.

AgenticOps licensing requirements

If you have licenses for the Secure Firewall Management Center, you can access AgenticOps by enabling AgenticOps Insights in your organization. The initial version of AgenticOps is included as part of your firewall license and is granted on a per-device basis.

Prerequisites to use AgenticOps

- Ensure that AgenticOps Insights is enabled for your Security Cloud Control organization and that Cloud-Delivered Firewall Management Center is provisioned.
- You must have **Super Admin** or **Admin** user roles to opt in and opt out of AgenticOps Insights for your organization.
- If you are using an On-Premises Firewall Management Center, ensure it is integrated with Cisco Security Cloud before onboarding AgenticOps.

  For information on supported on-prem Firewall Management Center software versions, see AgenticOps Support for On-Premises Firewall Management Center.
- Configure the required thresholds and preferences for supported AgenticOps features.

View summary dashboard

AgenticOps summary dashboard

The **Summary** dashboard provides a consolidated view of all insights across your environment. It enables identification of areas that require attention and gives you the ability to drill down for operational, configuration, and security analysis. You can filter insights by time range, severity, and status.

Figure 34: AgenticOps summary

- **Insights visualization panel**: Visual representation of your insights, helping you quickly understand overall system posture and where to prioritize action.
  - The inner ring summarizes insights by status and severity.
  - The outer ring represents insight categories. Selecting a category displays related details.

    The insight categories include:

    - **Operations**: Focuses on insights that help maintain the operational health and software lifecycle readiness of your devices. This includes upgrade recommendations for your Firewall Threat Defense devices and End-of-Life notifications.
    - **Configuration**: Focuses on insights that evaluate your network policies, configurations, and adherence to Cisco Firewall best practices. This includes identifying misconfigurations, policy anomalies, and deviations that may impact performance, security, or compliance.
    - **Security**: Focuses on insights that detect suspicious, risky, or anomalous activities within your environment. These insights highlight behaviors that may indicate compromised accounts and malicious intent.

  Select any insight category to view the insights associated with it.
- **Insights by device**: Click on a device to view insights.
- **Insights by priority**: Expand the section to view all devices with related insights.
- Use the icons at the top right of the page for additional actions:
  - **AgenticOps Insights**: Navigate to the view of all AgenticOps insights.
  - **Settings**: Navigate to configure preferences and thresholds for insights.

Confidence levels in AgenticOps

A confidence level represents the reliability of a forecast-based insight generated by AgenticOps. It indicates how accurately AgenticOps can predict future behavior for a given condition, helping you decide when immediate action is required versus when monitoring is sufficient.

Applicable forecast-based insight types

Confidence levels are displayed for the following forecast-based AgenticOps insights:

- Remote Access VPN – Maximum Sessions Nearing Limit
- CPU (LINA) Utilization Forecast Breach
- CPU (Snort) Utilization Forecast Breach
- Memory (LINA) Utilization Forecast Breach
- Memory (Snort) Utilization Forecast Breach

How AgenticOps determines confidence levels ?

For forecast-based insights, such as **High Snort Memory Usage**, **High Snort CPU Usage**, and **RA VPN Forecast,** AgenticOpsevaluates how accurately its machine learning models can predict future behavior using historical patterns and current trends.

Based on this forecast accuracy, each insight is automatically assigned a confidence level. Insights that do not meet a minimum reliability threshold are not generated.

- **High**
  - The forecast is highly reliable and strongly supported by historical data.
  - Recommended action: Prioritize the investigation and take proactive corrective measures.
- **Medium**
  - The forecast is reliable but may show moderate variability.
  - Indicates a strong trend that is likely to continue.
  - Recommended action: Review the insight and plan mitigation.
- **Low**
  - The forecast indicates a possible emerging condition.
  - Limited data or higher variability reduces certainty.
  - Recommended action: Monitor closely and validate with additional operational context.
- **Very low**
  - The forecast signal is weak or in an early stage.
  - Higher uncertainty due to insufficient or inconsistent data.
  - Recommended action: Observe trends. No immediate action is required.

Insight statuses and transitions

This table outlines the possible insight statuses, their descriptions, transitions, and examples.

Status	Description	Transition	Triggered by	Example
Active	• An issue is detected and ongoing. • This is the initial state when an issue is identified.	–	System	Upgrade options suggested for Firewall Threat Defense devices.
Resolved	• AgenticOps automatically marks an active insight as resolved when the issue no longer exists. • Historical details are available for reference.	**Active** to **Resolved**: After you fix the issue and the system confirms it in the next check.	• Automatically by the system for performance issues. • By the user (with system confirmation) for configuration issues.	Overlapping firewall rules corrected by the user.

Status	Description	Transition	Triggered by	Example
Not Applicable (N/A)	• The issue existed earlier but it is no longer present. • No historical data is available for reference.	**Active** to **Not Applicable**	System	• When an Access Control policy is deleted, the corresponding insight is marked as NA. • When a device is deleted from FMC inventory, all insights for that device are marked as NA. • When earlier Policy Analyzer and Optimizer results showed issues but a recheck finds zero issues and no details to display, the insight is marked as NA.

View AgenticOps insights

The **AgenticOps Insights** page provides AI-driven alerts that help you detect, prioritize, and resolve issues across your environment.

Procedure

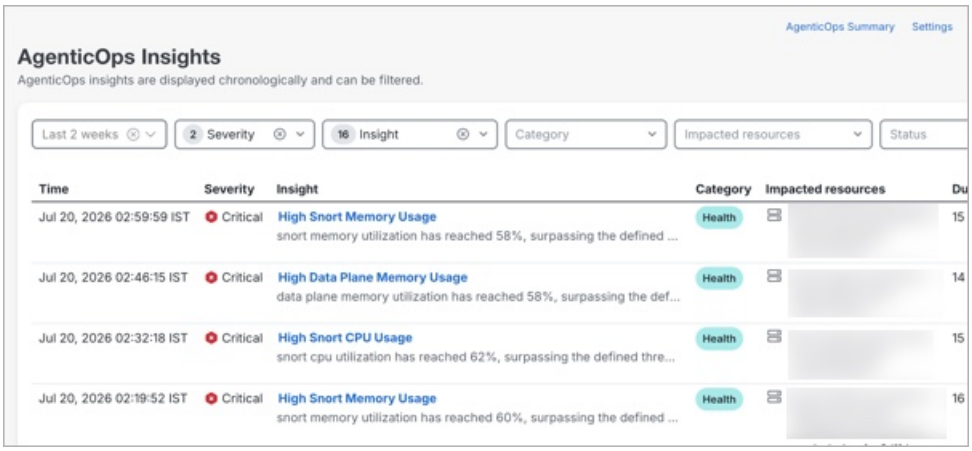
Step 1 In the left pane, click **Insights & Reports** > **Summary**.

Step 2 On the **Summary** page, click **AgenticOps Insights** at the top right.

Insights are displayed in chronological order and can be filtered by the following:

- **Time**: Select a time range to view insights generated within that window
- **Severity**: Select a severity level, such as **Critical**, **Warning**, or **Informational**.
- **Insight**: Select a type of insight to view.
- **Category**: Select a category such as **Configuration**, **Health**, **Operations**, and so on.

- **Impacted Resources**: Select a device or service affected by the insight.
- **Status**: Select a status, such as **Active**, **Not applicable**, or **Resolved** stauses.



Clicking **Reset all** clears all applied filters and returns to the default view.

Step 3 In the insights table, click an **Insight** or **Impacted Resource** to view additional details.

The details include a summary of the issue, the probable cause, related metrics, and recommended remediation or upgrade actions to ensure optimal performance.

Step 4 Use the icons at the top right of the page for additional actions:

Figure 35: AgenticOps insights

- **AgenticOps Summary**: Navigate to the view the high-level summary of all insights.
- **Settings**: Navigate to configure preferences for AgenticOps features.

AgenticOps for On-Premises Firewall Management Center

AgenticOps supports Firewall Threat Defense devices managed by an On-Premises Firewall Management Center that is integrated with Cisco Security Cloud and onboarded to AgenticOps. Support for individual AgenticOps features depends on the On-Premises Firewall Management Center software version.

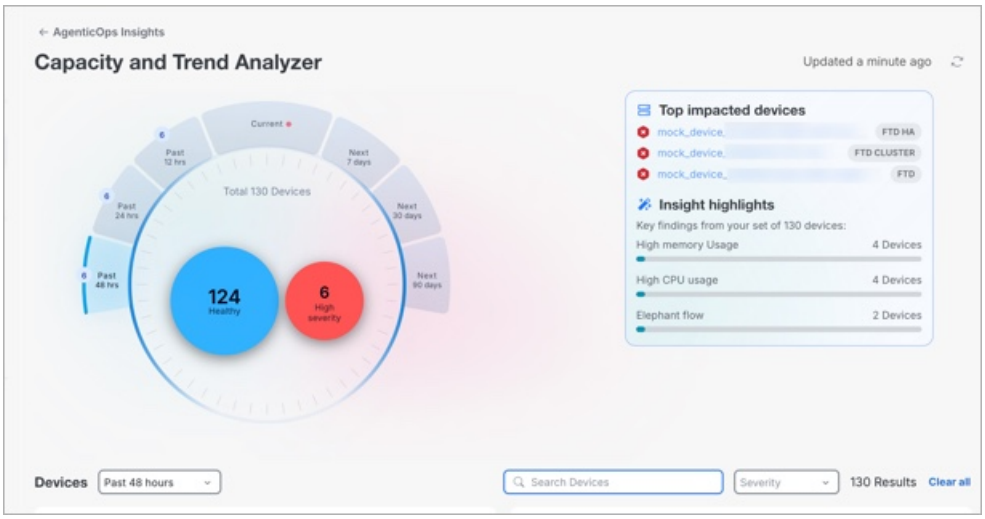
Note Currently, On-Premises Firewall Management Center registered through Secure Device Connector (SDC) are not supported.

AgenticOps feature	Supported On-Premises Firewall Management Center versions
Capacity and Trend Analyzer	10.0.0+
Policy Analyzer and Optimizer	7.4.0+

AgenticOps feature	Supported On-Premises Firewall Management Center versions
Software Upgrade Planner	7.4.0+
Best Practices and Recommendations	10.0.0+
Feature Adoption	10.0.0+
Application Insights (ThousandEyes)	7.6.0+
User Risks Insights	10.0.0+
Policy Analyzer and Optimizer - Network Address Translation	7.6 +
Policy Analyzer and Optimizer - Access Control Policy	7.2.0 +

After onboarding, supported On-Premises Firewall Management Center- managed devices are available throughout AgenticOps, including the Summary page, AgenticOps Insights, and supported feature dashboards.

About capacity and traffic insights



Capacity issues often develop gradually and only become visible when they begin to impact performance. The **Capacity and Trend Analyzer** provides visibility into resource utilization across your devices, highlights emerging risks, and predicts when those risks may lead to performance issues. By combining historical trends with predictive insights, it enables you to anticipate problems and take action before they affect users. This feature enables proactive capacity planning by identifying future risks before they impact system performance.

How AgenticOps generates capacity insights

Forecasted insights predict future resource utilization based on historical trends and patterns. AgenticOps continuously analyzes historical data and runs periodic forecasts to identify when resources are likely to reach configured thresholds.

AgenticOps uses multiple analytical approaches to identify and predict issues. AgenticOps runs forecasts on a recurring weekly basis to identify potential capacity risks in advance, including:

- Detect threshold breaches: Identifies when CPU or memory usage exceeds configured limits in real time.
- Detect anomalies: Identifies unusual deviations from expected behavior based on historical patterns.
- Detect elephant flows: Detects large traffic flows that can impact system performance and resource utilization.
- Detect Remote Access VPN session limits: Detects or predicts when VPN session capacity limits are reached.
- Forecast capacity risks: Predicts future threshold breaches using historical trends, enabling proactive planning.

Note

- The accuracy of insights depends on the availability and quality of historical data. Limited or inconsistent data may delay or reduce insight accuracy.
- In environments with limited activity or newly onboarded devices, insights and forecasts may take time to appear.

Table 17: Key features of Capacity and Trend Analyzer

Feature	Description
Capacity insights dashboard	Provides a fleet-level view of device capacity status, displaying past, current, and predicted capacity insights across all monitored devices.
Capacity insights	Generates insights based on CPU, memory, connection, throughput, and VPN session activity to highlight potential resource constraints.
Device capacity analysis	Displays detailed capacity insights for an individual device, including resource metrics, AI-generated summaries, and forecast information.
Predictive capacity forecasting	Uses historical resource utilization data to predict future usage trends and identify potential capacity risks before thresholds are reached.
Timeline-based analysis	Allows you to analyze capacity insights across different time windows, including past events, current conditions, and predicted future risks.
Device health indicators	Displays device health status based on active and predicted capacity insights, helping you quickly identify devices that require attention.

Supported devices

The Capacity and Trend Analyzer supports:

- Secure Firewall Threat Defense devices
- Secure Firewall Threat Defense High Availability (HA) deployments
- Secure Firewall Threat Defense cluster deployments

Note For High Availability (HA) and cluster deployments:

- Capacity analysis runs at the system level.
- Individual member devices are not displayed separately.

Analyze capacity trends and forecast resource usage

Before you begin

Ensure that **Capacity and Trend Analyzer** is enabled under **Settings**. For more information, see enable Capacity and Trend Analyzer.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Capacity and Trend Analyzer**.

This opens the dashboard where you can view capacity insights across your environment.

Step 2 Use the circular timeline to select a timeframe, such as **Current**, **Past (12 hours**, **24 hours**, or **48 hours)**, **Next (7 days**, **30 days**, or **90 days).**

- **Current** shows active capacity insights.
- **Past 12, 24, or 48 hours** show insights from the selected past period.
- **Next 7, 30, or 90 days** show predicted capacity risks.

The timeline also displays the total number of devices and their health status, such as **Healthy**, **Needs attention**, and **High severity**.

Step 3 Review the summary panel.

- Use the **Top impacted devices** section to identify devices with the most critical capacity issues.
- Use the **Insight highlights** section to understand the most common capacity risks across your organization.

Step 4 Review device insights in the **Devices** section.

- Search for a device or use filters such as timeframe and severity to locate devices that require attention.

- Each device displays a summary of detected or predicted issues, along with associated insight tags.

Step 5 Select a device to view detailed insights.

This view provides summaries and detailed insights for the selected device.

Step 6 On the device details page, review the **AI summary**, **Resolved insights**, **Active insights**, and **Future insights**.

Step 7 In the **Device metrics** section, select a metric to view historical trends and forecast data.

Step 8 Use the insights and forecasts to determine appropriate actions, such as redistributing traffic, scaling resources, or planning capacity upgrades. After taking action, use the **Current** view to monitor whether the issue has been resolved.

The **Capacity and Trend Analyzer** helps you move from reactive troubleshooting to proactive capacity management by enabling you to identify risks early and take informed action.

About policy change impact insights

Changes to an access control policy can affect network traffic in unexpected ways. A modification that appears minor, such as updating a network object, expanding a rule, or changing rule conditions, can alter how traffic is evaluated by other rules in the policy. These effects are often difficult to identify before deployment.

Policy Change Impact Analyzer helps you review the potential impact of pending access control policy rule changes across devices before deployment. The analysis helps you identify affected rules, impacted connections, and traffic segments so that you can better understand the consequences of a change before deploying it. The **Policy Change Impact Analyzer** evaluates proposed policy changes and provides visibility into:

- The overall analysis result for each device
- Affected devices and rules
- Impacted traffic segments
- Historical connections affected by a changed rule, when traffic data is available
- Rule-level inferred impact
- AI-generated summaries that explain the potential effect of a rule change

Limitations and considerations

- Currently, **Policy Change Impact Analyzer** supports Cloud-Delivered Firewall Management Center-managed Firewall Threat Defense devices only.
- **Policy Change Impact Analyzer** is available only for deployments in the US, AUS and EU regions.
- High Availability and cluster deployments are represented by their parent target during analysis.
- Impacted connection counts are available only when **Security Analytics and Logging** is enabled and connection events are sent for FTD Management Services.
- Running an analysis does not deploy, edit, approve, or reject policy changes.

- AI-generated explanations support decision-making. Validate important findings against your security requirements and operational policies before deployment.
- Review analysis results before approving production changes, especially high-risk policy modifications.

Understand analysis results

Review the assessment result to understand the likely effect of pending policy changes and the recommended next steps.

Note An analysis result does not indicate whether a change is approved. Review the transition direction, affected rule, and traffic conditions before deployment.

Analysis result	What it means	Recommended action
Critical	One or more changes may expose the network to threats or disrupt services.	• Review affected rules and traffic segments before deployment. • Revise and rerun when the change is not intended.
Potential impact	One or more changes expand access or may affect traffic.	Validate the affected traffic and the expected business outcome before deploying.
Improved security posture	One or more changes reduce exposure or block risky traffic.	Confirm that the affected traffic is intentionally restricted, then continue through normal change review.
No traffic impact	No behavior-changing traffic transition was identified from the policy comparison.	• Confirm that the proposed rule is needed and is positioned as intended. • This result is different from a change that has zero observed connections.
Indeterminate	The available evidence was insufficient to determine a reliable impact.	• Review the changed rule and traffic criteria manually. • Consider gathering additional operational context and rerunning the analysis.

Understand job statuses

Job Status shows the current state of the policy impact analysis and whether the latest result is available and up to date.

Job status	Description
Verifying analysis is up to date	The system is checking whether the latest analysis still matches the pending policy changes.
Queued	The analysis request was accepted and is waiting to run. Wait for the status to change to **In progress**.
Completed	The latest analysis completed successfully. A warning icon may appear if a policy analysis returned an error.
Partial success	Useful assessment results are available, but one or more stages did not complete. Review the available details and **Workflows** before deciding whether to rerun.
In progress	The system is preparing policy data, calculating impact, or collecting connection evidence. Wait for the result or open **Workflows** to monitor progress.
Out of date	The policy changed after the analysis started, or the analysis is more than 24 hours old and its traffic evidence may no longer be current. Rerun the analysis to get the latest results.
Failed	The latest overall analysis failed. Review the error and **Workflows** details, then rerun the analysis if appropriate.
Cancelled	The analysis was cancelled by an authorized user before completion.
Not analyzed	No analysis is available for the device, or the device has pending changes that have not yet been analyzed. Select a device and run the analysis.
Not applicable	No pending policy changes are available for analysis. Create or save the intended policy changes, then run the analysis.
Unknown	The system could not determine a reliable current status. Refresh the device list and try again later. If the issue persists, review the workflow details.

Understand inferred impact

Inferred Impact describes the likely effect of an individual changed rule or affected rule.

Inferred impact	Description
Potential threat exposure risk	The change may allow risky applications, risky URL categories, broad application or URL scope, sensitive destination ports, or broad Internet exposure.
Potential service disruption	The change may block sensitive services or high-volume business traffic.
Access expansion	The change may allow traffic that was previously blocked without a clear risky-application or sensitive-port signal.
Indeterminate	The available evidence was insufficient, or the impact assessment did not complete.
Improved security	The change blocks risky or untrusted traffic, or reduces broad external exposure.
No traffic impact	No behavior-changing traffic transition was detected.

Impacted traffic segments and connections

An **Impacted Traffic Segment** is a distinct combination of traffic conditions whose policy outcome, such as allow or block, changes when the proposed policy changes are deployed.

- Traffic conditions may include source and destination zones, networks, applications, URLs, users, services, ports, security-group tags, and geolocation identities.
- The number of impacted traffic segments is not the number of rules, packets, IP addresses, or historical connections.

Impacted Connections shows the number of historical connections associated with traffic affected by a changed rule.

- The count is based on available Security Analytics and Logging connection-event data. It represents observed historical activity, not a forecast of future traffic.
- If connection events are unavailable, the analyzer can still identify impacted traffic segments, but historical connection counts are not available.
- Review the policy comparison and traffic segments instead of treating unavailable data as zero traffic.

Understand policy analysis limitations

Some policy constructs are not fully evaluated during analysis. Review affected rules manually before deployment when these constructs are involved.

- Object overrides are not considered during analysis. For example, if a port object has the value `8080` but is overridden to `80` for a particular device, the device-specific value `80` is not considered.
- Country, continent, and custom geolocation objects are expanded to country-level identities. They are not expanded to IP-level identities, and individual IP addresses are not compared.

- URL category reputation is not considered. For example, if a new rule uses the same URL category with a different reputation, the analyzer may report **No Traffic Impact** even though the reputation changed.
- URL list and URL feed objects are not expanded into individual URLs. The analyzer reports an impact only when the object is used in an affected traffic fragment or segment. Individual entries in the list or feed are not evaluated separately.
- Time-range support is limited. Only active time ranges are considered. Rules with future or expired time ranges are treated as disabled. Changes to the time-range configuration itself are not considered during analysis.
- Dynamic-attribute support is limited to Security Group Tags (SGTs), including supported FMC and ISE SGT references. CSDAC-backed dynamic attributes and other unsupported dynamic-object criteria are not analyzed.
- Application filters entered directly in the application field, such as **Very High** or **High** risk or business relevance criteria, are not supported when they are inline filters rather than user-defined application filter objects. User-defined application filters, including filters that combine multiple criteria, are supported.

Analyze policy change impact

Before you begin

- Enable the **Policy Change Impact Analyzer** toggle under **Insights & Reports** > **Settings**.
- To view historical impacted connection counts, enable **Security Analytics and Logging**.
- **Policy Change Impact Analyzer** currently supports Cloud-Delivered Firewall Management Center-managed Firewall Threat Defense devices.

Procedure

Step 1 In the left pane, click **Insights & Reports > Policy Change Impact Analyzer**.

The **Policy Change Impact Analyzer** page displays an **Impact Analysis** summary, including the number of identified impacts.

The device list displays:

- **Device Name**
- **Job Status**
- **Analysis Result**

Step 2 Select one or more devices, and then click **Run Impact Analyzer**.

You can select up to 10 devices for analysis. The analyzer evaluates the pending policy changes for the selected devices.

Step 3 Monitor the analysis in the device list.

Use the search field to search by device name, analysis result, or job status.

Step 4 Click a device row to open the details pane.

The pane displays the device status and may include these actions:

- **View change impact details** to open the detailed analysis.
- **Re-analyze** to generate an updated result.
- **Deploy** to open the standard deployment workflow.
- **Workflows** to review analysis execution details and errors.

Step 5 Click the device name to open the analysis report.

The analysis details page displays the overall impact assessment for the selected device.

Step 6 Review the **Analysis Result**, **Rule Change Summary**, **Impacted Traffic Segments**, **Impacted Connections**, and **Inferred Impact**.

Step 7 If the analysis is incomplete, failed, out of date, or indeterminate, review the policy manually before deployment and rerun the analysis as needed.

Note
Policy Change Impact Analyzer does not deploy, edit, approve, or reject policy changes. Use the standard deployment and change-control process after reviewing the analysis results.

The **Policy Change Impact Analyzer** displays the potential impact of pending access control policy changes, including changed rules, impacted traffic segments, historical connections, inferred impact, and rule change summaries.

About best practices and recommendations

Enhance your organization’s security posture with AgenticOps by identifying deviations from Cisco Secure Firewall best practices. Run assessments on your devices, generate reports, and receive insights that guide you toward optimal performance.

- Assessment: Evaluates your firewall configuration across multiple categories. Each check determines alignment with Cisco Secure Firewall best practices. The report summarizes the total number of checks performed. It categorizes the results as **Passed** or **Requires review**.

  Checks that require review indicate deviations that could impact firewall efficiency and security. Each failed check presents an opportunity for improvement. Addressing these checks contributes directly to optimizing firewall performance.

- Recommendation: Provides specific recommendations to address identified issues, ensuring optimal firewall performance. These include detailed information such as the nature of the problem, symptoms, impact, and required actions.

The best practices and recommendations checks are developed with input from Cisco's Technical Assistance Center (TAC) and Customer Experience (CX) teams. This input helps address trending issues, incorporate industry best practices, and enhance the reliability of recommendations. Implement these recommendations to resolve issues, align with best practices, and optimize firewall performance.

Table 18: Key features

Feature	Description
Automated assessments	Runs periodic evaluations of firewall devices against Cisco best practices.
Checks summary	Displays how many checks passed and highlights those requiring review.
Trend visualization	Shows the number of checks over time, helping you compare passed and failed checks across assessment cycles.
Device reports	Provides device-specific results and percentage of improvement potential.
Review category and check control	Enable or disable review categories or individual checks for future assessments.

Implement best practices and recommendations

Before you begin

Ensure that **Best Practices** is enabled under **Settings**. For more information, see Enable Best Practices.

Procedure

Step 1 In the left pane, click **Insights & Reports > Best Practices and Recommendations**.

The **Assessment Summary** provides a high-level overview of assessment results. It includes two tiles:

- **Checks summary**: Displays the total number of checks and highlights those requiring review.
- **Best practices assessment trend**: Helps you track assessment outcomes over time. The Y-axis represents the number of checks, and the X-axis shows assessment dates. You can hover over data points to view summary statistics.
- **Feedback**: A mechanism for you to provide feedback on the assessments. You can enter optional comments and grant consent for follow-up contact regarding your feedback.

Step 2 In the **Device reports** section, you can view the list of all available device reports. Filter devices by **Device status, Review categories,** or **Assessment status** to narrow down results.

Assessment Statuses: Each device report has an **Assessment Status**, which indicates the current state of the assessment.

- In progress: An assessment is actively running. After completion, a report will be generated.
- In queue: The previous assessment is outdated, and a new one has been scheduled.
- Updated: The assessment is complete, and the latest report is available for review.

- Error: The assessment could not be completed due to an error. The report will be automatically generated after 24 hours. If the issue persists, contact **Cisco TAC** for assistance.

Step 3 From the three-dot menu icon next to each device:

a. Click **Run assessment** to initiate a new assessment.

b. Click **Download report** to export the Best Practices assessment summary report in PDF format.

Schedule Device Assessment

Periodic assessments run automatically, but you can also run assessments manually at any time. In environments with more than **50 devices**, only **50 devices can be analyzed per day**. Use the **Select devices** option on the **Best Practices and Recommendations** page to choose which devices are included in automated assessments.

- **Select devices for automated assessments**:
  a. Click **Select devices** in the notification banner to open the **Schedule devices for assessment** dialog. This dialog allows you to choose which devices run automated assessments.
  b. Devices in the **Scheduled devices** panel are included in automated assessments. Click **Save**.
- **Mange scheduled devices**: You can update the list of scheduled devices at any time. Devices removed from the **Scheduled devices** panel are no longer included in automated assessments. Devices added to this panel are included in future automated assessments.
- **Device scheduling limits**: You can schedule a maximum of **50 devices** for automated assessments. The **Scheduled devices** panel displays the number of currently scheduled devices, for example **48 / 50 devices**. When 50 devices are selected, further selection is disabled and a tooltip indicates that the maximum number of scheduled devices has been reached.

Step 4 Click on a **Device name** to view a detailed report for that specific device.

- Check the **Show passed checks** checkbox to view successful checks in the detailed view. This provides full visibility into all checks.
- In the **Best practices assessment** section, view the **Total checks**, how many **Passed** and **Require review**.
- Expand each check to view the remediations and corrective actions.

Step 5 Enable or disable an entire category from future assessments. You can also disable individual checks within a category.

- Disable the toggle to exclude a review category or check from future assessments.
- Enable the toggle to include it in future assessments.

Note
Disabling a category or check does not affect the actual feature or its operation. The feature continues to function normally, but it is excluded from **Best Practices** assessments.

About feature adoption insights

The **Feature Adoption** dashboard provides a comprehensive view of how effectively different features are being utilized across your environment. Each feature has an adoption rate. This rate is calculated based on the total number of eligible devices and the number of those devices configured with the feature. This insight helps you identify underutilized capabilities and take steps to improve overall adoption.

The dashboard groups features into license categories such as **Essentials**, **IPS**, **Remote Access VPN**, **Features not requiring license**, and **Subscription-Based Features** to help you understand adoption patterns.

Note If a license is not available for a given category, the adoption rate for that category will always be **0%**.

By tracking the adoption rate at both the feature and license category levels, you can prioritize improvements and maximize the usage of available features. **Feature Adoption** helps you use available capabilities to achieve your intended outcomes

Assess and improve feature adoption

Before you begin

Ensure that you have selected the list of features under **Insights & Reports** > **Settings** > **Feature Adoption**.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Feature Adoption**.

- The **Summary** tile provides a quick overview of overall adoption status:
  - **Adoption rate**: Percentage of features currently adopted across their applicable scope.
  - **Total features**: Total number of features available for adoption.
  - **Not adopted**: Number of features that have not been enabled or configured.
  - **Partially adopted**: Number of features that are enabled or in use but not fully across all applicable scope.
  - **Adopted**: Number of features that are fully enabled and in use.
- In the **Feature Recommendation** tile, you can watch short videos about recommended features that will help enhance your organization's security.

Note

- The data updates every 24 hours, but you can click **Refresh** to update it manually.
- We recommend that you increase the usage of these features to improve overall performance.

Step 2 Click on a feature name to view the following details:

- A short description of the feature.
- The feature adoption rate can range from 0% to 100%, based on how much the feature is used. Enable the toggle to include the feature in adoption calculations or disable it to exclude it.

  Note
  Enabling or disabling a feature affects only the adoption score and does not impact the functionality of the feature.

- Steps to improve your feature adoption rate.

About software upgrade insights

The **Software Upgrade Planner** helps simplify firewall software upgrade planning and management. It analyzes your deployed Firewall Threat Defense devices and provides upgrade recommendations based on compatibility, stability, security vulnerabilities, and bug fixes. This helps you make informed upgrade decisions and maintain a consistent software version across the environment.

The feature provides a centralized view of the current software version running on each device along with the suggested version. It also highlights important details such as bug fixes, vulnerability fixes, and upgrade readiness insights. By identifying potential risks and compatibility concerns before the upgrade process begins, the planner helps reduce operational issues and minimizes downtime.

Need a visual guide? Explore the Software Upgrade Planner feature walkthrough to see it in action.

Guided remediation

Software Upgrade Planner also provides guided remediation insights for vulnerabilities and bugs affecting your devices.

When you view the details of a security vulnerability or bug, guided remediation provides AI-generated insights to help you understand the issue and determine an appropriate upgrade version. These insights can include:

- **Root cause analysis**: Summarizes the issue and its potential impact.
- **Workaround**: When available, helps mitigate the issue before upgrading.
- **Remediation guidance**: Identifies how many devices in your deployment are affected and recommends whether upgrading to a specific software version resolves the issue.

Threat campaign insights

Software Upgrade Planner identifies devices that are exposed to active threat campaigns. When applicable, you can view the active threat campaigns affecting a device and access Cisco Talos intelligence resources to learn more about each campaign, including its scope, impact, and recommended mitigations.

Manage software upgrades

Use the Software Upgrade Planner to review suggested software versions for your Firewall Threat Defense devices and evaluate the security and operational benefits of upgrading. In addition to suggested upgrade versions, the planner provides insights into active threat campaigns and guided remediation for vulnerabilities and bugs affecting your devices.

Before you begin

Ensure that the **Software Upgrade Planner** toggle is enabled under **Insights & Reports** > **Settings** > **Operations**.

Procedure

Step 1 In the left pane, click **Insights & Reports > Software Upgrade Planner**.

The **Software Upgrade Planner** page displays a summary of upgrade opportunities across your deployment. The **Summary** section provides an overview of:

- Devices with upgrades available
- Total available fixes
- Details on threat campaigns
- Security vulnerability fixes
- Bug fixes

You can click **View all** in the **CVE Fixes** or **Bug Fixes** tiles to review the corresponding issues across your deployment.

Step 2 Review the suggested upgrade versions for your devices.

- Multiple upgrade options are available based on vulnerabilities, bugs, and new features. The Cisco-suggested version is indicated by a gold star. Choose the version that suits your requirements.
- For each device, the planner displays the current software version and suggested upgrade versions. If a device is affected by one or more active threat campaigns, the current software version displays the number of threat campaigns affecting the device.
- Hover over the **Current version** to view additional details, including the current software version, vulnerabilities found, bugs found, and the active threat campaigns affecting the device.
- Select a threat campaign to open the corresponding Cisco Talos Intelligence blog and learn more about the campaign.

Step 3 To perform an upgrade, click **More actions** (⋮) for the device, and click **Go to product upgrade**

The **Product Upgrades** page opens in Cloud-Delivered Firewall Management Center, where you can perform the upgrade.

- View available upgrade packages.

- Perform an upgrade by clicking **Upgrade** in the **Actions** column. For more information, see Cisco Secure Firewall Threat Defense Upgrade Guide for Cloud-delivered Firewall Management Center.

Step 4 In the **Software Upgrade Planner** page, select a device to view more details.

The device details page displays **Suggested** and **Golden** versions. For each suggested version, you can review:

- Active threat campaigns resolved
- Security vulnerability fixes and bug fixes
- Estimated downtime
- New features included in the release
- Link to detailed release notes

Use this information to compare the available upgrade versions and determine the most appropriate upgrade version for your deployment.

Step 5 Review the **Security vulnerability fixes** or **Bug fixes** tabs.

- These tabs list the vulnerabilities and bugs affecting the selected device. You can search and filter the results or export the list as a CSV file.
- Select a CVE ID or bug ID to open the details pane. The details pane provides AI-generated insights to help you understand the issue, including:
  - **Root cause analysis** that summarizes the issue and its potential impact.
  - **Workaround** information, when available, to help mitigate the issue before upgrading.
  - **Remediation** guidance that identifies how many devices in your deployment are affected and explains whether upgrading resolves the issue.
- In the **Bug fixes** tab, bugs are categorized as **Impacting bugs** and **Other bugs**. Impacting bugs are affecting the selected device and its environment. You can search the list, filter bugs by status (**Fixed bugs**, **Open bugs**, or **All**), and export the results as a CSV file.

You can use the **Software Upgrade Planner** to evaluate suggested software versions, review threat campaign exposure, analyze security vulnerabilities and bug fixes, and use AI-generated remediation insights to make informed upgrade decisions.

About application insights

Application Insights identifies outages for monitored cloud applications by consuming outage intelligence provided by **ThousandEyes Internet Insights.**

ThousandEyes Internet Insights collects telemetry from globally distributed vantage points that continuously measure application and network availability. When an outage affecting a SaaS or cloud service is detected, an outage event is generated. Application Insights uses this intelligence to display outage details such as affected applications, outage duration, impacted regions, and affected domains for the applications you monitor.

For more information about **ThousandEyes Internet Insights**, see Internet Insights.

How application insights work

- Once **Application Insights** is enabled, AgenticOps periodically evaluates Cloud-Delivered Firewall Management Center policies to determine which applications are eligible for monitoring.
- The Cloud-Delivered Firewall Management Center policy is scanned every 24 hours. Applications that are enabled in the policy are automatically monitored, and any detected outages are reported on the **Application Insights** page using outage intelligence from **ThousandEyes Internet Insights**.
- On the **Settings** page, applications that are allowed in the Cloud-Delivered Firewall Management Center policy are preselected by default. You can optionally select additional applications from the list to include them in outage monitoring.

Need a visual guide? Explore the Application Insights feature walkthough to see it in action.

Detect application outages

Before you begin

Ensure that the **Application outage insights** toggle is enabled under **Insights & Reports** > **Settings** > **Application Insights**.

Procedure

Step 1 In the left pane, click **Insights & Reports > Application Insights**.

The Application Insights page displays a summary of detected outages, including the total number of outages, active outages, resolved outages, and the number of applications being monitored for the selected time range.

Step 2 Review the list of affected applications. For each application outage, the following information is displayed:

- Application name
- Affected domains
- Outage duration
- Start and end timestamps
- Affected regions

Step 3 Click an application to view detailed outage information in the right pane.

About compliance insights

Organizations spend significant time and effort validating firewall configurations against industry security standards. This process is often manual, inconsistent, and dependent on specialized expertise. As compliance

requirements evolve, teams must repeatedly revisit configurations, which slows down deployments and increases operational overhead.

Even small misconfigurations such as, overly permissive access rules or missing segmentation controls, can lead to compliance violations that are difficult to detect through manual review.

Compliance Posture in AgenticOps evaluates firewall configurations against industry-standard requirements. It translates compliance guidelines into programmatic checks that can be applied consistently across environments. The current implementation evaluates firewall configurations against the **Payment Card Industry Data Security Standard (PCI DSS) v4.0.1 framework**. Currently, **Compliance Posture** is available only for deployments in the US, EU, and AUS regions.

Disclaimer: The report is provided for informational purposes only and is created using AI. It does not constitute legal or professional compliance advice and is not a substitute for a formal audit or assessment performed by a qualified security assessor. You are responsible for independently verifying the contents of the report for accuracy and completeness. Cisco disclaims all liability related to the report.

Benefits

- **Automate compliance validation** by evaluating firewall policies against predefined rules, eliminating manual review and reducing the risk of human error.
- **Generate compliance reports** that provide detailed findings and recommendations to help you assess and improve your security posture.
- **Review actionable recommendations** that guide remediation, such as restricting overly broad access, validating business intent, or removing redundant rules.
- **Review security zone mappings** to evaluate segmentation controls based on relationships between network zones.

Prepare your environment for compliance evaluation

Before generating a compliance report, make sure that:

- Cloud-Delivered Firewall Management Center is provisioned in your organization.
- AgenticOps is activated in your organization.
- Firewall Threat Defense devices are onboarded and managed through Security Cloud Control Firewall Management.
- The device that you want to evaluate is online and reachable.

Generate compliance reports

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Compliance Posture**.

The **Compliance Posture** page displays previously generated reports and allows you to create new compliance evaluations.

Step 2 Click **Generate Report** to begin defining the report.

Step 3 Enter a name and choose the device to evaluate.

- Currently, **PCI DSS 4.0.1 Compliance Template** is the only supported template. This template evaluates firewall configurations against requirements for network security, access control, secure configuration, and logging.
- Only devices that are currently online are available for selection.

Step 4 Review the security zones.

PCI DSS requires the Cardholder Data Environment (CDE) to be accurately defined. The CDE includes systems that store, process, or transmit cardholder data or sensitive authentication data, as well as environments with unrestricted connectivity to systems handling such data. An automated assessment identifies security zones that are likely to be part of the CDE based on the existing configuration. Review the selected security zones and update the selections based on your knowledge of the network before generating the report.

Step 5 In the **Security Zones** table, select the checkbox in the **CDE** column for each security zone that is part of the CDE. Clear the checkbox for any zone that is not part of the CDE.

Note
Incorrect security zone selections can result in inaccurate compliance findings, particularly for checks related to segmentation and traffic between network zones.

Step 6 Click **Generate Report** to begin the compliance evaluation process.

Note
- Compliance reports are generated manually and are not evaluated automatically.
- The system analyzes firewall policies and validates them against the selected compliance template. Report generation can fail due to device connectivity issues. Verify that the device is online and reachable.
- The page confirms that report generation has started. A comprehensive review and analysis of the policies on the selected device will be performed. This process may take some time.
- Click **Return to compliance reports** to return to the **Compliance Posture** page.

Step 7 Find the generated report.

Use the search field to search reports by name, user, or template. You can also click **Filters** to narrow the results. The **Compliance Status** column shows the number of checks that passed, need review, or failed.

Step 8 Click the report name to view the detailed compliance results.

- The report page displays the report name, evaluated device, last update time, compliance score, and compliance summary.
- The **Compliance Score** shows the number of compliant checks out of the total number of checks.
- The **Compliance Summary** displays total findings, checks that passed, need review, or failed.
- The report displays a list of **Compliance Checks**, each representing a specific requirement being evaluated (for example, restricting inbound traffic to the CDE or validating VPN security). Select a compliance check to view its details, which may include:
  - A description

- References to relevant compliance standards
- Identified findings associated with the check
- Recommendations for remediation

The number next to each compliance check indicates how many findings were identified for that check.

Step 9 Click **Download Report** to export the report in JSON format for audit and offline review.

Step 10 Rerun a report.

After making changes to address compliance findings, rerun the report to evaluate the updated configuration.

You can view compliance findings from the **Summary** page. Navigate to **Insights & Reports > Summary** and click **Operations** to view compliance-related insights for the selected time range.

Manage insight preferences

You can enable or disable insight preferences for your tenant for the following AgenticOps features:

Enable AgenticOps insights

To take advantage of AgenticOps' benefits, you must enable AgenticOps insights. You must have **Super Admin** or **Admin** user roles to enable **AgenticOps Insights** in your tenant.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Select **Confirm AgenticOps activation**, and click **Get Started**.

Step 3 Review the available AgenticOps features for each detected Firewall Management Center. The page displays the supported AgenticOps features, software version, and the number of managed devices for each Firewall Management Center. Click **Setup AgenticOps**.

Step 4 Click **Confirm Onboard**.

The onboarding process begins, and it takes a few minutes to fetch the data that is required to provide the insights. When completed, the **AgenticOps** > **summary** page is displayed.

Disable AgenticOps insights

You can choose to opt out of AgenticOps if you no longer want to use the capabilities. When you opt out, AgenticOps stops collecting data from your devices and deactivates all data processing and alerts. You must have **Super Admin** or **Admin** user roles to disable AgenticOps insights in your tenant.

Data cleanup options

When opting out, you can decide how existing data is handled:

- **Keep existing data**: Stops the AgenticOps service but retains your historical data. If you choose to opt in again later, this data can be reused for improved insights.
- **Remove all data**: Stops the AgenticOps service and permanently deletes all existing AgenticOps data. Deleted data cannot be recovered.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Click **Miscellaneous**.

Step 3 Under **Opt out of AgenticOps**, choose your preferred data cleanup option.

Step 4 Click **Opt out of AgenticOps**.

Manage AgenticOps data sources

Before you begin

- Ensure that AgenticOps is enabled for your organization.
- If you're using an On-Premises Firewall Management Center, ensure that it is integrated with Cisco Security Cloud.

Manage the data sources such as Cloud-Delivered Firewall Management Center and On-Premises Firewall Management Centers registered with Cisco Security Cloud, that provide information to AgenticOps. You can onboard the data sources to enable AgenticOps capabilities or offboard data sources that you no longer want AgenticOps to use.

Note Cloud-Delivered Firewall Management Center is required for AgenticOps and can't be offboarded.

Onboard a data source

1. In the left pane, click **Insights & Reports > Settings**.
2. Under **AgenticOps Settings**, click **Data Sources**.
3. When AgenticOps detects a supported data source that isn't onboarded, a banner appears on the **Data Sources** page. Click **Review & Onboard**.
4. Review the supported AgenticOps features for the selected data source.
5. Click **Confirm Onboard**.

The selected data source is onboarded and becomes available for supported AgenticOps features.

Offboard a data source

1. In the left pane, click **Insights & Reports > Settings**.
2. Under **AgenticOps Settings**, click **Data Sources**.
3. Locate the onboarded data source.
4. Turn off the toggle for the data source.

AgenticOps no longer collects data or generates insights from the selected data source.

Capacity and traffic insights

You can modify the preferences for Capacity and Traffic-related insights. These insights help monitor firewall performance, detect anomalies, and identify potential capacity risks.

Procedure

Step 1 In the left pane, click **Insights & Reports > Settings**.

Step 2 Click **Capacity & Traffic Analysis**.

Step 3 Enable the toggle buttons for the insights you want to monitor:

a. Traffic-related insights

- High traffic caused by elephant flow
- RAVPN capacity assessment

b. System health-related insights

- High data plane CPU usage
- High snort CPU usage
- High data plane memory usage
- High snort memory usage

c. Anomaly detection-related insights

- Connections rate (CPS) anomaly
- Network throughput anomaly

Step 4 For each insight, expand the section and configure the available settings. Depending on the insight, you can select severity levels, configure thresholds, or specify forecast parameters.

Step 5 Click **Submit**.

After you enable the feature for the organization, you can view the detected anomalies in the **Summary** page, and the respective widgets are also displayed in the dashboard.

Best practices and recommendations insights

You can modify the preferences for **Best Practices & Recommendations**-related insights.

Note The setting for **Best Practices & Recommendations** is enabled by default.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Click **Best Practices**.

Step 3 Enable the **Best Practices & Recommendations Analysis** toggle button to view the assessment categories, checks performed under each category, and the number of failed checks for each device.

Step 4 Enable the **Automatic assessment** toggle to activate automated report generation.

Step 5 Click **Submit**.

After you enable the feature for your tenant, you can view the detected anomalies in the **Summary** page, and the respective widget is displayed on the dashboard.

Policy change impact analyzer insights

You can modify the preferences for Policy Change Impact Analyzer-related insights.

Note The **Policy Change Impact Analyzer** toggle is enabled by default.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Click **Policy Change Impact Analyzer** .

Step 3 Enable the **Policy Change Impact Analyzer** toggle.

This feature helps you review the potential impact of pending rule changes in Access Control policies before deployment. It currently supports Cloud-delivered Firewall Management Center-managed Firewall Threat Defense devices.

Step 4 Click **Submit**.

After the feature is enabled, you can access it by clicking **Insights & Reports** > **Policy Change Impact Analyzer**.

Policy change impact analyzer insights

You can modify the preferences for Policy Change Impact Analyzer-related insights.

Note The **Policy Change Impact Analyzer** toggle is enabled by default.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Click **Policy Change Impact Analyzer** .

Step 3 Enable the **Policy Change Impact Analyzer** toggle.

This feature helps you review the potential impact of pending rule changes in Access Control policies before deployment. It currently supports Cloud-delivered Firewall Management Center-managed Firewall Threat Defense devices.

Step 4 Click **Submit**.

After the feature is enabled, you can access it by clicking **Insights & Reports** > **Policy Change Impact Analyzer**.

Operational insights

You can modify the preferences for operations-related insights.

Note The setting for **Software Update Planner** is enabled by default.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Click **Operations**.

Step 3 Enable the **Software Update Planner** toggle. You can view the software versions running on your devices and our upgrade recommendations.

Step 4 Click **Submit**.

After you enable this feature for your tenant, detected insights are listed in the **Summary** page.

Application insights

You can modify the preferences for application outages- related insights.

Note The setting for **Application Insights** is enabled by default.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Settings**.

Step 2 Click **Application insights**.

Step 3 Enable the **Application outage insights** toggle button to receive insights and notifications when application outages occur.

Step 4 In the **Selected applications** list, search for an application and check the checkbox to include it for monitoring. Clear the checkbox to remove an application from monitoring.

Step 5 Click **Submit**.

After you enable the feature for your organization, you can view detected application outages on the **Application Insights** page, and corresponding insights are displayed on the **AgenticOps Summary** dashboard under the **Operations** category.

Frequently asked questions about AgenticOps

What is AgenticOps?

AgenticOps for firewalls leverages artificial intelligence (AI) and machine learning (ML) to streamline and enhance firewall management. By continuously analyzing the data, AgenticOps provides insights that help you:

- Optimize firewall policies and configurations.
- Detect misconfigurations before they impact performance.
- Improve feature adoption and adherence to best practices.
- Receive upgrade suggestions for Secure Firewall Threat Defense devices, including bugs fixes and security vulnerabilities fixes.

Are AgenticOps features available for all types of FMC-managed Firewall Threat Defense devices?

AgenticOps supports Firewall Threat Defense devices managed by Cloud-Delivered Firewall Management Center and On-Premises Firewall Management Centers registered with Cisco Security Cloud. Feature availability varies by management type. For details, see **AgenticOps Support for On-Premises Firewall Management Centers**.

Can onboarding AgenticOps fail?

If an onboarding failure occurs, open a support ticket with Cisco Technical Assistance Center (TAC).

Can AgenticOps Insights be disabled?

Opting out of AgenticOps stops data collection and disables insights. You can choose whether to retain or permanently delete historical data. For more information, see Disable AgenticOps insights, on page 349.

Can I disable specific AgenticOps modules?

Yes. From AgenticOps Settings, you can enable or disable modules such as Feature Adoption, Best Practices & Recommendations, and Operations. Disabled modules stop generating insights but do not affect device functionality.

Can I manually run Best Practices and Recommendations assessments?

Periodic assessments run automatically, but you can also run assessments manually at any time. For large-scale deployments with more than 50 devices, you must run assessments manually due to processing limits.

Does AgenticOps automatically make changes to my firewall configuration?

No. AgenticOps provides recommendations and guidance based on analysis of your environment. Configuration changes are not automatically applied unless you explicitly review and implement them.

PART V

Simplify Firewall Operations with Agent Workforce

- Introduction to Agent Workforce, on page 359

CHAPTER 17

Introduction to Agent Workforce

This chapter introduces Agent Workforce, an AI-driven operational framework in Security Cloud Control that helps you troubleshoot network issues, analyze operational behavior, and manage firewall policies using natural language interactions.

Agent Workforce uses specialized agents to assist with operational workflows such as VPN troubleshooting, traffic remediation, and policy analysis. You can interact with agents conversationally to investigate issues, review recommendations, and perform guided operational tasks.

- About Agent Workforce , on page 359
- Troubleshoot site-to-site VPN issues with VPN agent, on page 361
- Remediate traffic congestion with Elephant flow agent , on page 363
- Analyze firewall data with Firewall insight agent, on page 365

About Agent Workforce

Agent Workforce is an AI-driven operational framework that enables you to interact with specialized agents using natural language to troubleshoot issues, analyze network behavior, and manage firewall policies.

Instead of relying solely on manual investigation, command-line analysis, or complex configuration workflows, Agent Workforce allows you to describe operational problems or intended actions conversationally. Based on the user query, the appropriate agent analyzes telemetry, configurations, policies, and operational data to provide insights, recommendations, diagnostics, or policy actions. Each agent is optimized for a specific operational area and performs focused analysis based on its specialization.

Available agents in Agent Workforce

Agent Workforce includes specialized agents designed to assist with different operational and security workflows. Each agent focuses on a specific operational domain and uses relevant telemetry, protocol awareness, policy analysis, and contextual operational data to provide diagnostics, recommendations, and actionable outcomes.

When you enter a query, Agent Workforce interprets the intent and automatically routes the conversation to the most appropriate agent. You can describe operational issues or tasks in natural language without determining which agent should handle the request.

Note Currently, Agent Workforce capabilities are available only for deployments in the US, EU, and AUS regions.

Depending on the workflow, Agent Workforce may also present contextual quick actions to help you initiate common investigative or remediation tasks more efficiently. Currently, Agent Workforce includes the following agents:

- **VPN agent** helps troubleshoot site-to-site VPN connectivity, routing, tunnel negotiation, and secure traffic flow issues.
- **Elephant flow agent** helps analyze and remediate high-bandwidth traffic flows that may impact firewall performance and operational stability.
- **Firewall insight agent** helps analyze firewall inventory, configurations, policies, routing, and device status.

Manage Conversations in Agent Workforce

Use the **Conversations** page to create new conversations, monitor active investigations, and interact with specialized agents for troubleshooting, investigation, and remediation workflows.

Procedure

	Command or Action	Purpose
Step 1	In the left pane, click **Insights & Reports** > **Agent Workforce** > **Conversations.**	
Step 2	Review the list of available conversation threads.	Each conversation displays information such as the thread title, assigned agent, workflow status, creator, and creation date.
Step 3	To locate a specific conversation, use the **Search** field to search by keywords.	
Step 4	To narrow the conversation list, click **Filters** and filter conversations using one or more criteria.	
Step 5	To create a new conversation, click **New Conversation**.	
Step 6	Enter your query in natural language.	Agent Workforce automatically selects the most appropriate agent based on the operational intent of the request.
Step 7	Continue interacting with the assigned agent if additional investigation, troubleshooting, or remediation actions are required.	

Limitations and considerations

- Currently, Agent Workforce capabilities are available only for deployments in the US, EU, and AUS regions.
- AI-generated insights, recommendations, and remediation actions must always be reviewed and validated before deployment.
- The accuracy of generated responses depends on the availability, completeness, and correctness of telemetry, policies, device configurations, logs, objects, and operational context within the environment.
- Missing, incomplete, or unresolved configuration entities may prevent certain workflows, recommendations, remediation actions, or deployment operations from completing successfully.
- Agent responses and operational analysis may vary depending on the enabled platform capabilities, configured integrations, available data sources, and device reachability.
- Some workflows may require manual validation, administrative approval, or additional configuration updates before operational changes can be applied to managed devices or policies.
- AI-generated operational guidance is intended to assist administrators and must not replace standard security review, compliance validation, or change-management procedures.

Troubleshoot site-to-site VPN issues with VPN agent

The VPN agent is an intelligent troubleshooting agent that helps you diagnose and resolve site-to-site VPN connectivity and access issues. The agent analyzes operational telemetry, VPN configurations, routing behavior, packet flow, and access control policies to identify issues affecting secure connectivity between sites. It provides protocol-aware diagnostics across technologies such as BGP, EIGRP, OSPF, IPsec, and IKE to accelerate root-cause analysis and reduce manual troubleshooting effort.

Benefits of using the VPN agent

- Investigate VPN tunnel failures and connectivity disruptions.
- Analyze traffic flow between remote networks.
- Detect routing inconsistencies affecting VPN communication.
- Identify access control or policy-related packet drops.
- Perform packet-level troubleshooting and operational analysis.

How VPN agent works

When a query is submitted, the VPN agent correlates operational data across routing protocols, tunnel negotiation states, traffic flow behavior, and policy enforcement to identify the most likely root cause and provide actionable insights. Depending on the issue being investigated, the VPN agent can:

- Identify affected site-to-site VPN tunnels.
- Analyze IKE Phase 1 and Phase 2 negotiation states.

- Review tunnel establishment and peer connectivity status.
- Investigate routing behavior across the VPN tunnel.
- Evaluate traffic flow behavior between local and remote networks.
- Correlate logs, telemetry, and operational events to identify likely root causes.
- Generate operational findings, root-cause analysis, and remediation recommendations.

Note The VPN agent works only for Firewall Threat Defense site-to-site VPN configurations managed by Cloud-delivered Firewall Management Center or On-Premises Firewall Management Center.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Agent Workforce** > **Conversations**.

Step 2 Click **New Conversation**.

Step 3 Enter a query describing the VPN connectivity issue or traffic-flow problem.

Agent Workforce automatically assigns the request to the VPN agent based on the operational intent.

Step 4 Review the generated diagnostics, tunnel analysis, routing behavior, traffic flow analysis, and remediation recommendations.

Step 5 Continue refining the investigation by providing additional operational details such as affected sites, peer devices, tunnel names, or observed behavior.

Step 6 Review the recommended remediation actions and validate the operational impact before applying configuration changes.

After the analysis is completed, the VPN agent summarizes operational findings, identified root cause, impact assessment, additional observations, recommended remediation steps and next actions.

Best practices for using the VPN agent

To improve troubleshooting accuracy and reduce analysis time:

- Include source and destination networks whenever possible.
- Specify the affected VPN tunnel, site, or peer device if known.
- Clearly describe observed behavior such as packet drops, intermittent connectivity, or failed tunnel establishment.
- Refine prompts with additional operational context if further analysis is needed.
- Validate recommended remediation steps before deployment.

Example prompts and expected outcomes for the VPN agent

User intent	Example prompt	Expected outcome
Troubleshoot connectivity between remote sites	Troubleshoot why the connectivity is down between [remote site 1] and [remote site 2].	VPN agent identifies the relevant Site-to-Site VPN tunnel associated with the affected networks and performs guided troubleshooting analysis.
Troubleshoot a VPN tunnel outage	My VPN tunnel is down. Help me troubleshoot the issue.	VPN agent identifies available VPN tunnels, allows tunnel selection if needed, and analyzes tunnel state, negotiation behavior, routing, and connectivity conditions.
Investigate VPN traffic flow issues	Investigate why VPN traffic is not flowing across the [tunnel name].	VPN agent analyzes traffic forwarding behavior, routing conditions, and policy enforcement affecting traffic flow across the VPN tunnel.
Review configured VPN tunnels	How many VPN tunnels are configured and what state are they in?	VPN agent displays configured site-to-site VPN tunnels along with operational state, tunnel health, and connectivity status details.
Visualize VPN routing paths	Visualize the routing between various devices connected by my VPN tunnels.	VPN agent analyzes VPN topology, connected networks, and routing relationships, and provides communication paths across VPN tunnels.

Remediate traffic congestion with Elephant flow agent

Large traffic flows, commonly referred to as elephant flows, can consume excessive bandwidth, increase firewall processing overhead, and degrade application performance across the network. The Elephant flow agent is an intelligent remediation agent that helps you remediate high-bandwidth traffic flows that impact network performance and critical applications. It relies on a valid AgenticOps-generated insight and uses the device and application information provided in the insight to construct a trust rule and guide the remediation workflow. Unlike traditional troubleshooting workflows that require manual investigation across multiple dashboards and telemetry sources, the Elephant flow agent provides a guided remediation experience directly within the conversation workflow.

Note The Elephant flow agent remediates only high-bandwidth traffic flows identified in a valid AgenticOps-generated insight; it does not detect elephant flows.

Benefits of using the Elephant flow agent

- Analyze previously detected elephant flows affecting network performance.
- Investigate abnormal traffic spikes and sustained utilization.
- Identify applications or traffic flows contributing to congestion.
- Recommend remediation actions to reduce processing overhead and congestion.
- Stage policy updates associated with remediation workflows.

How Elephant flow remediation works

Before you begin

- Ensure that **Cloud-Delivered Firewall Management Center** is provisioned in your organization.
- Ensure that AgenticOps is onboarded in your organization.
- Ensure that **High traffic caused by elephant flow** is enabled under **Insights & Reports** > **AgenticOps Insights** > **Settings** > **Capacity & Traffic Analysis**. For more information, see Capacity and traffic insights.
- Ensure that valid AgenticOps-generated elephant flow insights exist. Remediation cannot begin without a valid insight.

Procedure

Step 1 In the left pane, click **Insights & Reports** >**Summary**.

Step 2 On the AgenticOps **Summary** page, select the **Traffic & Capacity** insights category.

Step 3 In the **High traffic caused by elephant flow** section, select the affected device.

Step 4 Review the detected elephant flow insight details, affected resources, applications, and traffic impact information.

Step 5 Click **Review proposed remediation** to open the remediation workflow in **Agent Workforce** > **Conversations**.

a. Alternatively, navigate to **Insights & Reports > Agent Workforce > Conversations**.

b. Click **New Conversation** and select **View elephant flow insights** to start the remediation workflow.

Note
Manual prompt entry is not required to start the workflow.

Step 6 Review the proposed remediation actions, operational warnings, shared policy impact, and success criteria.

Step 7 Approve or cancel the remediation workflow as required.

Step 8 Deploy the generated policy updates to the affected devices.

Note

Elephant flow events displayed in the Unified Event Viewer might not be available to the remediation agent if AgenticOps did not generate a corresponding insight.

Best practices for using the Elephant flow agent

To improve remediation accuracy and operational visibility:

- Review affected applications before approving remediation actions.
- Verify the operational impact of policy updates before deployment.
- Review shared policy impact warnings before approving remediation actions.
- Monitor application and network behavior after remediation is completed.

Analyze firewall data with Firewall insight agent

The Firewall insight agent helps you investigate the configuration and operational state of your managed firewalls. It provides information about device inventory, interfaces, routing, policies, licensing, compliance, software, and security configuration, and identifies conflicts, inconsistencies, and other issues that may require attention.

Benefits of using the Firewall insight agent

- View firewall inventory by device type, connectivity state, licensing status, compliance status, and onboarding state.
- Identify unlicensed or out-of-compliance devices.
- Identify access control or policy-related packet drops.
- Review routing configuration, BGP configurations, and route exchange between devices.
- Review interface status and device connectivity information.
- Review syslog and email alert configuration.
- Ask follow-up questions to investigate findings in greater detail.

How Firewall insight agent works

When you submit a query, Firewall insight agent identifies the relevant devices, configurations, policies, or operational data and returns the associated information. The agent can:

- Identify the devices, policies, routes, interfaces, or configurations related to the query.
- Correlate information across devices, policies, routing, security configuration, and operational state.
- Compare related configurations and identify conflicts, overlaps, redundancies, or inconsistencies.

- Explain when a device or configuration cannot be found and identify the information required to continue the investigation.
- Generate operational findings, root-cause analysis, and recommended next steps.

Procedure

Step 1 In the left pane, click **Insights & Reports** > **Agent Workforce** > **Conversations**.

Step 2 Click **New Conversation**.

Step 3 Enter a query about firewall inventory, device state, routing, policies, security configuration, or operational data.

Agent Workforce automatically assigns the request to an agent based on the operational intent.

Step 4 Review the returned firewall information, analysis, and key observations.

The Firewall insight agent analyzes firewall data and reports findings, comparisons, and recommended next steps. It does not modify configurations, create or deploy policies, or approve changes.

Step 5 Continue the investigation by providing additional context, such as device names, policy names, object names, interfaces, or other relevant identifiers.

Step 6 Review the recommended next steps and validate the operational impact before applying configuration changes.

After the analysis is completed, Firewall insight agent summarizes the operational findings, identified root cause, impact, additional observations, and recommended next steps.

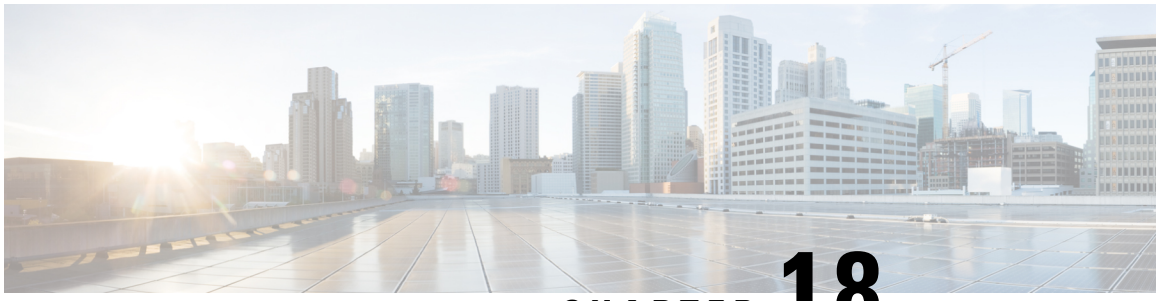
Best practices for using the Firewall insight agent

To improve troubleshooting accuracy and reduce analysis time:

- Include device names, policy names, object names, or other identifiers when available.
- Clearly describe observed behavior such as packet drops, intermittent connectivity, unexpected policy behavior, or configuration inconsistencies.
- Provide additional operational context if further analysis is needed.
- Review recommended next steps and validate their operational impact before deployment.

Example prompts and expected outcomes for the Firewall insight agent

User intent	Example prompt	Expected outcome
Review firewall inventory	What devices do I have in my firewall inventory?	The agent summarizes devices by type and connectivity state. It can also provide software versions, addresses, manager associations, licensing status, and compliance status.



User intent	Example prompt	Expected outcome
Review interfaces	List all interfaces and their status for `[device name]`.	The agent lists the device interfaces and their status. If the device cannot be found, it explains the lookup failure.
Review BGP configuration	Show the current BGP configuration on `[device name]`.	The agent returns BGP neighbors, local and remote AS numbers, peering type, tunnel interfaces, redistribution, and related configuration details.
Review licensing and compliance	Which Firewall Threat Defense devices are unlicensed or out of compliance?	The agent lists affected devices and provides their license and compliance status, software version, and other relevant device details.
Review software updates	Which Firewall Threat Defense devices have a recommended software update?	The agent identifies devices with available updates and provides current versions, target versions, fixes, and affected defects or threats.

PART VI

Health and Monitoring

- Health, on page 371
- Troubleshooting, on page 419

CHAPTER 18

Health

The following topics describe how to use health monitoring:

- Requirements and prerequisites for health monitoring, on page 371
- Health monitoring in Cloud-Delivered Firewall Management Center, on page 371
- Health policies, on page 383
- Device exclusion in health monitoring, on page 389
- Health monitor alerts, on page 393
- About the health monitor, on page 398
- Health event views, on page 407
- Sending device health metrics to OpenConfig, on page 410
- system auditing, on page 416

Requirements and prerequisites for health monitoring

This reference provides the requirements and prerequisites needed to implement health monitoring functionality.

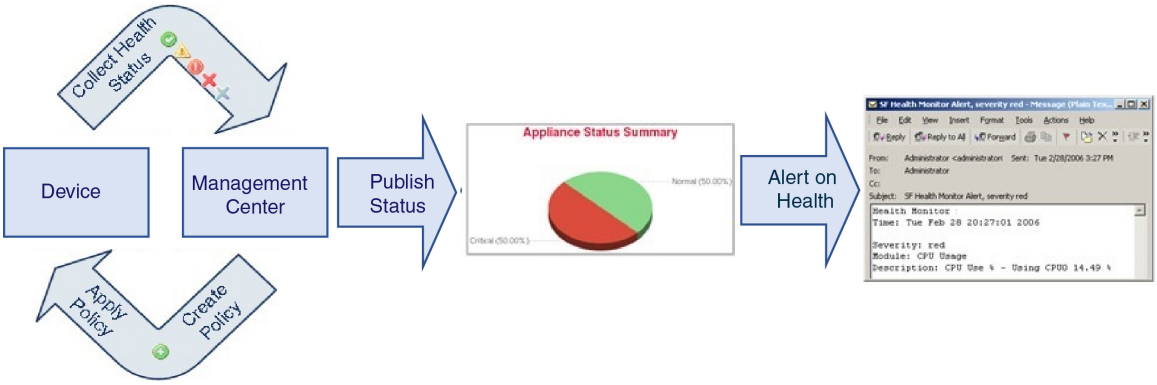
Model support

Any

Supported domains

Any

Health monitoring in Cloud-Delivered Firewall Management Center



Health monitoring is a system capability that

- tracks various health indicators to ensure hardware and software are working correctly,
- checks the status of critical functionality across your deployment, and
- enables configuration of test frequency for alerting and time series data collection.

Health monitoring capabilities

Health monitoring includes two key capabilities: health status monitoring through health policies and health modules, and time series data collection for metrics analysis.

With time series data collection, you can configure how frequently metric data is collected for the device and its health modules. The device monitor reports these metrics in several predefined health monitor dashboards by default. This metric data is collected for analysis. Some alerts are generated from metric values when they cross the thresholds specified in the health policy.

You can use the health monitor to create a collection of tests, referred to as a *health policy*, and apply the health policy to one or more appliances. The tests, referred to as *health modules*, are scripts that test for the criteria you specify. You can modify a health policy by enabling or disabling tests or by changing test settings, and you can delete health policies that you no longer need. You can also suppress messages from selected appliances by excluding them.

The health monitoring system run the tests in a health policy at the configured intervals. You can also run all tests, or a specific test, on demand. The health monitor collects health events based on the test conditions configured.

Note All appliances automatically report their hardware status via the Hardware Alarms health module. The Cloud-Delivered Firewall Management Center also automatically reports status using the modules configured in the default health policy. Some health modules, such as the Appliance Heartbeat module, run on the Cloud-Delivered Firewall Management Center and report the status of the Cloud-Delivered Firewall Management Center's managed devices. For the health modules to provide managed device status, you must deploy all health policies to the device.

You can use the health monitor to access health status information for the entire system and for a particular appliance. In a multi-domain deployment, you can view the health status summary for a device in the domain where the device is located.

A hexagon-shaped widget and status tables on the **Health Status** page provide a visual summary of the status of all appliances on your network, including the Cloud-Delivered Firewall Management Center. Individual appliance health monitors let you drill down into health details for a specific appliance.

Fully customizable event views allow you to quickly and easily analyze the health status events gathered by the health monitor. These event views allow you to search and view event data and to access other information that may be related to the events you are investigating. For example, if you want to see all the occurrences of CPU usage with a certain percentage, you can search for the CPU usage module and enter the percentage value.

You can also configure alerting in response to health events. A *health alert* is an association between a standard alert and a health status level. SNMP and syslog are not supported as the primary methods for sending health alerts to external systems. Use email or webhook alert responses for external health alerting. For example, if you want to make sure an appliance never fails due to hardware overload, you can set up an email alert. You can then create a health alert that triggers an email alert whenever CPU, disk, or memory usage reaches the Warning level you configure in the health policy applied to that appliance. You can set alerting thresholds to minimize the number of repeating alerts you receive.

Note The health monitoring can take 5–6 minutes from the occurrence of the health event to generate the health alert.

You can also generate troubleshooting files for an appliance if you are asked to do so by Support.

High availability pair

In a Cloud-Delivered Firewall Management Center high availability deployment, the active peer creates a health monitor page that uses REST APIs to show detailed metric-based information. The standby peer creates the health monitor page that shows the alert information and provide a visual summary of the status of all appliances on your network using pie charts and status tables. The standby peer does not display the metric-based information.

Health modules

Describes health modules that monitor system conditions and provide alerts or metrics for managing device health and performance.

Health modules, or *health tests,* test for the conditions that you specify in a health policy.

Health monitoring includes both health alerts or tests and metric or time series data collection. The two types of health modules are alert modules and metrics modules. Alerts modules (sometimes called *legacy* modules) monitor system infrastructure and report only the health status. When the conditions specified in the health policy for these monitored systems are met, these modules raise health alerts. Metrics modules (sometimes called *telegraf* modules) collect statistics (sometimes called *time series data*) that you can view on the health monitoring dashboard. Some alerts are also generated from metric values when they cross the thresholds specified in the health policy. You can create custom dashboards with your preferred health metrics, allowing you to monitor statistics or troubleshoot appliance health issues.

Note The health alerts generated from the Secure Firewall 200 series device is limited to the essential health modules, to optimize performance and ensure effective resource utilization. For more information about the available health modules, refer to Health alerts for Secure Firewall 200 Series device, on page 394.

Table 19: Device Health Modules

Module	Type	Description
AMP Connection Status	Metrics	The module alerts if the device cannot connect to the AMP cloud or Cisco AMP Private Cloud after an initial successful connection, or if the private cloud cannot contact the public AMP cloud. Disabled by default.

Module	Type	Description
AMP Threat Grid Connectivity	Metrics	The module alerts if the device cannot connect to the AMP Threat Grid cloud after an initial successful connection.
ASP Drop	Alert	Monitors the connections dropped by the data plane accelerated security path.
Automatic Application Bypass	Alert	Monitors bypassed detection applications.
Certificate Monitoring	Alert	Alerts when service authentication certificates are near expiration or have expired, based on a configurable threshold (in days). This alert helps you to identify certificates that are about to expire and renew them before a service disruption occurs.
Chassis Environment Status	Alert	Monitors chassis parameters such as fan speed and chassis temperature, and enables you to set a warning threshold and critical threshold for temperature. The **Critical Chassis Temperature (Celsius)** default value is `85`. The **Warning Chassis Temperature (Celsius)** default value is `75`.
Cluster/HA Failover Status	Alert	For threat defense clusters, alerts when a unit joins, leaves, or is elected primary.
Configuration Resource Utilization	Alert	Alerts if the size of your deployed configurations puts a device at risk of running out of memory. The alert shows you how much memory your configurations require, and by how much this exceeds the available memory. If this happens, reevaluate your configurations. You may be able to reduce the number or complexity of access control rules or intrusion policies.
Connection Statistics	Metrics	Monitors connection statistics and NAT translation counts. For standby Firewall Threat Defense devices in a high availability pair, this widget reflects only the statistics of connections replicated from the active device.
CPU Usage (per core)	Metrics	Alerts when CPU core use exceeds a configurable threshold.
Critical Process Statistics	Metrics	Monitors the state of critical processes, their resource consumption, and the restart counts.
CPU Usage Date Plane	Metrics	Alerts when data plane CPU use exceeds a configurable threshold.
Memory Usage Data Plane	Metrics	Alerts when data plane memory use exceeds a configurable threshold.
Deployed Configuration Statistics	Metrics	Monitors statistics about the deployed configuration, such as the number of ACEs and IPS rules.
Disk Status	Alert	Alerts if there is an issue with the hard disk or RAID controller. If this module alerts, contact Cisco TAC. This will prevent upgrade.

Module	Type	Description
Disk Usage	Metrics	This module compares disk usage on the appliance's hard drive to the limits configured for the module and alerts when usage exceeds the thresholds configured for the module. This module also alerts when the system excessively deletes files in monitored disk usage categories, or when disk usage excluding those categories reaches excessive levels, based on module thresholds. Use the Disk Usage health status module to monitor disk usage for the `/` and `/volume` partitions on the appliance and track draining frequency. Although the disk usage module lists the `/boot` partition as a monitored partition, the size of the partition is static so the module does not alert on the boot partition. Use the **Clear disk space** option to free up disk space by removing the temporary files from your threat defense device. For more information, refer to Clear disk space, on page 432
File System Integrity Check	Alert	This module performs a file system integrity check and runs if the system has CC mode or UCAPL mode enabled, or if the system runs an image signed with a DEV key.
Firewall Threat Defense HA	Alert	Alerts if a threat defense high availability pair is split brain.
Firewall Threat Defense Platform Faults	Alert	Monitors Secure Firewall 1000 /3100 /4200 platform faults and generate health alerts for the faults. A platform fault represents a failure in the Firewall Threat Defense instance or an alarm threshold that has been raised. During the lifecycle of a platform fault, it can change from one state or severity to another. Each fault includes information about the operational state of the affected object at the time the fault was raised. If the fault is transitional and the failure is resolved, then the object transitions to a functional state. For more information, refer to *Cisco Firepower 1000/2100 FXOS Faults and Error Messages Guide*.
Flow Offload Statistics	Metrics	Monitors hardware flow offload.
Hardware Alarms	Alert	This module determines if hardware needs to be replaced on a physical managed device and alerts based on the hardware status. It also reports on the status of hardware-related daemons.
Identity Limits Monitor (supported only on Secure Firewall 200 Series devices)	Alert	Alerts when the device identity-related mappings and user-to-group mappings exceed the normal limit. Device identity-related mappings include user sessions, SGT Exchange Protocol (SXP) mappings, and dynamic object mappings. For more information, refer to Identity-limits-monitor.
Inline Link Mismatch Alarms	Alert	Alerts if inline pair interfaces negotiate different speeds.

Module	Type	Description
Interface Status	Alert	Determines if the device currently collects traffic and alerts based on the traffic status of physical interfaces and aggregate interfaces. For physical interfaces, the information includes interface name, link state, and bandwidth. For aggregate interfaces, the information includes interface name, number of active links, and total aggregate bandwidth. **Note** • This module also monitors the high availability standby device traffic flow. Though it is known that the standby device would not be receiving any traffic yet, the Cloud-Delivered Firewall Management Center alerts that the interface is not receiving any traffic. The same alerting principle is applied when traffic is not received by some of the subinterfaces on a port channel. • This module displays the traffic rates according to the values from Lina. However, if you use the **show interface** CLI command to know the interface statistics of your device, the input and output rates in the CLI command result can be different from the traffic rates that appear in the **Interface** widget. The sampling intervals of Lina and the Cloud-Delivered Firewall Management Center interface statistics are different. Due to the difference in sampling interval, throughput values in the Cloud-Delivered Firewall Management Center GUI can be different from the throughput values appears in the device CLI result. • Note that traffic rates in the **Interface Traffic Rate** widget (**Overview** > **Dashboards heading** > **Dashboard** page) can be different as it displays the input and output rates from Snort.
Intrusion and File Event Rate	Alert	Alerts if intrusion events per second exceed a configurable threshold. We recommend a warning threshold of 1.5 times your average intrusion event rate, and a critical threshold of 2.5 times. For example, for an average event rate on network segment of 20 events per second, we recommend a warning value of 30 and a critical value of 50. The critical limit must be lower than 1000, and higher than the warning limit. Event rates for your devices are available on **System** (⚙) > **Monitoring** > **Statistics**. If the rate is zero, the Snort process may be down or the device may not be sending events.
Link State Propagation	Alert	For the ISA 3000, alerts when an interface in a inline set fails.
Memory Usage	Alert	Alerts when memory use exceeds configurable thresholds. For appliances with more than 4 GB of memory, the preset alert thresholds are based on a formula that accounts for proportions of available memory likely to cause system problems. On >4 GB appliances, because the interval between Warning and Critical thresholds may be very narrow, it is recommended that you manually set the **Warning Threshold %** value to `50`. This will further ensure that you receive memory alerts for your appliance in time to address the issue. Complex access control policies and rules can command significant resources and negatively affect performance.

Module	Type	Description
Network Card Reset	Alert	Alerts when a network card restarts due to hardware failure.
NTP Statistics	Metrics	Monitors NTP synchronization status. Disabled by default.
Firewall Management Center Access Configuration Changes	Alert	Monitors configuration changes made on the Cloud-Delivered Firewall Management Center directly using the **configure network management-data-interface** command. This module alerts when there is a conflict between the existing Cloud-Delivered Firewall Management Center configuration and the out of band configuration changes made.
Process Status	Alert	Alerts when processes on the appliance exit or terminate outside of the process manager. If a process is deliberately exited outside of the process manager, the module status changes to Warning and the health event message indicates which process exited, until the module runs again and the process has restarted. If a process terminates abnormally or crashes outside of the process manager, the module status changes to Critical and the health event message indicates the terminated process, until the module runs again and the process has restarted.
Routing Statistics	Metrics	Monitors the current state of routing table.
Snort 3 Statistics	Metrics	Collects Snort 3 statistics for events, flows, and packets. This module also monitors metrics for sending advanced logging events and generates the following alerts: • **Advanced logging events to syslog servers were dropped**: This alert appears when syslog messages are dropped due to memory overflow. • **Advanced Logging events failed to transmit to syslog servers**: This alert appears when the syslog messages failed to transmit due to a connection issue with the syslog server or a configuration error. Check your syslog server status and syslog configuration in Cloud-Delivered Firewall Management Center.
CPU Usage Snort	Metrics	This module checks that the average CPU usage of the Snort processes on the device is not overloaded and alerts when CPU usage exceeds the percentages configured for the module. The **Warning Threshold %** default value is `80`. The **Critical Threshold %** default value is `90`.
Snort Identity Memory Usage	Alert	Enables you to set a warning threshold for Snort identity processing and alerts when memory usage exceeds the level configured for the module. The **Critical Threshold %** default value is `80`. This health module specifically keeps track of the total space used for the user identity information in Snort. It displays the current memory usage details, the total number of user-to-IP bindings, and user-group mapping details. Snort records these details in a file. If the memory usage file is not available, the Health Alert for this module displays *Waiting for data*. This could happen during a Snort restart due to a new install or a major update, switch from Snort 2 to Snort 3 or back, or major policy deployment. Depending on the health monitoring cycle, and when the file is available, the warning disappears, and the health monitor displays the details for this module with its status turned Green.

Module	Type	Description
Memory Usage Snort	Metrics	This module checks the percentage of allocated memory used by the Snort process and alerts when memory usage exceeds the percentages configured for the module. The **Warning Threshold %** default value is `80`. The **Critical Threshold %** default value is `90`.
Snort Reconfiguring Detection	Metrics	Alerts if a device reconfiguration has failed. This module detects reconfiguration failure for both Snort 2 and Snort 3 instances.
Snort Statistics	Metrics	Monitors Snort statistics for events, flows, and packets.
SSE Connection Status	Metrics	The module alerts if the device cannot connect to the security services exchange cloud after an initial successful connection. Disabled by default.
CPU Usage System	Metrics	This module checks that the average CPU usage of all system processes on the device is not overloaded and alerts when CPU usage exceeds the percentages configured for the module. The **Warning Threshold %** default value is `80`. The **Critical Threshold %** default value is `90`.

Module	Type	Description
Threat Data Updates on Devices	Alert	Certain intelligence data and configurations that devices use to detect threats are updated on the Cloud-Delivered Firewall Management Center from the cloud every 30 minutes. This module alerts you if this information has not been updated on the devices within the time period you have specified. Note that the Secure Firewall 200 series device does not maintain a local URL database and supports Cloud Only lookup. Local URL database related alerts are not available for this device type. Monitored updates include: • Local URL category and reputation data • Security Intelligence URL lists and feeds, including global Block and Do Not Block lists and URLs from Threat Intelligence Director • Security Intelligence network lists and feeds (IP addresses), including global Block and Do Not Block lists and IP addresses from Threat Intelligence Director • Security Intelligence DNS lists and feeds, including global Block and Do Not Block lists and domains from Threat Intelligence Director • Local malware analysis signatures (from ClamAV) • SHA lists from Threat Intelligence Director, as listed on the **Objects > Object Management > Security Intelligence > Network Lists and Feeds** page • Dynamic analysis settings configured on the **Administration** > **Dynamic Attributes Connector** page • Threat Configuration settings related to expiration of cached URLs, including the Cached URLs Expire setting on the **Integration** > **Other Integrations** > **Cloud Services** page. (Updates to the URL cache are not monitored by this module.) • Communication issues with the Cisco cloud for sending events. Refer to **Cisco Cloud** box on the **Integration** > **Other Integrations > Cloud Services** page. **Note** Threat Intelligence Director updates are included only if TID is configured on your system and you have feeds. By default, this module sends a warning after 1 hour and a critical alert after 24 hours. If this module indicates failure on the Cloud-Delivered Firewall Management Center or on any devices, verify that the Cloud-Delivered Firewall Management Center can reach the devices.
VPN Statistics	Metrics	Monitors site-to-site and remote access VPN tunnels between Firewall Threat Defense devices.
XTLS Counters	Metrics	Monitors XTLS/SSL flows, memory and cache effectiveness. Disabled by default.

Table 20: Management Center Health Modules

Module	Type	Description
Secure Endpoint Status	Alert	The module alerts if the Cloud-Delivered Firewall Management Center cannot connect to the AMP cloud or Cisco AMP Private Cloud after an initial successful connection, or if the private cloud cannot contact the public AMP cloud. It also alerts if you deregister an AMP cloud connection using the Secure Endpoint management console.
AMP for Firepower Status	Alert	Alerts if: • The Cloud-Delivered Firewall Management Center cannot contact the AMP cloud (public or private) or the Secure Malware Analytics Cloud or Appliance, or the AMP private cloud cannot contact the public AMP cloud. • The encryption keys used for the connection are invalid. • A device cannot contact the Secure Malware Analytics Cloud or Secure Malware Analytics Appliance to submit files for dynamic analysis. • An excessive number of files are detected in network traffic based on the file policy configuration. If your Cloud-Delivered Firewall Management Center loses connectivity to the Internet, the system may take up to 30 minutes to generate a health alert.
Appliance Heartbeat	Alert	This module determines if an appliance heartbeat is being heard from the appliance and alerts based on the appliance heartbeat status.
Dynamic Attributes Connector Status	Alert	This module monitors the operational status of the Dynamic Attributes Connector (CSDAC) service in Cloud-Delivered Firewall Management Center and raises an alert if the CSDAC service is not available. If the CSDAC service is not being used by a related service, try disabling and re-enabling it in the Cloud-Delivered Firewall Management Center UI, and check the health alert again after some time. For more information on how to enable CSDAC service, refer to Enable the dynamic attributes connector. If a related service such as an Azure AD realm is configured, you cannot disable the CSDAC service directly. First delete the Azure AD realm and then disable and re-enable the CSDAC service. For more information, refer to Configure realms and directories.
Firewall Threat Defense HA Status	Alert	Alerts if a threat defense high availability pair is split brain.
Hardware Statistics	Metrics	Monitors Cloud-Delivered Firewall Management Center hardware: fan speed, temperature, and power supply. Alerts when values exceed configurable thresholds.
Health Monitor Process	Alert	Monitors the health process itself, and alerts if there have been no health events in some number of minutes (configurable).
ISE Connection Monitor	Alert	This module monitors the status of the server connections between the Cisco Identity Services Engine (ISE) and the Cloud-Delivered Firewall Management Center. ISE provides additional user data, device type data, device location data, SGTs (Security Group Tags), and SXP (Security Exchange Protocol) services.

Module	Type	Description
Local Malware Analysis	Alert	This module monitors ClamAV updates for Local Malware Analysis.
Passive Identity Agent Status Monitor	Alert	Displays connection errors between the Cloud-Delivered Firewall Management Center and the machine on which it's installed. The passive identity agent periodically sends updates to the Cloud-Delivered Firewall Management Center. This health alert is displayed if the Cloud-Delivered Firewall Management Center receives an error from the passive identity agent or if the Cloud-Delivered Firewall Management Center has not received an update or response for five minutes or longer. Try verifying the connection between the two, restarting the passive identity agent software, and checking the health alert again in a few minutes. If issues persist, check the configuration at **Integration** > **Other Integrations** > **Identity Sources**.
Process Status	Alert	Alerts when processes on the appliance exit or terminate outside of the process manager. If a process is deliberately exited outside of the process manager, the module status changes to Warning and the health event message indicates which process exited, until the module runs again and the process has restarted. If a process terminates abnormally or crashes outside of the process manager, the module status changes to Critical and the health event message indicates the terminated process, until the module runs again and the process has restarted.
Security Intelligence	Alert	Alerts if Security Intelligence is in use and the Cloud-Delivered Firewall Management Center cannot update a feed, or feed data is corrupt or contains no recognizable IP addresses. Refer to the Threat Data Updates on Devices module.
Smart License Monitor	Alert	Monitors Smart Licensing status and alerts if: • There is a communication error between the Smart Licensing Agent (Smart Agent) and the Smart Software Manager. • The Product Instance Registration Token has expired. • The Smart License usage is out of compliance. • The Smart License authorization or evaluation mode has expired.
Talos Connectivity Status	Alert	Monitors connectivity with Talos, required to download URL filtering and event enrichment data.

Module	Type	Description
Threat Data Updates on Devices	Alert	Certain intelligence data and configurations that devices use to detect threats are updated on the Cloud-Delivered Firewall Management Center from the cloud every 30 minutes. This module alerts you if this information has not been updated on the devices within the time period you have specified. **Note** The Secure Firewall 200 does not maintain a local URL database and supports only cloud-based lookups. Local URL database-related alerts are not available for this device type. Monitored updates include: • Local URL category and reputation data. • Security Intelligence URL lists and feeds, including global Block and Do Not Block lists and URLs from Threat Intelligence Director. • Security Intelligence network lists and feeds (IP addresses), including global Block and Do Not Block lists and IP addresses from Threat Intelligence Director. • Security Intelligence DNS lists and feeds, including global Block and Do Not Block lists and domains from Threat Intelligence Director. • Local malware analysis signatures (from ClamAV). • SHA lists from Threat Intelligence Director, as listed on the **Objects** > **Object Management** > **Security Intelligence** > **Network Lists and Feeds** page. • Dynamic analysis settings configured on the **Administration** > **Dynamic Attributes Connector** page. • Threat Configuration settings related to expiration of cached URLs, including the Cached URLs Expire setting on the **Integration** > **Other Integrations** > **Cloud Services** page. (Updates to the URL cache are not monitored by this module.) • Communication issues with the Cisco cloud for sending events. Refer to the **Cisco Cloud** box on the **Integration** > **Other Integrations > Cloud Services** page. **Note** Threat Intelligence Director updates are included only if TID is configured on your system and you have feeds. By default, this module sends a warning after 1 hour and a critical alert after 24 hours. If this module indicates failure on the Cloud-Delivered Firewall Management Center or on any devices, verify that the Cloud-Delivered Firewall Management Center can reach the devices.
Time Synchronization Status	Alert	This module tracks the synchronization of a device clock that obtains time using NTP with the clock on the NTP server and alerts if the difference in the clocks is more than ten seconds.

Module	Type	Description
Unresolved Groups Monitor	Alert	Monitors Foreign Security Principals (FSPs) that are groups used in policies. Security principals are Active Directory objects, like authenticated user groups, to which security can be applied in access control policies. This module generates a warning alert for unresolved groups that exist but are not used in policies, and a critical alert for unresolved groups that are used in policies.
URL Filtering Monitor	Alert	Monitors connectivity with the Cisco cloud, which is required for downloading URL filtering data and doing URL filtering lookups.
Zero-Touch Provisioning	Alert	Alerts if there is a failure when registering a device using the serial number. It also shows errors related to zero-touch provisioning capable Cloud-Delivered Firewall Management Center s in high availability.

Configure health monitoring

Health monitoring enables proactive management of network appliances by tracking their operational status using customizable policies and alert mechanisms. You can configure specific monitoring policies for different appliance types, enabling only the relevant tests for each type.

Procedure

Step 1 Determine which health modules you want to monitor as discussed in Health modules, on page 373.

You can set up specific policies for each kind of appliance, enabling only the appropriate tests for that appliance.

Tip
To quickly enable health monitoring without customizing the monitoring behavior, you can apply the default policy provided for that purpose.

Step 2 Apply a health policy to each appliance where you want to track health status as discussed in Create a health policy, on page 385.

Step 3 (Optional.) Configure health monitor alerts as discussed in Create a health monitor alert, on page 396.

You can set up email or webhook alerts that trigger when the health status level reaches a particular severity level for specific health modules.

Health policies

A health policy is a configuration framework that

- enables you to define test criteria for monitoring the health of appliances,
- allows selective enabling of health modules and critical alert settings, and

- provides flexibility to apply, customize, or use default policies for each appliance.

Health policy configuration options

When you configure a health policy, you decide whether to enable each health module for that policy. You also select the criteria that control which health status each enabled module reports each time it assesses the health of a process.

You can enable or disable health alerts for individual attributes within a health module. By adjusting the settings for health alerts at the attribute level, you can reduce the number of health alerts and streamline your focus on the most critical health alerts without interrupting data collection. You can continue to monitor the attribute from your **Health Monitor** dashboard. When you enable a health module in the health policy, the health alert configuration for all the attributes within that health module gets enabled by default.

You can create one health policy that can be applied to every appliance in your system, customize each health policy to the specific appliance where you plan to apply it, or use the default health policy provided for you.

Note When you register an appliance, the Cloud-Delivered Firewall Management Center automatically assigns it the default health policy. To disassociate a health policy from an appliance, you must first associate a different health policy with it. An appliance must have at least one health policy assigned.

Default health policy

The Cloud-Delivered Firewall Management Center setup process creates and applies an initial health policy, in which most—but not all—available health modules are enabled. The system also applies this initial policy to devices added to the Cloud-Delivered Firewall Management Center.

This initial health policy is based on a default health policy. You cannot view or edit the default health policy, but you can copy it when creating a custom health policy.

You can create a custom health policy and set it as your default health policy. The Cloud-Delivered Firewall Management Center applies the default health policy to any managed device when you add the device to the Cloud-Delivered Firewall Management Center. Note that you cannot delete the health policy that you have set as the default. For detailed instructions for setting a default health policy, refer to Set a default health policy, on page 388.

Upgrades and the default health policy

When you upgrade the Cloud-Delivered Firewall Management Center, any new health modules are added to all health policies, including the initial health policy, default health policy, and any other custom health policies. Usually, new health modules are added in an enabled state.

Note For a new health module to begin monitoring and alerting, reapply health policies after upgrade.

Create a health policy

If you want to customize a health policy to use with your appliances, you can create a new policy. The settings in the policy initially populate with the settings from the health policy you choose as a basis for the new policy. You can edit the policy to specify your preferences, such as enable or disable modules within the policy, change the alerting criteria for each module as needed, and specify the run time intervals.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click **Create Policy**.

Step 3 Enter a name for the policy.

Note that the following names are reserved for the default policies, and you cannot create a health policy using these names:

- Default Device Policy
- Default Health Policy

Step 4 Choose the existing policy that you want to use as the basis for the new policy from the **Base Policy** drop-down list.

Step 5 Enter a description for the policy.

Step 6 Choose **Save**.

What to do next

- Apply the health policy on devices as described in Apply a health policy, on page 385.
- Edit the policy to specify the module-level policy settings as described in Edit a health policy, on page 386.

Apply a health policy

When you apply a health policy to an appliance, the health tests for all the modules you enabled in the policy automatically monitor the health of the processes and hardware on the appliance. Health tests then continue to run at the intervals you configured in the policy, collecting health data for the appliance and forwarding that data to the Cloud-Delivered Firewall Management Center.

If you enable a module in a health policy and then apply the policy to an appliance that does not require that health test, the health monitor reports the status for that health module as disabled.

To stop health monitoring for an appliance, create a health policy with all modules disabled, assign it to the appliance, and remove the appliance's other health policy assignments. The appliance retains one assigned health policy, but no health modules are monitored.

When you apply a different policy to an appliance that already has a policy applied, expect some latency in the display of new data based on the newly applied tests.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click the **Deploy health policy** (📥) next to the policy you want to apply.

Step 3 Choose the appliances where you want to apply the health policy.

Note
An appliance must have at least one health policy assigned to it. To stop health monitoring for an appliance, create a health policy with all modules disabled, assign it to the appliance, and remove the appliance's other health policy assignments. The appliance retains one assigned health policy, but no health modules are monitored. To disassociate a health policy from an appliance, you must first associate a different health policy with it.

Step 4 Click **Apply** to apply the policy to the appliances you chose.

The health policy is successfully applied to the selected appliances, and monitoring begins automatically.

What to do next

- Optionally, monitor the task status; see View task messages, on page 426.

  Monitoring of the appliance starts when the policy is successfully applied.

Edit a health policy

Edit a health policy when you need to adjust which modules are monitored, change critical or warning thresholds, or reassign policies to different devices.

Before you begin

- Ensure you have access to Cloud-Delivered Firewall Management Center.
- Identify the health policy you need to modify.

Follow these steps to edit a health policy:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click **Edit** (✎) next to the policy you want to modify.

Step 3 To edit the policy name and its description, click the **Edit** (✎) icon provided against the policy name.

Step 4 The **Health Modules** tab displays all the device modules and its attributes. Configure your health modules using the following actions:

- Click the toggle button that is provided against the module and its attributes—turn on () or turn off () to enable or disable testing of health status respectively.
- To execute a bulk enable or disable testing on the health modules, click the **Select All** toggle button
- After you enable a health module and when available, use the check box next to an individual attribute within a health module to enable or disable health alerts for that attribute. Note that disabling health alerts for an attribute does not stop the collection of metrics for that attribute. You can continue to monitor these attributes from the **Health Monitor** dashboard.

Note

- The modules and attributes are flagged with the supporting appliances—Firewall Threat Defense, Cloud-Delivered Firewall Management Center, or both.
- You cannot choose to include or exclude the individual attributes of CPU and Memory modules.

For information on the modules, refer to Health modules, on page 373.

Step 5 Where appropriate, set the **Critical** and **Warning** threshold percentages.

Step 6 In the **Settings** tab, enter the relevant values in the fields:

- **Health Module Run Time Interval**: The frequency for running the health modules. The minimum interval is 5 minutes.
- **Metric Collection Interval**: The frequency of collecting the time series data on the device and its health modules. The device monitor reports these metrics in several predefined health monitor dashboards by default. For detailed information on the dashboard, refer to View the device health monitor, on page 401. The metric data is collected for analysis and hence no alerting is associated with it.
- **OpenConfig Streaming Telemetry**—Configure a health metrics telemetry stream from the Firewall Threat Defense devices to an external data collection system which uses the vendor neutral, OpenConfig model. For more information, refer to Configure OpenConfig Streaming Telemetry.

Step 7 To view and modify the devices to which the policy is assigned, do the following:

a) Click **Policy Assignments & Deploy**.
b) From the **Available Devices** list, click the + icon next to the device to which you want to assign the health policy.
c) Click **Apply**.

Note
The UI prompts you to save unsaved changes before continuing with assignment and deployment.

Alternatively, you can apply the health policy to your appliance as described in Apply a health policy, on page 385

Apply the health policy to each appliance where you want to track health status. When you apply the health policy to an appliance, all the modules you enabled in the policy monitor the health of the processes and hardware on the appliance, and forwards that data to the Cloud-Delivered Firewall Management Center.

Step 8 Click **Save**.

Set a default health policy

You can set a user-created health policy as your default health policy. The Cloud-Delivered Firewall Management Center applies the default health policy to any managed device when you add the device to the Cloud-Delivered Firewall Management Center.

Note Setting a new default health policy does not affect the health policy assigned to devices that are already registered.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click the **More Actions** (⋮) icon next to the health policy that you want to set as the default, and click **Set as Default**.

Step 3 Click **Proceed**.

Delete a health policy

You can delete health policies that you no longer need. However, an appliance must have at least one health policy assigned to it. If you delete a policy that is still applied to an appliance, the policy settings remain in effect until you apply a different policy. In addition, if you delete a health policy that is applied to a device, any health monitoring alerts in effect for the device remain active until you disable the underlying associated alert response.

Note To stop health monitoring for an appliance, create a health policy with all modules disabled, assign it to the appliance, and remove the appliance's other health policy assignments. The appliance retains one assigned health policy, but no health modules are monitored.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click **Delete** (🗑) next to the policy that you want to delete.

Step 3 Click **Delete health policy** to delete it.

Note that you cannot delete a health policy that is set as the default policy. Set another health policy as the default before attempting to delete the current default policy. For more information, refer to Set a default health policy, on page 388.

Device exclusion in health monitoring

A device exclusion is a health monitoring configuration that

- prevents deliberate device or module outages from affecting the overall health summary,
- allows administrators to temporarily disable health monitoring for selected devices, Cloud-Delivered Firewall Management Center where supported, or specific health modules, and
- ensures health events generated during exclusion are marked as disabled and do not affect health calculations.

Device exclusion behavior

In the course of normal network maintenance, you may disable managed devices or make them temporarily unavailable. In Cloud-Delivered Firewall Management Center, you can also exclude Cloud-Delivered Firewall Management Center health monitoring where applicable. Because those outages or expected conditions are deliberate, you may not want their health status to affect the overall health summary.

When you disable health monitoring status, health events are still generated, but they have a disabled status and do not affect the health status for the health monitor. If you remove the device or module from the excluded list, the events that were generated during the exclusion continue to show a status of disabled.

Note If all health modules or a device are added to the exclusion list, the device's health status will be set to disabled. This status refers only to health monitoring and should not be interpreted as the device being offline or disconnected.

You can also disable an individual health module. For example, when you reach the host limit on the Cloud-Delivered Firewall Management Center, you can disable Host Limit status messages. Excluding health modules for individual interfaces is not supported on devices operating in transparent mode.

Note that on the main Health Monitor page you can distinguish between devices that are excluded if you expand to view the list of devices with a particular status by clicking the arrow in that status row.

Note On Cloud-Delivered Firewall Management Center, Health Monitor exclusion settings are local configuration settings. Therefore, if you exclude a device, then delete it and later re-register it with the Cloud-Delivered Firewall Management Center, the exclusion settings remain persistent. The newly re-registered device remains excluded.

Temporary device exclusion scenario

You can use the health monitor exclude feature to disable health monitoring status reporting for a device, Cloud-Delivered Firewall Management Center where applicable, or specific health modules. For example, if you know that a segment of your network will be unavailable, you can temporarily disable health monitoring for a managed device on that segment to prevent the health status on the Cloud-Delivered Firewall Management Center from displaying a warning or critical state because of the lapsed connection to the device.

To temporarily disable health events from a managed device, or from Cloud-Delivered Firewall Management Center where supported, go to the exclusion configuration page and add the target to the exclusion list. After the setting takes effect, the system no longer considers the excluded device when calculating the overall health status. The Health Monitor Appliance Status Summary lists the device as disabled.

Exclude devices from health monitoring

Exclude devices from health monitoring to disable their events and health status when needed for maintenance or troubleshooting purposes.

You can exclude managed devices individually or by group, model, associated health policy, or other supported scope. In Cloud-Delivered Firewall Management Center exclusion can also apply to Cloud-Delivered Firewall Management Center where supported.

If you need to set the events and health status for an individual managed device to disabled, you can exclude the device from health monitoring. Where supported, you can also exclude Cloud-Delivered Firewall Management Center health monitoring. After the exclusion settings take effect, the device shows as disabled in the Health Monitor Appliance Module Summary, and health events for the device have a status of disabled.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Exclude**.

Step 2 Click **Add Device**.

Step 3 In the **Device Exclusion** dialog box, under **Available Devices**, click **Add** (⊕) against the device that you want to exclude from health monitoring.

Step 4 Click **Exclude**.

The selected device is displayed in the exclusion main page.

Step 5 To remove the device from the exclusion list, click **Delete** (🗑).

Step 6 Click **Apply**.

Exclude health policy modules on a device

Excluding health policy modules is useful when certain modules produce irrelevant or temporary health alerts, which you do not want to affect the overall device status. Exclusion settings indicate the number of modules excluded from health monitoring.

Note Excluding health modules for individual interfaces is not supported on devices operating in transparent mode.

Tip Make sure that you keep track of individually excluded modules so you can reactivate them when you need them. You may miss essential warning or critical messages if you accidentally leave a module disabled.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Exclude**.

Step 2 Click **Edit** (✎) next to the Firewall Threat Defense device you want to modify.

Step 3 In the **Exclude Health Modules** dialog box, by default, all the modules of the device are excluded from health monitoring.

Certain modules are applicable to a specific device only; for more information, refer to Health modules, on page 373.

Step 4 To choose modules to be excluded from health monitoring, click the **Enable Module Level Exclusion** link.

The **Exclude Health Modules** dialog box displays all the modules of the device. The modules that are not applicable for the associated health policies are disabled by default. To exclude a module, perform these steps:

a. Click the **Slider** (⬭) button next to the desired module.

b. To specify the duration of the exclusion for the selected modules, from the **Exclude Period** drop-down list, select the duration.

Step 5 (Optional) To stop receiving health status updates for physical interfaces and instead focus on the health status of their subinterfaces, you can disable health monitoring for the physical interfaces while continuing to monitor and receive health alerts for the subinterfaces.

a) If not already enabled, click the toggle button next to the **Interface statistics** module.
b) From the **Exclude Period** drop-down list, choose a duration for which the health status of the physical interfaces is not required.
c) Click the **Exclude specific interfaces** radio button.
d) Check the check boxes next to the physical interfaces that you want to exclude.
e) Selecting a physical interface will automatically exclude both the physical interface and its subinterfaces. Therefore, uncheck the **Subinterfaces** check box next to the corresponding physical interface to continue receiving health alerts for the subinterfaces.

Step 6 If you select an **Exclude Period** other than **Permanent**, for your exclusion configuration, you can choose to automatically delete the configuration when it expires. To enable this setting, check the **Auto-delete expired configurations** check box.

Step 7 Click **OK**.

Step 8 Click **Apply**.

Note
Interface exclusion differs from other module exclusions because you can exclude selected physical interfaces while still monitoring associated subinterfaces, depending on the UI options available in your version.

Exclude interface health monitoring

Use interface exclusion when you want to suppress health status updates for selected physical interfaces without suppressing health monitoring for the entire device. Interface exclusion is useful when interface state is expected during maintenance or when you want to focus on subinterface health instead of physical interface status.

When you configure interface exclusion, select the physical interfaces that you want to exclude from the list of available interfaces. Depending on the available UI options in your version, selecting a physical interface can also exclude its subinterfaces. If subinterface controls are available, you can continue monitoring subinterfaces while excluding only the physical interface.

Use this option to reduce unnecessary health alerts when traffic loss or interface state changes are expected on a physical interface.

Manage expired health monitor exclusions

When monitoring device or module health, some items may have temporary exclusions. Once these exclusion periods lapse, you need to decide whether to renew the exclusion or clear the device/module from exclusion so alerts resume.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Exclude**.

The **Warning** (⚠) icon is displayed against the device indicating the expiry of the duration of exclusion of the device or the modules from alerting.

Step 2 To renew the exclusion of the device, click **Edit** (✎) next to the device. In the **Exclude Health Modules** dialog box, click the **Renew** link. The exclusion period of the device is extended with the current value.

Step 3 To clear the device from being excluded, click **Delete** (🗑) next to the device, click **Remove the device from exclusion**, and then click **Apply**.

Step 4 To renew or clear the modules from exclusion, click **Edit** (✎) next to the device. In the **Exclude Health Modules** dialog box, click the **Enable Module Level Exclusion** link, and then click the **Renew** or **Clear** link

against the modules. When you click **Renew**, the exclusion period is extended on the module with the current value.

Health monitor alerts

A health monitor alert is a notification mechanism that

- provides email or webhook notifications when module status changes occur,
- enables association of alert responses with health event levels to trigger notifications based on event severity, and
- allows customization to monitor specific system conditions such as disk space thresholds.

Disk space monitoring alert example

If you are concerned that your appliances may run out of hard disk space, you can automatically send an email to a system administrator when the remaining disk space reaches the warning level. If the hard drive continues to fill, you can send a second email when the hard drive reaches the critical level.

Health monitor alert information

The alerts generated by the health monitor contain specific information that helps identify issues and their severity.

Health monitor alerts include these attributes:

- Severity: Indicates the severity level of the alert.
- Module: Specifies the health module whose test results triggered the alert.
- Description: Includes the health test results that triggered the alert.

The table describes these severity levels.

Table 21: Alert severities

Severity	Description
Critical	The health test results met the criteria to trigger a Critical alert status.
Warning	The health test results met the criteria to trigger a Warning alert status.
Normal	The health test results met the criteria to trigger a Normal alert status.
Error	The health test did not run.
Recovered	The health test results met the criteria to return to a normal alert status, following a Critical or Warning alert status.

Health alerts for Secure Firewall 200 Series device

To optimize performance and ensure effective resource utilization, the health alerts in the Secure Firewall 200 Series device are limited only to the essential health modules. This table lists the health modules in the Secure Firewall 200 Series device, which generate health alerts. You can view all the metrics in the health monitoring dashboard, which is similar to that of other Threat Defense device models.

Table 22: Health Alerts for Secure Firewall 200 Series Device

Health Module	Health Alert
Certificate Monitoring	Alerts when service authentication certificates are nearing expiration or have expired.
Cluster/HA Failure Status	Provide alerts when a device joins, leaves, or is elected as the primary unit.
Database	Provide alerts on database integrity issues related to schema or configuration data.
Disk Usage	Monitors disk usage in the device's hard drive and alerts when usage exceeds the configured thresholds.
Disk Status	Provide alerts on hard disk or RAID controller issues.
Firewall Threat Defense Platform Faults	Monitors platform faults and generates health alerts for them.
FXOS Health	Alerts when the FXOS HTTPS service is not running in the device.
Identity Process	Monitors the health and operation of identity-related services.
Inline Link Mismatch Alarms	Provide alerts if inline pair interfaces negotiate different speeds.
Interface Statistics	Determines if the device currently collects traffic and alerts based on the traffic status of physical interfaces and aggregate interfaces.
Out of band Configuration Changes	Alerts when there is a conflict between the existing Cloud-Delivered Firewall Management Center configuration and the out-of-band configuration changes that are made.
Process Status	Provide alerts when processes in the device are terminated outside of the process manager.
Snort Identity Memory Usage	Enables you to set a warning threshold for Snort identity processing, and alerts when memory usage exceeds the level that is configured for the module.
Snort Reconfiguring Detection	Alerts if a device reconfiguration has failed.

Health Module	Health Alert
Threat Data Updates on Devices	Monitors updates of threat intelligence data and alerts if this information has not been updated in the devices within the time period you have specified.

Caution Generating troubleshooting files in a Firewall Threat Defense device is a CPU-intensive task. Because of limited CPU resources in the Secure Firewall 200 Series device, you may observe higher CPU usage and associated health alerts during this process. To prevent any potential traffic disruption, it's recommended to generate troubleshooting files only when the device is not actively handling network traffic.

Note

- The Secure Firewall 200 Series device raises alerts only for database integrity issues-related configuration data (sometimes called EO).
- The Secure Firewall 200 Series device does not maintain a local URL database, and supports cloud-only URL lookups. Local URL database-related alerts are not available for this device type.

Health event external notifications

Firewall Management Center uses separate configurations to detect a health condition and notify an external system about it.

A health policy defines what Cloud-Delivered Firewall Management Center monitors and which conditions produce a health event. An alert response configuration defines how Cloud-Delivered Firewall Management Center communicates with an external destination, such as an email server. The monitor alert rule configuration connects the health policy and alert response by specifying which health events should trigger a particular alert response.

How the configurations work together

These steps describe how you configure external notifications for health events and how Cloud-Delivered Firewall Management Center processes the health event.

1. Configure and apply the health policy: A health policy enables health modules and defines the criteria used to assess appliance health.

   For example, a health policy can enable the **Memory Usage** module and define **Critical** thresholds.

   Apply the health policy to the appliance, including the Cloud-Delivered Firewall Management Center when you want to monitor Cloud-Delivered Firewall Management Center resources.

2. Configure the alert response: An alert response defines how and where Cloud-Delivered Firewall Management Center sends the external notification. Depending on the response type, the alert response contains the destination address, server or endpoint information, and other communication settings.

   For example, an email alert response identifies the recipients, sender, and mail relay host that Cloud-Delivered Firewall Management Center uses to send the message.

For more information about alert responses, refer to Configuring external alerts with alert responses, on page 487.

3. Configure the monitor alert rule: A monitor alert rule associates a health-event severity and one or more health modules with an alert response.

   For example, a health monitor alert rule can specify:

   - Severity: **Critical**
   - Health module: **Memory Usage**
   - Alert response: **Critical memory email**

   This means that when Cloud-Delivered Firewall Management Center generates a **Critical** event for the **Memory Usage** module, it invokes the associated alert response.

   For more information about health monitor alerts, refer toHealth monitor alerts, on page 393.

4. Cloud-Delivered Firewall Management Center generates a health event: Cloud-Delivered Firewall Management Center evaluates the enabled health modules according to the health policy and its configured run interval. When a health module evaluates an appliance and the result meets a configured condition, Cloud-Delivered Firewall Management Center generates a health event.

   Note that a health event is an event log within Cloud-Delivered Firewall Management Center; it does not send an external notification by itself.

5. Cloud-Delivered Firewall Management Center matches the event and sends the notification: Cloud-Delivered Firewall Management Center evaluates the generated event against the configured health monitor alerts. If the event's module and severity match a monitor alert rule, Cloud-Delivered Firewall Management Center invokes the alert response associated with that rule and sends the notification to the configured external system.

Note Health alerts can take approximately 5–6 minutes to be generated after the corresponding health event occurs.

Create a health monitor alert

When you create a health monitor alert, you create an association between a severity level, a health module, and an alert response. You can use an existing alert or configure a new one specifically to report on system health. When the severity level occurs for the selected module, the alert triggers.

If you create or update a threshold in a way that duplicates an existing threshold, you are notified of the conflict. When duplicate thresholds exist, the health monitor uses the threshold that generates the fewest alerts and ignores the others. The timeout value for the threshold must be between 5 and 4,294,967,295 minutes.

Before you begin

- Ensure that you have configured alert responses that govern the Cloud-Delivered Firewall Management Center's communication with the email server or webhook where you send the health alert; For more information, refer to Configuring external alerts with alert responses, on page 487.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor Alerts**.

Step 2 Click **Add**.

Step 3 In the **Add Health Alert** dialog box, enter a name for the health alert in the **Health Alert Name** field.

Step 4 From the **Severity** drop-down list, choose the severity level you want to use to trigger the alert.

Step 5 From the **Alert** drop-down list, choose the alert response that you want to trigger when the specified severity level is reached. If you have not yet configured the alert responses, click **Alerts** to visit the **Alerts** page and set them.

Step 6 From the **Health Modules** list, choose the health policy modules for which you want the alert to apply.

Step 7 Optionally, in the **Threshold Timeout** field, enter the number of minutes that should elapse before each threshold period ends and the threshold count resets.

Even if the policy run time interval value is less than the threshold timeout value, the interval between two reported health events from a given module is always greater. For example, if you change the threshold timeout to 8 minutes and the policy run time interval is 5 minutes, there is a 10-minute interval (5 x 2) between reported events.

Step 8 Click **Save** to save the health alert.

Edit a health monitor alert

Administrators may need to update the alert parameters for health monitor alerts in order to adjust severity, change modules, or select different responses as requirements evolve.

Before you begin

Follow these steps to edit health monitor alerts:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor Alerts**.

Step 2 Click the **Edit** (✎) icon that is provided against the required health alert that you want to modify.

Step 3 In the **Edit Health Alert** dialog box, from the **Alert** drop-down list, select the required alert entry, or click **Alerts** link to configure a new alert entry.

Step 4 Click **Save**.

Delete health monitor alerts

Health monitor alerts notify you about system events, issues, or warnings. You may need to delete outdated or irrelevant alerts to streamline monitoring.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor Alerts**.

Step 2 Click **Delete** (🗑) next to the health alert you want to delete.

Step 3 Click **Delete health alert** to delete it.

What to do next

Disable or delete the underlying alert response to ensure that alerting does not continue. For more information, refer to Configuring external alerts with alert responses, on page 487.

About the health monitor

The health monitor provides the compiled health status for all devices managed by the Cloud-Delivered Firewall Management Center, plus the Cloud-Delivered Firewall Management Center itself.

The health monitor is composed of:

- The Health Status summary page — Provides you with an at-a-glance view of the health of the Cloud-Delivered Firewall Management Center and all of the devices that the Cloud-Delivered Firewall Management Center manages. In a multi-domain deployment, you can view the health status summary for a device in the domain where the device is located. Devices are listed individually, or grouped according to their geolocation, high availability, or cluster status where applicable.
  - View the health summary of the Cloud-Delivered Firewall Management Center and any device when you hover on the hexagon that represents the device health.
  - The dot to the left of a device indicates its health:
    - Green — No alarms.
    - Orange — At least one health warning.
    - Red — At least one critical health alarm.
- The Monitoring navigation pane — Allows you to navigate the device hierarchy. You can view health monitors for individual devices from the navigation pane.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Step 2 View the status of the Cloud-Delivered Firewall Management Center and its managed devices in the **Health Status** landing page.

a) Hover your pointer over a hexagon to view the health summary of a device. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

b) In the device list, click **Expand**( ) and **Collapse** ( ) to expand and collapse the list of health alerts for a device.

When you expand the row, all of the health alerts are listed, including the status, title, and details.

Note
Health alerts are sorted by their severity level.

Step 3 Use the Monitoring navigation pane to access device-specific health monitors.

a) In the device list, click **Expand** ( ) and **Collapse** ( ) to expand and collapse the list of managed devices.

When you expand the row, all of the devices are listed.

b) Click on a device to view a device-specific health monitor.

c) In the health monitor, hover over a graph to view all metrics and their respective values at that specific point on the graph. Click on the graph to pin the metrics statistics box, allowing you to explore the metrics and their values in detail. To close the statistics box and move to another point on the graph, simply click the close button.

You have accessed the health monitor and can view the compiled health status for all managed devices. You can interact with the Health Status landing page and use the Monitoring navigation pane to access device-specific health information.

What to do next

- See Device health monitors, on page 399 for information about the compiled health status and metrics for any device managed by the Cloud-Delivered Firewall Management Center.

Device health monitors

The device health monitor provides the compiled health status for any device managed by the Cloud-Delivered Firewall Management Center. The device health monitor collects health metrics for Secure Firewall devices in order to predict and respond to system events.

The device health monitor is comprised of these components:

- System Details: Displays information about the managed device, including the installed Secure Firewall version and other deployment details.
- Troubleshooting & Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Health alerts: A health alert monitor provides an at-a-glance view of the health of the device.
- Time range: An adjustable time window to constrain the information that appears in the various device metrics windows.

- Device metrics: An array of key firewall device health metrics categorized across predefined dashboards, including:
  - CPU: CPU utilization, including the CPU usage by process and by physical cores. The Firewall Threat Defense CPU core allocation dashboard shows core assignments for these categories:
    - **Data Plane**: Handles basic network functions, including core packet forwarding and network data processing.
    - **Snort**: Manages intrusion detection and deep packet inspection features.

Note Multi-threaded Snort processes are allocated across multiple Snort cores to improve device performance. The Snort core allocation shown in the **CPU** dashboard reflects the total number of Snort process threads assigned to Snort cores.

    - **System**: Includes all other system processes. While some processes may have dedicated CPU cores allocated, their usage is combined and displayed under the **System** category in the dashboard.
  - Memory: Device memory utilization, including data plane and Snort memory usage.
  - Interfaces: Interface status and aggregate traffic statistics.
  - Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
  - Snort: Statistics related to the Snort process.
  - Disk Usage: Device disk usage, including the disk size and disk utilization per partition.
  - Critical Processes: Statistics related to managed processes, including process restarts and other select health monitors such as CPU and memory utilization.

Note During a device upgrade or high-availability failover event, the Firewall Threat Defense device may briefly appear as **Offline** in the device's health monitoring dashboard. This happens because health alerts are cleared during the process and are only updated after the process is complete. Wait for the upgrade or failover operation to finish.

For a comprehensive list of the supported device metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

View system details and troubleshoot devices

Use this task when you need to monitor device health or initiate troubleshooting procedures on specific devices through the management center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access device-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed devices.

Step 3 Click on a device to view a device-specific health monitor.

Step 4 Click the link for **View System & Troubleshoot Details …**

This panel is collapsed by default. Clicking on the link expands the collapsed section to see **System Details** and **Troubleshooting & Links** for the device. The system details include:

- **Version:** The Secure Firewall software version.
- **Model:** The device model.
- **Mode:** The firewall mode. The Firewall Threat Defense device supports two firewall modes for regular firewall interfaces: Routed mode and Transparent mode.
- **VDB:** The Cisco vulnerability database (VDB) version.
- **SRU:** The intrusion rule set version.
- **Snort:** The Snort version.

Step 5 You have these troubleshoot choices:

- Generate troubleshooting files; refer to Generate troubleshooting files for specific system functions, on page 433
- Generate and download advanced troubleshooting files; refer to Download advanced troubleshooting files, on page 434.
- Create and modify health policies; refer to Create a health policy, on page 385.
- Create and modify health monitor alerts; refer to Create a health monitor alert, on page 396.

View the device health monitor

The device health monitor compiles device metrics and displays health status and trends using an array of dashboards.

Follow these steps to view the device health monitor.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access device-specific health monitors.

Step 2 In the device list, click **Expand**( ) and **Collapse** ( ) to expand and collapse the list of managed devices.

Step 3 View the **Health Alerts** for the device in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the device. The pop-up window shows a truncated summary of the top five health alerts. Click the pop-up to open a detailed view of the health alert summary.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click the **Show the deployment details on top of the graph** ( ) icon for a deployment overlay on the trend graph, with respect to the selected time range.

The icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. In the case of multiple deployments, multiple bands/lines can appear. Click the icon on top of the dotted line to view the deployment details.

Step 6 View the device monitor reports health and performance metrics in several predefined dashboards by default.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.
- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics related to the Snort process.
- ASP Drops: Statistics related to the Accelerated Security Path (ASP) performance and behavior.

Note

- Multi-threaded Snort processes are allocated across multiple Snort cores to improve device performance. Note that the Snort core allocation shown in the **CPU**dashboard reflects the total number of Snort process threads assigned to Snort cores.
- The **Process Health** widget in Cloud-Delivered Firewall Management Center displays the CPU% usage for each process. The CPU% metric reflects usage relative to the number of cores in the Firewall Threat Defense device, where 100% corresponds to full utilization of one core. For example, on an 8-core device, 200% indicates two fully utilized cores, leaving six available for other processes. To monitor overall system CPU usage, use the **CPU** widget instead of the **Process Health** widget.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported device metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 7 Click the **Add New Dashboard**(+) to create a custom correlation dashboard by building your own variable set from the available metric groups.

For more information, refer to Correlating device metrics, on page 403.

Correlating device metrics

The device health monitor includes an array of key Firewall Threat Defense device metrics that serve to predict and respond to system events. The health of any Firewall Threat Defense device can be determined by these reported metrics.

The device monitor reports these metrics in several predefined dashboards by default. These dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.
- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics related to the Snort process.
- ASP Drops: Statistics related to the Accelerated Security Path (ASP) performance and behavior.

You can add custom dashboards to correlate metrics that are interrelated. Select from predefined correlation groups, such as CPU and Snort; or create a custom correlation dashboard by building your own variable set from the available metric groups. For a comprehensive list of the supported device metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Before you begin

- To view and correlate the time series data (device metrics) in the health monitor dashboard, enable REST API (**System** (⚙) > **Configuration** > **REST API Preferences**).

Note Correlating device metrics is available only for Firewall Threat Defense 6.7 and later versions. Hence, for Firewall Threat Defense versions earlier than 6.7, the health monitor dashboard does not display these metrics even if you enable REST API.

Follow these steps to correlate device metrics:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**. In the **Devices** list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed devices, and choose the device for which you want to modify the dashboard.

Use the Monitoring navigation pane to access device-specific health monitors.

Step 2 Click the **Add New Dashboard**(+) icon to add a new dashboard, and specify a name to identify the dashboard.

Step 3 To create a dashboard from a predefined correlation group, click **Add from Predefined Correlations** drop-down, choose the group, and click **Add Dashboard**. To create a custom correlation dashboard, choose a group from the **Select Metric Group** drop-down, then choose corresponding metrics from the **Select Metrics** drop-down.

For a comprehensive list of the supported device metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Click **Add Metrics** to add and select metrics from another group, and to remove an individual metric, click the Remove ✕ icon on the right side of the item. Click the delete icon to remove the entire group. Click **Add Dashboard** to add the dashboard to the health monitor.

Step 5 You can **Edit** or **Delete** the predefined dashboards and the custom correlation dashboards.

Cluster health monitor

When a Firewall Threat Defense is the control node of a cluster, the Cloud-Delivered Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Cloud-Delivered Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:

- The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
- The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

View the cluster health monitor

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.

- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.
- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Health monitor status categories

The table summarizes the available health monitor status categories, their severity levels, icons, associated colors in pie charts, and descriptions.

Table 23: Health status indicator

Status Level	Status Icon	Status Color in Pie Chart	Description
Error	**Error** ()	Black	Indicates that at least one health monitoring module has failed on the appliance and has not been successfully re-run since the failure occurred. Contact your technical support representative to obtain an update to the health monitoring module.
Critical	**Critical** ()	Red	Indicates that the critical limits have been exceeded for at least one health module on the appliance and the problem has not been corrected.
Warning	**Warning** ()	Yellow	Indicates that warning limits have been exceeded for at least one health module on the appliance and the problem has not been corrected. This status also indicates a transitionary state, where, the required data is temporarily unavailable or could not be processed because of changes in the device configuration. Depending on the monitoring cycle, this transitionary state is auto-corrected.
Normal	**Normal** ()	Green	Indicates that all health modules on the appliance are running within the limits configured in the health policy applied to the appliance.
Recovered	**Recovered** ()	Green	Indicates that all health modules on the appliance are running within the limits configured in the health policy applied to the appliance, including modules that were in a Critical or Warning state.
Disabled	**Disabled** ()	Blue	Indicates that an appliance is disabled or excluded, that the appliance does not have a health policy applied to it, or that the appliance is currently unreachable.

Health event views

Health event views enable you to monitor health events logged by the health monitor in the Cloud-Delivered Firewall Management Center. The views are fully customizable, allowing you to analyze health statuses efficiently and access related event data.

You can search event data to easily access other information that may be related to the events you are investigating. If you understand what conditions each health module tests for, you can more effectively configure alerting for health events.

You can perform many of the standard event view functions on the health event view pages.

View health events

Use this task when you need to monitor the health of your appliances and review any incidents or events recorded.

When you access health events from the Health Monitor page on your Cloud-Delivered Firewall Management Center, you retrieve all health events for all managed appliances.

Tip You can bookmark this view to allow you to return to the page in the health events workflow containing the Health Events table of events. The bookmarked view retrieves events within the time range you are currently viewing, but you can then modify the time range to update the table with more recent information if needed.

Follow these steps to view health events.

Procedure

Choose **System** (⚙) > **Health** > **Events**.

Tip
If you are using a custom workflow that does not include the table view of health events, click **(switch workflow)**. On the **Select Workflow** page, click **Health Events**.

Note
If no events appear, you may need to adjust the time range.

View the health events table

The Health Events Table provides actionable insight into system health and allows users to organize, modify, and respond to health events.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Events**.

Step 2 You have the following choices:

- Bookmark: To bookmark the current page so that you can quickly return to it, click **Bookmark This Page**, provide a name for the bookmark, and click **Save**.

- Change Workflow: To choose another health events workflow, click **(switch workflow)**.
- Delete Events: To delete health events, check the check box next to the events you want to delete, and click **Delete**. To delete all the events in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
- Generate Reports: Generate a report based on data in the table view — click **Report Designer**.
- Modify: Modify the time and date range for events listed in the Health table view. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
- Navigate: Navigate through event view pages.
- Navigate Bookmark: To navigate to the bookmark management page, click **View Bookmarks** from any event view.
- Navigate Other: Navigate to other event tables to view associated events.
- Sort: Sort the events that appear, change what columns display in the table of events, or constrain the events that appear
- View All: To view event details for all events in the view, click **View All**.
- View Details: To view the details associated with a single health event, click the down arrow link on the left side of the event.
- View Multiple: To view event details for multiple health events, choose the check box next to the rows that correspond with the events you want to view details for and then click **View**.
- View Status: To view all events of a particular status, click status in the Status column for an event with that status.
- Search: Search for specific health events or health metrics recorded within your deployment. Customize your search query to analyze health events and other monitored data and save the search constraints for quick access. For more information, refer to Event searches, on page 519.

Health event fields

The health monitor modules you enable in your health policy run tests to determine appliance health status. When the health status meets specified criteria, a health event is generated. The health event table includes fields that are searchable and viewable for monitoring appliance health.

Table 24: Health event fields

Field	Description
Module Name	Specify the name of the module which generated the health events you want to view. For example, to view events that measure CPU performance, type **CPU**. The search should retrieve applicable CPU Usage and CPU temperature events.
Test Name (Search only)	The name of the health module that generated the event.
Time (Search only)	The timestamp for the health event.

Field	Description
Description	The description of the health module that generated the event. For example, health events generated when a process was unable to execute are labeled **Unable to Execute**.
Value	The value (number of units) of the result obtained by the health test that generated the event. For example, if the Cloud-Delivered Firewall Management Center generates a health event whenever a device it is monitoring is using 80 percent or more of its CPU resources, the value could be a number from 80 to 100.
Units	The units descriptor for the result. You can use the asterisk (*) to create wildcard searches. For example, if the Cloud-Delivered Firewall Management Center generates a health event when a device it is monitoring is using 80 percent or more of its CPU resources, the units descriptor is a percentage sign (%).
Status	The status (Error, Critical, Warning, Normal, Recovered, or Disabled) reported for the appliance.
Device	The appliance where the health event was reported.

Sending device health metrics to OpenConfig

OpenConfig is a vendor-independent software layer that provides a single way of streaming network telemetry data to multiple vendors to manage and monitor networks. The OpenConfig streaming telemetry option in the secure firewall uses gNMI (gRPC Network Management Interface) protocol and allows you to control and generate telemetry streams from your Firewall Threat Defense devices to a data collection system.

The Firewall Threat Defense health policy contains all the configurations to support and enable the OpenConfig streaming telemetry functionality. When you deploy the health policy to the device, the OpenConfig streaming telemetry configuration activates a gNMI server and starts listening to Remote Procedure Call (RPC) messages from the data collectors.

Subscription model of OpenConfig telemetry streams

OpenConfig uses a subscription-based model where the data collectors query the Firewall Threat Defense devices for telemetry data or act as collector for the streamed telemetry data. When a data collector wishes to receive updates and metrics from the Firewall Threat Defense device, it sends a subscribeRequest RPC message to the Firewall Threat Defense gNMI server. The subscription request includes details of one or more paths to which the data collector wishes to subscribe. The message also includes subscription mode which describes the longevity of the subscription.

The Firewall Threat Defense server supports these subscription modes:

- *Once subscription*: The Firewall Threat Defense device sends requested data to the gNMI paths only once.
- *Stream subscription*: The Firewall Threat Defense continuously streams telemetry data according to the triggers specified in the `SubscribeRequest` RPC message.

- *Sampled subscription*: The Firewall Threat Defense server streams the requested data as per the interval specified in the subscription message. The minimum interval that the threat defense support is one minute.
- *On-change subscription*: The Firewall Threat Defense sends the data whenever the requested values change.

The Firewall Threat Defense server generates `SubscribeResponse` RPC messages according to the type of subscription that is created, at the frequency requested by the data collectors.

You can use these deployment modes for OpenConfig streaming telemetry configuration:

- **DIAL-IN**: In this mode, the gNMI server opens a port on the Firewall Threat Defense and waits for `SubscribeRequest` RPC messages from data collectors. In the device health policy, you can specify the port number to use by the gNMI server and the IP address of the data collector that can connect with the gNMI service. If not specified, the gNMI server uses port number 50051. The DIAL-in mode is ideal to use in a trusted network where the endpoint that subscribes to telemetry streams are trusted.
- **DIAL-OUT**: The gNMI service is designed to work in server mode where it accepts subscription requests from gNMI data collectors and serve the telemetry data. If the gNMI data collectors cannot reach the gNMI server, the Firewall Threat Defense uses a tunnel client and establishes a gRPC tunnel with the external server. This tunnel allows exchange of RPC messages between gNMI server and client. The DIAL-OUT mode is ideal to use when the data collectors are hosted on the cloud or outside the trusted network.

In both DIAL-IN and DIAL-OUT mode, all the communication between gNMI server and gNMI client uses TLS encryption and this requires to generate a set of certificates with private keys for the TLS encryption. DIAL-OUT mode requires extra keys for the tunnel infrastructure. For more information, refer to How to Generate Certificate with Private Key.

Generate certificates and private keys

Certificates and private keys are required for OpenConfig streaming telemetry. You must use the same certificate authority (CA) for all components to ensure secure and consistent authentication.

Note To ensure that you generate certificates using the same CA, run these commands together and from the same endpoint. If you want to retry the commands, you must retry all commands.

Procedure

Step 1 Make a folder, for example `keys`, in the endpoint where you want to run these commands.

Example:

```
mkdir keys
```

Step 2 Create a self-signed CA certificate with a corresponding private key.

Example:

This sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information:

```
openssl req -x509 -newkey rsa:4096 -days 365 -nodes -keyout keys/ca-key.pem -out
keys/ca-cert.pem -subj "/C=XX
/ST=YY/L=ZZZ/O=Example/OU=EN/CN=gnmi-ca/emailAddress=abc@example.com"
```

The subject information includes the provided Country (C), State (ST), Locality (L), Organization (O), Organizational Unit (OU), Common Name (CN), and email address.

The private key is saved as `CA-key.pem` file, and the certificate is saved as `CA-cert.pem` file in the `keys` folder.

Step 3 Create a self-signed server certificate with the specified Common Name (CN) and Subject Alternative Name (SAN):

Example:

This sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information. In this example, 192.168.0.200 is the IP address of the Firewall Threat Defense device and 192.168.0.202 is the IP address of the client.

Note
Client IP is not required if you want to use this certificate and key sets in dial-in mode.

```
CN="192.168.0.200"
SAN="IP:192.168.0.200,IP:192.168.0.202"
openssl req -newkey rsa:4096 -nodes -keyout keys/server-key.pem -out keys/server-req.pem
-subj "/C=XX/ST=YY/L=ZZZ/O=Example/OU=EN/CN=${CN}/emailAddress=abc@example.com}"
openssl x509 -req -extfile <(printf "subjectAltName=${SAN}") -in keys/server-req.pem -days
 60 -CA keys/ca-cert.pem -CAkey keys/ca-key.pem -CAcreateserial -out keys/server-cert.pem
cat keys/server-key.pem keys/server-cert.pem keys/ca-cert.pem > keys/server-combined.pem
```

The `openssl req` command generates a new RSA private key and a Certificate Signing Request (CSR). The private key is saved as `server-key.pem` file, and the CSR is saved as `server-req.pem` file in the `keys` folder.

The `openssl x509` command processes the CSR and generates a server certificate. The server certificate is saved as `server-cert.pem` file in the `keys` folder.

The `cat` command combines the server key, server certificate, and the CA certificate into a single file named `server-combined.pem` and saves the file in the `keys` folder.

You have to upload the `server-combined.pem` while configuring **OpenConfig Streaming telemetry** from the Cloud-Delivered Firewall Management Center. The gNMI server that runs on the Firewall Threat Defense and the tunnel server (dial-out mode) uses this certificate for TLS communication. If you encrypt the private key with a passphrase, ensure that you specify the passphrase while uploading the certificate to the Cloud-Delivered Firewall Management Center.

Step 4 Create client certificate with the specified Common Name (CN) and Subject Alternative Name (SAN).

Example:

This sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information. In this example, 192.168.0.202 is the IP address of the client.

```
CN="192.168.0.202"
SAN="IP:192.168.0.202"
openssl req -newkey rsa:4096 -nodes -keyout keys/client-key.pem -out keys/client-req.pem
-subj "/C=XX/ST=YY/L=ZZZ/O=example/OU=EN/CN=${CN}/emailAddress=abc@example.com"
openssl x509 -req -extfile <(printf "subjectAltName=${SAN}") -in keys/client-req.pem -days
 60 -CA keys/ca-cert.pem -CAkey keys/ca-key.pem -CAcreateserial -out keys/client-cert.pem
```

The gNMI client uses the client certificate `client-cert.pem` and the private key for TLS communication.

Step 5 (Optional) For dial-out mode, create the tunnel server certificate with the specified Common Name (CN) and Subject Alternative Name (SAN).

Example:

This sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information. In this example, 192.168.0.202 is the IP address of the client.

```
CN="192.168.0.202"
SAN="IP:192.168.0.202"
openssl req -newkey rsa:4096 -nodes -keyout keys/tunnel-server-key.pem -out
keys/tunnel-server-req.pem -subj "
/C=XX/ST=YY/L=ZZZ/O=Example/OU=EN/CN=${CN}/emailAddress=abc@example.com}"
openssl x509 -req -extfile <(printf "subjectAltName=${SAN}") -in keys/tunnel-server-req.pem
 -days 60 -CA keys/ca-cert.pem -CAkey keys/ca-key.pem -CAcreateserial -out
keys/tunnel-server-cert.pem
```

Configure OpenConfig streaming telemetry

OpenConfig streaming telemetry allows network monitoring systems to collect real-time data from threat defense devices using the gNMI protocol. This configuration supports both DIAL-IN and DIAL-OUT deployment modes for flexible integration with existing network management infrastructure.

Before you begin

- Make sure the Firewall Threat Defense device where you want to deploy the health policy configuration allows installation of the SSL certificate and PRIVATE KEY.
- Ensure that you configure a gNMI client that supports the OpenConfig streaming telemetry implementation, from which you can make the gRPC requests to the gNMI server on the Firewall Threat Defense.
- To use DIAL-OUT mode and configure OpenConfig streaming telemetry, ensure that you configure a gRPC tunnel server and client on the management system. This tunnel configuration enables communication between the gNMI client and the Firewall Threat Defense device.

Follow these steps to configure OpenConfig streaming telemetry:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click the **Edit health policy** icon next to the threat defense health policy that you want to modify.

Step 3 Go to the **Settings** tab.

Step 4 Move the **OpenConfig Streaming Telemetry** slider to enable the configuration. This configuration is disabled by default.

Step 5 Upload the **SSL Certificate**. The gNMI server uses this certificate to enable server authentication for the TLS connection and encrypt all communications through the channel.

The OpenConfig streaming telemetry configuration supports only certificate with PEM format.

Step 6 (Optional) Specify the Passphrase if the PRIVATE KEY files are ENCRYPTED.

Step 7 Choose the deployment mode to use for streaming telemetry over gNMI protocol.

For **DIAL-IN** mode:

a. Assign a port number for the gNMI service.

The gNMI server opens the port and waits for gRPC requests from the collector.

b. Specify the IPv4/IPv6 address of the gNMI collectors that can connect to the Firewall Threat Defense device.

c. Click **Add Collector** to add more gNMI collectors. You can add a maximum of five collectors.

For **DIAL-OUT** mode:

a. Specify the hostname and port number for the gNMI collector, which can subscribe to streaming telemetry from the Firewall Threat Defense device.

b. Click **Add Collector** to add more gNMI collectors. You can add a maximum of five collectors.

Step 8 Specify the username and password to validate the gNMI collector.

The Firewall Threat Defense server uses this credential to authenticate the gNMI collector when receiving the **SubscribeRequest** RPC message. Each telemetry message is not authenticated using the username and password. The system uses the previously authenticated ENCRYPTED streaming channel to carry telemetry messages.

Step 9 Click **Save**.

What to do next

Deploy the health policy to your Firewall Threat Defense device, for the configuration changes to take effect.

Troubleshoot OpenConfig streaming telemetry

This reference provides troubleshooting procedures for OpenConfig streaming telemetry issues including certificate errors, server response failures, and status verification methods.

Certificate signed by unknown authority

- Ensure that you have uploaded the correct certificate to the Cloud-Delivered Firewall Management Center.
- Verify the certificate and key generation steps. Ensure that the IP Subject Alternative Name (SAN) is specified correctly.

Certificate is not valid

If the Cloud-Delivered Firewall Management Center displays the error "Request was made for (IP), but the certificate is not valid for (IP)" then verify the server certificate and key generation steps.

- Ensure that the IP SAN is correctly specified in the server certificate. If the configuration applies to more than one Firewall Threat Defense device, you must specify all the devices in the IP SAN field.
- If you are using dial-out mode, ensure that the client IP is specified in the server certificate.

Failed to generate response object

If you receive "Failed to generate response object, did not receive any data" error, the gNMI input plug-in is waiting for metric export. This is the sample response that appears when the telegraf is restarting:

```
root@cronserver:/home/secanup/openconfig-test# gnmic -a $ADDRESS:$PORT --tls-cert $CLIENTCERT
 --tls-ca $CACERT --tls-key $CLIENTKEY -u $USER -p $PASS sub --mode once --path
"openconfig-system/system/memory"
rpc error: code = Aborted desc = Error in gnmi_server: failed to generate response object.did
 not receive any data
Error: one or more requests failed
```

Wait for the gNMI input plug-in to restart and retry your request.

Restart telegraf

When telegraf is not responding, restart the process using this command on the Firewall Threat Defense CLI console:

```
pmtool restartbyid hmdaemon
```

Get current status of gNMI server

When OpenConfig streaming telemetry is enabled, to know the status of the gNMI server, run this command using the Firewall Threat Defense CLI console:

```
curl localhost:9275/OpenConfig/status
```

This is the sample response to the command:

```
root@firepower:/home/admin# curl localhost:9275/openconfig/status

system auditing

The appliances that are part of the system generate an audit record for each user interaction with the web interface.

Audit records

Cloud-Delivered Firewall Management Center logs read-only auditing information for user activity. Audit logs appear in a standard event view that allows you to view, sort, and filter audit log messages based on any item in the audit view. You can easily delete audit information, generate reports, and review detailed records of the changes that users make.

Audit record storage and limitations

The audit log stores a maximum of 100,000 entries. When the number of audit log entries exceeds 100,000, the appliance prunes the oldest records from the database to reduce the number to 100,000.

The audit logs do not display the user or the source IP for login errors:

- When wrong password is used, the source IP is not displayed.
- When the user account does not exist, both source IP and the user are not displayed.
- If the attempt for an LDAP user fails, no audit log is triggered.

Related Topics

Guidelines for SSO configuration on Cloud-Delivered Firewall Management Center

Audit log workflow fields

This table describes the audit log fields that can be viewed and searched.

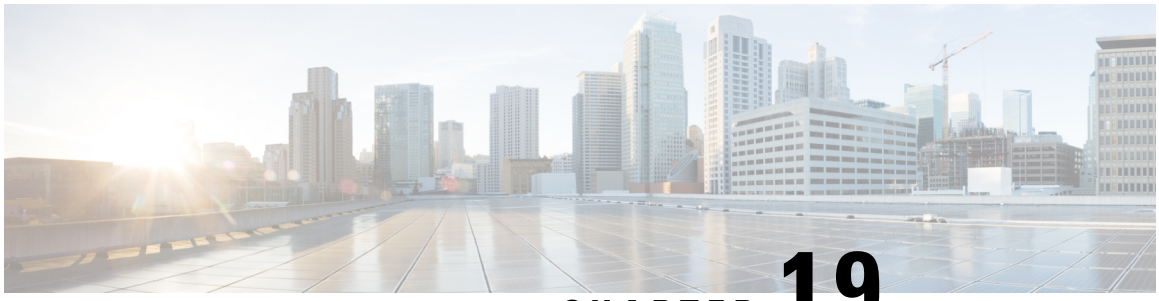
Table 25: Audit log fields

Field	Description
Time	Time and date that the appliance generated the audit record.
User	User name of the user that triggered the audit event.
Subsystem	In a few cases where a menu path is not relevant, the Subsystem field displays only the event type. For example, **Login** classifies user login attempts.
Message	The action the user performed or the button the user clicked on the page. For example, `Page View` signifies that the user simply viewed the page indicated in the Subsystem, while `Save` means that the user clicked the **Save** button on the page. Changes made to the system appear with a **Compare icon** that you can click to see a summary of the changes.

Field	Description
Source IP	IP address associated with the host used by the user. Note: When searching this field you must type a specific IP address; you cannot use IP ranges when searching audit logs.
Domain	The current domain of the user when the audit event was triggered. This field is only present if you have ever configured the Cloud-Delivered Firewall Management Center for multitenancy.
Configuration Change (search only)	Specifies whether to view audit records of configuration changes in the search results. (`yes` or `no`)
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable.

The audit events table view

You can customize the layout of the audit events table view or filter events by specific field value.



Use these options to customize the audit events table view:

- You can change the layout of the event view, or constrain the events in the view by a field value.
- To disable a column, click **Close** (✕) in the desired column heading. Click **Apply** in the pop-up window. When you disable a column, it is disabled for the duration of your session (unless you add it back later).

Note When you disable the first column, the Count column is added.

- To hide or show other columns, or to add a disabled column back to the view, select or clear the appropriate check boxes before you click **Apply**.
- Clicking a value within a row in a table view constrains the table view and does not drill down to the next page in the workflow.

Tip Table views always include "Table View" in the page name.

CHAPTER 19

Troubleshooting

The following topics describe ways to diagnose problems you may encounter:

- Guidelines and best practices for troubleshooting, on page 419
- System messages, on page 420
- View basic system information, on page 422
- Manage system messages, on page 423
- Memory usage thresholds for health monitor alerts, on page 427
- Disk usage and drain of events health monitor alerts, on page 428
- Clear disk space, on page 432
- Health monitor reports for troubleshooting, on page 433
- Enhanced troubleshooting experience using Cisco RADKit integration, on page 435
- General troubleshooting, on page 439
- Connection-based troubleshooting, on page 439
- Advanced troubleshooting for the Secure Firewall Threat Defense device, on page 440
- Feature-specific troubleshooting, on page 453

Guidelines and best practices for troubleshooting

Follow these best practices to troubleshoot system issues effectively and prepare for potential support escalation:

- Before you make changes to try to fix a problem, generate a troubleshooting file to capture the original problem. See Health monitor reports for troubleshooting, on page 433 and its subsections.

  You may need this troubleshooting file if you need to contact Cisco TAC for support.

- Start your investigation by looking at error and warning messages in the Message Center. See System messages, on page 420

- Look for applicable Tech Notes and other troubleshooting resources under the "Troubleshoot and Alerts" heading on the product documentation page for your product.

- During the troubleshooting process, as several commands are executed simultaneously, the CPU usage becomes high. We recommend that you perform troubleshooting during periods of lower network traffic and fewer users.

- The time taken to troubleshoot the system depends on the configuration settings and the number of devices configured. This duration can range from nine to sixty minutes.

System messages

When you need to track down problems occurring in the system, the Message Center is the place to start your investigation. This feature allows you to view the messages that the system continually generates about system activities and status.

Message center access and display

To open the Message Center, click the System Status icon, next to the **Deploy** button on the home page. This icon changes based on the system status:

- **Error** ( ): Indicates one or more errors and any number of warnings are present on the system.
- **Warning** ( ): Indicates one or more warnings and no errors are present on the system.
- **Success** ( ): Indicates no warnings or errors are present on the system.

If a number is displayed with the icon, it indicates the total current number of error or warning messages.

To close the Message Center, click anywhere outside of it within the web interface.

The web interface also displays pop-up notifications in response to your actions and ongoing system activities. Some pop-up notifications automatically disappear after five seconds, while others are "sticky," meaning they display until you explicitly dismiss them by clicking **Dismiss** ( ). Click the **Dismiss** link at the top of the notifications list to dismiss all notifications at once.

Tip Hovering your cursor over a non-sticky pop-up notification causes it to be sticky.

The system determines which messages it displays to users in pop-up notifications and the Message Center based on their licenses, domains, and access roles.

Message types

The Message Center displays messages reporting system activities and status organized into three different tabs.

The Message Center organizes system status messages into these tabs:

- **Deployments**: Displays current status related to configuration deployment for each appliance in your system, grouped by domain.
- **Upgrades**: Displays the current status related to software upgrade tasks for the managed devices.
- **Health**: Displays current health status information for each appliance in your system, grouped by domain.
- **Tasks**: Displays the status of long-running tasks such as configuration backups, update installation, etc,.

Deployment status

The system reports these deployment statuses. You can get additional detail about the deployment jobs by clicking **Show History**.

- Running (**Spinning**): The configuration is in the process of deploying.
- **Success**: The configuration has successfully been deployed.
- **Warning** ( ) : Warning deployment statuses contribute to the message count displayed with the **Warning System Status icon**.
- **Failure**: The configuration has failed to deploy. Failed deployments contribute to the message count displayed with the **Error System Status icon**.

Upgrade status

The system reports these upgrade status values on the Upgrade tab:

- **In progress**: Indicates that the upgrade task is in progress.
- **Completed**: Indicates that the software upgrade task is completed successfully.
- **Failed**: Indicates that the software upgrade task has failed to complete.

Health status

This tab displays current health status information for each appliance in your system, grouped by domain. Health status is generated by health modules as described in Health monitoring in Cloud-Delivered Firewall Management Center, on page 371. The system reports the following health status values on this tab:

- **Warning** ( ): Indicates that warning limits have been exceeded for a health module on an appliance and the problem has not been corrected. The Health Monitoring page indicates these conditions with a **Yellow Triangle** ( ). Warning statuses contribute to the message count displayed with the **Warning System Status icon**.
- **Critical** ( ): Indicates that critical limits have been exceeded for a health module on an appliance and the problem has not been corrected. The Health Monitoring page indicates these conditions with a **Critical** ( ) icon. Critical statuses contribute to the message count displayed with the **Error System Status icon**.
- **Error** ( ): Indicates that a health monitoring module has failed on an appliance and has not been successfully re-run since the failure occurred. The Health Monitoring page indicates these conditions with an **Error icon**. Error statuses contribute to the message count displayed with the **Error System Status icon**.

You can click the links in the Health tab to view related detailed information on the Health Monitoring page. If there are no current health status conditions, the Health tab displays no messages.

Task status

Certain tasks (such as configuration backups or update installation) can require some time to complete. This tab displays the status of these long-running tasks, and can include tasks initiated by you or, if you have

appropriate access, other users of the system. The tab presents messages in reverse chronological order based on the most recent update time for each message. Some task status messages include links to more detailed information about the task in question. The system reports the following task status values on this tab:

- **Waiting**(): Indicates a task that is waiting to run until another in-progress task is complete. This message type displays an updating progress bar.
- **Running**: Indicates a task that is in-progress. This message type displays an updating progress bar.
- **Retrying**: Indicates a task that is automatically retrying. Note that not all tasks are permitted to try again. This message type displays an updating progress bar.
- **Success**: Indicates a task that has completed successfully.
- **Failure**: Indicates a task that did not complete successfully. Failed tasks contribute to the message count displayed with the **Error System Status icon**.
- **Stopped or Suspended**: Indicates a task that was interrupted due to a system update. Stopped tasks cannot be resumed. After normal operations are restored, start the task again.
- Skipped: A process in progress prevented the task from starting. Try again to start the task.

New messages appear in this tab as new tasks are started. As tasks complete (status success, failure, or stopped), this tab continues to display messages with final status indicated until you remove them. We recommend you remove messages to reduce clutter in the Tasks tab as well as the message database.

Message management

From the Message Center you can perform these tasks:

- Choose to display pop-up notifications.
- Display more task status messages from the system database (if any are available that have not been removed).
- Download a report of all the task manager notifications.
- Remove individual task status messages. (This affects all users who can view the removed messages.)
- Remove task status messages in bulk. (This affects all users who can view the removed messages.)

Tip Cisco recommends that you periodically remove accumulated task status messages from the Task tab to reduce clutter in both the display and the database. When the number of messages in the database approaches 100,000, the system automatically deletes task status messages that you have removed.

View basic system information

The About page displays information about your appliance, including the model, serial number, and version information for various components of the system. It also includes Cisco copyright information.

Procedure

Step 1 Click **Help** (?) in the toolbar at the top of the page.

Step 2 Choose **About**.

View appliance information

Procedure

Choose **System** (⚙) > **Configuration**.

Manage system messages

Use the Message Center to monitor and manage different types of system notifications including configuration deployments, device upgrades, system health alerts, and long-running tasks.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Choose from the available notification types:

- Click **Deployments** to view messages related to configuration deployments. See View deployment messages, on page 424. You must be an Admin user or have the **Deploy Configuration to Devices** permission to view these messages.
- Click **Upgrades** to view messages related to device upgrade tasks. See Viewing Upgrade Messages. See Viewing Upgrade Messages. You must be an Admin user or have **Updates** permission to view these messages.
- Click **Health** to view messages related to the health of your Cloud-Delivered Firewall Management Center and the devices registered to it. See View health messages, on page 425. You must be an Admin user or have the **Health** permission to view these messages.

  You can navigate to the Health Monitor page by clicking the **Health monitor** link.

- Click **Tasks** to view or manage messages related to long-running tasks. See View task messages, on page 426 or Manage task messages, on page 427. Everyone can see their own tasks. To see the tasks of other users, you must be an Admin user or have the **View Other Users' Tasks** permission. You can remove the completed tasks from the notification by clicking the **Remove completed tasks** link.
- Click the **Download Report** icon to generate a report of all the notifications in the task manager. Choose **Download CSV** or **Download PDF** to download the report.

- Click **Show Notifications** slider to enable or disable pop-up notification display.

View deployment messages

View deployment messages to monitor the status of configuration deployments and access detailed deployment history for troubleshooting.

If you are an Admin user or have the **Deploy Configuration to Devices** permission, you can view deployment messages and history.

Complete these steps to view deployment messages and deployment history:

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Deployments**.

Step 3 You have the following choices:

- Click **total** to view all current deployment statuses.
- Click a status value to view only messages with that deployment status.
- Hover your cursor over the time elapsed indicator for a message (for example, **1m 5s**) to view the elapsed time, and start and stop times for the deployment.

Step 4 Click **show deployment history** to view more detailed information about the deployment jobs.

The Deployment History table lists the deployment jobs in the left column in reverse chronological order.

a) Select a deployment job.

The table in the right column shows each device that was included in the job, and the deployment status per device.

b) To view responses from the device, and commands sent to the device during deployment, click download in the **Transcript** column for the device.

The transcript includes the following sections:

- **Snort Apply**: If there are any failures or responses from Snort-related policies, messages appear in this section. Normally, this section is empty.
- **CLI Apply**: This section covers features that are configured using commands sent to the Lina process.
- **Infrastructure Messages**: This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript lists commands sent to the device as well as any responses returned from the device. These responses can be informative messages or error messages. If a deployment fails, review the error messages to understand which commands were problematic. If you use FlexConfig policies to configure features, these messages can help you identify and correct issues in your FlexConfig scripts.

Note

The transcript does not distinguish between commands sent for managed features and those generated from FlexConfig policies.

For example, this sequence shows that the Cloud-Delivered Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. The Firewall Threat Defense does not use the security level for anything.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

You can view deployment messages, monitor deployment statuses, and access detailed deployment history, including device transcripts to troubleshoot deployment issues.

View upgrade messages

View and monitor upgrade messages to track the status of current upgrade tasks and access detailed information about upgrade processes.

Only Admin users or users with the **Updates** permission can view these messages.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Upgrades**.

Step 3 You can do the following:

- Click **total** to view all current upgrade tasks.
- Click on a status value to see messages with only that status.
- Click **Device Management** for more details on the upgrade task.

View health messages

Monitor system status, identify issues, and access detailed health information for troubleshooting and maintenance.

You must be an Admin user or have the **Health** permission to view health messages. Using the Message Center provides a streamlined way to monitor the system's health and filter messages by severity.

Complete these steps to view health messages in the Message Center:

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Health**.

Step 3 You have the following choices:

- Click **total** to view all current health statuses. You also see the severity levels: warning, critical, and error.
- Click on a status value to view only messages with that status.
- Hover your cursor over the relative time indicator for a message (for example, **3 day(s) ago**) to view the time of the most recent update for that message.
- To view detailed health status information for a particular message, click the message.
- To view complete health status on the Health Monitoring page, click **Health Monitor**.

You can now view, filter, and access detailed health status messages for monitoring and troubleshooting your system.

View task messages

View task status messages to monitor the progress and completion status of various system tasks.

You can view your tasks. But, to see the tasks of other users, you must be an Admin user or have the **View Other Users' Tasks** permission.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Tasks**.

Step 3 You have these choices:

- Click **total** to view all current task statuses. To view tasks based on a specific status—such as waiting, running, retrying, success, or failure—click its corresponding label.
- Click a status value to view only messages for tasks with that status.

  Note
  Messages for stopped tasks appear only in the total list of task status messages. You cannot filter on stopped tasks.

- Hover your cursor over the relative time indicator for a message (e.g., **3 day(s) ago**) to view the time of the most recent update for that message.
- Click any link within a message to view more information about the task.
- If more task status messages are available for display, click **Fetch more messages** at the bottom of the message list to retrieve them.

Manage task messages

You can view your tasks. But, to see the tasks of other users, you must be an Admin user or have the **View Other Users' Tasks** permission.

Procedure

Step 1 Click System Status to display the Message Center.

Step 2 Click **Tasks**.

Step 3 Select one of the available management options:

- If more task status messages are available for display, click **Fetch more messages** at the bottom of the message list to retrieve them.
- To remove a single message for a completed task (status stopped, success, or failure), click **Remove** ( ) next to the message.
- To remove all messages for all tasks that have completed (status stopped, success, or failure), filter the messages on **total** and click **Remove all completed tasks**.
- To remove all messages for all tasks that have completed successfully, filter the messages on **success**, and click **Remove all successful tasks**.
- To remove all messages for all tasks that have failed, filter the messages on **failure**, and click **Remove all failed tasks**.

Memory usage thresholds for health monitor alerts

The memory usage health module compares memory usage on an appliance to the limits configured for the module and alerts when usage exceeds the levels. The module monitors data from managed devices and from the Cloud-Delivered Firewall Management Center itself.

Two configurable thresholds for memory usage, critical and warning, can be set as a percentage of memory used. When these thresholds are exceeded, a health alarm is generated with the severity level specified. However, the health alarm system does not calculate these thresholds in an exact manner.

With high memory devices, certain processes are expected to use a larger percentage of total system memory than in a low memory footprint device. The design is to use as much of the physical memory as possible while leaving a small value of memory free for ancillary processes.

Compare two devices, one with 32 GB of memory and one with 4 GB of memory. In the device with 32 GB of memory, 5% of memory (1.6GB) is a much larger value of memory to leave for ancillary processes than in the device with 4 GB of memory (5% of 4GB = 200MB).

To account for the higher percentage use of system memory by certain processes, the Cloud-Delivered Firewall Management Center calculates the total memory to include both total physical memory and total swap memory. Thus the enforced memory threshold for the user-configured threshold input can result in a Health Event where the **Value** column of the event does not match the value that was entered to determine the exceeded threshold.

Beginning with version 7.4.1, the memory usage health module calculates memory usage by taking into account the free memory available, swap memory available, and buffer cache. To avoid premature memory usage health alerts, it is recommended not to exceed the warning and critical alarm thresholds of 88% and 90%, respectively.

The following table shows examples of user-input thresholds and the enforced thresholds, depending on the installed system memory.

Note The values in this table are examples. You can use this information to extrapolate thresholds for devices that do not match the installed RAM shown here, or you can contact Cisco TAC for more precise threshold calculations.

Table 26: Memory usage thresholds based on installed RAM

User-Input Threshold Value	Enforced Threshold Per Installed Memory (RAM)			
	4 GB	6 GB	32 GB	48 GB
10%	10%	34%	72%	81%
20%	20%	41%	75%	83%
30%	30%	48%	78%	85%
40%	40%	56%	81%	88%
50%	50%	63%	84%	90%
60%	60%	70%	88%	92%
70%	70%	78%	91%	94%
80%	80%	85%	94%	96%
90%	90%	93%	97%	98%
100%	100%	100%	100%	100%

Disk usage and drain of events health monitor alerts

This topic describes the symptoms and troubleshooting guidelines for two health alerts generated by the Disk Usage health module:

- Frequent Drain of Events
- Drain of Unprocessed Events

Disk usage overview

The disk usage health module compares disk usage on a managed device's hard drive and malware storage pack to the limits configured for the module and alerts when usage exceeds the percentages configured for the module. This module also alerts when the system excessively deletes files in monitored disk usage categories, or when disk usage excluding those categories reaches excessive levels, based on module thresholds.

The disk manager process manages the disk usage of a device. Each type of file monitored by the disk manager is assigned with a silo. Based on the amount of disk space available on the system the disk manager computes a High Water Mark (HWM) and a Low Water Mark (LWM) for each silo.

To display detailed disk usage information for each part of the system, including silos, LWMs, and HWMs, use the **show disk-manager** command.

Examples

The following is an example of the disk manager information:

```
> show disk-manager
Silo                                Used        Minimum     Maximum
Temporary Files                     0 KB        499.197 MB  1.950 GB
Action Queue Results                0 KB        499.197 MB  1.950 GB
User Identity Events                0 KB        499.197 MB  1.950 GB
UI Caches                           4 KB        1.462 GB    2.925 GB
Backups                             0 KB        3.900 GB    9.750 GB
Updates                             0 KB        5.850 GB    14.625 GB
Other Detection Engine              0 KB        2.925 GB    5.850 GB
Performance Statistics              33 KB       998.395 MB  11.700 GB
Other Events                        0 KB        1.950 GB    3.900 GB
IP Reputation & URL Filtering       0 KB        2.437 GB    4.875 GB
Archives & Cores & File Logs        0 KB        3.900 GB    19.500 GB
Unified Low Priority Events         1.329 MB    4.875 GB    24.375 GB
RNA Events                          0 KB        3.900 GB    15.600 GB
File Capture                        0 KB        9.750 GB    19.500 GB
Unified High Priority Events        0 KB        14.625 GB   34.125 GB
IPS Events                          0 KB        11.700 GB   29.250 GB
```

Health alert format

When the Health Monitor process on the Cloud-Delivered Firewall Management Center runs (once every 5 minutes or when a manual run is triggered), the Disk Usage module looks into the diskmanager.log file and, if the correct conditions are met, the health alert is triggered.

The structures of these health alerts are as follows:

- Frequent drain of *SILO NAME*
- Drain of unprocessed events from *SILO NAME*

For example,

- Frequent drain of Low Priority Events
- Drain of unprocessed events from Low Priority Events

Its possible for any silo to generate a *Frequent drain of SILO NAME* health alert. However, the most commonly seen are the alerts related to events. Among the event silos, the *Low Priority Events* are often seen because device generates this type of events frequently.

A *Frequent drain of <SILO NAME>* event has a **Warning** severity level when seen in relation to an event-related silo, because events will be queued to be sent to the Cloud-Delivered Firewall Management Center. For a non-event related silo, such as the *Backups* silo, the alert has a **Critical** severity level because this information is lost.

Note Only event silos generate a *Drain of unprocessed events from SILO NAME* health alert. This alert always has a **Critical** severity level.

Additional symptoms besides the alerts can include:

- Slowness on the Cloud-Delivered Firewall Management Center user interface
- Loss of events

Common troubleshoot scenarios

A *Frequent drain of SILO NAME* event is caused by too much input into the silo for its size. In this case, the disk manager drains (purges) that file at least twice in the last 5-minute interval. In an event type silo, this is typically caused by excessive logging of that event type.

A *Drain of unprocessed events of SILO NAME* health alert is caused by a bottleneck in the event processing path.

There are three potential bottlenecks with respect to these Disk Usage alerts:

- Excessive logging — The EventHandler process on Firewall Threat Defense is oversubscribed (it reads slower than what Snort writes).
- Sftunnel bottleneck — The Eventing interface is unstable or oversubscribed.
- SFDataCorrelator bottleneck — The data transmission channel between the Cloud-Delivered Firewall Management Center and the managed device is oversubscribed.

Excessive logging

One of the most common causes for the health alerts of this type is excessive input. The difference between the Low Water Mark (LWM) and High Water Mark (HWM) gathered from the **show disk-manager** command shows how much space there is available to take on that silo to go from LWM (freshly drained) to the HWM value. If there are frequent drain of events (with or without unprocessed events), review the logging configuration.

- Check for double logging — Double logging scenarios can be identified if you look at the correlator *perfstats* on the Cloud-Delivered Firewall Management Center:

  ```
  admin@FMC:~$ sudo perfstats -Cq < /var/sf/rna/correlator-stats/now
  ```

- Check logging settings for the ACP — Review the logging settings of the Access Control Policy (ACP). If the logging setting includes both "Beginning" and "End" of connection, modify the setting to log only the end to reduce the number of events.

Communications Bottleneck – Sftunnel

Sftunnel is responsible for encrypted communications between the Cloud-Delivered Firewall Management Center and the managed device. Events are sent over the tunnel to the Cloud-Delivered Firewall Management Center. Connectivity issues and/or instability in the communication channel (sftunnel) between the managed device and the Cloud-Delivered Firewall Management Center can be due to:

- Sftunnel is down or is unstable (flaps).

  Ensure that the Cloud-Delivered Firewall Management Center and the managed device have reachability between their management interfaces on TCP port 8305.

  The sftunnel process should be stable and should not restart unexpectedly. Verify this by checking the `/var/log/message` file and search for messages that contain the **sftunneld** string.

- Sftunnel is oversubscribed.

  Review trend data from the Heath Monitor and look for signs of oversubscription of the Cloud-Delivered Firewall Management Center's management interface, which can be a spike in management traffic or a constant oversubscription.

  Use as a secondary management interface for eventing. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI using the **configure network management-interface** command.

Communications Bottleneck – SFDataCorrelator

The SFDataCorrelator manages data transmission between the Cloud-Delivered Firewall Management Center and the managed device; on the Cloud-Delivered Firewall Management Center, it analyzes binary files created by the system to generate events, connection data, and network maps. The first step is to review the **diskmanager.log** file for important information to be gathered, such as:

- The frequency of the drain.
- The number of files with Unprocessed Events drained.
- The occurrence of the drain with Unprocessed Events.

Each time the disk manager process runs it generates an entry for each of the different silos on its own log file, which is located under **[/ngfw]/var/log/diskmanager.log**. Information gathered from the diskmanager.log (in CSV format) can be used to help narrow the search for a cause.

Additional troubleshooting steps:

- The command **stats_unified.pl** can help you to determine if the managed device does have some data which must be sent to Cloud-Delivered Firewall Management Center. This condition can happen when the managed device and the Cloud-Delivered Firewall Management Center experience a connectivity issue. The managed device stores the log data on to a hard drive.

  ```
  admin@FMC:~$ sudo stats_unified.pl
  ```

- The **manage_proc.pl** command can reconfigure the correlator on the Cloud-Delivered Firewall Management Center side.

  ```
  root@FMC:~# manage_procs.pl
  ```

Before you contact Cisco TAC

It is highly recommended to collect these items before you contact Cisco TAC:

- Screenshots of the health alert seen.
- Troubleshoot file generated from the Cloud-Delivered Firewall Management Center.
- Troubleshoot file generated from the affected managed device.
- Date and Time when the problem was first seen.
- Information about any recent changes done to the policies (if applicable).
- The output of the stats_unified.pl command as described in Communications Bottleneck — SFDataCorrelator, on page 431.

Clear disk space

Low disk space can reduce the performance of the managed Firewall Threat Defense devices. It can also prevent device upgrades and increase the risk of accidentally deleting important files when trying to recover space.

You can free up disk space by removing the following temporary files from your Firewall Threat Defense device:

- **Backup files**: These are the Firewall Threat Defense device backup files. Device backups include only the configuration data. For more information, refer to Back Up Managed Devices, on page 462.
- **Content updates**: This includes SRU, VDB, and GeoDB update files. For more information, refer to About System Updates.
- **Troubleshooting files**: These are log files generated for troubleshooting purposes. For more information, refer to Health Monitor Reports for Troubleshooting.

When you clear the disk space, the system retains the latest file and deletes all older files.

Caution Clearing disk space will permanently delete the selected files.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Step 2 In the left navigation pane, click the device for which you want to clear disk space.

Step 3 In the **Disk Usage** widget, click **Clear disk space**.

Step 4 Choose the type of temporary files that you want to remove by checking the corresponding check box.

Step 5 Click **Clear disk space**.

Step 6 Click **Clear** to continue.

Check the message center for the progress of the disk cleanup task. When the task is complete, the **Disk Usage** widget will display the updated storage data.

Health monitor reports for troubleshooting

In some cases, if you have a problem with your appliance, support may ask you to supply troubleshooting files to help them diagnose the problem. The system can produce troubleshooting files with information targeted to specific functional areas, as well as advanced troubleshooting files you retrieve in cooperation with Support. You can select any of the options listed in the table below to customize the contents of a troubleshooting file for a specific function.

Note Some options overlap in terms of the data they report, but the troubleshooting files will not contain redundant copies, regardless of what options you select.

Table 27: Selectable troubleshoot options

This option...	Reports...
Snort Performance and Configuration	data and configuration settings related to Snort on the appliance
Hardware Performance and Logs	data and logs related to the performance of the appliance hardware
System Configuration, Policy, and Logs	configuration settings, data, and logs related to the current system configuration of the appliance
Detection Configuration, Policy, and Logs	configuration settings, data, and logs related to detection on the appliance
Interface and Network Related Data	configuration settings, data, and logs related to inline sets and network configuration of the appliance
Discovery, Awareness, VDB Data, and Logs	configuration settings, data, and logs related to the current discovery and awareness configuration on the appliance
Upgrade Data and Logs	data and logs related to prior upgrades of the appliance
All Database Data	all database-related data that is included in a troubleshoot report
All Log Data	all logs collected by the appliance database
Network Map Information	current network topology data

Generate troubleshooting files for specific system functions

You can generate and download customized troubleshooting files that you can send to support.

Before you begin

You must be an Admin, Maintenance, Security Analyst, or Security Analyst (Read Only) user to perform this task.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**, click the device in the left panel, then **View System & Troubleshoot Details**, and then click **Generate Troubleshooting Files**.

Note

- Troubleshooting files generated from the Cloud-Delivered Firewall Management Center web interface are stored on the Cloud-Delivered Firewall Management Center. Only the latest troubleshooting file for each appliance is stored.
- Troubleshooting files generated from the CLI are stored locally and are not overwritten.
- If you initiate the troubleshooting log generation while one is already in the queue, the new request is dropped.

Step 2 Choose **All Data** to generate all possible troubleshooting data, or check individual boxes as described in View task messages, on page 426.

Step 3 Click **Generate**.

Step 4 View task messages in the Message Center; see View task messages, on page 426.

Step 5 Find the task that corresponds to the troubleshooting files you generated.

Step 6 After the appliance generated the troubleshooting files and the task status changes to `Completed`, click **Click to retrieve generated files**.

Step 7 Follow your browser's prompts to download the file. (The troubleshooting files are downloaded in a single `.tar.gz` file.)

Step 8 Follow the directions from Support to send the troubleshooting files to Cisco.

Download advanced troubleshooting files

Download troubleshooting files and share them with Cisco support for advanced troubleshooting assistance when requested.

Before you begin

You must have **Admin**, **Maintenance**, **Security Analyst**, or **Security Analyst (Read Only)** user roles to perform this task.

Procedure

Step 1 View the health monitor for the appliance.

Step 2 Choose **System** (⚙) > **Health** > **Monitor**.

Step 3 Click a device in the left pane for which you dowload the troubleshooting files.

Step 4 Click **View System & Troubleshoot Details**, and then click **Advanced Troubleshooting.**

Step 5 In **File Download** field, enter the name of the file to download. Cisco support provides this file name.

Step 6 Click **Download**.

Step 7 Follow your browser's prompts to download the file.

Note
For managed devices, the system renames the file by prepending the device name to the file name.

Step 8 Follow the directions from Cisco support to send the troubleshooting files to Cisco.

Enhanced troubleshooting experience using Cisco RADKit integration

The Cisco Remote Automation Development Kit (RADKit) is a network-wide orchestrator designed to provide Cisco support engineers with secure access to network devices for diagnosing and troubleshooting system issues. You can install RADKit on a remote server and integrate its services with Cloud-Delivered Firewall Management Centers and their managed Firewall Threat Defense devices such that the data required for diagnosing issues are available automatically.

RADKit integration capabilities

Note RADKit supports only the instances of a cluster device, not the chassis itself.

Integrating RADKit with the Cloud-Delivered Firewall Management Center enables you to:

- Access the Cloud-Delivered Firewall Management Center and Firewall Threat Defense device remotely.
- Assign an engineer with controlled access to the Cloud-Delivered Firewall Management Center and Firewall Threat Defense devices for diagnosing configuration discrepancies and hardware issues.
- Leverage automation capabilities to collect diagnostic data and analyze problems.
- Navigate to the previous sessions, view, and download all the operations logs as an archive file.

Guidelines and limitations for RADKit integration

Follow these guidelines when configuring RADKit integration to ensure proper functionality:

- If the Cloud-Delivered Firewall Management Center is restored with a backup file of another Cloud-Delivered Firewall Management Center, the devices mapped to the current authorizations are cleared. You must edit the authorization and repeat device selection in the **Authorization** page.
- If you are using HTTP proxy, configure the proxy in the Cloud-Delivered Firewall Management Center before enabling the RADKit service for a sucessful enrolment of the service. In case of incorrect proxy configuration at the time of RADKit enablement, disable the RADKit service, after configuring the correct proxy, re-enable for sucessful enrolment of the service.

Enroll RADKit service

You can enroll the RADKit service with SSO, which establishes connectivity with the RADKit client.

Before you begin

If you intend to use HTTP proxy, configure the proxy in the management center before enabling the RADKit service for sucessful enrolment of the service.

Procedure

Step 1 Choose **Devices** > **Troubleshoot** > **Remote Diagnostics**.

Step 2 To enroll the service in the RADKit cloud, click the **Enable the RADKit service** toggle button, and then click **Enroll with SSO** .

Step 3 Enter your email address (with domain name), and click **Submit** .

Note
You cannot enroll multiple times within a short period using the same email ID. Each time that you enroll, a new certificate is generated for the email ID account. Creating multiple certificates for the same user account is not efficient. Hence, RADKit Cloud restricts the number of issued certificates per user to 12 new Service IDs for a six-month duration.

Step 4 Complete the SSO process.

Step 5 In the **Cisco RADKit Access** page, click **Accept** .

After enrollment, the page displays the success message and the token ID.

Step 6 (Optional) To disable the service, click the **Disable the RADKit service** toggle button.

Caution
When you disable the service, all the associated data and existing authorizations will be lost.

Manage RADKit service authorization

Before you begin

Enroll to RADKit service. For information about the procedure to enroll, see Enroll RADKit service, on page 436.

You can manage authorizations by enabling the TAC engineers to access the devices remotely for troubleshooting. You can also grant access to remote users to either access all the devices' inventory or only of selected devices for a specific duration.

Note The authorizations can be added and viewed only from the Global domain.

Procedure

Step 1 Choose **Devices** > **Troubleshoot** > **Remote Diagnostics**.

The **Remote Diagnostics** page lists the current authorizations. Ensure that you have enrolled to the RADKit service.

Step 2 To create a new authorization, click **Create New Authorization** .

Step 3 Under **Setup Authorization** , enter the support engineer's email address. The Email address must not exceed 40 characters.

Note

- The support engineer's email address is unique to an authorization record. Hence, you cannot modify this value after creating authorization.
- You cannot create an authorization account for the same email address.

Step 4 Click **Next** .

Step 5 Under **Device Selection**, specify the devices and the Cloud-Delivered Firewall Management Center that the support engineer can access. Select the relevant option:

- **Grant access to all devices**: Click this radio button, and then check the **I agree to provide access to all devices** check box to agree for granting access to all devices and the Cloud-Delivered Firewall Management Center.
- **Grant access to specific devices**: Click this radio button, and then from the **Select Devices** drop-down list, choose the device IP addresses and the Cloud-Delivered Firewall Management Center that the support engineer can access. Ensure to check the **I agree to provide access to the selected devices** check box.

  Note
  Only devices running Version 7.7 and later are supported and are available for selection.

Step 6 Click **Next**.

Step 7 Under **Schedule the Access**, specify the timeline during which the support engineer can access the devices:

- **Now** : Click this radio button, and then under **Duration** fields, specify the time duration for granting access. To set the duration preset, click the **Time presets** links, namely, 1 hour, 6 hours, 12 hours, 1 day, or 1 week.
- **Grant access until revoke** : Click this radio button to grant perpetual access to the devices.

  Note
  To revoke access, in the **Current Authorizations** grid, click the respective revoke icon under the **Actions** column.

Step 8 Under **Summary** , preview the selections you have made for the authorization account. To modify the choices made, click the Edit icon and make the corresponding changes.

Note
The support engineer's email address is unique to an authorization record. Hence, you cannot modify the email address.

Step 9 Click **Create** .

In the subsequent window, a confirmation message for the new authorization with the user email address and the RADKit service id used in the RADKit client is displayed.

Step 10 (Optional) To create another authorization, click **Create Another Authorization** .

Step 11 To exit, click **Close** .

What to do next

The **Remote Diagnostics** window displays a list of current authorizations. You can perform the following actions:

- Edit the settings.
- Revoke the authorization.
- Enable sudo access for the devices and Cloud-Delivered Firewall Management Center.

Enable sudo access for devices

When you provide sudo device access, regular users can have administrative rights to the devices. Irrespective of the user role, when you enable sudo access for a device, all the users of the device can enjoy this privilege.

Before you begin

Ensure that you have added the required devices in the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Troubleshoot** > **Remote Diagnostics**.

Step 2 To enable sudo access to devices, click the **Device Sudo Access** tab.

The devices deployed in the Cloud-Delivered Firewall Management Center and the Cloud-Delivered Firewall Management Center are listed.

Step 3 To enable sudo access for a device, click the respective toggle button under **Sudo Status**.

Step 4 For bulk action, check the check boxes adjacent to the devices, and click **Enable**.

Step 5 To disable sudo access, click the respective toggle button under **Sudo Status**.

Download session logs

The **Previous Sessions** tab displays a list of log files for the operations performed by the RADKit client in the Firewall Threat Defense devices and the Cloud-Delivered Firewall Management Center. These session logs can be downloaded as an archive. The RADKit sessions' logs are added to the Cloud-Delivered Firewall Management Center log rotate mechanism and fall under the default log rotate mechanism as that of other Cloud-Delivered Firewall Management Center log files.

Procedure

Step 1 Choose **Devices** > **Troubleshoot** > **Remote Diagnostics** and click the **Previous Sessions** tab.

Step 2 Search for a specific session log by entering the search string in the **Past Session Logs** search bar.

Step 3 Download the logs as an archive using **Download All Logs**.

Note
You can download the logs from the **Current Authorization** page too.

General troubleshooting

An internal power failure (hardware failure, power surge, and so on) or an external power failure (unplugged cord) can result in an ungraceful shutdown or reboot of the system. This can result in data corruption.

Connection-based troubleshooting

Connection-based troubleshooting or debugging provides uniform debugging across modules to collect appropriate logs for a specific connection. It also supports level-based debugging up to seven levels and enables uniform log collection mechanism across modules. Connection-based debugging supports the following:

- A common connection-based debugging subsystem to troubleshoot issues in Firewall Threat Defense
- Uniform format for debug messages across modules
- Persistent debug messages across reboots
- End-to-end debugging across modules based on an existing connection
- Debugging ongoing connections

For more information about the troubleshooting connections, see Troubleshoot a connection, on page 439.

Troubleshoot a connection

This task enables you to identify and analyze connection issues by capturing and examining packet debug information for specific traffic flows.

Procedure

Step 1 Configure a filter to identify a connection using the **debug packet-condition** command.

Example:

```
Debug packet-condition match tcp 192.168.100.177 255.255.255.255 192.168.102.177
255.255.255.255
```

Step 2 Enable debugs for the interested modules and the corresponding levels. Enter the **debug packet** command.

Example:

```
Debug packet acl 5
```

Step 3 Start debugging the packets using the following command:

```
debug packet-start
```

Step 4 Fetch the debug messages from database to analyze the debug messages using the following command:

```
show packet-debugs
```

Step 5 Stop debugging the packets using the following command:

```
debug packet-stop
```

Advanced troubleshooting for the Secure Firewall Threat Defense device

You can use Packet Tracer and Packet Capture features to perform an in-depth troubleshooting analysis on a Secure Firewall Threat Defense device. A packet tracer allows a firewall administrator to inject a virtual packet into a security appliance and track the flow from ingress to egress. Along the way, the packet is evaluated against flow and route lookups, ACLs, protocol inspection, NAT, and intrusion detection. This utility is effective because it can simulate real-world traffic by specifying source and destination addresses with protocol and port information. Packet capture is available with the trace option, which provides you with a verdict as to whether the packet is dropped or successful.

For more information about the troubleshooting files, see Download advanced troubleshooting files, on page 434.

Packet capture

The packet capture feature with trace option allows real packets that are captured on the ingress interface to be traced through the system. The trace information is displayed at a later stage. These packets are not dropped on the egress interface, as they are real data-path traffic. Packet capture for Firewall Threat Defense devices supports troubleshooting and analysis of data packets.

Snort verdict processing

Once the packet is acquired, Snort detects the tracing flag that is enabled in the packet. Snort writes tracer elements, through which the packet traverses. Snort verdict as a result of capturing packets can be one of the following:

Table 28: Snort verdicts

Verdict	Description
Pass	Allow analyzed packet.
Block	Packet not forwarded.

Verdict	Description
Replace	Packet modified.
AllowFlow	Flow passed without inspection.
BlockFlow	Flow was blocked.
Ignore	Flow was blocked; occurs only for sessions with flows blocked on passive interfaces.
Retry	Flow is stalled, waiting on a enamelware or URL category/reputation query. In the event of a timeout, processing continues with an unknown result: in the case of enamelware, the file is allowed; in the case of URL category/reputation, AC rule lookup continues with an uncategorized and unknown reputation.

Based on the Snort verdict, the packets are dropped or allowed. For example, the packet is dropped if the Snort verdict is **BlockFlow**, and the subsequent packets in the session are dropped before reaching Snort. When the Snort verdict is **Block** or **BlockFlow**, the **Drop Reason** can be one of these:

Table 29: Drop reasons

Blocked or Flow Blocked by...	Cause
Snort	Snort is unable to process the packet, erg., snort can't decode packet since it is corrupted or has invalid format.
the App Id preprocessed	App Id module/preprocessed does not block packet by itself; but this may indicate that App Id detection causes other module (erg., firewall) to match a blocking rule.
the SSL preprocessed	There is a block/reset rule in SSL policy to match the traffic.
the firewall	There is a block/reset rule in firewall policy to match the traffic.
the captive portal preprocessed	There is a block/reset rule using the identity policy to match the traffic.
the safe search preprocessed	There is a block/reset rule using the safe-search feature in firewall policy to match the traffic.
the SI preprocessed	There is a block/reset rule a in Security Intelligence tab of AC Policy to block the traffic, erg., DNS or URL SI rule.
the filterer preprocessed	There is a block/reset rule in filterer tab of AC policy to match the traffic.

Blocked or Flow Blocked by...	Cause
the stream preprocessed	There is an intrusion rule blocking/reset stream connection, erg., blocking when TCP normalization error.
the session preprocessed	This session was already blocked earlier by some other module, so session preprocessed is blocking further packets of the same session.
the fragmentation preprocessed	Blocking because earlier fragment of the data is blocked.
the snort response preprocessed	There is a react snort rule, erg., sending a response page on a particular HTTP traffic.
the snort response preprocessed	There is a snort rule to send custom response on packets matching conditions.
the reputation preprocessed	Packet matches a reputation rule, erg., blocking a given IP address.
the x-Link2State preprocessed	Blocking due to buffer overflow vulnerability detected in SMTP.
back orifice preprocessed	Blocking due to detection of back orifice data.
the SMB preprocessed	There is a snort rule to block SMB traffic.
the file process preprocessed	There is file policy that blocks a file, erg., enamelware blocking.
the IPS preprocessed	There is a snort rule using IPS, erg., rate filtering.

The packet capture feature allows you to capture and download packets that are stored in the system memory. However, the buffer size is limited to 32 MB due to memory constraint. Systems capable of handling very high volume of packet captures exceed the maximum buffer size quickly and thereby the necessity of increasing the packet capture limit is required. It is achieved by using the secondary memory (by creating a file to write the capture data). The maximum supported file size is 10 GB.

When the **file-size** is configured, the captured data gets stored to the file and the file name is assigned based on the capture name **recapture**.

The **file-size** option is used when you need to capture packets with the size limit more than 32 MB.

For information, see the *Cisco Secure Firewall Threat Defense Command Reference*.

Use a packet capture trace

Packet capture is a utility that provides a live snapshot of network traffic passing the specified interface of a device based on a defined criteria. This process continues to capture the packets as long as it has not paused, or the allocated memory has not exhausted.

Packet capture data includes information from Snort and preprocessors about verdicts and actions the system takes while processing a packet. Multiple packet captures are possible at a time. You can configure the system to modify, delete, clear, and save captures.

Note Capturing packet data requires packet copy. This operation may cause delays while processing packets and may also degrade the packet throughput. We recommend that you use packet filters to capture specific traffic data.

Before you begin

To use the packet capture tool on Secure Firewall Threat Defense devices, you must be an Admin or Maintenance user.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Troubleshoot** > **Packet Capture**.

Step 2 Select a device.

Step 3 Click **Add Capture**.

Step 4 Enter the **Name** for capturing the trace.

Step 5 Select the **Interface** for the capturing the trace.

Step 6 Specify **Match Criteria** details:

a) Select the **Protocol**.
b) Enter the IP address for the **Source Host**.
c) Enter the IP address for the **Destination Host**.
d) Check **SGT number** check box, and enter a Security Group Tag (SGT).

Step 7 Specify **Buffer** details:

a) Enter a maximum **Packet Size**.
b) Enter a minimum **Buffer Size**.
c) Select either **Continuous Capture** if you want the traffic captured without interruption, or **Stop when full** if you want the capture to stop when the maximum buffer size is reached.

Note
If **Continues Capture** is enabled, and when the allocated memory is full, the oldest captured packets in the memory is overwritten by the new captured packets.

d) Check the check box of **Trace**, if you want to capture the details for each packet.
e) Enter the value in **Trace Count** field. Default value is 128 . You can enter values in the range of 1-1000.

Step 8 Click **Save**.

The packet capture screen displays the packet capture details and its status. To have the packet capture page auto refreshed, check the **Enable Auto Refresh** check box and enter the auto refresh interval in seconds.

You can do the following on the packet capture:

- **Edit** ( ) to modify the capture criteria.
- **Delete** ( ) to delete the packet capture and the captured packets.
- **Clear** ( ) to erase all the captured packets from a Packet Capture. To erase the captured packets from all of the existing packet captures, click **Clear All Packets**.
- **Pause** ( ) to temporarily halt capturing packets.
- **Save** ( ) to save a copy of captured packets on a local machine in ASCII or PCAP format. Choose the required format option, and click **Save**. The saved packet capture is downloaded to your local machine.
- To view the details of the packets being captured, click the required capture row.

Packet tracer tool overview

A packet tracer tool is a network analysis utility. It simulates packet flows by modeling source and destination addresses and protocol characteristics. The tool validates network policies by performing lookups against access rules, NAT, routing, and rate-limiting policies. It also captures and logs detailed tracing information for each packet to assist with policy troubleshooting and debugging.

Packet tracer tool simulation and PCAP replay

Use the packet tracer tool to simulate the complete data path of a packet, including slow-path and fast-path modules. This simulation helps verify whether your configured policies allow or deny intended traffic. This tool helps you confirm your policy effectiveness and troubleshoot when your packets are blocked.

You can use packet capture (PCAP) files to replay complete traffic flows. Make sure your PCAP file contains a single Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) flow with up to 100 packets. On replay, the tool initializes client and server entities and synchronizes packet transmission, logging trace results for each packet in the flow.

Run a packet trace

Follow these steps to run a packet trace on your Firewall Threat Defense device.

Before you begin

- Ensure you have Admin or Maintenance user privileges.
- Have any required PCAP (.pcap or .pcapng) files ready if you intend to upload or replay captured traffic.
- Confirm the device supports packet tracing.

Procedure

Step 1 In Cloud-Delivered Firewall Management Center, choose **Devices** > **Troubleshoot** > **Packet Tracer**.

Step 2 From the **Select Device** drop-down, choose the device where you want to run the trace.

Step 3 Choose one of the following options:

- **Use Protocol**: Configure protocol and parameters manually.

- **Upload or Edit a PCAP file**: Upload a packet capture (PCAP) file.

Step 4 To upload a PCAP file:

a) Click the **Upload or Edit a PCAP File** drop-down, and choose the **Upload a PCAP File** option. To use a recently uploaded file, click the file name from the available list.

Note
- Only .pcap and .pcapng file formats are supported.
- The file can contain up to 100 packets. All packets must be from the same Ethernet connection or from the same VLAN-encapsulated TCP or UDP connection.
- Multiflow PCAP files are not supported. Upload only single-flow PCAP files.

b) If you choose to upload a PCAP file, drag and drop the PCAP file into the **Upload PCAP** dialog box or browse and select the PCAP file. After you select the file, the upload process starts automatically.

Note
- After you upload the file, the **Protocol**, **Source Type**, and **Destination Type** fields will be grayed, and cannot be edited. To make changes to these fields, you must upload a new PCAP file.
- You can edit the source and destination IP addresses, source and destination ports, VLAN ID, destination MAC address (for a firewall in transparent mode), and the PCAP file name.

c) Go to Step 6.

Step 5 If you choose to perform a manual configuration, do the following:

a) From the **Ingress Interface** drop-down, choose the ingress interface for the packet trace.

Note
Do not select **VTI**; VTI as ingress is not supported.

b) From the **Protocol** drop-down, select the packet type and specify protocol characteristics:
- **ICMP**: Enter the ICMP type, code (0-255), and optionally, an identifier.
- **TCP**/**UDP**/**SCTP**: Enter the source and destination port numbers.
- **GRE**/**IPIP**: Enter the protocol number 0-255.
- **ESP**: Enter the Security Parameter Index (SPI) value for the source (0-4294967295).
- **RAWIP**: Enter the port number (0-255).

c) Select the **Source Type** and enter the source IP address.

Types include IPv4, IPv6, and FQDN (domain name, if using Cisco TrustSec)

d) Select the **Source Port**, **Destination Type**, and enter the destination IP address.

Destination type options vary depending on the source type that you select.

e) Select the **Destination Port**.

f) To trace packets to a subinterface, enter a **VLAN ID**.

This value is optional for non-subinterfaces only, since all the interface types can be configured in a subinterface.

g) Specify a **Destination MAC Address**.

If the Secure Firewall Threat Defense device is running in transparent firewall mode and the ingress interface is VTEP, you must provide a **Destination MAC Address** when you enter a **VLAN ID** value. However, if the interface is a bridge group member, you can provide a **Destination MAC Address** optionally when you enter a **VLAN ID** value, but you must provide it when you do not enter a **VLAN ID** value.

In routed firewall mode, **VLAN ID** and **Destination MAC Address** are optional if the input interface is a bridge group member.

h) To ignore security checks for the simulated packet, click **Bypass all security checks for simulated packet**. This enables packet tracer to trace the packet through the system, which would otherwise be dropped.

i) To send the packet out through the device's egress interface, click **Allow simulated packet to transmit from device**.

j) If you want the packet tracer to consider the injected packet as an IPsec/SSL VPN-decrypted packet, click **Treat simulated packet as IPsec/SSL VPN decrypt**.

Step 6 From the **Ingress Interface** drop-down, choose the ingress interface for the packet trace.

Note
Do not select VTI. VTI as ingress interface is not supported for packet tracer.

Step 7 To use a PCAP replay in the packet tracer, do the following:

a) Click **Select a PCAP File**.

b) To upload a new PCAP file, click **Upload a PCAP file**. To reuse a recently uploaded file, click the file name from the list.

Note
Only .pcap and .pcapng file formats are supported. The PCAP file can contain only a single TCP/UDP-based flow with a maximum of 100 packets. The maximum character limit for the PCAP file name (including the file formats) is 64.

c) In the **Upload PCAP** box, you can either drag a PCAP file or click to browse to the location where the file is stored, and select the file. When you select the file, the upload process starts automatically.

d) Go to this step

Step 8 To define the trace parameters, from the **Protocol** drop-down list, select the packet type for the trace, and specify the protocol characteristics:

- **ICMP** : Enter the ICMP type, ICMP code (0-255), and optionally, the ICMP identifier.
- **TCP** / **UDP** / **SCTP** : Enter the source and destination port numbers.
- **GRE** / **IPIP** : Enter the protocol number, 0-255.
- **ESP** : Enter the Security Parameter Index (SPI) value for the source. Valid range is 0-4294967295.
- **RAWIP** : Enter the port number. Valid range is 0-255.

Step 9 Select the **Source Type** for the packet trace, and enter the source IP address.

Source and destination types include IPv4, IPv6, and fully-qualified domain names (FQDN). You can specify IPv4 or IPv6 addresses and FQDN, if you use Cisco TrustSec.

Step 10 Select the **Source Port** for the packet trace.

Step 11 Select the **Destination** type for the packet trace, and enter the destination IP address.

Destination type options vary depending on the source type that you select.

Step 12 Select the **Destination Port** for the packet trace.

Step 13 Optionally, if you want to trace a packet where the Security Group Tag (SGT) value is embedded in the Layer 2 CMD header (TrustSec), enter a valid **SGT number** .

Step 14 If you want packet tracer to enter a parent interface, which is later redirected to a sub-interface, enter a **VLAN ID** .

This value is optional for non-sub-interfaces only, since all the interface types can be configured on a sub-interface.

Step 15 Specify a **Destination MAC Address** for the packet trace.

If the Secure Firewall Threat Defense device is running in transparent firewall mode, and the ingress interface is VTEP, **Destination MAC Address** is required if you enter a value in **VLAN ID**. Whereas if the interface is a bridge group member, **Destination MAC Address** is optional if you enter a **VLAN ID** value, but required if you do not enter a **VLAN ID** value.

If the Secure Firewall Threat Defense is running in routed firewall mode, **VLAN ID** and **Destination MAC Address** are optional if the input interface is a bridge group member.

Step 16 (Optional) If you want the packet-tracer to ignore the security checks on the simulated packet, click **Bypass all security checks for simulated packet** . This enables packet-tracer to continue with tracing of packet through the system which, otherwise would have been dropped.

Step 17 (Optional) To allow the packet to be sent out through the egress interface from the device, click **Allow simulated packet to transmit from device** .

Step 18 (Optional) If you want the packet-tracer to consider the injected packet as an IPsec/SSL VPN decrypted packet, click **Treat simulated packet as IPsec/SSL VPN decrypt** .

Step 19 Click **Trace**.

Step 20 (Optional) If you modify any values, ensure you click **Save PCAP** to save your changes, then begin the trace.

Step 21 (Optional) If you do not save the modified values of the PCAP file and click **Trace**, the **Unsaved PCAP changes** dialog box appears and prompts you to save the file.

a. Check the **Save PCAP file** check box.

b. Enter a name for the PCAP file in the **Name** field.

c. Click **Save and Trace** to save the changes and continue with packet trace.

Note
The PCAP file name changes to the name entered in the **Name** field.

Step 22 You can track the status of trace in the **Events & Logs** > **Analysis** > **Audit Logs** window. These tasks can be tracked:

- Saving a PCAP file

- Uploading a PCAP file
- Details of the packet trace

The **Trace Result** displays the results for each phase that the PCAP packets have traveled through the system. Click an individual packet to view the traces results for the packet. You can do the following:

- Copy (Copy) the trace results to the clipboard.
- Expand or collapse (Expand or collapse) the displayed results.
- Maximize (Maximize) the trace result window.

The time elapsed information, useful to gauge the processing efforts, is displayed for each phase. The results section also displays the total time taken for packets flowing from an ingress to an egress interface.

The **Trace History** pane displays the stored trace details for each PCAP trace. It can store up to 100 packet traces. You can select a saved trace and run the packet trace activity again. You can do the following:

- Search for a trace using any of the trace parameters.
- Disable saving of the trace to history using the Slider button.
- Delete specific trace results.
- Clear all the traces.

CPU profiler overview

The CPU profiler gathers data on CPU usage by individual modules or inspectors of Snort 3, while packets are being processed within a specific timeframe. It provides information on the amount of CPU time that each module consumes in relation to the total CPU usage of the Snort 3 process. Using the CPU profiler does not require reloading the configuration or restarting Snort 3, thus minimizing downtime. The profiling result displays the processing time taken by all the modules during the last profiling session. CPU profiling results are saved in JSON format in the threat defense device and synchronized in the management center.

Caution CPU profiling might cause system performance degrade of approximately 3 percent.

Use the CPU profiler

Use the CPU profiler to identify which Snort 3 modules or inspectors are consuming the most processing time and contributing to performance issues.

Before you begin

You must have Version 7.6 or later devices with Snort 3 to use CPU Profiling.

Procedure

Step 1 From the management center, choose **Devices** > **Troubleshoot** > **Snort 3 Profiling**.

Step 2 Click the **CPU Profiling** tab.

Step 3 From the **Select device for CPU Profiling** drop-down list, choose a device for CPU profiling.

Note
You can run multiple profiling sessions simultaneously on different devices.

Step 4 To start a CPU profiling session, click **Start**. (The session automatically stops after 120 minutes.)

You can stop the profiling session at any time by clicking **Stop**. However, canceling it before the scheduled 120 minutes might not give precise results.

Note
While the CPU profiling session is in progress, a task is created. Click **Notifications** (message center), and then click the **Tasks** tab to view the details.

The latest profiling result is automatically displayed in the **CPU Profiling Results** section. The table contains statistics for the processing time taken by all the Snort 3 modules or inspectors during the last profiling session. You can view the CPU profiler output in tabular format:

- **Module**: Name of the module or inspector.
- **% Total of CPU Time**: Percentage of time taken by the module relative to the overall time taken by Snort 3 for processing traffic. If this value is considerably higher than that of other modules, it means the module is contributing more to the unsatisfactory performance of Snort 3.
- **Time (µs)**: Total time (in microseconds) taken by each module.
- **Avg/Check**: Average time taken by the module each time the module was invoked.
- **% Caller**: Time taken by the submodule (if configured) relative to the main module. This value is used for debugging purposes.

Step 5 (Optional) Click **Download Snapshot** to download the profiling result. The downloaded file is in CSV format and contains all the fields from the profiling results page.

Step 6 (Optional) Click the **Filter by % of Snort time** toggle button to filter out modules whose execution consumed more than *n*% of the profiling time.

Step 7 (Optional) Use the **Search** field to search through the fields in the **CPU Profiling Results** table.

Note
Except for **Module**, you can click any of the other column headers to sort the data.

Step 8 (Optional) Click the **Profiling History** section (collapsible panel on the left) to expand it and view a set of cards representing the previous profiling sessions for a chosen device. When you click a card from history, the details are displayed in the **CPU Profiling Results** section.

The CPU profiling session provides detailed statistics about the processing time of each Snort 3 module, helping you identify performance bottlenecks.

Note If you initiate a deployment while CPU profiling is running, the profiling session is automatically terminated to accommodate the deployment, except for deployments resulting from changes to the access control policy rules and security intelligence. You must run the CPU profiling for the device again.

Rule profiler overview

The Snort 3 rule profiler gathers data on the time spent processing a set of Snort 3 intrusion rules, highlights potential issues, and shows the rules with unsatisfactory performance. Within the Snort 3 engine, the rule profiler inspects traffic using the Snort 3 intrusion detection mechanism. The rule profiler displays the top 100 IPS rules that required the maximum time to check. Triggering the rule profiler does not require Snort 3 reload or restart. The rule profiling results are saved in JSON format in the threat defense device and synchronized in the management center.

Use the rule profiler

The Rule Profiler helps you identify IPS rules that consume excessive processing time, allowing you to optimize performance by analyzing rule execution statistics and identifying poorly performing rules that may need adjustment or replacement.

Before you begin

You must have version 7.6 or later devices with Snort 3 to use Rule Profiling.

Procedure

Step 1 From the management center, choose **Devices** > **Troubleshoot** > **Snort 3 Profiling**.

Step 2 Click the **Rule Profiling** tab.

Step 3 From the **Select device for Rule Profiling** drop-down list, choose a device for rule profiling.

Note
You can run multiple profiling sessions simultaneously on different devices.

Step 4 To start a rule profiling session, click **Start**.

The session automatically stops after 120 minutes. You can stop the profiling session at any time by clicking **Stop**. However, canceling it before the scheduled 120 minutes might not give precise results.

Note
While the rule profiling session is in progress, a task is created. Click **Notifications** > **Tasks** to view the details.

The latest profiling result is automatically displayed in the **Rule Profiling Results** section. The table contains statistics for the rules that took the most time to process (sorted in descending order) by the total time (in microseconds [µs]). You can view the IPS rule profiler output in tabular format:

- **% of Snort Time**: Time spent for processing the rule, relative to the total time of the Snort 3 operation.
- **Rev**: Revision number of the rule.

- **Checks**: Number of times the IPS rule was executed.
- **Matches**: Number of times the IPS rule fully matched in the traffic.
- **Alerts**: Number of times the IPS rule triggered an IPS alert.
- **Time**: Time (in microseconds) spent by Snort in checking the IPS rule.
- **Avg/Check**: Average time spent by Snort on a single check of the rule.
- **Avg/Match**: Average time spent by Snort on a single check, which resulted in a match.
- **Avg/Non-Match**: Average time spent by Snort on a single check, which did not result in a match.
- **Timeouts**: Number of times the rule exceeded the Rule Handling - Threshold configured in the Latency-Based Performance Settings of the access control policy.
- **Suspends**: Number of times the rule was suspended due to consecutive threshold violations.

Step 5 Click **Download Snapshot** to download the profiling result.

The downloaded file is in CSV format and contains all the fields from the profiling results page.

Step 6 Click the **Filter by % of Snort time** toggle button to filter out rules whose execution took more than *n*% of the profiling time.

In general, a rule is considered as performing unsatisfactorily if it consumes 0.2% or more of Snort's overall processing time.

Step 7 Use the **Search** field to search through the fields in the **Rule Profiling Results** table.

Step 8 Click the **Rule Profiling History** section (collapsible panel on the left) to expand it and view a set of cards representing the previous profiling sessions for a chosen device.

When you click a card from the history, the details are displayed in the **Rule Profiling Results** section.

Note If you initiate a deployment while rule profiling is running, the profiling session is automatically terminated to accommodate the deployment, except for deployments resulting from changes to the access control policy rules and security intelligence. You must run the rule profiling for the device again.

Use the Firewall Threat Defense diagnostic CLI from the web interface

Use the diagnostic CLI to execute selected commands for quick troubleshooting of your device from the web interface without requiring direct SSH access to the device.

You can execute the selected Firewall Threat Defense diagnostic CLI commands from the Cloud-Delivered Firewall Management Center. The commands **ping** (except **ping system**), **traceroute**, and select **show** commands run in the diagnostic CLI rather than the regular CLI.

When you run the **show** commands, if the message `Unable to execute the command properly. Please see logs for more details` is displayed, it means that the command is not valid in the diagnostic CLI. For example, **show access-list** works, but this message will be displayed if you enter **show**

access-control-policy. To use non-diagnostic commands, use SSH to log in to a device outside management center.

For more information on the Firewall Threat Defense CLI, see the *Cisco Secure Firewall Threat Defense Command Reference*.

Before you begin

- You must be an Admin, Maintenance, or Security Analyst to use the diagnostic CLI.
- The purpose of diagnostic CLI is to enable the quick use of a few commands that are useful in troubleshooting a device. For access to the full range of commands, open an SSH session directly with the device.
- In deployments using Cloud-Delivered Firewall Management Center high availability,diagnostic CLI is available only in the active Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Troubleshoot** > **Threat Defense CLI**.

You can also access the CLI tool through the health monitor for the device (**System** (⚙) > **Health** > **Monitor**). From there, you can select the device, click the **View System and Troubleshoot Details** link, click **Advanced Troubleshooting**, then click **Threat Defense CLI** on that page.

Step 2 From the **Device** drop-down list, choose the device on which to execute the diagnostic command.

Step 3 From the **Command** drop-down list, choose the command that you want to execute.

Step 4 Enter the command parameters in the **Parameters** field.

See the *Cisco Secure Firewall Threat Defense Command Reference* for the valid parameters.

For example, to execute **show access-list** command, choose **show** from the **Command** drop-down list, then enter **access-list** in the **Parameters** field.

Note
Do not type the full command in the **Parameters** field. Type only the relevant keywords.

Step 5 Click **Execute** to view the command output.

If the message `Unable to execute the command properly. Please see logs for more details.` is displayed, examine the parameters closely. There might be syntax errors.

This message can also mean that the command you are trying to execute is not a valid command within the context of the diagnostic CLI (which you have accessed from the device using the **system support diagnostic-CLI** command). Log in to the device using SSH to use these commands.

Feature-specific troubleshooting

This reference provides a comprehensive list of troubleshooting resources organized by feature. Each entry includes links to detailed troubleshooting information, best practices, and configuration guidance for specific system features and components.

CHAPTER 20

Backup/Restore

- About Backup and Restore, on page 457
- Requirements for Backup and Restore, on page 458
- Guidelines and Limitations for Backup and Restore, on page 459
- Best Practices for Backup and Restore, on page 460
- Back Up Managed Devices, on page 462
- Restore Security Cloud Control-Managed Devices, on page 464

About Backup and Restore

The ability to recover from a disaster is an essential part of any system maintenance plan. As part of your disaster recovery plan, we recommend that you perform periodic backups.

On-Demand Backups

You can perform on-demand backups for Secure Firewall Threat Defense devices in Security Cloud Control.

For more information, see Back Up Managed Devices, on page 462.

Scheduled Backups

You can use the scheduler on Cloud-Delivered Firewall Management Center to automate backups. You can also schedule remote device backups from Security Cloud Control.

The Cloud-Delivered Firewall Management Center setup process schedules weekly configuration-only backups, to be stored in Cisco's secure cloud storage. This is not a substitute for full off-site backups. After initial setup finishes, you must review your scheduled tasks and adjust them to fit your organization's needs.

For more information, see Scheduling, on page 471.

Store Backup Files

When you back up a device, the Cloud-Delivered Firewall Management Center stores the backup files in its secure cloud storage.

Note Cloud-Delivered Firewall Management Center stores only the 5 most recent Firewall Threat Defense backups per device.

To know how to download an existing backup file, see Step 3 in Restore a Firewall Threat Defense Device, on page 464.

For more information, see Back Up Managed Devices, on page 462.

Restore Managed Devices

You must use the Firewall Threat Defense CLI to restore the Firewall Threat Defense device.

For more information, see Restore Security Cloud Control-Managed Devices, on page 464.

What Is Backed Up?

Device backups are always configuration-only.

What Is Restored?

Restoring configurations overwrites *all* backed-up configurations.

Make sure you understand and plan for the following:

- You cannot restore what is not backed up.
- The Firewall Threat Defense restore process removes VPN certificates and all VPN configurations from Firewall Threat Defense devices, including certificates added after the backup was taken. After you restore a Firewall Threat Defense device, you must re-add/re-enroll all VPN certificates, and redeploy the device.

Requirements for Backup and Restore

Backup and restore have the following requirements:

Model Requirements: Backup

You can back up:

- Firewall Threat Defense standalone devices, native instances, container instances, HA pairs, and clusters
- Firewall Threat Defense Virtual for VMware devices, either standalone or HA pairs, and clusters

Backup is *not* supported for:

- Firewall Threat Defense Virtual implementations *other than* for VMware

If you must replace a device where backup and restore is not supported, you must manually recreate device-specific configurations.

Model Requirements: Restore

A replacement managed device must be the same model as the one you are replacing, with the same number of network modules and same type and number of physical interfaces.

Version Requirements

As the first step in any backup, note the patch level. To restore a backup, the old and the new appliance must be running the same Firewall version, including patches.

License Requirements

Address licensing or orphan entitlement concerns as described in the best practices and procedures. If you notice licensing conflicts, contact Cisco TAC.

Guidelines and Limitations for Backup and Restore

Backup and restore have the following guidelines and limitations.

Caution Users with CLI access can access the Linux shell access with the **expert** command, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firewall and Security Cloud Control user documentation.
- Restrict the list of users with Linux shell access..
- Do not add users directly in the Linux shell; only use the procedures in this chapter.

Backup and Restore Is for Disaster Recovery/Return Material Authorization

Backup and restore are primarily intended for Return Material Authorization (RMA) scenarios. Before you begin the restore process of a faulty or failed physical appliance, contact for replacement hardware.

Backup and Restore Is Not Configuration Import/Export

A backup file contains information that uniquely identifies an appliance, and cannot be shared. Do not use the backup and restore process to copy configurations between appliances or devices, or as a way to save configurations while testing new ones. Instead, use the import/export feature.

For example, Firewall Threat Defense device backups include the device's management IP address and all information the device needs to connect to its managing Security Cloud Control. Do not restore an FTD backup to a device being managed by a different manager; the restored device attempts to connect to the manager specified in the backup.

Restore Is Individual and Local

You restore threat defense devices individually and locally. This means:

- You cannot batch-restore to high availability (HA) devices. The restore procedures in this guide explain how to restore in an HA environment.

- You cannot use Security Cloud Control to restore a device. For Firewall Threat Defense devices, you must use the Firewall Threat Defense CLI, except for the ISA 3000 zero-touch restore, which uses an SD card and the reset button.
- You cannot use a Security Cloud Control user account to log into and restore one of its managed devices. Security Cloud Control and Firewall Threat Defense devices maintain their own user accounts.

Best Practices for Backup and Restore

Backup and restore have the following best practices.

When to Back Up

We recommend backing up during a maintenance window or other time of low use.

You must back up in the following situations:

- Regular backups.

  As part of your disaster recovery plan, we recommend that you perform periodic backups.

- Before upgrade or reimage.

  If an upgrade fails catastrophically, you may have to reimage and restore. Reimaging returns most settings to factory defaults, including the system password. If you have a recent backup, you can return to normal operations more quickly.

- After upgrade.

  Ensure that you back up the device after upgrade, so that you have a freshly upgraded device backup.

Maintaining Backup File Security

Backup files are stored as unencrypted archive (.tar) files; they should be stored in a secure repository.

Private keys in PKI objects, which represent the public key certificates and paired private keys that are required to support your deployment are decrypted before they are backed up. The keys are reencrypted with a randomly generated key when you restore the backup.

Backup file should be stored securely.

Backup and Restore in Firewall Threat Defense High Availability Deployments

In a Firewall Threat Defense HA deployment, you must:

- Back up the device pair from the Cloud-delivered Firewall Management Center, but restore individually and locally from the Firewall Threat Defense CLI.

  The backup process produces unique backup files for Firewall Threat Defense HA devices. Do not restore one HA peer with the backup file from the other. A backup file contains information that uniquely identifies an appliance, and cannot be shared.

  A Firewall Threat Defense HA device's role is noted in its backup file name. When you restore, make sure you choose the appropriate backup file: primary vs secondary.

- Do *not* suspend or break HA before you restore.

Maintaining the HA configuration ensures that replacement devices can easily reconnect after restore. Note that you will have to resume HA synchronization to make this happen.

- Do *not* run the restore CLI command on both peers at the same time.

  Assuming you have successful backups, you can replace either or both peers in an HA pair. Any physical replacement tasks that you can perform simultaneously: unracking, reracking, and so on. However, do *not* run the restore command on the second device until the restore process completes for the first device, including the reboot.

Backup and Restore in Firewall Threat Defense Clustering Deployments

In the Firewall Threat Defense clustering deployment, you must:

- Back up the entire cluster from the Cloud-delivered Firewall Management Center, but restore nodes individually and locally from the threat defense CLI.

  The backup process produces a bundled tar file that includes unique backup files for each cluster node. Do not restore one node with the backup file from another. A backup file contains information that uniquely identifies a device, and cannot be shared.

  The node's role is noted in its backup file name. When you restore, make sure you choose the appropriate backup file: control or data.

  You cannot back up individual nodes. If a data node fails to back up, the management center will still back up all other nodes. If the control node fails to back up, the backup is canceled.

- All the nodes that are part of the cluster must be registered in the management center, for the backup to be successful.

- Do *not* suspend or break clustering before you restore. Maintaining the cluster configuration ensures replacement devices can easily reconnect after restore.

- Do *not* run the **restore** CLI command on multiple nodes at the same time. We recommend that you restore the control node first and wait until it rejoins the cluster before you restore any data nodes.

  Assuming you have successful backups, you can replace multiple nodes in the cluster. Any physical replacement tasks you can perform simultaneously: unracking, reracking, and so on. However, do *not* run the **restore** command on an additional node until the restore process completes for the previous node, including the reboot.

Before Backup

Ensure that any firewall located between the Firewall Threat Defense and Security Cloud Control is configured to allow outbound HTTPS traffic from the Firewall Threat Defense to the Security Cloud Control host.

Before Restore

Before restore, you must:

- Revert licensing changes.

  Revert any licensing changes made since you took backup.

  Otherwise, you may have license conflicts or orphan entitlements after the restore. However, do *not* unregister from Cisco Smart Software Manager (CSSM). If you unregister from CSSM, you must unregister again after you restore, then re-register.

After the restore completes, reconfigure licensing. If you notice licensing conflicts or orphan entitlements, contact Cisco TAC.

- Disconnect faulty appliances.

  Disconnect the management interface, and for devices, the data interfaces.

  Restoring a Firewall Threat Defense device sets the management IP address of the replacement device to the management IP address of the old device. To avoid IP address conflicts, disconnect the old device from the management network before you restore the backup on its replacement.

- Do *not* unregister managed devices.

  Whether you are restoring a managed device, do not unregister devices from the Security Cloud Control, even if you physically disconnect an appliance from the network.

  If you unregister, you must redo some device configurations, such as security zone to interface mappings. After you restore, Security Cloud Control and devices should begin communicating normally.

- Reimage.

  In an RMA scenario, the replacement appliance arrives configured with factory defaults. However, if the replacement appliance is already configured, we recommend you reimage. Reimaging returns most settings to factory defaults, including the system password. You can only reimage to major versions, so you must patch after you reimage.

  If you do not reimage, keep in mind that Security Cloud Control intrusion events and file lists are merged rather than overwritten.

After Restore

After restore, you must:

- Reconfigure anything that was not restored.

  This can include reconfiguring licensing and audit log server certificate settings. You also must re-add/re-enroll failed Firewall Threat Defense VPN certificates.

- Deploy.

  After you restore a device, deploy to that device. You *must* deploy. If the device or devices are not marked out of date, force deploy from the Device Management page.

Back Up Managed Devices

You can perform on-demand or scheduled backups for supported Secure Firewall Threat Defense devices using Cloud-Delivered Firewall Management Center without a backup profile.

For more information, see Back Up a Firewall Threat Defense Device from Cloud-delivered Firewall Management Center, on page 463.

Related Information

Back Up a Firewall Threat Defense Device from Cloud-delivered Firewall Management Center

Use this procedure to perform an on-demand backup of any of the following devices:

- Firewall Threat Defense: Physical devices, standalone, HA, or cluster
- Firewall Threat Defense Virtual: VMware, standalone, HA, or cluster

Backup and restore is not supported for any other platforms or configurations.

Before you begin

You must read and understand the requirements, guidelines, limitations, and best practices. Do not skip any steps or ignore security concerns. Careful planning and preparation can help you avoid missteps.

- Requirements for Backup and Restore, on page 458
- Guidelines and Limitations for Backup and Restore, on page 459
- Best Practices for Backup and Restore, on page 460

Caution Users with CLI access can access the Linux shell access with the **expert** command, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firewall and Security Cloud Control user documentation.
- Restrict the list of users with Linux shell access..
- Do not add users directly in the Linux shell; only use the procedures in this chapter.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 From the Security Cloud Control menu, navigate **Administration** > **Firewall Management Center** to open the **Services** page.

Step 3 Select **Cloud-Delivered FMC** and in the **Management** pane, click **Devices** to navigate to the Cloud-Delivered Firewall Management Center user interface.

Step 4 Select **Administration** > **Advanced** > **Backup & Restore**
The **Device backup** page displays the device name, backup file name, device model, device version, and the backup file size.

Step 5 Click **Create device backup**.

Step 6 Select one or more Firewall Threat Defense devices in **Select devices to backup**.

You can filter the list based on the device groups, or device type—Standalone, High Availability, and Cluster. For clustering, choose the cluster. You cannot perform backups on individual nodes.

Note
If the device name has special characters other than hyphen, period, and underscore, those special characters will be replaced with an underscore.

Step 7 Click **Next** to view the summary of your selections.

Step 8 Click **Start backup** to start the on-demand backup.

Step 9 Monitor the progress under **Tasks** in the **Notifications** pane.

- The notifications will display one consolidated entry per backup action.
- To view detailed information for each of the devices being backed up, click **Details**.
- In the **Device backup information** dialog, you can monitor the backup progress at granular level.
- For cluster backup, you can view node-wise backup progress.
- To download the backup report in PDF format, click **Download report**.

Restore Security Cloud Control-Managed Devices

For Firewall Threat Defense devices, you must use the Firewall Threat Defense CLI to restore from backup. You cannot use the Cloud-Delivered Firewall Management Center to restore a device.

Related Information:

Restore a Firewall Threat Defense Device

Firewall Threat Defense backup and restore is intended for RMA. Restoring the configurations overwrites *all* configurations on the device, including the management IP address. It also reboots the device.

In case of hardware failure, this procedure outlines how to replace a firewall device, either standalone or in an HA pair. It assumes you have access to a successful backup of the device or devices you are replacing.

Note Do *not* unregister from the Security Cloud Control, even when disconnecting a device from the network. In a Firewall Threat Defense HA deployment, do *not* suspend or break HA. Maintaining these links ensures replacement devices can automatically reconnect after a restore.

In a Firewall Threat Defense HA deployment, you can use this procedure to replace either or both peers. To replace both, perform all steps on both devices simultaneously, except the restore CLI command itself. You cannot replace a Firewall Threat Defense HA device without a successful backup.

Note Starting from the next upgrade of Cloud-Delivered Firewall Management Center, Cisco will only store the 5 most recent Firewall Threat Defense backups per device and purge all the other backups. If you require the other backups for compliance purposes, we recommend that you download them to your private environment by May 31, 2025.

To know how to download an existing backup file, see Step 3 in the procedure below.

Before you begin

You must read and understand the requirements, guidelines, limitations, and best practices. Do not skip any steps or ignore security concerns. Careful planning and preparation can help you avoid missteps.

- Requirements for Backup and Restore, on page 458
- Guidelines and Limitations for Backup and Restore, on page 459
- Best Practices for Backup and Restore, on page 460

Procedure

Step 1 Contact Cisco TAC for replacement hardware.

Obtain an identical model, with the same number of network modules and same type and number of physical interfaces. You can begin the RMA process from the Cisco Returns Portal.

Step 2 Select **Administration** > **Advanced** > **Backup & Restore**
The **Device backup** page displays the device name, backup file name, device model, device version, and the backup file size.

Step 3 Locate a successful backup of the faulty device from **Device backup**.

Use **Download** that downloads the backup file(s) to your local storage or **Export backup link** that generates a URL to download the backup and exports it to a CSV file that gets downloaded. Use the URL to download the backup to a secure location. Note that the URL is valid only for six hours, after which you must export it again to get a different URL. In a cluster device backup, you can now download a specific cluster node backup.

In a Firewall Threat Defense HA deployment, you back up the pair as a unit but the backup process produces unique backup files for each device in the pair. The device's role is noted in the backup file name.

If the only copy of the backup is on the faulty device, copy it somewhere else now. If you reimage the device, the backup will be erased. If something else goes wrong, you may not be able to recover the backup.

The replacement device will need the backup, but can retrieve it with the secure copy (SCP) command during the restore process. We recommend you put the backup somewhere SCP-accessible to the replacement device. Or, you can copy the backup to the replacement device itself.

Step 4 Remove (unrack) the faulty device and disconnect all interfaces. In threat defense HA deployments, this includes the failover link.

See the hardware installation and getttign started guides for your model: Cisco Firepower NGFW: Install and Upgrade Guides.

Note

Do not unregister from the management center, even when disconnecting a device from the network. In threat defense HA deployments, do not suspend or break HA. Maintaining these links ensures replacement devices can automatically reconnect after restore.

Step 5 Install the replacement device and connect it to the management network.

Connect the device to power and the management interface to the management network. In Firewall Threat Defense HA deployments, connect the failover link. However, do *not* connect the data interfaces.

See the hardware installation guide for your model: Cisco Firepower NGFW: Install and Upgrade Guides.

Step 6 (Optional) Reimage the replacement device.

In an RMA scenario, the replacement device will arrive configured with factory defaults. If the replacement device is not running the same major version as the faulty device, we recommend you reimage.

See the Cisco Secure Firewall ASA and Threat Defense Reimage Guide.

Step 7 Perform initial configuration on the replacement device.

Access the Firewall Threat Defense CLI as the admin user. You can use the console or you can SSH to the factory-default management interface IP address (192.168.45.45). A setup wizard prompts you to configure the management IP address, gateway, and other basic network settings.

See the initial configuration topics in the getting started guide for your model: Cisco Firepower NGFW: Install and Upgrade Guides.

Note
If you need to patch the replacement device, start the management center registration process as described in the getting started guide. If you do *not* need to patch, do not register.

Step 8 Make sure the replacement device is running the same Firewall software version, including patches, as the faulty device.

The existing device should not be deleted from the management center. The replacement device should be unmanaged from the physical network and the new hardware as well as the replacing Firewall Threat Defense patch should have the same version. The Firewall Threat Defense CLI does not have an upgrade command. To patch:

a) From the management center web interface, complete the device registration process: See *Add a Device to the Management Center* in Cisco Secure Firewall Management Center Device Configuration Guide.

   Create a new AC policy and use the default action "Network Discovery". Leave this policy as is; do not add any features or modifications. This is being used to register the device and deploy a policy with no features so that you do not require licenses, and you will then be able to patch the device. Once backup is restored, it should restore the licensing and policy into the expected state.

b) Patch the device: Cisco Firewall Management Center Upgrade Guide.

c) Unregister the freshly patched device from the management center: See *Delete a Device from the Management Center* in Cisco Secure Firewall Management Center Device Configuration Guide.

   If you do not unregister, you will have a ghost device registered to the management center after the restore process brings your "old" device back up.

Step 9 Make sure the replacement device has access to the backup file.

The restore process can retrieve the backup with SCP, so we recommend you put the backup somewhere accessible. Or, you can manually copy the backup to the replacement device itself, to `/var/sf/backup`.

Step 10 From the FTD CLI, restore the backup.

Access the Firewall Threat Defense CLI as the admin user. You can use the console or you can SSH to the newly configured management interface (IP address or hostname). Keep in mind that the restore process will change this IP address.

To restore:

- With SCP: **restore remote-manager-backup location scp-hostname username filepath backup tar-file**
- From the local device: **restore remote-manager-backup backup tar-file**

Step 11 Log in to Security Cloud Control and wait for the devices to connect.

When the restore is done, the device logs you out of the CLI, reboots, and automatically connects to Security Cloud Control. At this time, the device should appear out of date.

At this time, the device should appear out of date.

Step 12 Before you deploy, perform any post-restore tasks and resolve any post-restore issues:

- Resolve licensing conflicts or orphan entitlements. Contact Cisco TAC.
- Resume HA synchronization.
- Re-add/re-enroll all VPN certificates. The restore process removes VPN certificates from FTD devices, including certificates added after the backup was taken.

Step 13 Deploy configurations.

You must deploy. If a restored device is not marked out of date, force deploy from the Device Management page.

Step 14 Connect the device's data interfaces.

See the hardware installation guide for your model: Cisco Secure Firewall Threat Defense: Install and Upgrade Guides.

Restore Firewall Threat Defense from Backup: Firewall Threat Defense Virtual

Use this procedure to replace a faulty or failed Firewall Threat Defense Virtual device for VMware.

In Firewall Threat Defense HA and clustering deployments, you can use this procedure to replace all peers. To replace all, perform all steps on all devices simultaneously, except the **restore** CLI command itself.

Note Do *not* unregister from the Firewall Management Center, even when disconnecting a device from the network. In Firewall Threat Defense HA and clustering deployments, do *not* suspend or break high availibility or clusters. Maintaining registration ensures that replacement devices can automatically reconnect after restore.

Before you begin

You must read and understand the requirements, guidelines, limitations, and best practices. Do not skip any steps or ignore security concerns. Careful planning and preparation can help you avoid missteps.

- Requirements for Backup and Restore, on page 458
- Guidelines and Limitations for Backup and Restore, on page 459
- Best Practices for Backup and Restore, on page 460

Procedure

Step 1 Navigate **System(⚙) > Tools > Backup/Restore**.

Step 2 Locate a successful backup of the faulty device from **Device Backups** under **Backup Management**.

For clustering, node backup files are bundled together in a single compressed file for the cluster (*cluster_name.timestamp***.tar.gz**). Before you can restore nodes, you need to extract the individual node backup files (*node_name***_control_***timestamp***.tar** or *node_name***_data_***timestamp***.tar**).

Use **Download** that downloads the backup file(s) to your local storage or **Export Backup Links** that generates a URL to download the backup and exports it to a CSV file that gets downloaded. Use the URL to download the backup to a secure location. Note that the URL is valid only for six hours, after which you must export it again to get a different URL.

In Firewall Threat Defense HA deployments, you back up the pair as a unit, but the backup process produces unique backup files for each device in the pair. The device's role is noted in the backup file name.

If the only copy of the backup is on the faulty device, copy it somewhere else now. If you reimage the device, the backup will be erased. If something else goes wrong, you may not be able to recover the backup.

The replacement device needs the backup, but can retrieve it with SCP during the restore process. We recommend you put the backup somewhere SCP-accessible to the replacement device. Or, you can copy the backup to the replacement device itself.

Step 3 Remove the faulty device.

Shut down, power off, and delete the virtual machine. For procedures, see the documentation for your virtual environment.

Step 4 Deploy a replacement device.

See the Cisco Firepower Threat Defense Virtual for VMware Getting Started Guide.

Step 5 Perform initial configuration on the replacement device.

Use the VMware console to access the Firewall Threat Defense Virtual CLI as the admin user. A setup wizard prompts you to configure the management IP address, gateway, and other basic network settings.

Do not set the same management IP address as the faulty device. This can cause problems if you need to register the device in order to patch it. The restore process will correctly reset the management IP address.

See the CLI setup topics in the getting started guide: Cisco Firepower Threat Defense Virtual for VMware Getting Started Guide.

Step 6 Make sure that the replacement device is running the same Firewall software version, including patches, as the faulty device.

Ensure that the existing device should not be deleted from the Security Cloud Control. The replacement device should be unmanaged from the physical network and the new hardware and the replacing Firewall Threat Defense Virtual patch should have the same version. The Firewall Threat Defense Virtual CLI does not have an upgrade command. To patch:

a. Complete the Firewall Threat Defense Virtual registration process in Security Cloud Control.

b. Patch the Firewall Threat Defense Virtual device.

c. Unregister the freshly patched device from Security Cloud Control.

Step 7 Make sure that the replacement device has access to the backup file.

The restore process can retrieve the backup with SCP, so we recommend you put the backup somewhere accessible. Or, you can manually copy the backup to the replacement device itself, to `/var/sf/backup`. For clusters, make sure you extract the individual node backup file from the main cluster bundle.

Step 8 From the Firewall Threat Defense CLI, restore the backup.

Access the Firewall Threat Defense Virtual CLI as the admin user. You can use the console or you can SSH to the newly configured management interface (IP address or hostname). Keep in mind that the restore process will change this IP address.

To restore:

- With SCP: **restore remote-manager-backup location scp-hostname username filepath backup tar-file**
- From the local device: **restore remote-manager-backup backup tar-file**

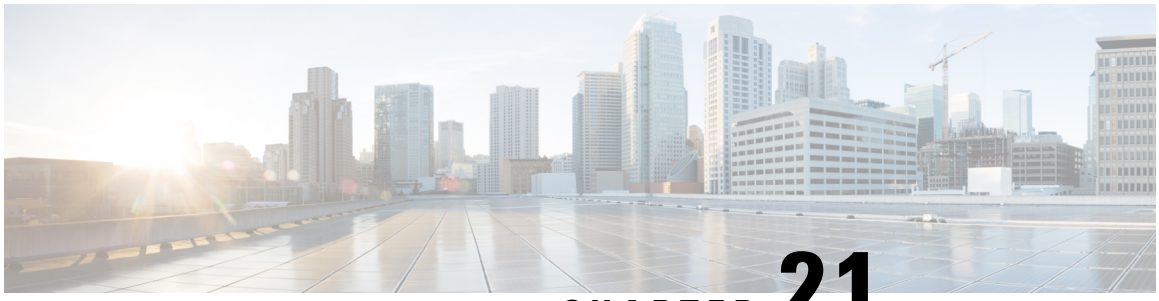
In Firewall Threat Defense HA and clustering deployments, make sure you choose the appropriate backup file: primary vs secondary, or control vs. data. The role is noted in the backup file name. If you are restoring all devices, do this sequentially. Do not run the **restore** command on the next device until the restore process completes for the first device, including the reboot.

Step 9 Log into Security Cloud Control and wait for the devices to connect.

When the restore is done, the device logs you out of the CLI, reboots, and automatically connects to Security Cloud Control. At this time, the device should appear out of date.

At this time, the device should appear out of date.

Step 10 Before you deploy, perform any post-restore tasks and resolve any post-restore issues:



- Resolve licensing conflicts or orphan entitlements. Contact Cisco TAC.
- Resume HA synchronization.
- Re-add/re-enroll all VPN certificates. The restore process removes VPN certificates from Firewall Threat Defense Virtual devices, including certificates added after the backup was taken.

Step 11 Deploy configurations.

You must deploy. If a restored device is not marked out of date, force deploy from the Device Management page.

Step 12 Connect the device's data interfaces.

See the hardware installation guide for your model: Cisco Secure Firewall Threat Defense: Install and Upgrade Guides.

CHAPTER 21

Scheduling

- Task scheduling, on page 471
- Guidelines for scheduled tasks, on page 471
- Scheduled task types, on page 472
- Schedule a task, on page 474

Task scheduling

Task scheduling is a system management feature that allows you to automate routine jobs to run once or on a recurring basis.

Time zones and seasonal time changes

Tasks are scheduled in Coordinated Universal Time (UTC), which remains constant year-round. Scheduled tasks do not adjust automatically for local time changes, such as daylight saving time or summer time. For example, a task scheduled for 2:00 a.m. during standard time runs at 3:00 a.m. after the local clock moves forward.

Automatically scheduled tasks

The system automatically schedules these tasks:

- A one-time task to download and install the latest VDB, at initial setup.
- A weekly task to download the latest available, starting at initial setup.
- A daily task to updated certificate revocation lists (CRL), when you configure user or audit log certificates.

Guidelines for scheduled tasks

This section provides general scheduling guidelines. Refer to Scheduled task types, on page 472 for task-specific guidelines and prerequisites.

When to run tasks

Follow these guidelines when scheduling tasks:

- Automatically scheduled tasks: Review automatically scheduled tasks to make sure they run at the right time for your environment.
- Traffic inspection and flow: Schedule tasks that might interrupt traffic during maintenance windows.

Scheduling task sequences

This table lists outcomes that require multiple tasks in sequence. Leave enough time so that each task can finish before the next begins.

Table 31: Outcomes requiring multiple scheduled tasks

Outcome	Tasks
VDB update	**1.** Download Latest Update **2.** Install Latest Update

Scheduled task types

This section describes the available scheduled task types (**Job Type** in the scheduler), as well as options, guidelines, and requirements for each task.

Backup

Purpose: Back up managed devices.

Options:

- **Backup Type**: Device

Guidelines:

- Supported devices: Some devices, such as devices in the public cloud, cannot be backed up.
- Simultaneous backups: Back up no more than 20 devices per task. Do not schedule multiple backup tasks for the same time; start with 30 minutes between backups.
- Bandwidth: If you are transferring backup files, consider scheduling backups during periods of low network use.

Download CRL

Purpose: Download certificate revocation list (CRL) updates. The system automatically schedules daily CRL updates when you configure user or audit log certificates in the system configuration. Use the scheduler to change the update interval or run a one-time update. Disabling the configurations removes the task.

Download latest update

Purpose: Download the latest VDB update. Initial setup schedules a weekly download of the latest applicable updates.

Note Use **System** (⚙) > **Product Upgrades** to upgrade software. Scheduled software upgrades are not supported, although the web interface allows configuration.

Options:

- **Update Items**: Choose **Vulnerability Database**.

Guidelines:

- Required task order: To update the VDB, download then install. Download must finish before install begins.
- Bandwidth: Consider scheduling downloads during periods of low network use.

Push latest update

Note Use **System** (⚙) > **Product Upgrades** to upgrade software. Scheduled software upgrades are not supported, although the web interface allows configuration.

Install latest update

Purpose: Install a VDB update.

Note Use **System** (⚙) > **Product Upgrades** to upgrade software. Scheduled software upgrades are not supported, although the web interface allows configuration.

Options:

- **Update Items**: Choose **Vulnerability Database**.
- **Device**: Choose the Cloud-Delivered Firewall Management Center.

Guidelines:

- Required task order: To update the VDB, download then install. Download must finish before install begins.
- Do not perform tasks related to mapped vulnerabilities while the VDB is updating. Even if the Message Center shows no progress for several minutes or indicates that the update has failed, do not restart the update. Instead, contact Cisco TAC.
- Deploy during a maintenance window to implement changes: Snort typically restarts during the first deployment after VDB update. Restarting the Snort process briefly interrupts traffic flow and inspection on all devices, including devices configured for high availability or clustering.

Queue intrusion policy apply

Purpose: Deploy intrusion policy changes from the Cloud-Delivered Firewall Management Center to managed devices.

Options:

- **Intrusion Policy**: The policy you want to deploy.
- **Device**: The device where you want to deploy the policy.

Guidelines:

- Traffic inspection and flow: When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. Refer to Snort restart traffic behavior, on page 196 and Configurations that restart the snort process when deployed or activated, on page 198.

Update URL filtering database

Purpose: Obtain the latest URL filtering data from Cisco. By default, when you enable URL filtering, automatic updates are enabled. However, if you need to control exactly when these updates occur, use the scheduler.

Guidelines:

- Licenses: URL Filtering
- Prerequisite configurations: You must enable URL filtering to schedule this task. Disable automatic updates on **Integration** > **Other Integrations** > **Cloud Services**.
- Update size, duration, and bandwidth: Daily updates are typically small. With longer intervals, expect larger downloads and additional time for the changes to propagate, and consider scheduling during periods of low network use.

Schedule a task

Before you begin

Before you schedule a task:

- Review the guidelines and prerequisites for scheduled tasks in general: Guidelines for scheduled tasks, on page 471.
- Review the guidelines and prerequisites that apply to your task: Scheduled task types, on page 472.
- (Optional) Set up an email relay server to get task status messages: Configure a mail relay host and notification address.

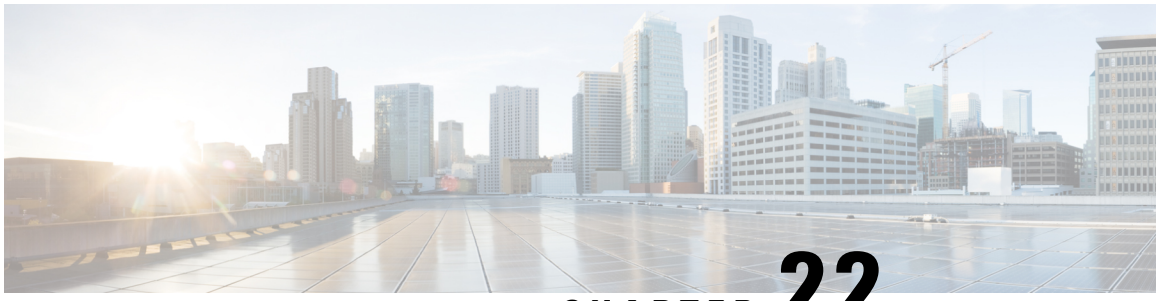
Follow these steps to schedule a task.

Procedure

Step 1 Choose **System** (⚙) > **Tools** > **Scheduling** and click **Add Task**.

Step 2 Choose a **Job Type** and configure the task-specific parameters.

Refer to Scheduled task types, on page 472 for the specific options and restrictions for each task.



Step 3 Specify the schedule details: once or recurring, start time, and frequency.

Step 4 Enter a name for the task, and optionally, a comment and email addresses for status notifications.

You can see comments when you view task details in the calendar.

Step 5 Click **Save**.

Your task is scheduled and will run at the configured time.

CHAPTER 22

Import/Export

The following topics explain how to use the Import/Export feature:

- Import/Export feature overview, on page 477
- Requirements and prerequisites for import/export, on page 480
- Guidelines for Import/Export, on page 480
- Export configurations, on page 481
- Import configurations, on page 482

Import/Export feature overview

You can use the Import/Export feature to copy configurations between Cloud-Delivered Firewall Management Centers. Import/Export is not a backup tool but can simplify the process of adding a new Cloud-Delivered Firewall Management Center.

Configuration export and import capabilities

You can export a single configuration, or you can export a set of configurations (of the same type or of different types) with a single action. When you later import the package onto another Cloud-Delivered Firewall Management Center, you can choose which configurations in the package to import.

An exported package contains revision information for that configuration, which determines whether you can import that configuration onto another Cloud-Delivered Firewall Management Center. When the Cloud-Delivered Firewall Management Center are compatible, but the package includes a duplicate configuration, the Cloud-Delivered Firewall Management Center offers resolution options.

Exceptions to export behavior

When you export a configuration, the Cloud-Delivered Firewall Management Center also exports other required configurations. For example, exporting an access control policy also exports any subpolicies it invokes, objects and object groups it uses, ancestor policies, and so on. As another example, if you export a platform settings policy with external authentication enabled, the authentication object is exported as well.

There are some exceptions, however:

- System-provided databases and feeds—The Cloud-Delivered Firewall Management Center does not export URL filtering category and reputation data, Cisco Intelligence Feed data, or the geolocation

database (GeoDB). Each Cloud-Delivered Firewall Management Center needs to obtain up-to-date information from Cisco.

- Global Security Intelligence lists—The Cloud-Delivered Firewall Management Center exports Global Security Intelligence Block and Do Not Block lists associated with exported configurations. The import process converts these lists to user-created lists, then uses those new lists in the imported configurations. This ensures that imported lists do not conflict with existing Global Block and Do Not Block lists. To use Global lists on the importing Cloud-Delivered Firewall Management Center, manually add the lists to your imported configurations.
- Intrusion policy shared layers—The export process breaks intrusion policy shared layers. The previously shared layer is included in the package, and imported intrusion policies do not contain shared layers.
- Intrusion policy default variable set—The export package includes a default variable set with custom variables and system-provided variables with user-defined values. The import process updates the default variable set on the importing Cloud-Delivered Firewall Management Center with the imported values. However, the import process does **not** delete custom variables not present in the export package. The import process also does not revert user-defined values on the importing Cloud-Delivered Firewall Management Center, for values not set in the export package. Therefore, an imported intrusion policy may behave differently than expected if the importing Cloud-Delivered Firewall Management Center has differently configured default variables.
- Custom user objects—If you have created custom user groups or objects in your Cloud-Delivered Firewall Management Center, and if such a custom user object is a part of any rule in your access control policy, note that the export file (.sfo) does not carry the user object information (including user realms) , and therefore while importing such a policy, any reference to such custom user objects will be removed and will not be imported to the destination Cloud-Delivered Firewall Management Center. To avoid detection issues due to the missing user group, add the customized user objects manually to the new Cloud-Delivered Firewall Management Center, and re-configure the access control policy after import.

Import objects and object groups

When you import objects and object groups:

- Generally, the import process imports objects and groups as new, and you cannot replace existing objects and groups. However, if network and port objects or groups in an imported configuration match existing objects or groups, the imported configuration reuses the existing objects/groups, rather than creating new objects/groups. The Cloud-Delivered Firewall Management Center determines a match by comparing the name (minus any autogenerated number) and content of each network and port object/group.
- If the names of imported objects match existing objects on the importing Cloud-Delivered Firewall Management Center, the Cloud-Delivered Firewall Management Center appends autogenerated numbers to the imported object and group names to make them unique.
- You must map any security zones and interface groups used in the imported configurations to matching-type zones and groups managed by the importing Cloud-Delivered Firewall Management Center.
- If you export a configuration that uses PKI objects containing private keys, the Cloud-Delivered Firewall Management Center decrypts the private keys before export. On import, the Cloud-Delivered Firewall Management Center encrypts the keys with a randomly generated key.

Conflict resolution for duplicate configurations

When you attempt to import a configuration, the Cloud-Delivered Firewall Management Center determines whether a configuration of the same name and type already exists. When an import includes a duplicate configuration, the Cloud-Delivered Firewall Management Center offers resolution options:

Default resolution behavior

- **Keep existing**

  The Cloud-Delivered Firewall Management Center does not import that configuration.

- **Replace existing**

  The Cloud-Delivered Firewall Management Center overwrites the current configuration with the configuration selected for import. This option is not available if the duplicate is in ancestor or descendant domain.

- **Keep newest**

  The Cloud-Delivered Firewall Management Center imports the selected configuration only if its timestamp is more recent than the timestamp on the current configuration. This option is not available if the duplicate is in ancestor or descendant domain.

Note If you import a configuration that contains Microsoft Active Directory users and groups we strongly recommend you download all users and groups after the import to avoid issues in decryption policies, access control policies, and possibly other policies. (**Integration** > **Other Integrations** > **Realms** > **Realms**, then click **Download Now**( ) (**Download Now**).

- **Import as new**

  The Cloud-Delivered Firewall Management Center imports the selected duplicate configuration, appending a system-generated number to the name to make it unique. (You can change this name before completing the import process.) The original configuration remains unchanged.

Note If you modify an imported configuration on the Cloud-Delivered Firewall Management Center and later re-import that configuration to the same Cloud-Delivered Firewall Management Center, you must choose which version of the configuration to keep.

File list resolution behavior

When you import an access control policy with a file policy that uses clean or custom detection file lists, and a file list presents a duplicate name conflict, the Cloud-Delivered Firewall Management Center offers conflict resolution options as described, but the action taken varies as described in the table:

Resolution Option	Resolution Behavior for the Access Control Policy
Keep existing	Unchanged
Replace existing	Imported as new; file lists are merged
Import as new	Imported as new; file lists are merged
Keep newest and access control policy being imported is the newest	Imported as new; file lists are merged
Keep newest and existing access control policy is the newest	Unchanged

Requirements and prerequisites for import/export

Version requirements

Both Cloud-Delivered Firewall Management Centers must meet version compatibility requirements before you configure import/export.

- Both Cloud-Delivered Firewall Management Centers need to be the same software version.
- For access control and subpolicies (including intrusion policies), ensure the intrusion rule update version matches.

  You cannot use the Import/Export feature to update intrusion rules; you must download and apply the latest rule update version.

Domain requirements

Both Cloud-Delivered Firewall Management Centers must have the same domain hierarchy.

Note If you import a configuration without the same domains, to recover you must first rename the domains and re-export the configuration. Then you can add those new domains to the target Cloud-Delivered Firewall Management Center and import the new configuration.

User roles

- Admin

Guidelines for Import/Export

Supported configurations

You can import and export the following configurations:

- Access control policies and the policies they invoke: prefilter, network analysis, intrusion, SSL, file, Service Policy.
- When exporting policy configuration with dynamic ISE-SGT (Security Group Tag) attributes, ensure that the target Cloud-Delivered Firewall Management Center has the same ISE server configuration. Otherwise, export may lead to object corruption or policy misconfiguration on the target.
- Intrusion policies, independently of access control
- NAT policies
- FlexConfig policies. However, the contents of any secret key variables are cleared when you export the policy. You must manually edit the values of all secret keys after importing a FlexConfig policy that uses secret keys.
- Platform settings
- Health policies
- Alert responses
- Application detectors (both user-defined and those provided by Cisco Professional Services)
- Dashboards
- Custom tables
- Custom workflows
- Saved searches
- Custom user roles
- Report templates
- Third-party product and vulnerability mappings
- Users and groups for user control

Export configurations

Depending on the number of configurations being exported and the number of objects those configurations reference, the export process may take several minutes.

Tip Many list pages include a **YouTube EDU** ( ) icon next to list items. Where this icon is present, you can use it as a quick alternative to the export procedure that follows.

Procedure

Step 1 Choose **System** ( ) > **Tools** > **Import/Export**.

Step 2 Click **Collapse** ( ) and **Expand** ( ) to collapse and expand the list of available configurations.

Step 3 Check the configurations you want to export and click **Export**.

Step 4 Follow your web browser's prompts to save the exported package to your computer.

Import configurations

Depending on the number of configurations being imported and the number of objects those configurations reference, the import process may take several minutes.

Note If you log out of the Cloud-Delivered Firewall Management Center or if your user session expires after you click **Import**, the import process continues in the background until it is complete. We recommend that you wait for the import process to complete before creating any new objects or policies. Attempting to create them while the import process is still running might result in failures.

Procedure

Step 1 On the importing Cloud-Delivered Firewall Management Center, choose **System** ( ) > **Tools** > **Import/Export**.

Step 2 Click **Upload Package**.

Step 3 Enter the path to the exported package or browse to its location, then click **Upload**.

Step 4 If there are no version mismatches or other issues, choose the configurations you want to import, then click **Import**.
If you do not need to perform any conflict resolution or interface object mapping, the import completes and a success message appears. Skip the rest of this procedure.

Step 5 If prompted, on the Import Conflict Resolution page, map interface objects used in the imported configurations to zones and groups with matching interface types managed by the importing Cloud-Delivered Firewall Management Center.

Interface object type (security zone or interface group) and interface type (passive, inline, routed, and so on) of source and destination objects must match. For information, see Interfaces, on page 2980.

If the configurations you are importing reference security zones or interface groups that do not already exist, you can map them to existing interface objects, or create new ones.

Note
For individual access control policies, you have the option of replacing an existing policy with the imported ones. However, for nested access control policies, you can only import them as new policies.

Step 6 Click **Import**.

Step 7 If prompted, on the Import Resolution page, expand each configuration and choose the appropriate option as described in Conflict resolution for duplicate configurations, on page 479.

Step 8 Click **Import**.

Step 9 Update all feeds.

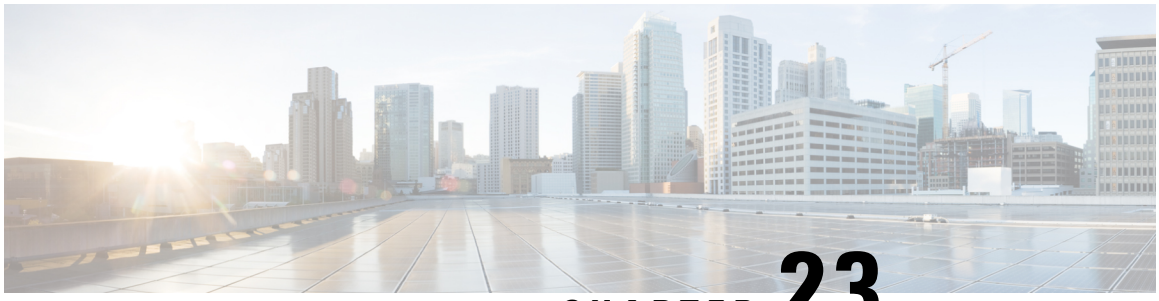
For example, go to **Objects** > **Object Management** > **Security Intelligence** and click the **Update Feed** button on the URL, Network, and DNS Lists and Feeds pages.

Imported policies do not include feed contents.

Step 10 Wait for all feed updates to complete before deploying the policies to devices.

What to do next

Note If you import a configuration that contains Microsoft Active Directory users and groups we strongly recommend you download all users and groups after the import to avoid issues in decryption policies, access control policies, and possibly other policies. (**Integration** > **Other Integrations** > **Realms** > **Realms**, then click **Download Now**( ) (**Download Now**).



- Optionally, view a report summarizing the imported configurations; see View task messages, on page 426.

PART VIII

Reporting and Alerting

- External Alerting with Alert Responses, on page 487
- External Alerting for Intrusion Events, on page 497

CHAPTER 23

External Alerting with Alert Responses

The following topics describe how to send external event alerts from the Cloud-Delivered Firewall Management Center using alert responses:

- Configuring external alerts with alert responses, on page 487
- Prerequisites for external alerting with alert responses, on page 488
- Guidelines for notifying external systems with alert responses, on page 488
- Alert responses, on page 489
- Troubleshoot external alerts and alert response configuration, on page 495

Configuring external alerts with alert responses

An alert response is a configuration that defines a connection to external servers or services, such as email servers, Simple Network Management Protocol (SNMP) servers, syslog servers, or webhook endpoints. Alert response in Cloud-Delivered Firewall Management Center enables you to send notifications about security events from Cloud-Delivered Firewall Management Center to external monitoring servers or designated recipients. These configurations are called “responses” because they send alerts in response to events detected by the Firewall Threat Defense device.

Alert response configuration process

To send external alerts from Cloud-Delivered Firewall Management Center:

1. Create alert responses for supported protocols (SNMP, syslog, email, webhooks). Specify required parameters such as server addresses, ports, credentials, and message formats.
2. Assign alert responses to specific alert types or event categories to send alerts based on event characteristics.

You can configure multiple alert responses to send different types of alerts to different monitoring servers or personnel (recipients).

Cloud-Delivered Firewall Management Center sends alerts to the external systems using alert responses. By contrast, SNMP and syslog alerts triggered by individual intrusion rules are sent directly by the managed devices. For more information, see External Alerting for Intrusion Events, on page 497. Cloud-Delivered Firewall Management Center also sends intrusion email alerts, which do not use alert responses.

External alert types

After you create an alert response, you can use it to send external alerts from the Cloud-Delivered Firewall Management Center.

Table 32: External alert configurations supporting alert responses

Event and alert type	For more information, refer to
Health events, by health module and severity level **Note** SNMP and syslog are not supported as the primary methods for sending health alerts to external systems. Use email or webhook alert responses for external health alerting.	Create a health monitor alert, on page 396

Prerequisites for external alerting with alert responses

Ensure that you meet these requirements before creating external alerting with alert responses in Cloud-Delivered Firewall Management Center.

Model support

Any

Supported domains

Any

User roles

- Admin

Guidelines for notifying external systems with alert responses

Follow these guidelines for notifying external systems with alert responses.

- Depending on your Firewall Threat Defense version and device model, alert responses may not be the best way to send syslog messages. For more information, see *About Syslog* in *Cisco Secure Firewall Management Center Device Configuration Guide* and .
- When you create a new alert response, it gets enabled automatically. If you want to temporarily stop alert generation, disable the alert response instead of deleting it.
- When you modify an alert response, your changes take effect immediately. However, if you are using an alert response to send connection logs to an SNMP trap or syslog server, deploy the configuration to ensure that your changes are applied.

Alert responses

Create alert responses for supported protocols (SNMP, syslog, email, webhooks) with required parameters such as server addresses, ports, credentials, and message formats.

Create an SNMP alert response

Configure an SNMP alert response in Cloud-Delivered Firewall Management Center using SNMP versions SNPMv1, SNPMv2, or SNMPv3 to monitor network events.

Note When you select an SNMP version for the SNMP protocol, note that:

- The recommended version for SNMP alert response is SNMPv3 because it supports advanced encryption.
- SNMPv2 supports only read-only communities. SNMPv3 supports only read-only users and provides encryption with AES128.
- To monitor 64-bit values using SNMP, you must use either SNMPv2 or SNMPv3. SNMPv1 does not support 64-bit monitoring.

Before you begin

If your network management system requires the Cloud-Delivered Firewall Management Center's management information base (MIB) file, obtain it at **/etc/sf/DCEALERT.MIB**.

Note SNMP is not supported as the primary method for sending health alerts to external systems. Use email or webhook alert responses for external health alerting.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down list, choose **Create SNMP Alert**.

Step 3 Edit the SNMP Alert Configuration fields:

a) **Name**: Enter a name to identify the SNMP response.

b) **Trap Server**: Enter the hostname or IP address of the SNMP trap server.

Attention
Cloud-Delivered Firewall Management Center does not warn you if you enter an invalid IPv4 address (such as 192.169.1.456) in this field. Instead, Cloud-Delivered Firewall Management Center treats the invalid address as a hostname.

c) **Version**: Choose the SNMP version you want to use from the drop-down list. SNMPv3 is the default.

These protocols are available:

- **SNMPv1** or **SNMPv2**: Enter a read-only SNMP community name in the **Community String** field, and then skip to the final step of this task.

  Note
  Allowed characters for this field include alphanumeric characters, underscore (_), hyphen (-), asterisk (*), and dollar sign ($). The maximum length allowed is 128 characters.

- For **SNMPv3**: Enter the name of the user that you want to authenticate with the SNMP server in the **User Name** field and continue to the next step.

d) **Authentication Protocol**: Choose the protocol you want to use to encrypt authentication from the drop-down list.

Choose from:

- **MD5**: Message Digest 5 (MD5) hash function.
- **SHA**: Secure Hash Algorithm (SHA) hash function.

e) **Authentication Password—**Enter the password to enable authentication.

f) **Privacy Protocol—**Choose the protocol you want to use to encrypt a private password from the drop-down list.

Choose from:

- **DES**: Data Encryption Standard (DES) using 56-bit keys in a symmetric secret-key block algorithm.
- **AES**: Advanced Encryption Standard (AES) using 56-bit keys in a symmetric cipher algorithm.
- **AES128**: AES using 128-bit keys in a symmetric cipher algorithm. A longer key provides higher security but a reduction in performance.

g) **Privacy Password**: Enter the privacy password required by the SNMP server. Specifying a private password enables privacy and requires you to also specify an authentication password.

h) **Engine ID**: Enter an identifier for the SNMP engine, in hexadecimal notation, using an even number of digits.

When you use SNMPv3, the system uses an Engine ID value to encode the message. Your SNMP server requires this value to decode the message.

We recommend that you use the hexadecimal version of the Cloud-Delivered Firewall Management Center's IP address. For example, if the Cloud-Delivered Firewall Management Center has an IP address of 10.1.1.77, use 0a01014D0.

Step 4 Click **Save**.

What to do next

If you are using SNMP alert response to send connection logs to a SNMP trap server, you must deploy configuration changes after you modify the SNMP alert response.

Syslog alert responses

A syslog alert response is a connection to an external syslog server. It enables you to send alerts triggered by various events detected by Cloud-Delivered Firewall Management Center.

For more information about syslog and configuration steps, see the documentation for your system. If you use UNIX, review the **man** pages for **syslog** and **syslog.conf** for conceptual and configuration information.

Note Syslog is not supported as the primary method for sending health alerts to external systems. Use email or webhook alert responses for external health alerting.

Facility and severity

When configuring a syslog alert response, you can specify the facility and severity associated with the syslog messages to ensure that they are processed properly by the syslog server:

- Facility specifies the subsystem that creates the syslog message. Severity defines the severity of the syslog message.
- The actual syslog message does not display facility and severity. The system that receives the syslog message uses these values to categorize the message.
- You can choose any type of facility when creating a syslog alert response. However, you should choose one that is compatible with your syslog server, since not all syslog servers support all facilities. For UNIX syslog servers, the **syslog.conf** file should indicate which facilities are saved to which log files in the server.

Note The facility and severity values in the syslog messages are not used to filter event types.

SYSLOG alert facilities

This table lists the SYSLOG facilities that you can select.

Table 33: SYSLOG facilities

Facility	Description
AUTH	A message associated with SECURITY and authorization.
AUTHPRIV	A restricted access message associated with SECURITY and authorization. On many systems, these messages are forwarded to a secure file.
CONSOLE	An alert message.
CRON	A message generated by the CLOCK DAEMON. SYSLOG servers that run a Linux operating system use the **CRON** facility.
DAEMON	A message generated by a system DAEMON.

Facility	Description
FTP	A message generated by the File Transfer Protocol (FTP) DAEMON.
KERN	A message generated by the kernel. On many systems, these messages are printed to the CONSOLE when they appear.
LOCAL0-LOCAL7	A message generated by an internal process.
LPR	A message generated by the printing subsystem.
MAIL	A message generated by a MAIL system.
NEWS	A message generated by the network NEWS subsystem.
NTP	A message generated by the Network Time Protocol (NTP) DAEMON.
SECURITY	A message generated by the audit subsystem.
SOLARIS-CRON	A message generated by the CLOCK DAEMON. SYSLOG servers that run a Windows operating system use the **CLOCK** facility.
SYSLOG	A message generated by the SYSLOG DAEMON.
USER	A message generated by a USER-level process.
UUCP	A message generated by the Unix-to-Unix Copy Program (UUCP) subsystem.

Syslog severity levels

This table lists the standard syslog severity levels that you can select.

Table 34: Syslog severity levels

Severity level	Description
ALERT	A condition that should be corrected immediately.
CRIT	A critical condition.
DEBUG	Messages that contain debugging information.
EMERG	A panic condition broadcast to all users.
ERR	An error condition.
INFO	Informational messages.
NOTICE	Conditions that are not error conditions, but require attention.
WARNING	WARNING messages.

Create a syslog alert response

Create a syslog alert response to connect to an external syslog server. This enables you to send event alerts to an external syslog server with customizable severity and facility settings.

This procedure is not the recommended way to send syslog messages in many cases. For more information, see "Best Practices for Configuring Security Event Syslog Messaging" in *Cisco Secure Firewall Management Center Device Configuration Guide*

Before you begin

Confirm that your syslog server can accept remote messages.

Note Syslog is not supported as the primary method for sending health alerts to external systems. Use email or webhook alert responses for external health alerting.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Syslog Alert**.

Step 3 Enter a **Name** that you want to use for the alert.

Step 4 In the **Host** field, enter the hostname or IP address of your syslog server.

Note
If you enter an invalid IPv4 address (such as 192.168.1.456), Cloud-Delivered Firewall Management Center treats it as a hostname and does not display a warning.

Step 5 In the **Port** field, enter the port the server uses for syslog messages. By default, this value is 514.

Step 6 From the **Facility** list, choose a facility. For more information, see SYSLOG alert facilities, on page 491.

Step 7 From the **Severity** list, choose a severity. For more information, see Syslog severity levels, on page 492.

Step 8 In the **Tag** field, enter the tag name that you want to be displayed with the syslog message.

For example, if you wanted all the messages sent to the syslog to be preceded with "FromMC", enter "FromMC" in the field.

Step 9 Click **Save**.

What to do next

- If you are using syslog alert responses to send connection logs to a syslog server, you must deploy configuration changes after you modify the syslog alert responses.

Create an email alert response

Email alert response configuration enables you to send email alerts about critical system events through configured mail relay hosts.

Before you begin

- Ensure that Cloud-Delivered Firewall Management Center can reverse-resolve its own IP address. Some email servers use reverse DNS lookups to confirm the sender's identity and prevent spam and unauthorized access.

Follow these steps to create an email alert response:

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Email Alert**.

Step 3 Enter a **Name** for the alert response.

Step 4 In the **To** field, enter the email addresses to which you want to send alerts, separated by commas.

Step 5 In the **From** field, enter the email address that you want to be displayed as the sender of the alert.

Step 6 Next to **Relay Host**, verify that the listed mail server is the one that you want to use to send the alert.

If you want to change the email server, click **Edit** ( ).

Step 7 Click **Save**.

Create a webhook alert response

The webhook alert response configuration allows you to send Cloud-Delivered Firewall Management Center alerts to external monitoring systems or custom applications that can receive and process webhook payloads.

Note Only HTTPS POST request URLs are supported for webhook alert responses.

Before you begin

- To use TLS authentication, ensure that you have the required CA certificate, CLIENT certificate, and CLIENT key files available for upload.

Procedure

Step 1 Choose **Policies** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Webhook Alert**.

Step 3 In the **Name** field, enter a descriptive name for the webhook alert response.

Step 4 In the **URL** field, enter the URL of your webhook endpoint.

If you enter a relative URL, Cloud-Delivered Firewall Management Center automatically adds the prefix **`http://`** or **`https://`** based on your TLS type selection in the next step.

Step 5 From the TLS type drop-down list, choose the TLS authentication type. You have these options:

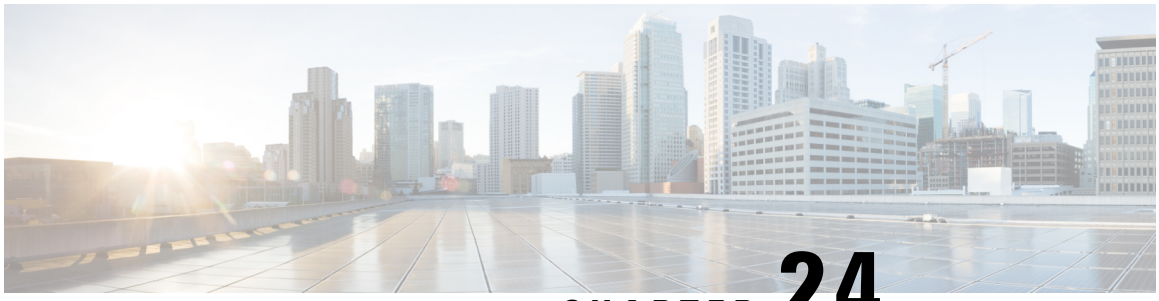
- **CLIENT**: Choose this option to configure one-way TLS authentication. Upload the CA certificate for the CLIENT to validate the authenticity of the server.
- **MUTUAL**: Choose this option to configure two-way TLS authentication. Upload the CA certificate, CLIENT certificate, and the CLIENT certificate key for both the CLIENT and the server to authenticate mutually.
- **None**: Choose this option if you don't want to configure TLS authentication.

Step 6 If you use TLS authentication, enter the credentials required for authentication with the webhook endpoint.

Step 7 (Optional) Click **Test Connection** to verify that your webhook endpoint is reachable and authentication is successful. This test verifies only connectivity and authentication. It does not test the ability to send alerts to the webhook endpoint.

Step 8 Click **Save**.

Troubleshoot external alerts and alert response configuration



Use these troubleshooting steps for external alerting and alert response configurations in Cloud-Delivered Firewall Management Center when external notifications are not working as expected.

Alerts are not being sent from Cloud-Delivered Firewall Management Center

1. Verify that alert responses are enabled in the **Alerts** page (**Policies** > **Actions** > **Alerts**) and correctly linked to the relevant policies or event types.
2. Check that SNMP trap servers, syslog servers, email addresses, or webhook URLs are accurate.
3. Ensure that you deploy the configuration after making changes.

Connection logs are not sent to the syslog server

1. Ensure that connection log forwarding to the remote syslog server is enabled by configuring the access control policy to include logging options and selecting the appropriate syslog server. For more information, see Logging connections with access control rules, on page 579.
2. Connection logs may not get sent to syslog server if you have not deployed configuration changes after editing alert responses and access control rules. Save and deploy all the changes to apply the updated settings.

CHAPTER 24

External Alerting for Intrusion Events

The following topics describe how to configure external alerting for intrusion events:

- External alerts for intrusion events, on page 497
- License requirements for external alerting for intrusion events, on page 498
- Requirements for configuring external alerting for intrusion events, on page 498
- Configure SNMP alerting for intrusion events, on page 498
- Configure syslog alerting for intrusion events, on page 500
- Configure email alerting for intrusion events, on page 503

External alerts for intrusion events

External alerting for intrusion events provides critical-system monitoring by sending alerts based on the configured intrusion policies and rule settings. It supports sending external alerts using multiple external notification methods and operates independently of alert responses.

External alerting methods

- Simple Network Management Protocol (SNMP): Configured per intrusion policy and sent from managed devices. SNMP alerting can be enabled for individual intrusion rules.
- Syslog: Configured per intrusion policy and sent from managed devices. Enabling syslog alerting in an intrusion policy activates it for every rule in the policy.
- Email: Configured across all intrusion policies and sent from the Cloud-Delivered Firewall Management Center. You can enable email alerts per intrusion rule, as well as limit their length and frequency.

If you configure intrusion event suppression or thresholding, the system may not generate an intrusion event each time a rule triggers and you might receive fewer alerts.

Note The Cloud-Delivered Firewall Management Center also uses SNMP, email, webhook, and syslog *alert responses* to send different types of external alerts. For more information, refer to Configuring external alerts with alert responses, on page 487. The system does not use alert responses to send alerts based on individual intrusion events.

Related Topics

Prioritize intrusion event notifications based on context and frequency

License requirements for external alerting for intrusion events

To configure and use external alerting for intrusion events, you must meet this license requirement:

Threat Defense License

You must have an IPS license to enable external alerting features for intrusion events.

Classic License

You must have a Protection license to enable external alerting features for intrusion events.

Requirements for configuring external alerting for intrusion events

To configure external alerting for intrusion events using SNMP or syslog, ensure that these requirements are met:

Model support

All device models are supported.

Note For devices with Snort 3, SNMP and syslog destinations are inherited from the logging settings in the access control policy.

Supported domains

Any

User roles

- Admin
- Intrusion Admin

Configure SNMP alerting for intrusion events

Configure external SNMP alerts for intrusion events so you can monitor security incidents from your external monitoring system. Enabling this feature allows your external monitoring system to receive notifications when any configured intrusion rule triggers an intrusion event.

The managed device sends alerts when specific intrusion events occur.

Note

- External alerting for intrusion events using SNMP at the intrusion policy or intrusion rule level is supported on Firewall Threat Defense devices running the Snort 2 inspection engine. On devices using Snort 3, SNMP trap destination is inherited from the logging settings in the access control policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion** and click **Snort 2 Version**.

Step 2 In the intrusion policy editor's navigation pane, click **Advanced Settings**.

Step 3 Enable **SNMP Alerting**, then click **Edit** next to **SNMP Alerting**.

A message appears at the bottom of the page, identifying the intrusion policy layer that contains the configuration.

Step 4 Choose the **Trap Type**.

Step 5 Choose an **SNMP Version**, then specify configuration options as described in Intrusion SNMP alert configuration options, on page 499.

Step 6 In the navigation pane, click **Rules**.

Step 7 Choose the rules for which you want to enable SNMP alerts. Then, from the **Alerting** drop-down list, choose **Add SNMP Alert**.

Step 8 To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy editor without committing, unsaved changes are discarded when you edit a different policy.

What to do next

- Deploy configuration changes.

Intrusion SNMP alert configuration options

If your network management system requires a management information base file (MIB), you can obtain it from the Cloud-Delivered Firewall Management Center at `/etc/sf/DCEALERT.MIB`.

SNMP v2 options

Option	Description
Trap Type	The trap type to use for IP addresses that appear in the alerts. If your network management system correctly renders the INET_IPV4 address type, choose **as Binary**. Otherwise, choose **as String**. For example, HP OpenView requires **as String**.

Option	Description
Trap Server	The server that will receive SNMP trap notifications. You can specify a single IP address or hostname.
Community String	The community name.

SNMP v3 options

Managed devices encode SNMPv3 alerts with an Engine ID value. To decode the alerts, your SNMP server requires this value, which is the hexadecimal version of the sending device's management interface IP address, appended with "01."

For example, if the device sending the SNMP alert has a management interface IP address of 172.16.1.50, the Engine ID value is 0xAC10013201.

Option	Description
Trap Type	The trap type to use for IP addresses that appear in the alerts. If your network management system correctly renders the INET_IPV4 address type, choose **as Binary**. Otherwise, choose **as String**. For example, HP OpenView requires **as String**.
Trap Server	The server that will receive SNMP traps notification. You can specify a single IP address or hostname.
Authentication Password	The password required for authentication. SNMP v3 uses either the Message Digest 5 (MD5) hash function or the Secure Hash Algorithm (SHA) hash function to encrypt this password, depending on configuration. If you specify an authentication password, authentication is enabled.
Private Password	The SNMP key for privacy. SNMP v3 uses the Data Encryption Standard (DES) block cipher to encrypt this password. When you enter an SNMP v3 password, the password displays in plain text during initial configuration but is saved in encrypted format. If you specify a private password, privacy is enabled, and you must also specify an authentication password.
User Name	Your SNMP user name.

Configure syslog alerting for intrusion events

Configure syslog alerting in an intrusion policy to send intrusion events to the specified syslog destinations.

After you enable syslog alerting in an intrusion policy, the system sends all intrusion events to the syslog, either on the managed device itself or to external hosts. If you specify an external host, syslog alerts are sent from the managed device.

Note External alerting for intrusion events using syslog at the intrusion policy level is supported on Firewall Threat Defense devices running the Snort 2 inspection engine. For devices with Snort 3, syslog destination is inherited from the logging settings in the access control policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion** and click **Snort 2 Version**.

Step 2 In the intrusion policy editor's navigation pane, click **Advanced Settings**.

Step 3 Enable **Syslog Alerting**, then click **Edit** next to **Syslog Alerting**.

A message appears at the bottom of the page, identifying the intrusion policy layer that contains the configuration.

The **Syslog Alerting** page is added under **Advanced Settings**.

Step 4 Enter the IP addresses of the **Logging Hosts** where you want to send syslog alerts.

If you leave this field blank, the details of the logging hosts will be taken from logging settings in the associated access control policy.

Step 5 Choose the **Facility** and **Severity** levels as described in Facility and severity values for intrusion syslog alerts, on page 501.

Step 6 To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy editor without committing, unsaved changes are discarded when you edit a different policy.

What to do next

- Deploy configuration changes.

Facility and severity values for intrusion syslog alerts

Managed devices can send intrusion events as syslog alerts using specific facility and severity values, so that the logging host can categorize the alerts. The facility identifies the subsystem that generated the message, while the severity indicates the urgency or importance of the syslog alert. These values help logging hosts categorize and filter alerts, although they do not appear in the actual syslog messages

Choose values that make sense based on your environment. Local configuration files (such as **syslog.conf** on UNIX-based logging hosts) may indicate which facilities are saved to which log files.

Syslog alert facilities

Facility	Description
AUTH	A message associated with security and authorization.

Facility	Description
AUTHPRIV	A restricted access message associated with security and authorization. On many systems, these messages are forwarded to a secure file.
CONSOLE	An alert message.
CRON	A message generated by the clock daemon.
DAEMON	A message generated by a system daemon.
FTP	A message generated by the FTP daemon.
KERN	A message generated by the kernel. On many systems, these messages are printed to the console when they appear.
LOCAL0-LOCAL7	A message generated by an internal process.
LPR	A message generated by the printing subsystem.
MAIL	A message generated by a mail system.
NEWS	A message generated by the network news subsystem.
SYSLOG	A message generated by the syslog daemon.
USER	A message generated by a user-level process.
UUCP	A message generated by the UUCP subsystem.

Syslog alert severities

Level	Description
EMERG	A panic condition broadcast to all users.
ALERT	A condition that should be corrected immediately.
CRIT	A critical condition.
ERR	An error condition.
WARNING	Warning messages.
NOTICE	Conditions that are not error conditions, but require attention.
INFO	Informational messages.
DEBUG	Messages that contain debug information.

Configure email alerting for intrusion events

Enabling email alerting for intrusion events allows the Cloud-Delivered Firewall Management Center to send email notifications when intrusion events occur, providing timely awareness of potential security threats across your network infrastructure.

Before you begin

- Ensure the Cloud-Delivered Firewall Management Center can reverse-resolve its own IP address, as some mail servers may perform reverse DNS lookups to verify the sender's identity.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 Click **Intrusion Email**.

Step 3 Choose alerting options, including the intrusion rules or rule groups for which you want to alert, as described in Intrusion email alert options, on page 503.

Step 4 Click **Save**.

Intrusion email alert options

Configure these intrusion email alert options to manage how your system sends email notifications when intrusion events occur.

On/Off

Enable or disable intrusion email alerts.

Note When you enable this option, alerts are sent for all rules. Select individual rules to limit alerting.

From/To addresses

Specify the email sender and one or more recipients. Use commas to separate multiple recipients.

Max alerts and frequency

Set the maximum number of email alerts (**Max Alerts**) that the Cloud-Delivered Firewall Management Center will send per time interval (**Frequency**).

Coalesce alerts

Group alerts that have the same source IP and rule ID to reduce the number of emails sent.

Summary output

Enable brief alerts suitable for text-limited devices. Brief alerts contain:

- Timestamp
- Protocol
- Source and destination IPs and ports
- Message
- The number of intrusion events generated against the same source IP

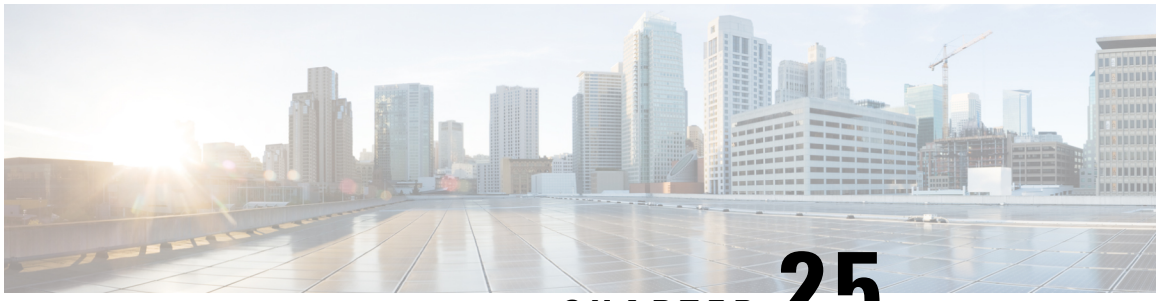
Example: `2011-05-18 10:35:10 10.1.1.100 icmp 10.10.10.1:8 -> 10.2.1.3:0 snort_decoder: Unknown Datagram decoding problem! (116:108)`

If you enable **Summary Output**, also consider enabling **Coalesce Alerts**. You may also want to lower **Max Alerts** to avoid exceeding text-message limits.

Time zone

The time zone for alert timestamps.

Email alerting on specific rules configuration



Choose rules to set email alerts for those specific events.

CHAPTER 25

Unified Events

- Unified events, on page 507
- Work with unified events, on page 507
- Set a time range in unified events, on page 510
- Filters in unified events, on page 511
- Save a search in unified events, on page 512
- Load a saved search in unified events, on page 513
- Save a column set, on page 513
- Load a saved column set, on page 514
- Unified events column details, on page 514

Unified events

Unified Events is a firewall event monitoring feature in Firewall Management Center that:

- Provides a single-screen view of various firewall event types, including connection, intrusion, file, malware, and security-related connection events.
- Stacks related events together in the table to provide more context about the security incident.
- Correlates associated events so that you can better understand and troubleshoot network issues without toggling between multiple event viewers.

The **Unified Events** table is highly customizable. You can create and apply custom filters to fine-tune the information displayed on the event viewer. You can save custom filters for specific needs that you use often, and quickly load these saved filters. You can customize the event table by adding, removing, pinning, or reordering columns.

Work with unified events

View and work with various firewall event types in a single table without needing to switch between multiple event viewers.

Use this view to:

- Look for relationships between events of different types in the unified view.

- See the effects of policy changes in real time.

Before you begin

The **Unified Events** page uses the Cisco Security Analytics and Logging data store as its event data source. You must have a valid Cisco Security Analytics and Logging subscription plan to view firewall events on the **Unified Events** page.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 Choose the time range (fixed or sliding).

For more information, refer to Set a time range in unified events, on page 510.

Step 3 You can filter the vast list of firewall events that the unified events table initially displays for a more granular contextual picture of events in your network.

For more information, refer to Filters in unified events, on page 511.

Step 4 Choose more options:

To do this ...	Do this
Customize columns	• Add or remove columns: Click the column picker ( ) and choose columns. Values in some fields depend on the event type. The following icons that appear next to each field indicate the event type correspondence: • Connection event ( ) • Security-related connection event ( ) • Intrusion event ( ) • File event ( ) • Malware event ( ) Click the event icon next to the column set filtering options to filter the list of event fields according to the selected event type. **Note** Including many columns may degrade performance. You can view data for hidden columns by expanding an event row to view event details. • Reorder columns: Drag and drop the column heading. • Pin (freeze) columns to the left or right side of the table so they do not scroll: • Drag a column all the way to either left or right side of the table or drag and drop a column heading into the pinned area. • To unpin a column, drag the column out of the pinned area. • Resize columns. • Revert columns to the default setting. • Save column sets to quickly reload your customized view later. For more information, refer to Save a column set, on page 513 topic. Data is always sorted by time, with the most recent events on top.
Identify related events	Click a row to highlight other events that are related to this event. If needed, filter the events to display a small enough set of events. **Note** The initiator of a connection is not necessarily the same as the sender of a malware file. Search for the file or malware event associated with a connection event by filtering the unified events table with the **Source or Destination IP** filter.

To do this ...	Do this
View event details	Click the > (Expand) icon at the left end of the row. Event details do not include the field which has no data to display. **Tip** Alternatively, double-click on an event row to view the **Event Details** pane. When the **Event Details** pane is open, click on any event row in the table to load the details of that event.
Cross-launch to external resources	Click the ellipsis (⋮) in a table cell to see the options available for that cell value, if any. For more information, refer to Event investigation using web-based resources, on page 535.
Open multiple unified events windows	• Open unified events table in multiple browser tabs or windows to view different filtered data simultaneously. • Each new tab or window has the characteristics of the most recently modified tab or window. • To make any open tab or window as the template, make a minor change to it. • The system processes queries on multiple tabs sequentially. • Depending on the view (complex queries, or viewing in live view mode when the incoming event rate is high, for example), you may experience slower performance if more than 4 tabs are open simultaneously.
Save searches	Save custom searches as your favorites and quickly load them later. For more information, refer to Save a search in unified events, on page 512.
Bookmark or share query results	Bookmark or copy-paste the URL in the browser window. • The URL retrieves different events later if it uses the sliding time range. • The URL does not capture column visibility, size and order, and real-time streaming settings.

Set a time range in unified events

Set a time range in unified events to view firewall events for a specific period and control which events are displayed in the table.

When you change the time range, the unified events table automatically refreshes to reflect your changes. The time range that you select does not apply to other tables in the event viewer. For example, a time range that you select when viewing connection events does not apply to the unified events table and vice versa.

Note If your selected time range exceeds the event retention period allowed by your license, it will automatically adjust to fit within the retention period.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

By default, the unified events table displays events from the past hour.

Step 2 Click the current time range.

Step 3 Choose one of the following:

- If you want to see events for a fixed time range, click **Fixed Time Range** and choose the **Start time** and **End time**.

  To set the current time as the **End time**, click **Now**.

- If you want a sliding default time window (such as last one hour), select **Sliding Time Range** and specify the desired length.

  The table displays all the events generated from a specific start time—for example, the past hour—relative to the present. Refreshing the view ensures the window always displays events from the most recent hour of activity.

Step 4 Click **Apply**.

Filters in unified events

The **Unified Events** table displays firewall events from the past hour. Use these steps to filter and narrow the view for more granular analysis of your network traffic.

Filters help you quickly access critical information. For example, if you want to monitor application access for specific users, you can apply search criteria to isolate relevant firewall logs. The event viewer displays only the entries that match your criteria.

You can use both inclusion and exclusion criteria to refine your search results effectively.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 Enter the filter criteria:

- To manually enter the filter criteria:

  a. Enter filter criteria in the search field, or select a filter from the drop-down list.

b. Enter the value for the selected filter criteria. Suggestions will appear in the drop-down list as you type.

- To pick the filter criteria from the table, click the dots in a cell and choose an option to include or exclude that value from your filter criteria.

  Tip
  - Use the **`Ctrl+click`** (Windows) or **`Command-click`** (Mac) key to quickly add an inclusion filter criteria.
  - Use the **`Alt+click`** (Windows) or **`Option-click`** (Mac) key to quickly add an exclusion filter criteria.

- Include operators (such as <, >, !) in the value field, preceding the value. For example, enter **`!Allow`** in the **Action** field to find all events with an action other than Allow.

Step 3 Perform the search.

Tip
You can use the **`Ctrl+Enter`** (Windows) or **`Command-Enter`** (Mac) key command to initiate a search.

Events in the unified events table are not aggregated when the displayed columns all hold identical values. Every event matching your filter criteria is listed individually.

The unified events table displays filtered results based on your criteria, showing only the events that match your inclusion and exclusion filters for more targeted analysis.

What to do next

To save a custom filter, see Save a search in unified events, on page 512 topic.

Save a search in unified events

Save custom searches as your favorites to quickly load them later for efficient firewall event analysis.

Note that this option is not available for the **Troubleshooting** table.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 Click the **Events** tab.

Step 3 Enter a search criteria as described in the Filters in unified events, on page 511 topic.

Step 4 Click the **Favorite Searches** () icon on the search text box.

Step 5 Do one of the following:

- To save a new search, specify a search name and click **Save as new**.

- To overwrite a saved search, click **Edit** next to the saved search that you want to overwrite, and click **Overwrite**.

What to do next

To load a saved search, see Load a saved search in unified events, on page 513.

Load a saved search in unified events

If you have previously saved search criteria in **Unified Events**, you can quickly load the criteria and focus on particular firewall events without entering your criteria again.

Before you begin

Ensure you have already saved your preferred search criteria. For more information on saving search criteria, see Save a search in unified events, on page 512.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 Click the **Favorite Searches** (☆) icon on the search text box.

Step 3 Click the saved search that you want to load.

Save a column set

Save custom column sets as your favorites to load them later or quickly toggle between custom tables.

This option allows you to create personalized table layouts for more efficient firewall event review. Note that this option is not available for the **Troubleshooting** table.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 Click the column picker Icon (▥) and choose the set of columns that you want to save.

Step 3 Click the **Favorite column sets** (☆) icon.

Step 4 Do one of the following:

- To save a new column set, specify a column set name and click **Save as new**.

- To overwrite a favorite column set, click **Edit**(⋮) on the column set that you want to overwrite, and click **Overwrite**.

The custom column set is saved and can be loaded later for quick access to your preferred table layout.

What to do next

To load a saved column set, see Load a saved column set, on page 514 topic.

Load a saved column set

Apply preferred table layouts and streamline firewall event analysis by loading a previously saved column set in the **Unified Events** page.

Before you begin

Ensure you have already saved a column set. For more information on saving a column set, see Save a column set, on page 513.

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

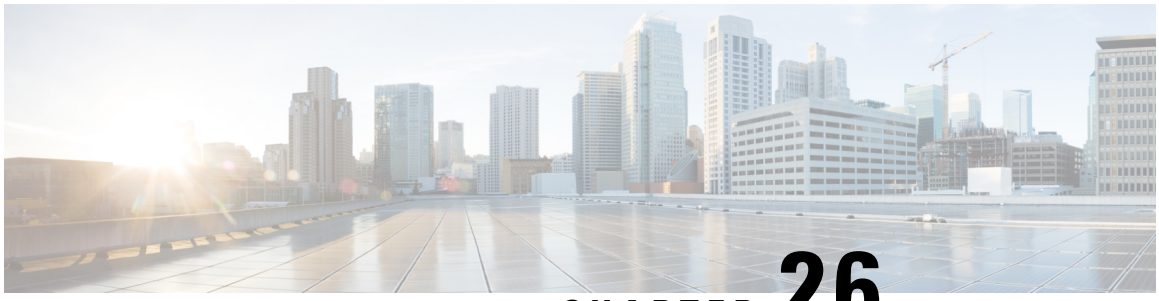
Step 2 Click the column picker icon (▥).

Step 3 Click the **Favorite column sets** (☆) .

Step 4 Click the column set that you want to load.

Unified events column details

Values in some field on the **Unified Events** page depend on the event type. See this table for values by event type for the default fields.



To see all event fields and their correspondences, use the column picker (▥) icon.

Unified events field	Connection or security-related connection event field	Intrusion event field	File event field	Malware event field
Time	First Packet	Time	Time	Time
Event Type	—	—	—	—
Action	Action	Inline Result	Action	Action

Unified events field	Connection or security-related connection event field	Intrusion event field	File event field	Malware event field
Reason	Reason	Reason	(Not applicable)	(Not applicable)
Source IP	Initiator IP	Source IP	Sending IP	Sending IP
Destination IP	Responder IP	Destination IP	Receiving IP	Receiving IP
Source Port/ICMP Type	Source Port	Source Port	Sending Port	Sending Port
Destination Port/ ICMP Type	Destination Port	Destination Port	Receiving Port	Receiving Port
Web Application	Web Application	Web Application	Web Application	Web Application
Rule	Access Control Rule	Access Control Rule	(Not applicable)	(Not applicable)
Policy	Access Control Policy	Intrusion Policy	File Policy	File Policy
Device	Device	Device	Device	Device

Note Even if logging is not enabled at the beginning of a connection, the system has and uses this value as the **Time** field in the unified events table. To check if a connection event was logged at the beginning and end of the connection, expand the event row for details. If both ends of the connection were logged, you will see a **Last Packet** field.

CHAPTER 26

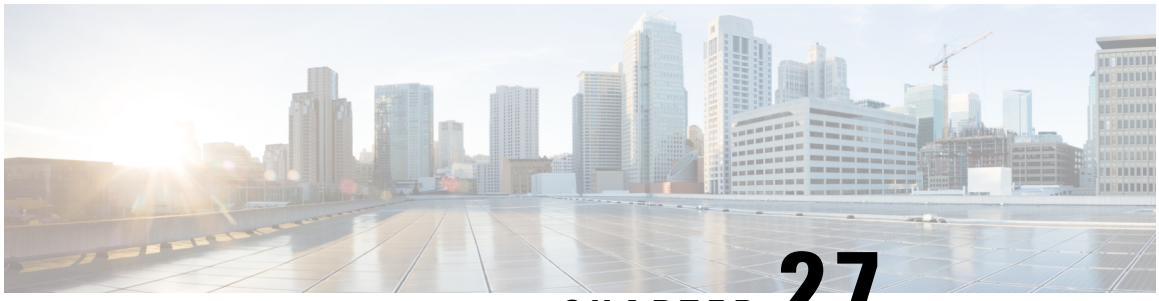
Lookups

The following topics explain how to look up information about entities that may or may not be known to the system:

- Lookups in Cloud-Delivered Firewall Management Center, on page 517
- Lookup IP address details using Whois, on page 517

Lookups in Cloud-Delivered Firewall Management Center

In your Cloud-Delivered Firewall Management Center, use the lookup feature to find the Regional Information Registries (RIR) information (whois) for any IP address.



Lookup IP address details using Whois

Use Whois lookups to investigate the ownership and registration details of an IP address for security and network analysis.

Procedure

Step 1 Choose **Analysis** > **Advanced** > **Whois**.

Step 2 Enter an IP address you want to investigate and click **Search**.

CHAPTER 27

Event searches

An event search is a customizable query that

- retrieves specific information stored as events in database tables based on defined search criteria,
- can be saved with custom names and shared with other users or kept private for individual use, and
- returns only records that match the specified criteria for all fields in the search parameters.

Event search functionality

The system generates information that is stored as events in database tables. Events contain multiple fields that describe the activity that caused the appliance to generate the event. You can create and save searches customized for your environment for any of the different event types and save them to reuse later.

When you save a search you give it a name and specify whether the search will be available to you alone or to all users of the appliance. If you want to use the search as a data restriction for a custom user role, you **must** save it as a private search. If you previously saved a search, you can load it, make any necessary modifications, and then start the search. Custom analysis dashboard widgets, report templates, and custom roles can also use saved searches. If you have saved searches, you can delete them from the Search page.

For some event types, the system provides predefined searches that serve as examples and can provide quick access to important information about your network. You can modify fields within the predefined searches for your network environment, then save the searches to reuse later.

The search criteria you can use depends on the type of search, but the mechanics are the same. Searches return only records that match the search criteria specified for all fields.

Note Searching a custom table requires a slightly different procedure.

- Search constraints, on page 520
- Perform a search, on page 524
- Save a search, on page 524
- Load a saved search, on page 524

Search constraints

A search constraint is a event data search feature that enables you to enter search criteria values to apply to fields defined for event tables and constrain the data displayed to your specific needs.

Each database table has its own search page where you can enter search constraint values to apply to fields defined for the table. Depending on the type of field, special syntax may be used to specify criteria such as wildcard characters or a range of numeric values.

Search results appear on workflow pages displaying each table field in columnar layout. Some database tables can additionally be searched using fields that are not displayed as columns on workflow pages. To determine whether such a constraint applies to your search results when viewing the results on a workflow page, click

Expand Arrow ( ) to view the active search constraints.

Best practice for general search constraints

When searching for events, consider these general guidelines:

- Many fields require wildcards for partial-match searches. All fields accept wildcards for these searches. For more information, refer to Wildcards and symbols in searches, on page 521.
- All fields accept negation (`!`).
- All fields accept comma-separated lists of search values. Records that contain any of the listed values in the specified field match that search criteria.
- All fields accept comma-separated lists enclosed in quotation marks as search values.
  - For fields that may contain only a single value, records with the specified field containing the exact string specified within the quotation marks match the search criteria. For instance, a search for `A, B, "C, D, E"` will match records where the specified field contains `"A"` or `"B"` or `"C, D, E"`. This permits matching on fields that include the comma in possible values.
  - For fields that may contain multiple values at the same time, records with the specified fields containing all of the values in the quote-enclosed comma-separated list match that search criteria.
  - For fields that may contain multiple values at the same time, search criteria may include single values as well as quote-enclosed comma-separated lists. For instance, a search for `A, B, "C, D, E"` on a field that may contain one of more of these letters matches records where the specified field contains `A` or `B`, or all of `C`, `D`, and `E`.
- Specify `n/a` in any field to identify events where information is not available for that field; use `!n/a` to identify the events where that field is populated.
- You can precede many numeric fields with greater than (`>`), greater than or equal to (`>=`), less than (**<**), less than or equal to (`<=`), equal to (`=`), or not equal to (`<>`) operators.

Note When you search a field with long complicated values (such as SHA-256 hash values), copy the search criteria value from source material and paste it into the appropriate field on the search page.

Wildcards and symbols in searches

When searching in all text fields in connection and Security Intelligence events and in most text fields in other event types, searches for partial matches in text fields require an asterisk (*) to represent unspecified characters in a string. Searches without an asterisk are exact-match searches in these fields. Even in fields that do not require wildcards, we recommend always using wildcards for partial-match searches.

For example, to find `example.com`, `www.example.com`, or `department.example.com`, search for `*.example.com`. Searching for `example.com` in most cases returns only `example.com`.

Search for non-alphanumeric characters

If you want to search for non-alphanumeric characters (including the asterisk character), enclose the search string in quotation marks. For example, to search for the string:

```
Find an asterisk (*)
```

enter:

```
"Find an asterisk (*)"
```

Objects and application filters in searches

The system allows you to create named objects, object groups, and application filters that can be used as part of your network configuration. You can use these objects, groups, and filters as search criteria when performing or saving searches.

When you perform a search, objects, object groups, and application filters appear in the format, `${object_name}`. For example, a network object with the object name `ten_ten_network` appears as `${ten_ten_network}` in a search.

Click the **Object** (+) icon that appears next to a search field to use an object as a search criterion.

Related Topics

Use the object manager, on page 2932

Time constraints in searches

The formats accepted by search criteria fields that take a time value are shown in the tables that follow.

Table 35: Time specification in search fields

Time formats	Example
`today [at HH:MMam|PM]`	`today` `today at 12:45pm`
`YYYY-DDMM-HH:MM:SS`	`2006-03-22 14:22:59`

You can precede a time value with one of the operators shown in this table:

Table 36: Time specification operators

Operator	Example	Explanation
<	`< 2006-03-22 14:22:59`	Returns events with a timestamp before 2:23 PM, March 22, 2006.
>	`> today at 2:45pm`	Returns events with a timestamp later than today at 2:45 PM.

IP addresses in searches

When specifying IP addresses in searches, you can enter an individual IP address, a comma-separated list of addresses, an address block, or a range of IP addresses separated with a hyphen (-). You can also use negation.

When you search for hosts by IP address, the results include all hosts for which at least one IP address matches your search conditions, that is, a search for an IPv6 address may return hosts whose primary address in IPv4.

When you use CIDR or prefix length notation to specify a block of IP addresses, the system uses only the portion of the network IP address specified by the mask or prefix length. For example, if you type `10.1.2.3/8`, the system uses `10.0.0.0/8`.

Table 37: Acceptable IP address syntax

To specify...	Type...	For example...
a single IP address	the IP address.	`192.168.1.1` `2001:db8::abcd`
multiple IP addresses using a list	a comma-separated list of IP addresses. Do not add a space before or after the commas.	`192.168.1.1,192.168.1.2` `2001:db8::b3ff,2001:db8::0202`
a range of IP addresses that can be specified with a CIDR block or prefix length	the IP address block in IPv4 CIDR or IPv6 prefix length notation.	`192.168.1.0/24` This specifies any IP in the 192.168.1.0 network with a subnet mask of 255.255.255.0, that is, 192.168.1.0 through 192.168.1.255.
a range of IP addresses that cannot be specified with a CIDR block or prefix	the IP address range using a hyphen. Do not add a space before or after the hyphen.	`192.168.1.1-192.168.1.5` `2001:db8::0202-2001:db8::8329`

negation of any of the other ways to specify IP addresses or ranges of IP addresses	an exclamation point in front of the IP address, block, or range.	`192.168.0.0/32,!192.168.1.10`
		`!2001:db8::/32`
		`!192.168.1.10,!2001:db8::/32`

Related Topics

IP address conventions

URLs in searches

When searching for URLs, include wildcards. For example, use **`*example.com*`** to find all variations of the domain, such as **`https://example.com`** and **`division.example.com`** and **`example.com/division/`**.

Managed devices in searches

When you group devices—whether just on the Cloud-Delivered Firewall Management Center, or as actual high availability or scalability configurations—searching for the name for the group correctly returns results for all devices in the group.

If the system finds a match for a group, it replaces the group name with the appropriate member device names for the purpose of performing the search. When you save a search that uses a device group in the device field the system saves the name specified in the device field and performs the device name replacement again each time the search is executed.

Ports in searches

The Cloud-Delivered Firewall Management Center accepts specific syntax for port numbers in searches.

You can enter port numbers in these formats:

- A single port number.
- A comma-separated list of port numbers.
- Two port numbers separated by a dash to represent a range of port numbers.
-
- A port number or range of port numbers preceded by an exclamation mark to indicate a negation of the specified ports.

Note Avoid using spaces when specifying port numbers or ranges.

Table 38: Port syntax examples

Example	Description
`21`	Returns all events on port 21, including TCP and UDP events.
`!23`	Returns all events except those on port 23.
`25/tcp`	Returns all TCP-related intrusion events on port 25.
`21/tcp,25/tcp`	Returns all TCP-related intrusion events on ports 21 and 25.
`21-25`	Returns all events on ports 21 through 25.

Perform a search

Search for specific events or data records within the system to analyze health events, and other types of monitored data.

Procedure

Step 1 Click **Search** from a workflow page.

Step 2 From the table drop-down list, select the type of event or data to search.

Step 3 Enter your search criteria in the appropriate fields.

Step 4 If you want to use the search again in the future, save the search as described in Save a search, on page 524.

Step 5 Click **Search** to start the search.

Your search results appear in the default workflow for the table you are searching, constrained by time (if applicable).

Save a search

Save search criteria for future use to streamline repeated searches and maintain consistent filtering parameters.

Before you begin

- Establish search criteria as described in Perform a search, on page 524, or load a saved search as described in Load a saved search, on page 524.

Procedure

Step 1 From the Search page, if you want to save the search as private so only you can access it, check the **Private** checkbox.

Step 2 You have these options:

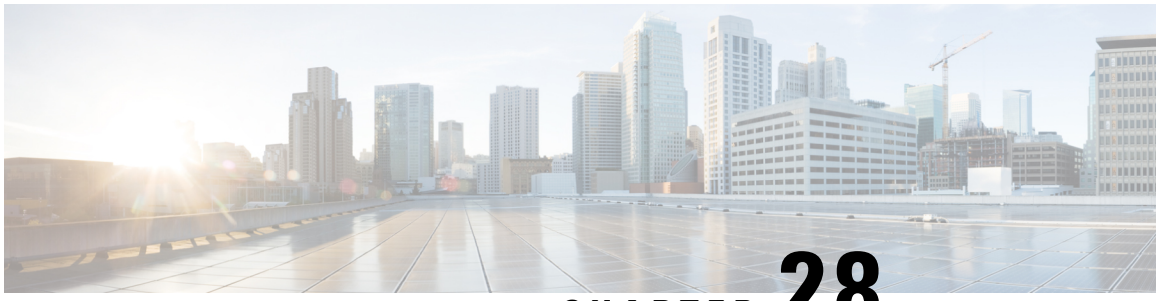
- To save a new version of a loaded search, click **Save As New**.
- To save a new search, or overwrite a custom search using the same name, click **Save**.

Load a saved search

Load a saved search to quickly access previously configured search criteria without having to recreate the search constraints.

Procedure

Step 1 Click **Search** from a workflow page.



Step 2 From the table drop-down list, choose the type of event or data to search.

Step 3 Choose the search you want to load from the **Custom Searches** list or the **Predefined Searches** list.

Step 4 If you want to use different search criteria, change the search constraints.

Step 5 If you want to use a changed search again in the future, save the search as described in Save a search, on page 524.

Step 6 Click **Search**.

CHAPTER 28

Send Firewall Threat Defense Events to Cisco Splunk

- Splunk integration: Send events directly from Cloud-Delivered Firewall Management Center , on page 527
- Guidelines and limitations for Splunk integration, on page 527
- Configure Splunk in Cloud-Delivered Firewall Management Center , on page 528
- Configure Secure Firewall App in Splunk, on page 533

Splunk integration: Send events directly from Cloud-Delivered Firewall Management Center

Cisco Splunk is a Security Information and Event Management (SIEM) tool that provides visibility and monitoring of security events across Cisco Secure Firewall devices.

In Cloud-Delivered Firewall Management Center versions earlier to 10.0, security events were sent to Splunk using eStreamer. From Cloud-Delivered Firewall Management Center version 10.0, you can send events to Splunk from the Firewall Threat Defense device. The wizard-driven interface helps you set up Splunk integration effortlessly.

This integration allows you to perform these actions.

- Customize event flow by specifying event types—such as connection, intrusion, malware, file, user activity, correlation, discovery, intrusion packet—and their sources (Firewall Threat Defense device) according to your monitoring requirements.
- Select the source interface for sending syslog events. You can choose to send events from the Firewall Threat Defense device's management or data interfaces.
- Create profiles with various configurations to suit different monitoring requirements.

Guidelines and limitations for Splunk integration

This topic lists the guidelines and limitations that apply to Splunk integration for event forwarding and syslog processing.

- When you enable Splunk integration, your existing syslog server configuration is not migrated.
- When migrating to Cloud-Delivered Firewall Management Center, you must repeat the Splunk integration procedure because the Splunk configuration from the On-Prem Firewall Management Center does not get migrated.
- If you set up domains in Cloud-Delivered Firewall Management Center, you can configure Splunk only from leaf domains.
- You can create a maximum of 15 Splunk profiles per domain. However, multiple domains can be configured to send syslog messages to the same or different servers.
- Do not create duplicate profiles for the same devices because it results in devices sending duplicated events to the Splunk server.
- Events are duplicated in Splunk destinations, under any of the following scenarios:
  - Platform Settings are configured with at least one syslog configuration.
  - Splunk profile is enabled using at least one data interface option for events.
- Only basic TLS encryption is supported over data interfaces from devices; client and server authentication are not supported.
- The syslog payload is sent to the Splunk server in JSON format.
- In a high availability set up, Splunk configuration is synchronized between the Cloud-Delivered Firewall Management Center HA pair. Only active unit sends the events. In the case of a failover, the new active unit will start sending the events.
- The message header of syslog events sent through data interfaces contains only the syslog tag and not the device IP address.
- cdFMC does not support sending events from a Cloud-Delivered Firewall Management Center source. Hence, cdFMC cannot have events that support only Cloud-Delivered Firewall Management Center source.

Configure Splunk in Cloud-Delivered Firewall Management Center

The Splunk integration wizard in Secure Firewall Management Center allows you to create profiles that send events and syslog data to a designated server. You can create multiple profiles to configure any number of servers for different combinations of devices and event types.

Before you begin

- Ensure that the Splunk server can be reached by Firewall Threat Defense device.
- The Cisco Secure Firewall App in Splunk does not support TLS. Hence, if you choose to use the TLS protocol to send events to Splunk, configure TLS on the Splunk server. For TLS configuration instructions, refer to the section *Configure Splunk indexing and forwarding to use TLS certificates* under *Manage Users and Security* in the Splunk Administer guide.

- Create required objects such as host, security zone, interface group, certificate, and so on, before starting the configuration procedure. Although you can navigate from the **Splunk integration** wizard to create objects, having them in advance will provide a smoother integration experience.

The Splunk integration wizard allows you to create a profile that enables you to stream events and syslog from managed devices to a specific server.

You can create multiple profiles to configure any number of servers for various combinations of devices and events. For example, you can create multiple profiles to send a specific set of events to one server and all the remaining events to a different server. Each profile is independent, but they all apply additively.

Procedure

	Command or Action	Purpose
Step 1	To open the **Splunk integration** wizard, go to **Integration** > **Splunk**.	
Step 2	The steps for configuring Splunk integration in Cloud-Delivered Firewall Management Center are listed in this table.	

	Do This	More Information
Step 1	Configure Splunk or similar SIEM tool server.	Refer to Configure Splunk server, on page 530.
Step 2	Choose the event types that you want to send to the Splunk server.	Refer to Select event types, on page 530.
Step 3	Specify the devices and the interfaces from which you want to send syslog events to Splunk.	Refer to Select devices and interfaces, on page 531.
Step 4	(Optional) Specify the device certificate to be used for sending events securely to Splunk.	Refer to Configure Firewall certificates for TLS, on page 532.
Step 5	View the summary of the profile that is being created.	Refer to Review and submit the Splunk profile, on page 532.

Configure Splunk server

Set up a Splunk syslog server to efficiently collect and manage log events from Secure Firewall devices. Use this task when adding a Splunk server as an external syslog destination for your Secure Firewall deployment.

Procedure

Step 1 In the **Configure Splunk server** page, from the **Host object or IP address** drop-down, choose the host object or enter an IP address of the Splunk server. To create a host object, click the **Create** link in the drop-down list.

Step 2 Click the **Protocol** (UDP, TCP, or TLS) that you want the Splunk server to use for communicating with Cloud-Delivered Firewall Management Center and Firewall Threat Defense device.

Step 3 In the **Port** field, enter the port number applicable for the selected protocol:

- UDP: Enter the port number 514, or a number between 1025 and 65535. The default UDP port is 514.
- TCP: Enter the port number between 1025 and 65535. The default TCP port is 1470.
- TLS: Enter the port number between 1 and 65535. The default TLS port is 6514.

Step 4 (Optional) If you selected **TLS**, specify the trusted CA name to securely establish the connection on the Splunk server. From the **Trusted certificate authority** drop-down list, choose the CA. (To import a new CA object, click the **Create** link in the drop-down list.)

Step 5 To forward the events logged by a facility, from the **Facility** drop-down list, choose the corresponding facility.

Step 6 To forward the events with a specific severity, from the **Severity** drop-down list, choose the severity level.

Step 7 (Optional) In the **Tag** field, enter an alphanumeric string by which to identify the message in the server.

Step 8 (Optional) To cancel the creation of the Splunk profile, click **Cancel**.

Step 9 To move to the next step in the Splunk configuration, click **Next**.

Select event types

You can specify the type of events that you want to send to Splunk. The recommended event types are selected by default. In Cloud-Delivered Firewall Management Center , the source for event types is always **FTD**.

Procedure

Step 1 Select the check box to specify the event types.

Step 2 After selection of the event types, to reset to default settings, click **Revert to system defaults**.

Step 3 (Optional) To cancel the creation of the Splunk profile, click **Cancel**.

Step 4 (Optional) To go back to the previous step, click **Back**.

Step 5 To move to the next step in the Splunk configuration, click **Next**.

Select devices and interfaces

You can specify the Firewall Threat Defense devices and interfaces from which you want to send syslog events to Splunk. To send events from multiple interfaces, use security zones or interface groups.

Note If you are using security zones or interface groups, only routed, management, switched, and loopback zones and groups are allowed.

Procedure

Step 1 Under **Select devices**, click the relevant options:

- **Use management interface** : Click this button to configure the management interface of Firewall Threat Defense device to send the events to Splunk. When this option is chosen, all the devices in the current domain also receive the Splunk configuration.
- **Use security zones and interface groups to specify devices and interfaces** : Click this button to configure the interfaces of corresponding devices in the selected security zones and interface groups to send their respective events to Splunk.
  - From the **Security zones and interface groups** drop-down list, choose the required zones and groups.
  - To create a security zone or interface group for the device's interfaces, click **Create** in the **Certificates** drop-down list.
- **Manually select devices and interfaces** : Click this button to send the events from the deployed device to Splunk. From the **Interface** drop-down list, choose the configured interface through which you want the events to be sent to Splunk. You can choose only security zones that include this device.

  Note
  - Virtual Tunnel Interface (VTI) and Dynamic Virtual Tunnel Interface (DVTI) are excluded from Splunk configuration.
  - To encrypt syslog events over TLS, use the management interface to add a certificate. Encryption is not supported for data interfaces configured for TLS.
  - Click the **Send events from this device** toggle button corresponding to the device and its selected interface.
  - To create a security zone or interface group for the device's interfaces, click **Create**.

Step 2 (Optional) To cancel the creation of the Splunk profile, click **Cancel**.

Step 3 (Optional) To go back to the previous step, click **Back**.

Step 4 To move to the next step in the Splunk configuration, click **Next**.

Configure Firewall certificates for TLS

You can specify the device certificate to be used for sending events securely to Splunk. This step is optional. It is applicable only if you use the TLS protocol to send events to Splunk.

Before you begin

You can configure the certificates when you have set TLS protocol while configuring the Splunk server. Add certificate object for these clients:

- For Cloud-Delivered Firewall Management Center, use internal certificate objects for authentication.
- For Firewall Threat Defense, use a certificate enrollment object. First, create the object at **Objects** > **Object Management** > **PKI** > **Certificate Enrollment**. Then, enroll the certificate on a device at **Devices** > **Certificates**.

Procedure

Step 1 From the **Firewall Management Center client certificate** drop-down list, choose the certificate. To create an internal certificate, click **Create**.

Step 2 In the **Firewall Threat Defense certificates** box, use the search box to choose the device whose certificate you want to assign.

Step 3 From the **Certificates** drop-down list, choose the certificate. Only successfully enrolled device certificates are listed. To enroll a new device certificate, click **Create**.

Step 4 (Optional) To cancel the creation of the Splunk profile, click **Cancel**.

Step 5 (Optional) To go back to the previous step, click **Back**.

Step 6 To move to the next step in the Splunk configuration, click **Next**.

Review and submit the Splunk profile

You can view the selections made for the Splunk configuration profile.

Procedure

Step 1 Under **Profile Name**, a system-generated name is displayed. Edit the value in the **Name** field, if you want to use a different name.

Note
The name must start with a letter, a number, or an underscore (_). The name can contain include letters, numbers, and special characters: period (.), hyphen (-), underscore (_), and plus (+).

Step 2 To change a value from a previous Splunk server configuration, click **Edit** next to the attribute.

Step 3 (Optional) To cancel the creation of the Splunk profile, click **Cancel**.

Step 4 (Optional) To go back to the previous step, click **Back**.

Step 5 To save the Splunk profile, click **Submit**.

Step 6 If you have configured Threat Defense events to be sent to Splunk, click **Deploy**.

Configure Secure Firewall App in Splunk

To ensure that the Splunk server is reachable to receive the events, configure the Cisco Secure Firewall App in Splunk.

Before you begin

Ensure that you have obtained a Splunk server license and a Cisco Security Cloud account.

Procedure

Step 1 Download and install the Splunk server using the instructions provided in Splunk Enterprise Installation Manual.

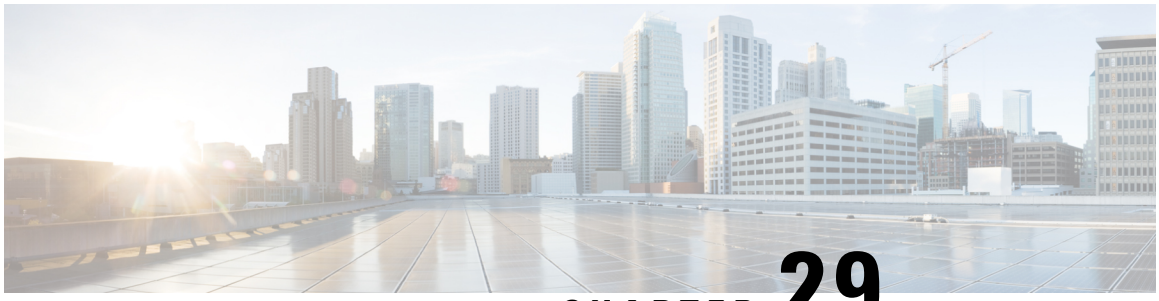
Step 2 To install Splunk license, log in to your Splunk server's web interface.

Step 3 Go to **Settings** > **Licensing** > **Add license**. Use the license received by email.

Note
Make sure to restart Splunk to complete license registration.

Step 4 Download Cisco Security Cloud from Splunkbase Apps.

Step 5 To install Cisco Security Cloud, log in to your Splunk server's web interface.



Step 6 Go to **Apps** > **Manage Apps** > **Install app from file**.

Step 7 Click **Browse** and select the downloaded application file and upload.

Step 8 To configure the server to receive the syslog events from the Firewall Threat Defense device, go to **Apps** > **Cisco Security Cloud** > **Secure Firewall** > **Configure Application**, and then click the **Syslog** tab.

- In the **Input Name** field, enter any name.
- In the **Input Type** field, enter UDP or TCP.

  TLS is not supported in the Cisco Security Cloud application. Use rsyslog or syslog-ng to establish TLS on Splunk server. For detailed procedures, refer to Configure TLS on Splunk Server.
- In the **Port** field, enter a value between 1025 and 65535. The default port is 514.
- Leave the **Host** field blank. This will allow the Splunk to process events from any Firewall Threat Defense.
- In the **Source Type** field, enter *cisco:ftd:syslog*.
- In the **Interval** field, enter *600* seconds.

CHAPTER 29

Event Investigation Using Web-Based Resources

• Event investigation using web-based resources, on page 535

Event investigation using web-based resources

Event investigation using web-based resources is a security analysis method that

- enables quick access to threat intelligence from external sources outside of the Cloud-Delivered Firewall Management Center,
- allows direct navigation from events to relevant information in external resources based on IP addresses, ports, protocol, domain, and SHA-256 hash, and
- provides access to predefined links to commonly used Cisco and third-party threat intelligence services, plus custom links to other web-based services and SIEMs.

Event investigation capabilities

The contextual cross-launch feature supports various investigation scenarios:

- Look up a suspicious source IP address in a Cisco or third-party cloud-hosted service that publishes information about known and suspected threats
- Look for past instances of a particular threat in your organization's historical logs, if your organization stores that data in a Security Information and Event Management (SIEM) application
- Look for information about a particular file, including file trajectory information, if your organization has deployed Cisco Secure Endpoint

When investigating an event, you can click directly from an event in the event viewer or dashboard in the Cloud-Delivered Firewall Management Center to the relevant information in the external resource. This lets you quickly gather context around a specific event based on its IP addresses, ports, protocol, domain, and/or SHA-256 hash.

Note Some resources may require an account or a product purchase.

Talos IP address investigation

Suppose you are looking at the Top Attackers dashboard widget and you want to find out more information about one of the source IP addresses listed. You want to see what information Talos publishes about this IP address, so you choose the "Talos IP" resource. The Talos website opens to a page with information about this specific IP address.

Manage contextual cross-launch resources

Manage external web-based resources using the **Analysis** > **Advanced** > **Contextual Cross-Launch** page.

Pre-defined resources offered by Cisco are marked with the Cisco logo. The remaining links are third-party resources.

You can disable or delete any resources that you do not need, or you can rename them, for example by prefixing a name with a lower-case "z" so the resource sorts to the bottom of the list. Disabling a cross-launch resource disables it for all users. You cannot reinstate deleted resources, but you can re-create them.

To add a resource, refer to Add contextual cross-launch resources, on page 536.

Requirements for custom contextual cross-launch resources

A custom contextual cross-launch resource is an integration feature that

- enables web browser access to predefined or custom resources, and
- restricts configuration and usage based on user role permissions.

Custom contextual cross-launch resource specifications

Custom contextual cross-launch resources must meet these requirements:

- Resources must be accessible via web browser.
- Only HTTP and HTTPS protocols are supported.
- Only GET requests are supported; POST requests are not.
- Encoding of variables in URLs is not supported. While IPv6 addresses may require colon separators to be encoded, most services do not require this encoding.
- Up to 100 resources can be configured, including pre-defined resources.

Add contextual cross-launch resources

In multidomain deployments, you can see and use resources in parent domains, but you can only create and edit resources in the current domain. The total number of resources across all domains is limited to 100.

Before you begin

- If you are adding links to a Secure Network Analytics appliance, check to see if the links you want already exist; most links are automatically created for you when you configure Security Analytics and Logging (On Premises).

- Refer to Requirements for custom contextual cross-launch resources, on page 536.
- If needed for the resource you will link to, create or obtain an account and the credentials needed for access. Optionally, assign and distribute credentials for each user who needs access.
- Determine the syntax of the query link for the resource that you will link to:

  Access the resource via browser and, using the documentation for that resource as needed, formulate the query link needed to search for a specific sample of the type of information you want your query link to find, such as an IP address.

  Run the query, then copy the resulting URL from the browser's location bar.

  For example, you might have the query URL **`https://www.talosintelligence.com/reputation_center/lookup?search=10.10.10.10`**.

Procedure

Step 1 Choose **Analysis** > **Advanced** > **Contextual Cross-Launch**.

Step 2 Click **New Cross-launch**.

In the form that appears, all fields marked with an asterisk require a value.

Step 3 Enter a unique resource name.

Step 4 Paste the working URL string from your resource into the **URL Template** field.

Step 5 Replace the specific data (such as an IP address) in the query string with an appropriate variable: Position your cursor, then click a variable (for example, **IP**) once to insert the variable.

In the example from the "Before You Begin" section above, the resulting URL might be **`https://www.talosintelligence.com/reputation_center/lookup?search={IP}`**. When the contextual cross-launch link is used, the {IP} variable in the URL will be replaced by the IP address that the user right-clicks on in the event viewer or dashboard.

For a description of each variable, hover over the variable.

You can create multiple contextual cross-launch links for a single tool or service, using different variables for each.

Step 6 Click **Test with example data** ( ) to test your link with example data.

Step 7 Fix any problems.

Step 8 Click **Save**.

Investigate events using contextual Cross-Launch

Contextual cross-launch allows you to right-click on event data and immediately access external analysis tools and threat intelligence resources. The available options depend on the data type you select, ensuring you only see relevant investigation resources.

Before you begin

If the resource you will access requires credentials, make sure you have those credentials.

Follow these steps to investigate events using contextual cross-launch:

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, click **Analysis** > **Unified Events**.

Step 2 Right-click the event of interest and choose the contextual cross-launch resource to use.

If necessary, scroll down in the context menu to see all available options.

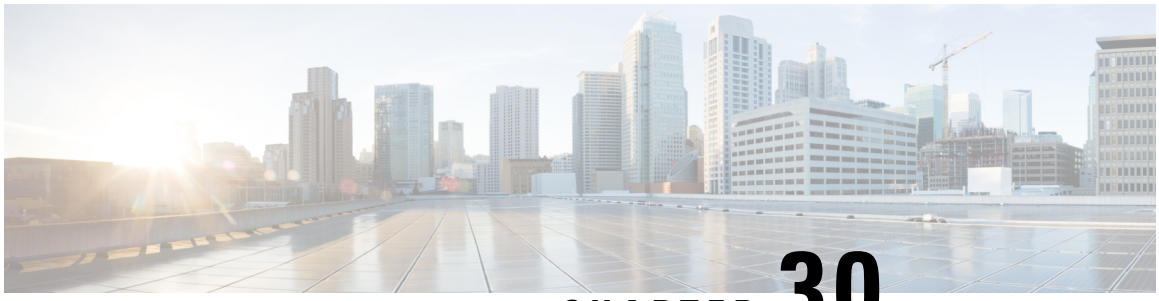
The data type you right-click on determines the options you see; for example, if you right-click an IP address, you will only see contextual cross-launch options that are relevant to IP addresses.

For example, to get threat intelligence from Cisco Talos about a source IP address in the intrusion event, choose **Talos SrcIP** or **Talos IP**.

If a resource includes multiple variables, the option to choose that resource is available only for events that have a single possible value for each included variable.

The contextual cross-launch resource opens in a separate browser window.

It may take some time for the query to be processed, depending on the amount of data to be queried, speed of and demand on the resource, and so on.



Step 3 Sign in to the resource if necessary.

PART X

Events and Assets

- Monitor Cloud-Delivered Firewall Management Center-Managed Threat Defense Device Events, on page 541

- Advanced Logging Syslog Fields, on page 587
- User Identity and Activity, on page 595

CHAPTER 30

Monitor Cloud-Delivered Firewall Management Center-Managed Threat Defense Device Events

View events from Threat Defense devices that are managed by Cloud-Delivered Firewall Management Center in Security Cloud Control.

- About Security Analytics and Logging, on page 541
- Comparison of SAL Remote Event Storage and Monitoring Options, on page 542
- About SAL (OnPrem), on page 542
- Manage SAL (OnPrem) for Security Cloud Control-Managed Firewall Threat Defense Devices, on page 543
- Configure SAL (OnPrem) Integration, on page 545
- About Security Analytics and Logging(SaaS) for Firewall Threat Defense, on page 548
- Configure the SAL (SaaS) Integration, on page 548

About Security Analytics and Logging

Security Analytics and Logging (SAL) is a central log management and advanced threat detection service which delivers scalable Cisco firewall logging and correlated analytics. Central logging helps in providing visibility, helps troubleshoot network access issues including disruptions, and enables device and overall network health monitoring. Analytics provide detection against advanced threats.

The SAL service is available in the following two methods:

- Security Analytics and Logging (SaaS)—A hosted software as a service (SaaS) which stores events and provides data for security analytics. This service connects the Security Analytics and Logging cloud data store to the firewall cloud manager, Security Cloud Control (Security Cloud Control).

  In this documentation, this method is also referred to as SAL (SaaS).

- Security Analytics and Logging (On Premises)—A service that runs on the Secure Network Analytics appliances to store event logs at the customer's own premises. This service connects the Security Analytics and Logging (On Premises) data to the on-premises manager, Secure Firewall Management Center.

  In this documentation, this method is also referred to as SAL (OnPrem).

For more information about Security Analytics and Logging, see https://www.cisco.com/c/en/us/products/security/security-analytics-logging/index.html.

Comparison of SAL Remote Event Storage and Monitoring Options

SAL integration shows similar options for storing event data externally to a Firewall Management Center and Security Cloud Control:

	SAL (OnPrem)	SAL (SaaS)
Why choose this solution?	You want to increase your on-premises firewall event data storage capacity, retain this data for a longer period, and export your event data to the Secure Network Analytics appliance.	You want to send firewall events to the Cisco cloud for storage and optionally make your firewall event data available for security analytics using integrated cloud services such as Cisco XDR.
Licensing	Purchase license and set-up the storage system behind your firewall. For more information, see Licensing for SAL (OnPrem), on page 543	Purchase license and a data storage plan and send your data to the Cisco cloud. For more information, see Licensing for SAL (SaaS), on page 548
Supported event types	• Connection • File and Malware • Intrusion • LINA • Security Intelligence	• Connection • File and Malware • Intrusion • Security Intelligence
Supported methods to send events	Supports both, syslog and direct integration.	Supports both, syslog and direct integration.
Event viewing	• View events on the Secure Network Analytics Manager. • Cross-launch from the Firewall Management Center event viewer to view events on the Secure Network Analytics Manager. • View remotely stored connection and security intelligence events in the management center.	View events in Security Cloud Control or Secure Network Analytics Manager, depending on your license. Cross-launch from the Firewall Management Center event viewer.

About SAL (OnPrem)

You can configure SAL (OnPrem) to store firewall event data for increased storage at a larger retention period. By deploying Secure Network Analytics appliances and integrating them with your firewall deployment, you can export your event data to a Secure Network Analytics appliance.

This provides you with the following capabilities:

- Store events on the Secure Network Analytics appliance.
- Specify this remote data source to view these events in the management center.
- Review event data from the Secure Network Analytics Manager (formerly Stealthwatch Management Console) Web App UI using the *Event Viewer*.
- Cross-launch from the management center UI to the *Event Viewer* to view additional context on the information from which you cross-launched.

Licensing for SAL (OnPrem)

You must obtain the Logging and Troubleshooting smart license to use SAL (OnPrem). You can obtain the license based on the amount of data you anticipate while sending the syslog data from your firewall deployment to your Secure Network Analytics appliance on a daily basis.

For information on licensing the Secure Network Analytics appliances, see Secure Network Analytics Smart Software Licensing Guide.

For information on the available SAL (OnPrem) licensing options, see the Cisco Security Analytics and Logging Ordering Guide.

Note For license calculation purposes, the amount of data is reported to the nearest whole GB. For example, If you send 4.9 GB in a day, it is reported as 4 GB.

Manage SAL (OnPrem) for Security Cloud Control-Managed Firewall Threat Defense Devices

Starting with Secure Firewall Threat Defense(formerly Firepower Threat Defense) version 7.2, you can choose to send fully qualified events that are generated by Security Cloud Control-managed Firewall Threat Defense devices to the Firewall Management Center. The Firewall Management Center receives and displays data analytics for these events. The Firewall Management Center receiving and displaying the event data is also referred to as an analytics-only management center. .

If your devices are enabled to send connection events to a Secure Network Analytics Manager using SAL (OnPrem), you can view and work with these remotely stored events in the management center event viewer and context explorer, and include them when generating reports. By deploying the Secure Network Analytics appliance and integrating it with the firewall deployment, you can export the event data to the Secure Network Analytics appliance. This allows you to view and manage the events in the management center UI. From the management center interface, you can also cross-launch to Secure Network Analytics Manager to view and manage the events data.

The management center can receive and display event analytics for the following Security Cloud Control-managed Firewall Threat Defense devices:

- New or existing Firewall Threat Defense devices onboarded to Security Cloud Control

For information on onboarding a Firewall Threat Defense device to Security Cloud Control, see Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 21.

The workflow is as follows:

1. Onboard a Firewall Threat Defense device to Security Cloud Control.

   Onboard the Firewall Threat Defense devices using the onboarding methods that are described in Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 21. The onboarding process includes assigning policies and choosing the appropriate licenses.

2. Register this Firewall Threat Defense device in the appropriate management center.

   For the management center to display events generated by a Security Cloud Control-managed Firewall Threat Defense device, you must register the Firewall Threat Defense device in the management center. To register this device in the Firewall Management Center, enable the device to be registered using the **configure manager add** {*hostname* | *IPv4_address* | *IPv6_address*}*reg_key*[*nat_id*] CLI, and then add the device to the Firewall Management Center using the **Security Cloud Control Managed Device** check box.

Note The registration key and the NAT ID must be unique from those used while onboarding the device to Security Cloud Control.

   For more information, see *Add a Device to the Management Center* and *Complete the Threat Defense Initial Configuration Using the CLI* in Firepower Management Center Device Configuration Guide.

3. View events in the management center or cross-launch to a configured Secure Network Analytics Manager.

   To view and work with the events in the management center event viewer. If the Secure Network Analytics appliance is deployed and integrated with the firewall deployment, you can export the event data to the Secure Network Analytics appliance. This allows you to cross-launch from the management center UI to the Secure Network Analytics Manager to view and manage the events data.

   For more information, see *Events and Assets* and *Event Analysis Using External Tools*.

- Existing Firewall Threat Defense devices on the management center.

  You can change the management of the Firewall Threat Defense devices from management center to Security Cloud Control using the change threat defense manager functionality. The change threat defense manager functionality provides you to ability to change the management of Firewall Threat Defense devices from management center to Security Cloud Control. While changing the manager, you can choose to retain the events data generated by these threat defense devices on the management center. If you choose to retain the events data on the management center, a copy of the Firewall Threat Defense device in an analytics-only mode is retained on the management center.

  For more information, see Migrate Secure Firewall Threat Defense to Cloud.

  The workflow is as follows:

  1. Onboard the management center to Security Cloud Control

     To onboard the existing Firewall Threat Defense devices from management center to Security Cloud Control, you must onboard the appropriate management center to Security Cloud Control.

For more information, see Onboard an FMC.

2. Complete the change threat defense management process

   During the change threat defense management process, while changing the device manager, you can choose to retain events data generated by these Firewall Threat Defense devices on the management center.

   For more information, see Migrate Secure Firewall Threat Defense to Cloud.

3. View events in the management center or cross-launch to configured Secure Network Analytics appliance.

   To view and work with the events in the management center event viewer. If the Secure Network Analytics appliance is deployed and integrated with the firewall deployment, you can export the event data to the Secure Network Analytics appliance. This allows you to cross-launch from the management center UI to the Secure Network Analytics Manager to view and manage the events data.

   For more information, see Events and Assets and Event Analysis Using External Tools.

Configure SAL (OnPrem) Integration

Configure Security Cloud Control to send events to the Secure Network Analytics appliance.

Deploy a Cisco Secure Network Analytics Flow Collector to receive events, a Cisco Secure Network Analytics Data Store (containing 3 Cisco Secure Network Analytics Data Nodes) to store events, and a manager. The Firewall Threat Defense devices send event data to the flow collector from where the events are sent to the Data Store for storage. From the Cloud-Delivered Firewall Management Center user interface, you can cross-launch the manager to view more information about the stores events.

Starting with Firewall Threat Defense Version 7.2, you can choose to associate different flow collectors to different devices.

Configure a Secure Network Analytics Manager

Configure the Secure Network Analytics Manager deployment to integrate SAL (OnPrem) with Security Cloud Control-managed Firewall Threat Defense devices.

Before you begin

Ensure the following:

- You have a provisioned Security Cloud Control tenant and have the following Security Cloud Control user roles:
  - Admin
  - Super admin
- Your Firewall Threat Defense devices are working as expected and are generating events.
- If you are currently using syslog to send events to the Secure Network Analytics Manager from device versions that support sending events directly, disable syslog for those devices (or assign those devices

an access control policy that does not include syslog configurations) to avoid duplicating events on the remote volume.

- You have the hostname or the IP address of your Secure Network Analytics Manager.

Note You may be logged out of the Secure Network Analytics Manager during the registration process; complete any work in progress before you start with the deployment wizard.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 From the Security Cloud Control menu, navigate **Administration** > **Firewall Management Center** to open the **Services** page.

Step 3 Select **Cloud-Delivered FMC** and then click **Configuration**.

Step 4 Navigate to **Integration** > **Security Analytics & Logging**.

Step 5 In the **Secure Network Analytics Manager Only** widget, click **Start**.

Step 6 Enter the hostname or the IP address and port number of the Secure Network Analytics Manager and click **Next**.

Step 7 Deploy the changes to the managed devices.

The event data is not logged to the SAL (OnPrem) until the logging policy changes are deployed to the registered Firewall Threat Defense devices.

Note
If you must change any of these configurations, run the wizard again. If you disable the configuration or run he wizard again, all settings except the account credentials are retained.

You can view and work with these remotely stored events in the event viewer and context explorer in the management center, and include them when generating reports. You can also cross-launch from an event in the management center to view related data on your Secure Network Analyticss appliance.

For more information, see the online help for the management center.

Step 8 Click **OK**.

Configure a Secure Network Analytics Data Store

Configure a Secure Network Analytics data store deployment to integrate SAL (OnPrem) with Firewall Threat Defense devices that are Security Cloud Control-managed.

Before you begin

Ensure the following:

- You have a provisioned Security Cloud Control tenant and have the following Security Cloud Control user roles:

- Admin
- Super admin

- Your Firewall Threat Defense devices are working as expected and generating events.
- If you are currently using syslog to send events to the Secure Network Analytics appliance from device versions that support sending events directly, disable syslog for those devices (or assign those devices an access control policy that does not include syslog configurations) to avoid duplicate events on the remote volume.
- Gather the following information:
  - The hostname or the IP address of your Secure Network Analytics Manager.
  - The IP address of your flow collector.

Note You may be logged out of the Secure Network Analytics Manager during the registration process; complete any work in progress before you start with the deployment wizard.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 From the Security Cloud Control menu, navigate **Administration** > **Firewall Management Center** to open the **Services** page.

Step 3 Choose **Cloud-Delivered FMC** and click **Configuration**.

Step 4 Navigate to **Integration** > **Security Analytics & Logging**.

Step 5 In the **Secure Network Analytics Data Store** widget, click **Start**.

Step 6 Enter the hostname or the IP address and port number of the flow collector.

To add more flow collectors, click **+Add another Flow Collector**.

Step 7 If you have configured more than one flow collector, associate the managed devices with different flow collectors:

Note
By default, all the managed devices are assigned to the default flow collector.

a) Click **Assign Devices**.
b) Select the managed devices that you want to assign.
c) From the reassign device drop-down list, choose the flow collector.

If you do not want a managed device to send event data to any of the flow collectors, select that device, and choose **Do not log to flow collector from the reassign device drop-down list.**

You can change the default flow collector by hovering over the intended flow collector and clicking **Set default**.

d) Click **Apply Changes**.

e) Click **Next**.

Step 8 Click **Next**.

Step 9 Deploy the changes to the registered managed devices.

The event data is not logged to the SAL (OnPrem) until the logging policy changes are deployed to the registered Firewall Threat Defense devices.

Note
If you must change any of these configurations, run the wizard again. If you disable the configuration or run he wizard again, all settings except the account credentials are retained.

You can view and work with these remotely stored events in the event viewer and context explorer in the management center, and include them when generating reports. You can also cross-launch from an event in the management center to view related data on your Secure Network Analytics Manager.

For more information, see the online help for the management center.

About Security Analytics and Logging(SaaS) for Firewall Threat Defense

SAL (SaaS) allows you to capture connection, intrusion, file, malware, and Security Intelligence events from all of your Firewall Threat Defense devices and view them in one place in Security Cloud Control. The events are stored in the Cisco cloud and are viewable from the **Event Logging** page in Security Cloud Control, where you can filter and review them to gain a clear understanding of what security rules are triggering in your network.

Licensing for SAL (SaaS)

The SAL (SaaS) licenses allows you to use a Security Cloud Control tenant to view firewall logs from all your managed devices at one place. For details on the available SAL (SaaS) licensing options, see the Cisco Security Analytics and Logging Ordering Guide.

Configure the SAL (SaaS) Integration

To deploy this integration, you must set up event data storage in SAL (SaaS) using either syslog or a direct connection.

- Send Cloud-Delivered Firewall Management Center-Managed Events to SAL (SaaS) Using Syslog, on page 553
- Send Cloud-Delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection, on page 555

Requirements and Guidelines

Type	Description
Cisco Secure Firewall Threat Defense	• Security Cloud Control-managed standalone Firewall Threat Defense devices, Version, 7.2 and later. • To send events using syslog, you must have Firewall Threat Defense device, Version 6.4 or later. • To send events directly, you must have Firewall Threat Defense device, Version 7.2 or later. • To optionally exclude individual Firewall Threat Defense devices from sending events directly, you must have Firewall Threat Defense device, Version 7.4.1 or later. • Your firewall system must be deployed and successfully generating events.
Regional cloud	• Determine the regional cloud that you want to send events to. • Events cannot be viewed from or moved between different regional clouds. • If you use a direct connection to send events to the Cisco Security Cloud for integration with Cisco SecureX, or Cisco SecureX threat response, or Cisco XDR, you must use the same cloud region for this integration. • If you send events directly, the regional cloud you specify in Security Cloud Control must match the region of your Security Cloud Control tenant.
Security Analytics and Logging subscription plan	• You must have a valid Security Analytics and Logging subscription plan. For more information about the subscription plans, see Security Analytics and Logging Licenses. • If your do not have a Security Analytics and Logging plan subscribed, you can request a 90-day trial by logging in to Security Cloud Control and navigating to **Events & Logs** > **Events** > **Event Logging** tab. You can purchase the desired subscription plan by following the instructions in the Security Cloud Control Firewall Management Ordering Guide. • You must buy a data plan that reflects the number of events the Cisco cloud receives from your threat defense devices daily. This is called your daily ingest rate. • Use the Logging Volume Estimator Tool to estimate your data storage requirements.

Type	Description
Accounts	When you purchase a license for this integration, you are provided with a Security Cloud Control tenant account to support the integration.

Type	Description
Connectivity	

Type	Description
	The Firewall Threat Defense devices must be able to connect outbound on port 443 to the Cisco Security Cloud at the following addresses: • US region: • api-sse.cisco.com • mx*.sse.itd.cisco.com • dex.sse.itd.cisco.com • eventing-ingest.sse.itd.cisco.com • registration.us.sse.itd.cisco.com • us.manage.security.cisco.com • edge.us.cdo.cisco.com • EU region: • api.eu.sse.itd.cisco.com • mx*.eu.sse.itd.cisco.com • dex.eu.sse.itd.cisco.com • eventing-ingest.eu.sse.itd.cisco.com • registration.eu.sse.itd.cisco.com • eu.manage.security.cisco.com • edge.eu.cdo.cisco.com • Asia (APJ) region: • api.apj.sse.itd.cisco.com • mx*.apj.sse.itd.cisco.com • dex.apj.sse.itd.cisco.com • eventing-ingest.apj.sse.itd.cisco.com • registration.apj.sse.itd.cisco.com • apj.cdo.cisco.com • edge.apj.cdo.cisco.com • Australia region: • api.aus.sse.itd.cisco.com • mx*.aus.sse.itd.cisco.com • dex.au.sse.itd.cisco.com

Type	Description
	• eventing-ingest.aus.sse.itd.cisco.com • registration.au.sse.itd.cisco.com • aus.cdo.cisco.com • India region: • api.in.sse.itd.cisco.com • mx*.in.sse.itd.cisco.com • dex.in.sse.itd.cisco.com • eventing-ingest.in.sse.itd.cisco.com • registration.in.sse.itd.cisco.com • in.cdo.cisco.com

Send Cloud-Delivered Firewall Management Center-Managed Events to SAL (SaaS) Using Syslog

This procedure provides information about the configuration for sending syslog messages for security events (connection, security intelligence, intrusion, file, and malware events) from devices managed by Security Cloud Control.

Before you begin

- Configure policies to generate security events, and verify that the events you expect to see are displayed in the applicable tables under the **Events & Logs** menu.
- Gather information relating to the syslog server IP address, port, and protocol (UDP or TCP).
- Ensure that your devices can reach the syslog server.

Procedure

Step 1 In the left pane, click **Administration** > **Firewall Management Center** to open the **Services** page.

Step 2 Click and select **Cloud-Delivered FMC** and then click **Configuration**.

Step 3 Configure the syslog settings for your threat defense device:

a) Click **Devices** > **Platform Settings** and edit the platform settings policy that is associated with your threat defense device.

b) In the left-side navigation pane, click **Syslog** and configure the syslog settings as follows:

Click this UI Element...	To Do the Following:
Logging Setup	Enable logging, specify FTP server settings, and the Flash usage.
Logging Destination	Enable logging to specific destinations and to specify filtering by message severity level, event class, or by a custom event list.
E-mail Setup	Specify the email address that is used as the source address for syslog messages that are sent as emails.
Events Lists	Define a custom event list that includes an event class, a severity level, and an event ID.
Rate Limit	Specify the volume of messages being sent to all the configured destinations and define the message severity level to which you want to assign the rate limits.
Syslog Settings	Specify the logging facility, enable the inclusion of a time stamp, and enable other settings to set up a server as a syslog destination.
Syslog Servers	Specify the IP address, protocol that is used, format, and security zone for the syslog server that is designated as a logging destination.

c) Click **Save**.

Step 4 Configure the general logging settings for the access control policy (including file and malware logging):

a) Click **Policies** > **Access Control** and then edit the access control policy that is associated with your threat defense device.

b) Click **More** and then choose **Logging**. Configure the general logging settings for the access control policy (including file and malware logging) as follows:

Click this UI Element...	To Do the Following:
Send using specific syslog alert	Select a syslog alert from the list of existing predefined alerts or add one by specifying the name, logging host, port, facility, and severity.
Use the syslog settings configured in the FTD Platform Settings policy deployed on the device	Unify the syslog configuration by configuring it in **Platform Settings** and reuse the settings in the access control policy. The selected severity is applied to all the connection and intrusion events. The default severity is **ALERT**.
Send Syslog messages for IPS events	Send events as syslog messages. The default syslog settings are used unless you override them.

Click this UI Element...	To Do the Following:
Send Syslog messages for File and Malware events	Send file and malware events as syslog messages. The default syslog settings are used unless you override them.

c) Click **Save**.

Step 5 Enable logging for security intelligence events for the access control policy:

a) In the same access control policy, click the **Security Intelligence** tab.

b) Click the logging icon and enable security intelligence logging using the following criteria:

- By Domain Name—Click the logging icon next to the **DNS Policy** drop-down list.
- By IP address—Click the logging icon next to **Networks**.
- By URL—Click the logging icon next to **URLs**.

c) Click **Save**.

Step 6 Enable syslog logging for each rule in the access control policy:

a) In the same access control policy, click the **Access Control** tab.

b) Click a rule to edit.

c) Click the **Logging** tab in the rule.

d) Check the **Log at beginning of connection** and **Log at end of connection** check boxes.

e) If you want to log file events, check the **Log Files** check box.

f) Check the **Syslog Server** check box.

g) Verify that the rule is **Using default syslog configuration in Access Control Logging**.

h) Click **Confirm**.

i) Click **Apply** to save the rule.

j) Repeat steps 7.a through 7.h for each rule in the policy and click **Save** to save the policy.

Step 7 If you have made all the required changes, deploy your changes to the managed devices.

Send Cloud-Delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection

Configure the Cloud-Delivered Firewall Management Center to send events directly to SAL (SaaS). Follow this procedure to enable the Cisco cloud event global setting in the Cloud-Delivered Firewall Management Center. When needed, you can exclude individual Firewall Threat Defense devices from sending event logs to SAL (SaaS). For more information, see Enable or Disable Threat Defense Devices to Send Event logs to SAL (SaaS) Using a Direct Connection.

Before you begin

- Onboard devices to the Cloud-Delivered Firewall Management Center, assign licenses to these devices, and configure these devices to send events directly to SAL (SaaS).

- Enable connection logging on a per-rule basis by editing a rule and choosing the **Log at Beginning of Connection** and **Log at End of Connection** options.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the left pane, click **Administration** > **Firewall Management Center**.

Step 3 Click **Cloud-Delivered FMC**, and in the **System** pane that is located at the right-side, click **Cisco Cloud Events**.

Step 4 In the **Configure Cisco Cloud Events** widget, do the following:

a. Click the **Send Events to the Cisco Cloud** toggle button to enable the overall configuration.

b. Check the **Send Intrusion Events to the cloud** check box to send the intrusion events to the cloud.

Note
When you enable sending intrusion events, the Firewall Threat Defense device sends the captured packet data to the cloud along with the intrusion events. Cisco Talos uses this packet data to analyze and eliminate false threats. This ensures focus on actual threats, enhancing the accuracy and efficiency of Talos' threat recommendations.

c. Check the **Send File and Malware Events to the cloud** check box to send the file and malware events to the cloud.

d. Choose an option to send the connection events to the cloud:

- Click the **None** radio button to not send connection events to the cloud.
- Click the **Security Events** radio button to send only security intelligence events to the cloud.
- Click the **All** radio button to send all the connection events to the cloud.

e. Click **Save**.

Enable Individual Threat Defense Devices to Send Events to SAL (SaaS) Using a Direct Connection

Enable or disable the FTD devices managed by the Cloud-Delivered Firewall Management Center to send events directly to SAL (SaaS). This device-level control allows you to optionally exclude specific FTD devices from sending event logs to the Cisco cloud to reduce traffic or to maintain a combination of SAL and on-premises event log storage.

Note

- To enable or disable sending events to the Cisco cloud from the FTD devices, enable the Cisco cloud event global setting in the Cloud-Delivered Firewall Management Center. For more information on enabling the Cisco cloud event global setting, see Send Cloud-Delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection, on page 555.

  Sending events to the Cisco cloud is enabled by default for all FTD devices when the Cisco cloud event global setting is enabled in the Cloud-Delivered Firewall Management Center.

- The option to enable or disable FTD devices to send event logs to the cloud is supported on FTD Version 7.4.1 or later.

Before you begin

- Onboard devices to the Cloud-Delivered Firewall Management Center, assign licenses to these devices, and configure these devices to send events directly to SAL (SaaS).
- Enable connection logging on a per-rule basis by editing a rule and choosing the **Log at Beginning of Connection** and **Log at End of Connection** options.

Procedure

Step 1 Log in to Security Cloud Control.
Step 2 From the left pane, click **Security Devices**.
Step 3 Click the **Devices** tab to view the device.
Step 4 Click the **FTD** tab to view FTD devices.
Step 5 Choose the FTD devices whose configurations you want to edit, from the **Security Devices** list.
Step 6 In the **Device Management** pane, click **Cloud Events**.
Step 7 Click the **Send Events to the Cisco Cloud** toggle button to enable or disable the configuration.
Step 8 Click **Save**.

View and Work with Events in Security Cloud Control

Procedure

Step 1 Log in to Security Cloud Control.
Step 2 From the Security Cloud Control menu, choose **Events & Logs** > **Events** > **Event Logging**.
Step 3 Use the **Historical** tab to view all historical events data. By default, the viewer displays this tab.
Step 4 To view the live events, click the **Live** tab.

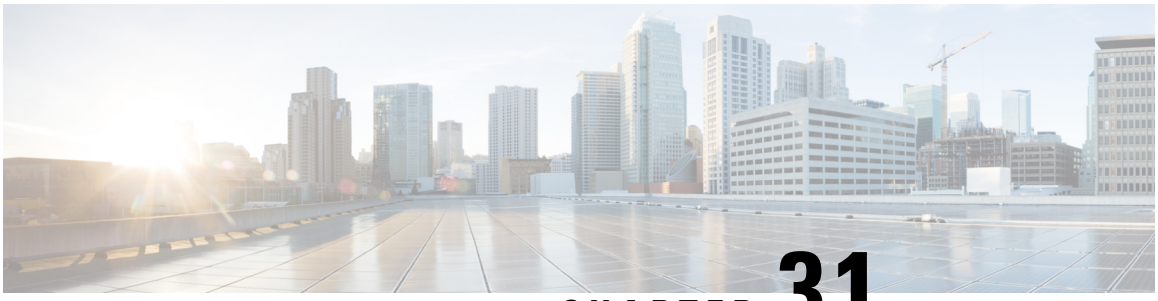
What to do next

For more information about what you can do on this page, see the Security Cloud Control online help.

View AI Defense Events in Security Cloud Control

AI Defense events record activities within your AI environment. They capture interactions such as prompts submitted, responses generated, and any triggered AI Defense policy violations. Each event includes key information, such as the application and AI model involved, the specific rule triggered, and the action taken.

Before you begin



- Enable the AI Defense service in your Security Cloud Control tenant. For information on enabling the AI Defense service, see the AI Defense User Guide.
- You must be managing Firewall Threat Defense devices with Version 10.0 or higher.
- Enable your Firewall Threat Defense device to send events to the cloud. For more information, see Send Cloud-Delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection, on page 555.

Procedure

Step 1 In the navigation pane, choose **Events & Logs** > **Events** > **Event Logging**.

Step 2 Click the filter icon ( ).

Step 3 Check the **AI Defense** check box.

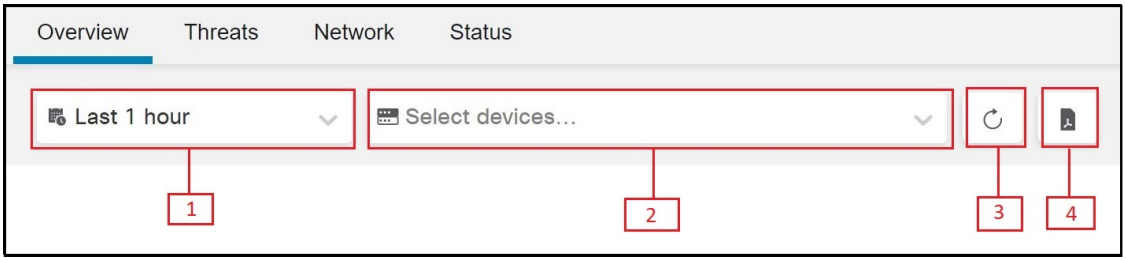
CHAPTER 31

FTD Dashboard

This chapter provides information about the FTD dashboard and describes the predefined widgets that offer an overview of your system.

- About the FTD Dashboard, on page 559
- View the FTD Dashboard, on page 560
- FTD Dashboard Widgets, on page 561
- Modify Time Settings for the FTD Dashboard, on page 564

About the FTD Dashboard



The FTD dashboard provides you an at-a-glance view of the status, including events data collected and generated by all Security Cloud Control-managed Firewall Threat Defense devices.

You can use this dashboard to view collective information that is related to the device status and the overall health of the devices in your deployment. The information that the FTD dashboard provides depends on how you license, configure, and deploy the devices in your system. Although, the FTD dashboard displays data for all Security Cloud Control-managed Firewall Threat Defense devices, you can choose to filter device-based data. You can also choose the time range to display for specific time range.

This dashboard uses tabs to display predefined widgets: small, self-contained components that provide insights into different aspects of the system. For example, the Network Activity widget shows you event graphs that display information about all connection, malware, and intrusion events. The widgets in the dashboard are predefined and cannot be customized. This dashboard is visible to all Security Cloud Control users who have access to a Security Cloud Control tenant.

- The dashboard does not displays any event statistics for historic events.
- Since the aggregation service batch processes the events to aggregate every five minutes, you can expect a five-minute latency between the time the events are aggregated to the time the statistics are displayed.

Figure 36: FTD Dashboard

Number	Description
1	Allows you to change the time range to reflect a period as short as the last hour or as long as the last year. When you change the time range, the widgets automatically update the events data to reflect the new time range.
2	Allows you to filter the events data based on selected devices. If no devices are selected, the widgets display all available events data.
3	Reinitiates the events data query
4	Displays the events data in a PDF output format. You can choose to download or save a copy of this PDF on your local machine.

View the FTD Dashboard

From the Security Cloud Control menu, choose **Insights & Reports** > **Firewall Threat Defense** > **Dashboard** to view the **FTD Dashboard**.

By default, the home page for your tenant displays the **Overview** tab.

The dashboard includes widgets that are listed under each tab: Threat, Network, Applications, and Status tab.

The following table lists the widgets available under each tab:

Name of the Tab	Available Widgets
Overview	All available widgets
Threat	• Top Intrusion Rules • Top Intrusion Attackers • Top Intrusion Targets • Top Malware Signatures • Top Malware Senders • Top Malware Receivers • Malware Events by Disposition

Name of the Tab	Available Widgets
Network	• Network Activity • Event Activity • Access Control Actions • Top Access Control Policies • Top Access Control Rules • Top Devices • Top Users • Top Users by Blocked Connections
Status	• Top Devices with Health Alerts • Top Loaded Devices
Applications	• Top Web Applications • Top Client Applications • Blocked Web Applications

FTD Dashboard Widgets

The FTD dashboard displays predefined widgets that can provide you with at-a-glance views of the current system status. These views include:

- Data about the events collected and generated by Firewall Threat Defense devices managed FMC.
- Information about the status and the overall health of the devices in your deployment.

Top Intrusion Rules Widget

The **Top Intrusion Rules** widget displays counts of the intrusion events that have occurred over the specified time range and are organized by priority. These counts include statistics on intrusion events with dropped packets and different impacts. The generated list is scrollable.

Top Intrusion Attackers Widget

The **Top Intrusion Attackers** widget displays counts of intrusion events for the top attacking host IP addresses (causing those events) on your monitored network.

Top Intrusion Targets Widget

The **Top Intrusion Targets** widget displays counts of intrusion events for the top target host IP addresses (targeted in the connections causing those events) on your monitored network.

Top Malware Signatures Widget

The **Top Malware Signatures** widget displays counts of the top malware signatures detected in the network traffic for top file-sending host IP addresses.

Top Malware Senders Widget

The **Top Malware Senders** widget displays counts of the top malware threats that are detected in the network traffic for top file-sending host IP addresses.

Top Malware Receivers Widget

The **Top Malware Receivers** widget displays counts of the top malware threats that are detected in the network traffic for all top file-receiving host IP addresses.

Malware Events by Disposition Widget

The **Malware Events by Disposition** widget displays counts of all disposition of malware events that are generated when the managed device detects a file containing malware.

Network Activity Widget

The **Network Activity** widget displays all ingress and egress data rate that is based on information from the connection events.

Event Activity Widget

The **Event Activity** widget displays counts of events that have occurred in the last hour and the total number of each event type that is available in the database.

Access Control Actions Widget

The **Access Control Actions** widget displays counts of events that are logged based on the allowed or blocked access control actions for each event. If you hover on the pie chart, you can view the percentage of the allowed and blocked actions.

Top Access Control Policies Widget

The **Top Access Control Policies** widget displays counts of top access control policies generating events.

Top Access Control Rules Widget

The **Top Access Control Rules** widget displays the top five counts of the access control rules that are used for each event. These counts can be sorted by bytes or events.

Top Devices Widget

The **Top Devices** widget displays counts of events per devices. These count can be sorted by bytes or events.

Top Users Widget

The **Top Users** widget displays a list of users on your monitored network that are associated with the highest intrusion event counts. It draws data primarily from the intrusion detection (IDS) User Statistics and Intrusion Events tables. It displays authoritative user data.

Top Users by Blocked Connections Widget

The **Top Users by Blocked Connections** widget displays users who have the highest number of blocked connection events associated with them in your monitored network.

Top Devices with Health Alerts Widget

The **Top Devices with Health Alerts** widget displays the current compiled health status for Security Cloud Control-managed Firewall Threat Defense devices.

Top Loaded Devices Widget

The **Top Loaded Devices** widget displays a list of Secure Firewall Threat Defense devices along with the CPU usage information.

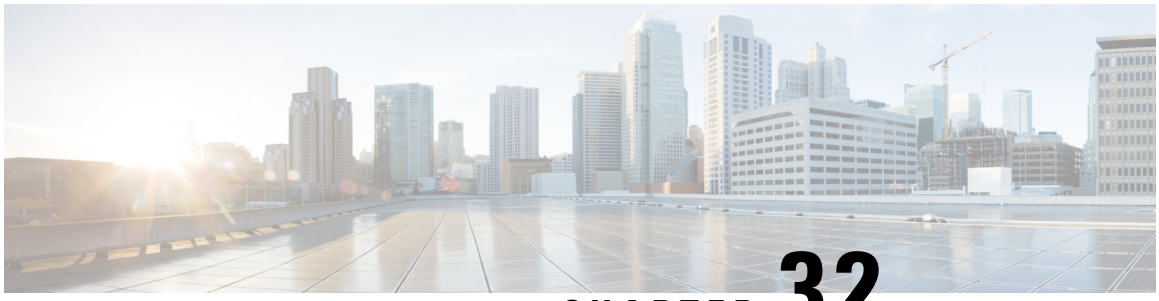
Top Web Applications Widget

The **Top Web Applications** widget displays the web applications that are associated with the highest number of connection events in your monitored network. You can sort this list based on bytes or event count.

Top Client Applications Widget

The **Top Client Applications** widget displays the most used client applications in your monitored network. You can sort this list based on bytes or event count.

Top Blocked Web Applications Widget



The **Top Web Applications** widget displays the top web applications that are associated with blocked connection events and the count of blocked connection events in your monitored network.

Modify Time Settings for the FTD Dashboard

You can change the time range to reflect a period as short as the last hour (the default) or as long as the last year. When you change the time range, the widgets that can be constrained by time automatically update to reflect the new time range.

The maximum number of data points in any graph is 300, and the time setting determines how much time is summarized within each data point. Following is the number of data points, and the time span covered, in the FTD dashboard for each time range:

- 1 hour = 12 data points, 5 minutes each
- 6 hours = 72 data points, 5 minutes each
- 1 day = 288 data points, 5 minutes each
- 1 week = 300 data points, 33.6 minutes each
- 2 weeks = 300 data points, 67.2 minutes each
- 30 days = 300 data points, 144 minutes each
- 90 days = 300 data points, 432 minutes each
- 180 days = 300 data points, 864 minutes each
- 1 year = 300 data points, 1752 minutes each

CHAPTER 32

Connection Logging

The following topics describe how to configure the system to log connections made by hosts on your monitored network:

- Connection logging, on page 565
- Connection logging limitations, on page 574
- Best practices for connection logging, on page 574
- Requirements and prerequisites for connection logging, on page 576
- Connection logging, on page 576
- Application-aware and protocol-aware syslogs, on page 581

Connection logging

Connection logging is a system feature that

- generates logs of connections detected by managed devices known as *connection events*,
- provides granular control through rules and policies over which connections to log, when to log them, and where to store the data, and
- creates special connection events called *security-related connection events* that represent connections blocked by the reputation-based Security Intelligence feature.

Connection event data

Connection events contain data about the detected sessions. The specific data available for any event can vary, but generally includes:

- Basic connection properties: timestamp, source and destination IP address, ingress and egress zones, the device that handled the connection, and so on
- Additional connection properties discovered or inferred by the system: applications, requested URLs, or users associated with the connection, and so on
- Metadata about why the connection was logged: which configuration handled the traffic, whether the connection was allowed or blocked, details about encrypted and decrypted connections, and so on

Log connections according to the security and compliance needs of your organization. When setting up connection logging, remember that the system can log a connection for multiple reasons. Disabling logging in one place does not guarantee that matching connections will not get logged elsewhere.

The information contained in a connection event depends on factors such as traffic characteristics and relevant configuration.

Note You can supplement the connection logs gathered by your managed devices with connection data generated from exported NetFlow records. This is particularly useful if you have NetFlow-enabled routers or other devices monitoring networks that managed devices cannot access.

Logged connections

Logged connections are network connections that

- are automatically saved to the Cloud-Delivered Firewall Management Center database as end-of-connection events,
- generate logs regardless of other logging configurations unless connection event storage is disabled, and
- include connections associated with intrusions, file and malware events, intelligent application bypass, and monitored traffic.

Connection types and logging behavior

The system automatically logs specific connection types based on their association with security events and traffic monitoring.

Connection types that generate automatic logs:

- Connections associated with intrusions: The system automatically logs connections associated with intrusion events, unless the connection is handled by the access control policy's default action.
- Connections associated with file and malware events: The system automatically logs connections associated with file and malware events.
- Connections associated with intelligent application bypass: The system automatically logs bypassed and would-have-bypassed connections associated with IAB.
- Monitored connections: The system always logs the ends of connections for monitored traffic, even if the traffic matches no other rules and you do not enable default action logging.

Note File events generated by inspecting NetBIOS-SSN (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.

Special behavior for default action connections:

- When an intrusion policy associated with the access control default action generates an intrusion event, the system does *not* automatically log the end of the associated connection. Instead, you must explicitly enable default action connection logging.
- However, if you enable beginning-of-connection logging for the default action, the system *does* log the end of the connection when an associated intrusion policy triggers, in addition to logging the beginning of the connection.

For more information about monitored connections, refer to Logging for monitored connections, on page 568.

Other Connections You Can Log

So that you log only critical connections, enable connection logging on a per-rule basis. If you enable connection logging for a rule, the system logs all connections handled by that rule.

You can also log connections handled by policy default actions. Depending on the rule or default action (and for access control, a rule's inspection configuration), your logging options differ.

Prefilter Policy: Rules and Default Action

You can log connections (including entire plaintext, passthrough tunnels) that you fastpath or block with a prefilter policy.

Prefiltering uses outer-header criteria to handle traffic. For tunnels that you log, the resulting connection events contain information from the outer, encapsulation headers.

For traffic subject to further analysis, logging in the prefilter policy is disabled, although matching connections may still be logged by other configurations. The system performs all further analysis using inner headers, that is, the system independently handles and logs each connection within an allowed tunnel.

Decryption Policy: Rules and Default Action

You can log connections that match a decryption rule or decryption policy default action.

For blocked connections, the system immediately ends the session and generates an event. For monitored connections and connections that you pass to access control rules, the system generates an event when the session ends.

Access Control Policy: Security Intelligence Decisions

You can log a connection whenever it is blocked by the reputation-based Security Intelligence feature.

Optionally, and recommended in passive deployments, you can use a monitor-only setting for Security Intelligence filtering. This allows the system to further analyze connections that would have been blocked by Security Intelligence, but still log the match. Security Intelligence monitoring also allows you to create traffic profiles using Security Intelligence information.

When the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately, and that is also stored and pruned separately. So that you can identify the matching IP address in the connection, host icons beside blocked and monitored IP addresses look slightly different in the tables on the pages under the **Analysis** > **Connections** > **Events** menus.

Access Control Policy: Rules and Default Action

You can log connections that match an access control rule or access control policy default action.

Related Topics

Rules and policy actions effect on logging, on page 568

Rules and policy actions effect on logging

Rules and policy actions effect on logging is a traffic handling mechanism that

- determines how the system inspects and handles matching traffic,
- controls when and how details about matching traffic can be logged, and
- provides metadata about why the connection was logged, including which configurations handled the traffic.

Connection event metadata

Connection events contain metadata about why the connection was logged, including which configurations handled the traffic. Where you can configure connection logging, rule actions, and policy default actions determine not only how the system inspects and handles matching traffic, but also when and how you can log details about matching traffic.

Logging for fastpathed connections

Logging for fastpathed connections is a monitoring capability that

- records connection events for traffic that matches tunnel rules and prefilter rules with **Fastpath** actions,
- captures information for non-encrypted tunnels including outer session details for tunnel rules, and
- provides limited information in connection events since fastpathed traffic bypasses access control and QoS processing.

Supported traffic types

You can log fastpathed connections and non-encrypted tunnels, which include traffic matching these rules and actions in the prefilter policy:

- Tunnel rules—**Fastpath** action (logs the outer session)
- Prefilter rules—**Fastpath** action

Fastpathed traffic bypasses the rest of access control and QoS, so connection events for fastpathed connections contain limited information.

Logging for monitored connections

Logging for monitored connections is a system function that

- automatically logs connection ends for traffic matching specific monitoring configurations,
- operates independently of default action logging settings, and

- consolidates multiple Monitor rule matches into single connection events.

Monitored traffic configurations

The system always logs the ends of connections for traffic matching these configurations, even if the traffic matches no other rules and you do not enable default action logging:

- Security Intelligence: Block lists set to monitor (also generates a Security Intelligence event)
- SSL rules: **Monitor** action
- Access control rules: **Monitor** action

The system does not generate a separate event each time a single connection matches a Monitor rule. Because a single connection can match multiple Monitor rules, each connection event can include and display information on the first eight Monitor access control rules that the connection matches, as well as the first matching SSL Monitor rule.

Similarly, if you send connection events to an external syslog or SNMP trap server, the system does not send a separate alert each time a single connection matches a Monitor rule. Rather, the alert that the system sends at the end of the connection contains information on the Monitor rules the connection matched.

Logging for trusted connections

Logging for trusted connections is a system capability that

- records the beginnings and ends of trusted connections for traffic matching access control rules with **Trust** action
- captures events for traffic matching the access control default action **Trust All Traffic**, and
- generates limited information because trusted connections are not subject to deep inspection or discovery.

Trusted connection logging behavior

You can log the beginnings and ends of trusted connections, which include traffic matching these rules and actions:

- Access control rules: **Trust** action
- Access control default action: **Trust All Traffic**

Note Although you *can* log trusted connections, we recommend you do not do so because trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

TCP connections detected by a Trust rule on the first packet generate only an end-of-connection event. The system generates the event one hour after the final session packet.

Logging for blocked connections

Logging for blocked connections is a security feature that

- records traffic matching blocking rules and actions across multiple policy types,
- generates connection events with different timing based on the blocking mechanism, and
- provides visibility into denied traffic for security monitoring and analysis.

Blocked connection types

You can log blocked connections, which include traffic matching these rules and actions:

- Tunnel rules—**Block**
- Prefilter rules—**Block**
- Prefilter default action—**Block all tunnel traffic**
- Security Intelligence—Block lists not set to Monitor (also generates a Security Intelligence event)
- Decryption rules—**Block** and **Block with reset**
- SSL default action—**Block** and **Block with reset**
- Access control rules—**Block**, **Block with reset**, and **Interactive Block**
- Access control default action—**Block All Traffic**

Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Caution Firewall Threat Defense device logs end-of-connection events for TCP connections where the three-way handshake does not complete, including SYN-only, SYN-SYN/ACK (no ACK), and SYN-RST/ACK scenarios (except when TLS Identity is enabled). These logs provide visibility into incomplete or suspicious connection attempts. However, logging blocked TCP connections during a Denial of Service (DoS) attack can affect system performance and overwhelm the database with multiple similar events. Before you enable logging for a Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

Beginning vs. end-of-connection logging for blocked connections

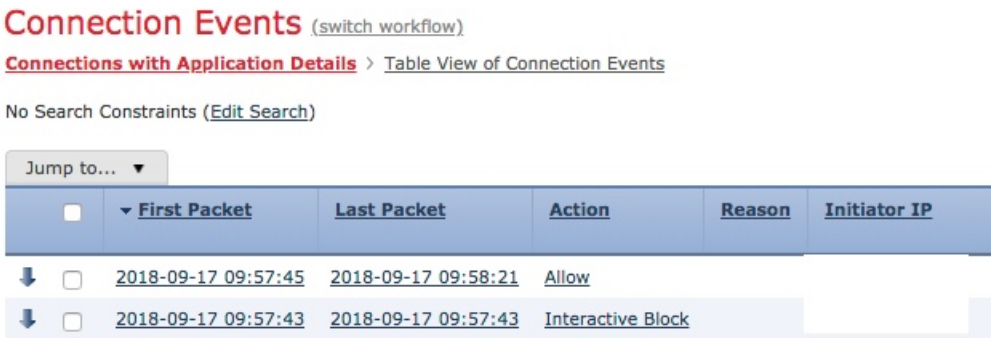
When you log a blocked connection, how the system logs it depends on why the connection was blocked. This is important to keep in mind when configuring correlation rules based on connection logs:

- For decryption rules and decryption policy default actions that block encrypted traffic, the system logs **end**-of-connection events. This is because the system cannot determine if a connection is encrypted using the first packet in the session.
- For other blocking actions, the system logs **beginning**-of-connection events. Matching traffic is denied without further inspection.

Logging bypassed interactive blocks

Interactive blocking access control rules, which cause the system to display a warning page when a user browses to a prohibited website, allow you to configure end-of-connection logging. This is because if the user

clicks through the warning page, the connection is considered a new, allowed connection which the system can monitor and log.



Therefore, for packets that match an Interactive Block or Interactive Block with Reset rule, the system can generate these connection events:

- A beginning-of-connection event when a user's request is initially blocked and the warning page is displayed; this event has an associated action of **Interactive Block** or **Interactive Block with Reset**
- Multiple beginning- or end-of-connection events if the user clicks through the warning page and loads the originally requested page; these events have an associated action of **Allow** and a reason of **User Bypass**

Interactive block example

The following figure shows an example of an interactive block followed by allow.

Figure 37: Interactive block followed by allow

Logging for allowed connections

Logging for allowed connections is a security feature that

- generates file and malware events when file policies detect or block files during traffic inspection, and
- provides configurable logging options on a per-access-control-rule basis.

Connection logging details

You can log allowed connections, which includes traffic matching the following rules and actions:

- SSL rules—**Decrypt** action
- SSL rules—**Do not decrypt** action
- SSL default action—**Do not decrypt**
- Access control rules—**Allow** action
- Access control default action—**Network Discovery Only** and any intrusion prevention option

Enabling logging for these configurations ensures the connection is logged, while also permitting (or specifying) the next phase of inspection and traffic handling. SSL logging is always end-of-connection; access control configurations also allow beginning-of-connection logging.

Although the **Analyze** action in tunnel and prefilter rules also allows connections to continue with access control, logging is disabled for rules with this action. Matching connections may still be logged by other configurations. Allowed tunnels might have their encapsulated sessions evaluated and logged individually.

When you allow traffic with an access control rule or default action, you can use an associated intrusion policy to further inspect traffic and block intrusions. For access control rules, you can also use a file policy to detect and block prohibited files, including malware. Unless you disable connection event storage, the system automatically logs most allowed connections associated with intrusion, file, and malware events. For detailed information, refer to Logged connections, on page 566.

Connections with encrypted payloads are not subject to deep inspection, so connection events for encrypted connections contain limited information.

When a file policy detects or blocks a file, it logs one of these events to the Cloud-Delivered Firewall Management Center database:

- *File events*, which represent detected or blocked files, including malware files.
- *Malware events*, which represent detected or blocked malware files only.
- *Retrospective malware events*, which are generated when the malware disposition for a previously detected file changes.

You can disable this logging on a per-access-control-rule basis. You can also disable file and malware event storage entirely.

Note We recommend you leave file and malware event logging enabled.

Connection logging modes

A connection logging mode is a connection monitoring approach that

- provides two distinct timing options for capturing connection events,
- handles blocked traffic differently than allowed traffic, and
- requires optimization choices to balance performance with information completeness.

Connection logging timing and exceptions

You can log a connection at its beginning or its end, with specific exceptions for blocked traffic:

- Blocked traffic: Because blocked traffic is immediately denied without further inspection, only beginning-of-connection events are typically available for logging; there is no unique end-of-connection to log.
- Blocked encrypted traffic: When you enable connection logging in a decryption policy, the system logs end-of-connection rather than beginning-of-connection events. This occurs because the system cannot

determine if a connection is encrypted with the first packet and therefore cannot immediately block encrypted sessions.

To optimize performance, log either the beginning or the end of any connection, but not both. Monitoring a connection for any reason forces end-of-connection logging. For a single non-blocked connection, the end-of-connection event contains all information present in the beginning-of-connection event, as well as data gathered over the duration of the session.

The table presents differences between beginning and end-of-connection events, along with the advantages of logging each.

Table 39: Comparing beginning and end-of-connection events

Attributes	Beginning-of-Connection Events	End-of-Connection Events
Can be generated...	When the system detects the beginning of a connection (or, after the first few packets if event generation depends on application or URL identification).	When the system: • Detects the close of a connection. • Does not detect the end of a connection after a period of time. • Can no longer track the session due to memory constraints.
Can be logged for...	All connections except those blocked by the decryption policy.	Most connections.
Contain...	Only information that can be determined in the first packet (or the first few packets, if event generation depends on application or URL identification).	All information in the beginning-of-connection event, plus information determined by examining traffic over the duration of the session; for example, the total amount of data transmitted or the timestamp of the last packet in the connection. **Note** The connection event does not count the amount of data transmitted after the threat defense returns a snort verdict for the connection or if you fastpath the connection.
Are useful...	If you want to log: • Blocked connections. • Only the beginning of a connection because the end-of-connection information does not matter to you.	If you want to: • Log encrypted connections handled by a decryption policy. • Perform any kind of detailed analysis on, or trigger correlation rules using, information collected over the duration of the session. • View connection summaries (aggregated connection data) in custom workflows, view connection data in graphical format, or create and use traffic profiles.

Connection logging limitations

Connection logging limitations are restrictions that prevent certain types of network connections from being logged by firewall systems.

Connection types that cannot be logged

Connection logging cannot capture information for these connection types:

- The outer session of a plaintext, passthrough tunnel whose encapsulated connections are inspected by access control.
- TCP connections if the three-way handshake is not completed, to avoid denial-of-service attacks against your firewalls. To monitor or debug failed connections, you can use the packet capture feature (Packet capture, on page 440).

Best practices for connection logging

Best practices for connection logging are guidelines that

- ensure you log only critical connections by enabling connection logging on a per-access-control-rule basis,
- help avoid logging unnecessary traffic such as trusted connections or infrastructure traffic not related to your service offering, and
- optimize storage and performance by preventing duplicate logging and configuring appropriate event limits.

Connections that are always logged

The system automatically logs these connections:

- Some connections associated with detected files, malware, intrusions, and Intelligent Application Bypass (IAB).

  For more information, refer to Logged connections, on page 566.

- Monitored connections.

  For more information, refer to Logging for monitored connections, on page 568.

Connections to never log

Do not enable logging for the following:

- Access control rules with a Trust action.

  Trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

- Do not enable logging for Block rules in passive deployments. To log connections that the system would have blocked if your devices were deployed inline, use a Monitor rule instead of a Block rule.

Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

- Traffic you're not interested in. Examples follow:
  - Specific allowed traffic, such as DNS requests to a trusted DNS host.
  - Infrastructure traffic that is not related to your service offering.

(As previously mentioned, you can still monitor this traffic for threats.)

As discussed in Logged connections, on page 566, even if you disable logging for the preceding, intrusion events, malware, and IAB are still logged.

Avoid logging what is being logged elsewhere

If another device or service is logging connection data for a network segment, disable logging for that segment's data in the Cloud-Delivered Firewall Management Center. Examples:

- If a router logs connection events on the same network segment as the Cloud-Delivered Firewall Management Center, avoid logging the same connections on the Cloud-Delivered Firewall Management Center unless you need those connection events for something else, such as correlation policies or traffic profiles.
- If you use Secure Network Analytics to leverage NetFlow records reported from switches and routers to identify potential behavioral anomalies and suspicious traffic patterns, you can disable connection logging for rules monitoring those segments and instead rely on Secure Network Analytics for behavioral analytics for those parts of your network.

  For more information, consult the Secure Network Analytics documentation.

Log either the beginning or end of the connection (not both)

If you have a choice between beginning and end-of-connection logging, enable end-of-connection logging. This is because end-of-connection logs information from beginning-of-connection events, as well as information gathered over the duration of the session.

Log the beginning of connections only if you want to log blocked connections, or if end-of-connection information does not matter to you.

For more information, refer to Connection logging modes, on page 572.

Logging for blocked traffic

Because blocked traffic is immediately denied without further inspection, usually you can log only beginning-of-connection events.

For more information, refer to Logging for blocked connections, on page 569.

Log events to an external location

If your company's security policy permits it, you can save disk space on your Cloud-Delivered Firewall Management Center by streaming logs to an external source using any of the following:

- eStreamer, which enables you to stream logs from a Cloud-Delivered Firewall Management Center to a custom-developed client application. For more information, refer to the *Secure Firewall Management Center Event Streamer Integration Guide* .
- Syslog or SNMP trap are referred to as alert responses. For more information, refer to Configuring external alerts with alert responses, on page 487.

Control what is displayed in connection events

To specify the number of rows displayed in connection events, click your username in the upper right of the Cloud-Delivered Firewall Management Center, click **User Preferences**, and then click the **Event View Settings**tab. The maximum you can set is 1000 events per page.

Requirements and prerequisites for connection logging

This reference provides the technical requirements and prerequisites that must be met to implement and use connection logging features.

Model support

Any.

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Connection logging

Connection logging is a network monitoring feature that records network connection activities to match various rules and conditions.

Logging connections with tunnel and prefilter rules

This task enables logging for prefilter policy rules to monitor and analyze connection events for troubleshooting and security analysis purposes.

The prefilter policy applies to Secure Firewall Threat Defense devices only.

Before you begin

- Set the rule action to **Block** or **Fastpath**. Logging is disabled for the **Analyze** action, which allows connections to continue with access control, where other configurations determine their handling and logging.
- Logging is performed on inner flows, not on the encapsulating flow.

Follow these steps to configure logging for tunnel and prefilter rules:

Procedure

Step 1 In the prefilter policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**.

To optimize performance, log either the beginning or the end of any connection, but not both. Because blocked traffic is immediately denied without further inspection, you cannot log end-of-connection events for Block rules.

Step 4 Specify where to send connection events:

Step 5 Click **Save** to save the rule.

Step 6 Click **Save** to save the prefilter policy.

What to do next

Deploy configuration changes.

Configure logging for decryptable connections with TLS/SSLDecryption rules

Logging decryptable connections allows you to track and analyze traffic that is being monitored by decryption rules. This is particularly important for security analysis and compliance requirements.

Procedure

Step 1 In the decryption policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Check the **Log at End of Connection** check box.

For monitored traffic, end-of-connection logging is required.

Step 4 Specify where to send connection events.

Send events to the event viewer if you want to perform Cloud-Delivered Firewall Management Center-based analysis on these connection events. For monitored traffic, this is required.

Step 5 Click **Save** to save the rule.

Step 6 Click **Save** to save the decryption policy.

What to do next

Deploy configuration changes.

Logging connections with security intelligence

Enable Security Intelligence logging to monitor and analyze network connections, IP addresses, URLs, and domain names for security threats and policy compliance.

The Security Intelligence policy requires the Threat Smart License or Protection Classic License.

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**.

Step 2 Click the **Logging** ( ) icon to enable Security Intelligence logging using the following criteria:

- By IP address: Click the logging icon next to **Networks**.
- By URL: Click the logging icon next to **URLs**.
- By Domain Name: Click the logging icon next to the **DNS Policy** drop-down list.

If the logging icon is disabled, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Check the **Log Connections** check box.

Step 4 Specify where to send connection and Security-Related connection events.

Send events to the Security Cloud Control if you want to perform Security Cloud Control-based analysis, or if you set a Block list to monitor-only.

Step 5 Click **OK** to set logging options.

Step 6 Click **Save** to save the policy.

What to do next

Deploy configuration changes.

Logging connections with access control rules

Depending on your choices for the rule action and deep inspection options, your logging options differ; refer to Rules and policy actions effect on logging, on page 568.

Procedure

Step 1 In the access control policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**.

To optimize performance, log either the beginning or the end of any connection, but not both.

Step 4 (Optional) Check the **Log Files** check box to log file and malware events associated with the connection.

It is recommended to leave this option enabled.

Step 5 Specify where to send the connection events:

- **Event Viewers**: Send events to the Cloud-Delivered Firewall Management Center. When using cloud management, send events to the cloud-delivered Cloud-Delivered Firewall Management Center and to an on-premises Cloud-Delivered Firewall Management Center if you have configured it to perform event analytics only. You can view the events in the event viewer of either product.
- **Syslog Server**: Send connection events to the syslog server configured in the Logging tab in Access Control Policy, unless overridden.

  Show Overrides: Displays the options to override the settings configured in the access control policy.

  - **Override Severity**: When you choose this option and select a severity for the rule, connection events for this rule will have the selected severity regardless of the severity configured in the Logging tab in Access Control Policy.
  - **Override Default Syslog Destination**: Send the syslog generated for the connection event for this rule to destination specified in this alert.

- **SNMP Trap**: Connection events are sent to the selected SNMP trap.

Step 6 Click **Confirm**.

Step 7 Click **Apply** to save the rule.

What to do next

Deploy configuration changes.

Logging connections with a policy default action

A policy's default action determines how the system handles traffic that matches none of the rules in the policy (except Monitor rules in access control and decryption policies, which match and log—but do not handle or inspect—traffic).

Logging settings for the decryption policies default action also govern how the system logs undecryptable sessions.

Before you begin

For prefilter default action logging, set the default action to **Block all tunnel traffic**. Logging is disabled for the **Allow all tunnel traffic** action, which allows connections to continue with access control, where other configurations determine their handling and logging.

Procedure

Step 1 In the policy editor, click the **Default Logging and Inspection** ⚙ next to the **Default Action** drop-down list.

Step 2 Specify when you want to log matching connections:

- Log at Beginning of Connection: Not supported for SSL default actions.
- Log at End of Connection: Not supported if you choose the access control **Block All Traffic** default action or the prefilter **Block all tunnel traffic** default action.

To optimize performance, log either the beginning or the end of any connection, but not both.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. In an access control policy, the configuration may also be inherited from an ancestor policy.

Step 3 Specify where to send connection events.

Send events to the event viewer if you want to perform Cloud-Delivered Firewall Management Center-based analysis on these connection events.

Step 4 Click **Apply**.

Step 5 Click **Save** to save the policy.

What to do next

Deploy configuration changes.

Limiting logging of long URLs

End-of-connection events for HTTP traffic record the URL requested by monitored hosts. Disabling or limiting the number of stored URL characters may improve system performance. Disabling URL logging (storing zero characters) does not affect URL filtering. The system filters traffic based on requested URLs even though the system does not record them.

Procedure

Step 1 In the access control policy editor, click **More** > **Advanced Settings**, then click **Edit** (✎) next to **General Settings**.

If **View** (👁) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Enter the **Maximum URL characters to store in connection events**.

Step 3 Click **OK**.

Step 4 Click **Save** to save the policy.

What to do next

Deploy configuration changes.

Application-aware and protocol-aware syslogs

Application-aware and protocol-aware syslogs are a logging mechanism that

- generate logs that include application-specific and protocol-specific traffic data,
- provide enhanced network visibility through comprehensive data collection, and
- use the Snort 3 engine's deep packet inspection capabilities to extract protocol data.

Advanced logging protocols

The Firewall Threat Defense device generates these logs alongside existing connection, intrusion, file, and malware events. As syslogs, you can send these logs to external event management solutions for analysis. When enabled, advanced logging provides a configurable solution for sending these logs from the Firewall Threat Defense device to destination such as Splunk or a syslog alert server.

Advanced logging supports these protocols.

Table 40: Protocols supported by advanced logging

Protocol	Description
CONN	Logs the data collected from end-of-connection events, including the transport protocol, service protocol, and session duration.
DNS	Logs the data collected from responses to TCP and UDP DNS sessions, including commands, their arguments, response codes, and response messages.

Protocol	Description
FTP	Logs the commands and data exchanged during an FTP session, including the command and its arguments, response codes, and response messages.
HTTP	Logs the data collected from the HTTP responses, including the HTTP method, header, and status code.
NOTICE	Logs the data collected for intrusion events, including the GID:SID pair, rule messages, and associated references.
WEIRD	Logs the data about anomalies detected in traffic flow.

For more information about application log fields, refer to Advanced Logging Syslog Fields, on page 587.

Advanced logging guidelines and limitations

Advanced logging guidelines and limitations are operational constraints and performance considerations that

- affect network performance when configured without proper filtering,
- require selective configuration to avoid device memory consumption issues, and
- have specific platform and version requirements for support.

Advanced logging restrictions and requirements

Consider these guidelines when implementing advanced logging:

- Advanced logging can degrade network performance if used without filters in the access control rule. To reduce the volume of logs, use access control rules to filter specific traffic types and use networks and ports to limit logging to a particular network configuration.
- Enabling advanced logging for all protocols can impact the Firewall Threat Defense device's performance. Configure advanced logging selectively to avoid increased device memory consumption.
- Advanced logging is supported only on Snort 3-based Firewall Threat Defense devices running Version 10.0 or later.
- Advanced logging does not support sending logs to a syslog server configured in the platform settings. To send events to the default logging destination configured in the access control policy, you must configure a syslog alert server as the default logging destination.
- Advanced logging does not support Splunk profiles that use data interfaces for sending events to Splunk. To send events to Splunk, you must configure the Splunk profile to use the management interface for sending events. For more information about configuring a Splunk profile, refer to Splunk integration: Send events directly from Cloud-Delivered Firewall Management Center , on page 527.

Enable advanced logging

Configure the Firewall Threat Defense device to generate Snort 3 inspector logs that include application-specific and protocol-specific data and send these logs to event management solutions for analysis.

Caution Advanced logging might cause a performance drop within the network if used without the filters configured in the access control rule. Filter the specific traffic types using the access control rules to reduce the volume of logged traffic. Use the networks and ports in the access control rules to limit logging to a particular network configuration.

Before you begin

- Ensure that connection logging is enabled in your access control policy.
- Ensure that you have configured the logging destination, such as Splunk or the local syslog server, to which you want to send the logs.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy that you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 In the access control policy editor, select **Advanced Settings** from the **More** drop-down menu at the end of the packet flow line.

Step 4 Click the **Edit** ( ) icon next to **Advanced Logging**.

Step 5 Check the **Enable advanced logging** check box to enable logging.

Step 6 Choose the log file format. By default, JSON format is selected.

Step 7 You can send event logs to the default logging destination configured in the access control policy's logging settings, or to one or more of the following destinations:

- **All Splunk profiles**
- **Syslog**

Note

- If you choose to send event logs to the default logging destination configured in the access control policy, note that advanced logging does not support sending logs to the syslog server configured in the platform settings. You must configure a syslog alert server as the default logging destination.
- If you choose the **All Splunk profiles** option, note that advanced logs are sent to all Splunk profiles configured for a Firewall Threat Defense device.
- Advanced logging does not support Splunk profiles that use data interfaces for sending events to Splunk. To send events to Splunk, you must configure the Splunk profiles to use the management interface for sending events.

Caution

Sending advanced logging syslog to multiple destinations might impact device's performance.

Step 8 Click **Save**.

Step 9 Click **Save** to save the policy.

What to do next

Deploy configuration changes.

Configure protocols for advanced logging

Advanced logging for application protocols allows you to monitor and analyze network connections by capturing detailed information about specific application protocols. This feature is configured at the access control policy level and can be applied to individual rules within the policy.

Before you begin

Ensure that you have enabled the advanced logging feature for the access control policy that you want to modify.

Follow these steps to configure protocols for advanced logging:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 In the access control policy editor, you have the options to add a new rule or edit an existing rule.

- To add a new rule, click **Add Rule**.
- To edit an existing rule, click **Edit** ( ).

Step 4 Click **Advanced Logging**.

Step 5 Check the check box next to the application protocol for which you want to log the connection.

Caution
Enabling logging for all the protocols in a Firewall Threat Defense device might affect its performance, because the device must extract data, convert it to targeted formatting, and send it to the configured destination.

Step 6 Click **Confirm**.

Step 7 Click **Apply** to save the rule.

Step 8 Click **Save** to save the policy.

What to do next

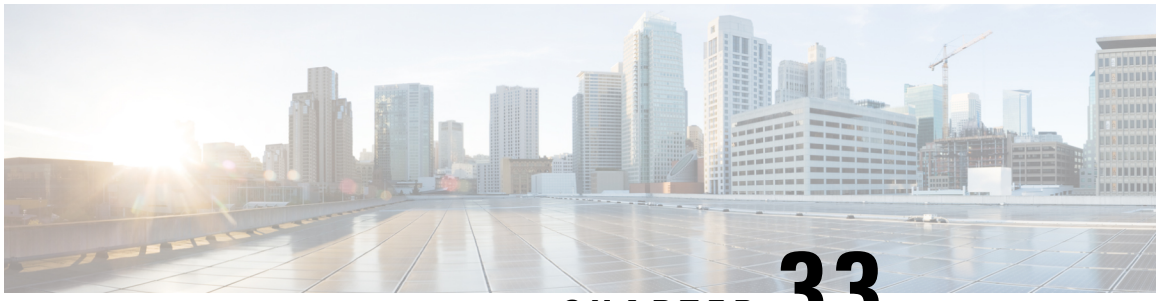
Deploy configuration changes.

Monitor and troubleshoot advanced logging

To collect statistics of the advanced logging events and to get health alerts, you must enable the **Snort 3 Statistics** module in your Firewall Threat Defense device's health policy (**System** (⚙) > **Health** > **Policy**). When enabled, you can monitor metrics such as the number of advanced logging events that are dropped, failed to send, or sent successfully.

To view these health metrics, navigate to **System** (⚙) > **Health** > **Monitor** and then add the metrics to a dashboard by selecting them from the **Snort 3 Performance Statistics** group.

Advanced Logging events failed to transmit to syslog servers



This alert appears when the syslog messages fail to transmit due to a connection issue with the syslog server or a configuration error.

- Check the status of your syslog server to ensure it is operational and accessible.
- Verify the syslog configuration within the Cloud-Delivered Firewall Management Center for any errors.

Advanced logging events to syslog servers were dropped

This alert appears when syslog messages are dropped due to memory overflow in the Firewall Threat Defense device, suggesting that the device cannot process logs at the current rate.

Review your advanced logging configuration. Consider applying more granular filters in your access control rules to reduce the volume of logs generated, or selectively enable advanced logging for fewer protocols, to decrease device memory consumption. For more information, refer to Advanced logging guidelines and limitations, on page 582.

CHAPTER 33

Advanced Logging Syslog Fields

Advanced logs are generated and sent as syslog messages to the configured destinations for consumption by an external tool. The syslog fields for all advanced logging protocols are detailed here.

- Common fields, on page 587
- CONN protocol fields, on page 588
- DNS protocol fields, on page 589
- FTP fields, on page 590
- HTTP fields, on page 591
- Notice protocol fields, on page 592
- Weird protocol fields, on page 592

Common fields

These fields appear in the syslog message across all protocols:

Table 41: HTTP fields

Field	Description
id.orig_h	The client IP address involved in a connection.
id.orig_p	The client TCP or UDP port used for a connection.
id.resp_h	The server IP address involved in a connection.
id.resp_p	The server TCP or UDP port used for a connection.
pkt_num	The packet number within a network flow.
tenant_id	The identifier for a tenant associated with an event.
ts	The timestamp of the packet that triggered the log record shows when the event occurred.
uid	A unique connection ID that enables you to correlate log records related to the same network flow.

CONN protocol fields

Conn protocol fields capture various aspects of network connections, including state, duration, event history, byte counts, packet counts, transport protocol, and application service information.

Fields available in the CONN protocol for connection analysis:

Field	Description
conn_state	Captures the state of the connection based on the protocol in use. • **UDP**: States include CLT_SRV_UDP_SEEN (packets from both client and server observed), CLT_UDP_SEEN (only client packets observed), and SRV_UDP_SEEN (only server packets observed). • **TCP**: Tracks the client and server states independently using prefixes CLT_ (client) and SRV_ (server), reflecting the TCP STATE machine per RFC standards, with additional states for MID-STREAM activity (TCP_MID_STREAM_SENT, TCP_MID_STREAM_REC) and TCP_STATE_NONE. • **Other traffic**: Indicates non-UDP and non-TCP traffic or error cases.
duration	The duration of the connection, in seconds.

history	A code that indicates the event sequence of the connection.
	Each letter in the history code represents a specific event. Uppercase letters indicate client-side events, and lowercase letters indicate server-side events. Events are recorded only once per direction.
	• For UDP, events include: `d` (packet with payload).
	• For TCP, events include:
	  • `s` (SYN)
	  • `h` (SYN-ACK)
	  • `a` (pure ACK or PUSH)
	  • `d` (packet with payload)
	  • `f` (FIN)
	  • `r` (reset)

orig_bytes	The total number of TCP or UDP payload bytes transmitted by the client during the connection.
orig_pkts	The number of packets sent by the originator.
proto	The transport layer protocol of a connection, for example, IP, ICMP, TCP, or UDP.

Field	Description
resp_bytes	The total number of TCP or UDP payload bytes transmitted by the server during the connection.
resp_pkts	The number of packets sent by the responder.
service	A connection's application protocol. This value indicates the last detected service on the traffic flow.

DNS protocol fields

This reference provides detailed information about DNS protocol fields, including boolean values, resource records, transport protocols, and various identifiers used in DNS transactions.

DNS protocol fields contain specific data elements that define the behavior and content of DNS transactions:

Field	Description
AA	A boolean value that indicates whether this value is an authoritative answer (AA) to a query. For example, T or F.
addl	The list of additional responses. This list contains all the resource records (RR) found in the **addl** section. The resource record types are handled in the same way as for the **answers** field.
answers	A list of resource records that directly answer a DNS query. Each resource record provides specific information about a domain. This may include its IP address, mail server, or other properties, depending on the type of query. All resource records appear in the answers section of a DNS response. The decoding process represents each resource record by summarizing its contents. Each resource record type has specific decoding rules, depending on the type of information it represents. The following resource record types contains type-specific information when decoded—A, AAAA, BIND9 signing, CNAME, DNSKEY, DS, LOC, MX, NS, NSEC, OPT, PTR, RRSIG, SOA, SPF, SRV, SSHFP, TXT. All other resource record types are decoded by the default decoder. If the resource record type is not known or not specifically handled, it is displayed as UNKNOWN followed by the resource record type numeric value.
auth	The list of authoritative responses. This list contains all the resource records found in the **auth** section. The resource record types are handled the same way as those for the **answers** field.
proto	The transport protocol used for the DNS connection, TCP or UDP.
qclass	A 16-bit integer specifying the class of a DNS query.
qclass_name	A descriptive name for the class of a DNS query.
qtype	A 16-bit integer specifying the type of a DNS query.
qtype_name	A descriptive name for the type of a DNS query.

Field	Description
query	The domain name that is the subject of a DNS transaction.
RA	A boolean value indicating the availability of recursive query support in a server, for example, T or F.
rcode	A 16-bit integer specifying the response code to a DNS query.
rcode_name	A descriptive name for the response code to a DNS query.
RD	A boolean value indicating whether a client asked the server to pursue the query recursively, for example, T or F.
rejected	A boolean value indicating whether the server responded with an error code and no query, for example, T or F.
TC	A boolean value indicating whether a message was truncated because of UDP PDU size limits, for example, T or F.
trans_id	A 16-bit identifier assigned to a DNS query.
TTLs	The list of caching intervals for the corresponding answers. The values in the list are separated by an empty space.
Z	A 3-bit integer set to 0 unless Domain Name System Security Extensions (DNSSEC) is used.

Values in the list are separated by an empty space.

FTP fields

FTP protocol analysis relies on specific fields that capture essential command parameters, data channel information, file transfers, and server responses. Understanding these fields enables accurate interpretation of FTP activity and troubleshooting.

The following fields are commonly used during FTP protocol analysis:

Field	Description
arg	The parameters associated with an FTP command.
command	The last FTP command seen in a session.
data_channel.orig_h	The IP address of a data channel originator.
data_channel.passive	A boolean value indicating whether passive mode was used for a data channel, for example, true or false.
data_channel.resp_h	The IP address of a data channel receiving point.
data_channel.resp_p	The TCP port of a data channel receiving point.
file_size	The size of a file transferred during an FTP session.

Field	Description
reply_code	The FTP reply code from a server in response to a command.
reply_msg	The FTP reply message from a server.
user	The username used for an FTP session.

HTTP fields

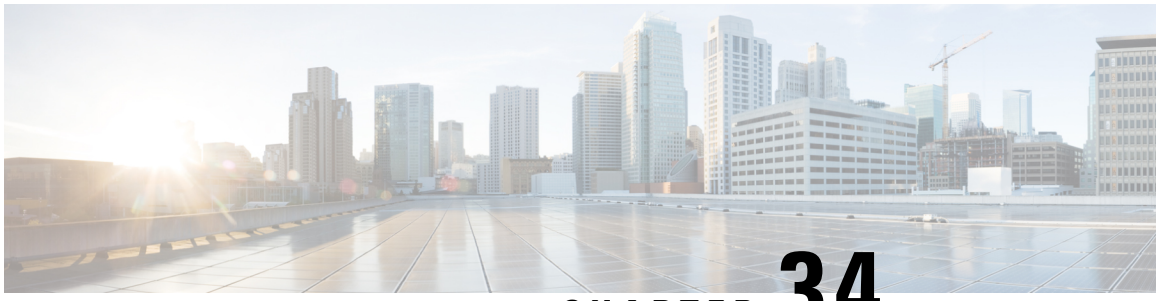
This reference provides details about HTTP protocol fields that are captured and available in application event logs for analysis and monitoring purposes.

Field	Description
host	The host header from an HTTP request, indicating the target server.
info_code	The last informational status code returned by a server.
info_msg	The last informational reason phrase returned by a server.
method	The HTTP method used in a request, for example, GET or POST.
origin	The origin header from a client.
orig_filenames	List of file names sent by a client. Values in the list are separated by empty spaces.
orig_mime_types	List of the content type (MIME type) files sent by a client. Values in the list are separated by empty spaces.
proxied	List of headers associated with proxied requests. Values in a list are separated by empty spaces.
referrer	The referrer header, indicating the URL of a page that is linked to the requested resource.
request_body_len	The length of an HTTP request body (decompressed and normalized).
response_body_len	The length of an HTTP response body (decompressed and normalized).
resp_filenames	List of file names sent by a server. Values in the list are separated by empty spaces.
resp_mime_types	List of the content type files sent by a server. Values in the list are separated by empty spaces.
status_code	The HTTP status code returned by a server, for example, 200 or 404.
status_msg	The HTTP status message returned by a server, for example, OK or Not Found.
trans_depth	The number of request-response pairs seen in an HTTP session.

Field	Description
uri	The Uniform Resource Identifier (URI) from an HTTP request, specifying the resource being requested.
user_agent	The user-agent header from a client, identifying the client software.
version	The HTTP version used in a request.

Notice protocol fields

This reference provides definitions for the protocol fields that appear in notice logs when intrusion policy rules are triggered, helping you understand the information captured in security event logs.



The notice protocol fields provide detailed information about intrusion events. These fields include:

Field	Description
action	The intrusion policy action that was configured for the triggered intrusion policy rule, for example alert, drop, or pass.
gid	The GID of the intrusion rule that triggered the log. This value is collected and displayed even if the rule is disabled.
msg	The message associated with the intrusion rule that triggered the log. This field provides a description of why the flow was logged.
proto	The transport layer protocol associated with the event, for example, IP, ICMP, TCP, or UDP.
rev	The revision number of the intrusion rule that was triggered.
refs	A list of references (URLs) associated with the intrusion rule. These references provide additional information about the specific threat or vulnerability the rule is designed to detect. The references are expanded to full URLs in the log.
sid	The SID of the intrusion rule that triggered the log. This value is collected and displayed even if the rule is disabled.
source	The name of the inspector module that was assigned to process the flow. This identifies the specific component within Snort that detected the anomaly. The name of the module appears similar to that in the Network Analysis Policy.

Weird protocol fields

This reference describes the various protocol fields that can appear in intrusion detection logs, including rule identifiers, messages, transport protocols, and inspector modules.

Field	Description
gid	The GID of the intrusion rule that triggered the log. This value is collected and displayed even if the rule is disabled.
msg	The message associated with the intrusion rule that triggered the log. This field provides a description of why the flow was logged.
proto	The transport layer protocol associated with the event, for example, IP, ICMP, TCP, or UDP.
sid	The SID of the intrusion rule that triggered the log. This value is collected and displayed even if the rule is disabled.
source	The name of the inspector module that was assigned to process the flow. This identifies the specific component within Snort that detected the anomaly. The name of the module appears similar to that in the Network Analysis Policy.

CHAPTER 34

User Identity and Activity

A identity source is a user data management system that

- collects active session data, user data, and user activity data from network users,
- organizes this data into distinct workflows for individual user analysis, and
- enables administrators to monitor and manage user behavior across the network.

Identity sources collect active session data, user data, and user activity data. The data is displayed in individual user-related workflows:

- Active Sessions: This workflow displays all current user sessions on your network. A single user running several simultaneous active sessions would occupy several rows in this table. For more information about the types of user data displayed in this workflow, refer to Active sessions data, on page 602.
- Users: This workflow displays all users seen on your network. A single user occupies a single row in this table. For more information about the types of user data displayed in this workflow, refer to User data, on page 603.
- User Activity: This workflow displays all user activity seen on your network. A single user with more than one instance of user activity would occupy several rows in this table. For more information about the types of user activity displayed in this workflow, refer to User activity data, on page 606.

- User-related fields, on page 595
- Active sessions data, on page 602
- User data, on page 603
- User activity data, on page 606
- User profile and host history, on page 608

User-related fields

User-related data is displayed in the active sessions, users, and user activity tables.

Note Active sessions for Azure AD realm users are displayed only in the **Active Sessions** new UI layout and not in the legacy UI.

Table 42: Active sessions, users, and user activity field descriptions

Field	Description	Active Sessions Table	Users Table	User Activity Table
Active Session Count	The number of active sessions associated with the user.	No	Yes	No
Authentication Type	The type of authentication: `No Authentication`, `Passive Authentication`, `Active Authentication`, `Guest Authentication`, `Failed Authentication`, or `VPN Authentication`. For more information about the supported identity sources for each Authentication Type, refer to the *Cisco Secure Firewall Management Center Device Configuration Guide* .	Yes	No	Yes
Available for Policy	A value of **Yes** means the user was retrieved from the user store (for example, Active Directory).) A value of **No** means the Cloud-Delivered Firewall Management Center received a report of a login for that user but the user is not in the user store. One way this can happen is if a user in an excluded group logs in to the user store. You can exclude groups from being downloaded when you configure a realm. Users not available for policy are recorded in the Cloud-Delivered Firewall Management Center but are not sent to managed devices.	No	Yes	No
Count	**Note** The **Count** field is displayed only after you apply a constraint that creates two or more identical rows. Depending on the table, the number of sessions, users, or activity events that match the information that appears in a particular row.	Yes	Yes	Yes
Current IP	(See also Current IP/Domain and IP address.) The IP address associated with the host that the user is logged into. This field is blank in the Users table if there are no active sessions for a user.	Yes	No	No

Field	Description	Active Sessions Table	Users Table	User Activity Table
Department	The user's department, as obtained by a realm. If there is no department explicitly associated with the user on your servers, the department is listed as whatever default group the server assigns. For example, on Active Directory, this is `Users (ad)`. This field is blank if: • You have not configured a realm. • The Cloud-Delivered Firewall Management Center cannot correlate the user in the Cloud-Delivered Firewall Management Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login).	Yes	Yes	No
Description	More information, if available, about the session, user, or user activity.	No	No	Yes
Device	For user activity detected by traffic-based detection or an active authentication identity source, the name of the device that identified the user. For other types of user activity, the managing Cloud-Delivered Firewall Management Center. **Note** If you have configured your VPN in a high-availability deployment, the device name displayed against active VPN sessions can be the primary or secondary device that identified the user session.	Yes	No	Yes
Discovery Application	The application or protocol used to detect the user. • For user activity detected by traffic-based detection, one of the following: ldap, pop3, imap, oracle, sip, http, ftp, mdns, or aim. **Note** Users are not added to the database based on SMTP logins. • For all other user activity: ldap.	Yes	Yes	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
Current IP Domain / **Domain**	In the Active Sessions table, the multitenancy domain where the user activity was detected. In the Users table, the multitenancy domain associated with the user's realm. In the User Activity table, the multitenancy domain where the user activity was detected. This field is only present if you have ever configured the Cloud-Delivered Firewall Management Center for multitenancy.	Yes	Yes	Yes
Email	The user's email address. This field is blank if: • The user was added to the database via an AIM login. • The user was added to the database via an LDAP login and there is no email address associated with the user on your LDAP servers.	Yes	Yes (as E-Mail)	No
End Port	If the user was reported by the TS Agent and their session is currently active, this field identifies the end value for the port range assigned to the user. This field is blank if the user's TS Agent session is inactive or if the user was reported by another identity source.	No	No	Yes
Endpoint Location	The IP address of the network device that used ISE to authenticate the user, as identified by ISE. If you do not configure ISE, this field is blank.	No	No	Yes
Endpoint Profile	The user's endpoint device type, as identified by Cisco ISE. If you do not configure ISE, this field is blank.	No	No	Yes
Event	The user activity event type.	No	No	Yes
First Name	The user's first name, as obtained by a realm. This field is blank if: • You have not configured a realm. • The Cloud-Delivered Firewall Management Center cannot correlate the user in the Cloud-Delivered Firewall Management Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login). • There is no first name associated with the user on your servers.	Yes	Yes	No

Field	Description	Active Sessions Table	Users Table	User Activity Table
IP Address	For **User Login** user activity, the IP address or internal IP address involved in the login: • LDAP, POP3, IMAP, FTP, HTTP, MDNS, and AIM logins — the address of the user's host • SMTP and Oracle logins — the address of the server • SIP logins — the address of the session originator (See also Current IP and Current IP/Domain.) An associated IP address does not mean the user is the current user for that IP address; when a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user. For other types of user activity, this field is blank.	No	No	Yes
Last Name	The user's last name, as obtained by a realm. This field is blank if: • You have not configured a realm. • The Cloud-Delivered Firewall Management Center cannot correlate the user in the Cloud-Delivered Firewall Management Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login). • There is no last name associated with the user on your servers.	Yes	Yes	No
Last Seen	The date and time that a session was last initiated (or user data was updated) for the user.	Yes	Yes	No
Login Time	The date and time that the session was initiated for the user.	Yes	No	No

Field	Description	Active Sessions Table	Users Table	User Activity Table
Phone Number	The user's telephone number, as obtained by a realm. This field is blank if: • You have not configured a realm. • The Cloud-Delivered Firewall Management Center cannot correlate the user in the Cloud-Delivered Firewall Management Center database with an LDAP record (for example, for users added to the database via an AIM, Oracle, or SIP login). • There is no telephone number associated with the user on your servers.	Yes (as Phone)	Yes	No
Realm	The identity realm associated with the user.	Yes	Yes	Yes
Security Group Tag	The Security Group Tag (SGT) attribute applied by Cisco TrustSec as the packet entered a trusted TrustSec network. If you do not configure ISE, this field is blank.	No	No	Yes
Session Duration	The duration of the user session, calculated from the **Login Time** and the current time.	Yes	No	No
Start Port	If the user was reported by the TS Agent and their session is currently active, this field identifies the start value for the port range assigned to the user. This field is blank if the user's TS Agent session is inactive or if the user was reported by another identity source.	No	No	Yes
Time	The time that the system detected the user activity.	No	No	Yes
User	At minimum, this field displays the user's realm and username. For example, `Lobby\jsmith`, where Lobby is the realm and jsmith is the username. If a realm downloads additional user data from an LDAP server and the system associates it with a user, this field also displays the user's first name, last name, and type. For example, `John Smith (Lobby\jsmith, LDAP)`, where John Smith is the user's name and LDAP is the type. **Note** Because traffic-based detection can record unsuccessful AIM logins, the Cloud-Delivered Firewall Management Center may store invalid AIM users (for example, if the username is misspelled by the user).	Yes	Yes	No
Username	The username associated with the user.	Yes	Yes	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
VPN Bytes In	For Remote Access VPN-reported user activity, the total number of bytes received from the remote peer or client by the Firewall Threat Defense. **Note** You can view the total number of bytes received once the user's VPN session is terminated. For ongoing VPN sessions, this is not a dynamic counter. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Bytes Out	For Remote Access VPN-reported user activity, the total number of bytes transmitted to the remote peer or client by the Firewall Threat Defense. **Note** You can view the total number of bytes transmitted once the user's VPN session is terminated. For ongoing VPN sessions, this is not a dynamic counter. For other types of user activity, this field is blank.	No	No	Yes
VPN Client Application	For Remote Access VPN-reported user activity, the remote user's AnyConnect VPN module of Cisco Secure Client application. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Client Country	For Remote Access VPN-reported user activity, the country name as reported by the Secure Client VPN. For other types of user activity, this field is blank.	No	No	Yes
VPN Client OS	For Remote Access VPN-reported user activity, the remote user's endpoint operating system as reported by the Secure Client VPN. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Client Public IP	For Remote Access VPN-reported user activity, the publicly routable IP address of the Secure Client VPN device. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Connection Duration	For Remote Access VPN-reported user activity, the total time (HH:MM:SS) that the session was active. For other types of user activity, this field is blank.	No	No	Yes

Field	Description	Active Sessions Table	Users Table	User Activity Table
VPN Connection Profile	For Remote Access VPN-reported user activity, the name of the connection profile (tunnel group) used by the VPN session. Connection profiles are part of a Remote Access VPN Policy. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Group Policy	For Remote Access VPN-reported user activity, the name of the group policy assigned to the client when the VPN session is established; either the statically-assigned group policy associated with the VPN Connection Profile, or the dynamically-assigned group policy if RADIUS is used for authentication. If assigned by the RADIUS server, this group policy overrides the static policy configured for the VPN Connection Profile. Group policies configure common attributes for groups of users in Remote Access VPN policies. For other types of user activity, this field is blank.	Yes	No	Yes
VPN Session Type	For Remote Access VPN-reported user activity, the type of session: LAN-to-LAN or Remote. For other types of user activity, this field is blank.	Yes	No	Yes

Active sessions data

The **Integrations** > **Users** > **Active Sessions** workflow displays select information about current user sessions.

When a user on your network runs several sessions simultaneously, the system can uniquely identify the sessions if:

- they have unique **IP Address** values.
- they have unique **Start Port** and **End Port** values, as provided by the Cisco Terminal Services (TS) Agent.
- they have unique **Current IP Domain** values.
- they were authenticated by different identity sources.
- they were associated with different identity realms.

For more information about the user and user activity data stored by the system, refer to User data, on page 603 and User activity data, on page 606.

View active session data

You can view a table of active sessions, and then manipulate the event view depending on the information you are looking for.

The page you see when you access users differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of users that lists all detected users, and terminates in a user details page. The user details page provides information on every user that meets your constraints.

Procedure

Step 1 Choose **Analysis** > **Users heading** > **Active Sessions**.

Step 2 You have these options:

- Perform basic workflow actions.
- Learn more about the contents of the columns in the table; refer to Active sessions data, on page 602 and User-related fields, on page 595.

User data

This reference describes how user records are created and updated in the database and what identity-related information the system stores.

When an identity source reports a user login for a user who is not already in the database, the user is added to the database, unless you have specifically restricted that login type.

The system updates the users database when one of the following occurs:

- A user on the Cloud-Delivered Firewall Management Center manually deletes a non-authoritative user from the Users table.
- An identity source reports a logoff by that user.
- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

Note If you have ISE/ISE-PIC configured, you may see host data in the users table. Because host detection by ISE/ISE-PIC is not fully supported, you cannot perform user control using ISE-reported host data.

The type of user login that the system detected determines what information is stored about the new user.

Identity Source	Login Type	User Data Stored
ISE/ISE-PIC	Active Directory LDAP RADIUS RSA	• username • current IP address • Security Group Tag (SGT) — not supported with ISE-PIC • endpoint profile/device type — not supported with ISE-PIC • endpoint location/location IP — not supported with ISE-PIC • type (LDAP)
TS Agent	Active Directory	• username • current IP address • start port • end port • type (LDAP)
captive portal	Active Directory LDAP	• username • current IP address • type (LDAP)
traffic-based detection	LDAP AIM Oracle SIP HTTP FTP MDNS	• username • current IP address • type (AD)
	POP3 IMAP	• username • current IP address • email address • type (`pop3` or `imap`)

Note No data about Microsoft Azure Active Directory users is displayed in this table.

If you configure a realm to automatically download users, the Cloud-Delivered Firewall Management Center queries the servers based on the interval you specified. It may take five to ten minutes for the Cloud-Delivered Firewall Management Center database to update with user metadata after the system detects a new user login. The Cloud-Delivered Firewall Management Center obtains the following information and metadata about each user:

- username
- first and last names
- email address
- department
- telephone number
- current IP address
- Security Group Tag (SGT), if available
- endpoint profile, if available
- endpoint location, if available
- start port, if available
- end port, if available

The number of users the Cloud-Delivered Firewall Management Center can store in its database depends on your Cloud-Delivered Firewall Management Center model. When a non-authoritative user login is detected on a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user login is detected for that host, only another authoritative user login changes the current user.

Note that traffic-based detection of AIM, Oracle, and SIP logins create duplicate user records because they are not associated with any of the user metadata that the system obtains from LDAP servers. To prevent overuse of user count because of duplicate user records from these protocols, configure traffic-based detection to ignore those protocols.

You can search, view, and delete users from the database; you can also purge all users from the database.

For information about general user-related event troubleshooting, refer to *Cisco Secure Firewall Management Center Device Configuration Guide*.

View user data

You can view a table of users, and then manipulate the event view depending on the information you are looking for.

The page you see when you access users differs depending on the workflow you use. You can use the predefined workflow, which includes a table view of users that lists all detected users, and terminates in a user details page. The user details page provides information on every user that meets your constraints.

Procedure

Step 1 Choose **Analysis** > **Users heading** > **Users**.

Step 2 Choose from the following options:

- Perform basic workflow actions.
- Learn more about the contents of the columns in the table; refer to User-related fields, on page 595.

User activity data

A user activity data record is a security event type that

- logs the appearance and login of users on a network,
- enables correlation between user actions and other network events such as intrusions, and
- supports automated remediation and alerting through customizable rules.

The system generates events that communicate the details of user activity on your network. When the system detects user activity, the user activity data is logged to the database. You can view, search, and delete user activity; you can also purge all user activity from the database.

The system logs a user activity event when a user is seen on your network for the first time. Subsequent appearances by that user do not log new user activity events. However, if the user's IP address changes, the system logs a new user activity event.

The system also correlates user activity with other types of events. For example, intrusion events can tell you the users who were logged into the source and destination hosts at the time of the event. This correlation can tell you who was logged into the host that was targeted by an attack, or who initiated an internal attack or portscan.

You can also use user activity in correlation rules. Based on the type of user activity as well as other criteria that you specify, you can build correlation rules that, when used in a correlation policy, launch remediations and alert responses when network traffic meets your criteria.

Note If you have ISE/ISE-PIC configured, you may see host data in the users table. Because host detection by ISE/ISE-PIC is not fully supported, you cannot perform user control using ISE-reported host data.

Descriptions of the four types of user activity data follow.

New User Identity

This type of event is generated when the system detects a login by an unknown user that is not in the database.

The system logs a user activity event when a user is seen on your network for the first time. Subsequent appearances by that user do not log new user activity events. However, if the user's IP address changes, the system logs a new user activity event.

User Login

This type of event is generated when any of the following occur:

- Captive portal performs a successful or failed user authentication.
- Traffic-based detection detects a successful or failed user login.

Note SMTP logins detected by traffic-based detection are not recorded unless there is already a user with a matching email address in the database.

When a non-authoritative user logs into a host, that login is recorded in the user and host history. If no authoritative user is associated with the host, a non-authoritative user can be the current user for the host. However, after an authoritative user logs into the host, only a login by another authoritative user changes the current user.

If you are using captive portal or traffic-based detection, note the following about failed user login and failed user authentication data:

- Failed logins reported by traffic-based detection (LDAP, IMAP, FTP, and POP3 traffic) are displayed in the table view of user activity, but not in the table view of users. If a known user failed to log in, the system identifies them by their username. If an unknown user failed to log in, the system uses **Failed Authentication** as their username.
- Failed authentications reported by captive portal are displayed in both the table view of user activity and the table view of users. If a known user failed to authenticate, the system identifies them by their username. If an unknown user failed to authenticate, the system identifies them by the username they entered.

Delete User Identity

This type of event is generated when you manually delete a user from the database.

User Identity Dropped: User Limit Reached

This type of event is generated when the system detects a user that is not in the database, but cannot add the user because you have reached the maximum number of users in the database as determined by your Cloud-Delivered Firewall Management Center model.

After you reach the user limit, in most cases the system stops adding new users to the database. To add new users, you must either manually delete old or inactive users from the database, or purge all users from the database.

However, the system favors authoritative users. If you have reached the limit and the system detects a login for a previously undetected authoritative user, the system deletes the non-authoritative user who has remained inactive for the longest time, and replaces it with the new authoritative user.

User Indications of Compromise Events

The following user IOC changes are logged in the user activity database:

- When indications of compromise are resolved.
- When indication of compromise rules are enabled or disabled for users.

For information about general user-related event troubleshooting, refer to the *Cisco Secure Firewall Management Center Device Configuration Guide*.

View user activity data

You can view a table of user activity, and then manipulate the event view depending on the information you are looking for. The page you see when you access user activity differs depending on the workflow you use. You can use the predefined workflow, which includes the table view of user activity and terminates in a user details page, which contains user details for every user that meets your constraints.

Procedure

Step 1 Choose **Analysis** > **Users heading** > **User Activity**.

Step 2 You have the following options:

- Perform basic workflow actions.
- Learn more about the contents of the columns in the table; refer to User-related fields, on page 595.

User profile and host history

A user profile is a web interface display that

- provides detailed information about a specific user through the User pop-up window (titled "User Identity" in the web interface)
- shows the same user data as you would see in the table view of users, and
- includes host history that provides a graphic representation of the last twenty-four hours of the user's activity.

User profile access points

You can learn more about a specific user by viewing the User pop-up window. The page that appears, called the "User Profile" in this document, is titled "User Identity" in the web interface.

You can display the window from:

- any event view that associates user data with other kinds of events
- the table view of active sessions
- the table view of users

User information also appears in the terminating page for users workflows.

The user data you see is the same as you would see in the table view of users.

Host history section

The host history provides a graphic representation of the last twenty-four hours of the user's activity. A list of IP addresses of the hosts that the user logged into and logged off of approximates login and logout times with bar graphs. A typical user might log on to and off of multiple hosts in the course of a day. For example, periodic automated logins to a mail server would display as multiple short sessions, while longer logins (such as during working hours) display longer sessions.

If you use traffic-based detection or captive portal to capture failed logins, the host history also includes hosts where the user failed to log in.

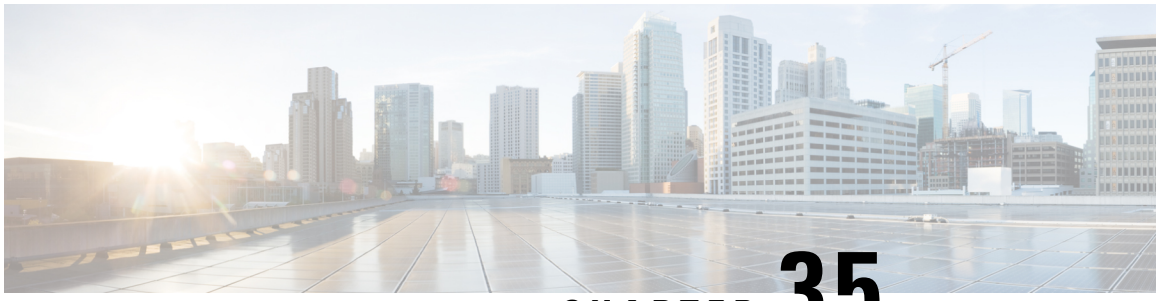
The data used to generate the host history is stored in the user history database, which by default stores 10 million user login events. If you do not see any data in the host history for a particular user, either that user is inactive, or you may need to increase the database limit.

View user details and host history

User details and host history provide valuable insights for security analysis and incident investigation.

Procedure

You have two options:



- In any event view that lists users, click user that appears next to a user identity **User icon**, or, for users associated with an indication of compromise, **Red User icon**.
- In any users workflow, click the Users terminating page.

PART XI

High Availability and Scalability

- Multi-Instance Mode, on page 613
- High Availability for Devices, on page 681
- Clustering: Secure Firewall 3100/4200, on page 723
- Clustering: Private Cloud , on page 799
- Clustering: Public Cloud, on page 845
- Clustering: Firepower 4100/9300, on page 935

CHAPTER 35

Multi-Instance Mode

You can deploy the Secure Firewall 3100/4200 as a single device (*appliance mode*) or as multiple container instances (*multi-instance mode*). This chapter describes how to deploy the device in multi-instance mode.

- Multi-instance mode, on page 613
- Licenses for instances, on page 625
- Requirements and prerequisites for instances, on page 625
- Guidelines and limitations for instances, on page 626
- Instance configuration, on page 629
- Multi-instance mode, on page 676

Multi-instance mode

Multi-instance mode is a deployment mode that enables multiple container instances on a single chassis that act as completely independent devices.

Multi-instance modes and appliance modes

A multi-instance mode and an appliance mode are deployment types for network devices that

- determine whether the device operates as a single instance or supports multiple, independent instances,
- offer distinct management and configuration options at both the chassis and instance levels, and
- provide different approaches to resource allocation, interface assignment, and monitoring.

You can run the device in either appliance mode or multi-instance mode.

Appliance mode

Appliance mode is the default. The device runs the native Firewall Threat Defense image and acts as a single device. The only chassis-level configuration available (on the **Chassis Manager** page) is for network module management (breakout ports or enabling/disabling a network module).

Multi-instance mode

If you change to multi-instance mode, the device runs the Secure Firewall eXtensible Operating System (FXOS) on the chassis, while each instance runs separate Firewall Threat Defense images. You can configure the mode using the FXOS CLI.

Because multiple instances run on the same chassis, you need to perform chassis-level management of:

- CPU and memory resources using resource profiles.
- Interface configuration and assignment.
- Deployment and monitoring of instances.

For a multi-instance device, you add the *chassis* to the Cloud-Delivered Firewall Management Center and configure chassis-level settings on the **Chassis Manager** page.

Chassis management interface

A chassis management interface is a network hardware feature that

- provides a dedicated pathway for device management and control,
- supports multi-instance modes by allowing each software instance its own management IP address, and
- separates management, eventing, and application access to streamline security, access, and monitoring.

Chassis management

The chassis uses the dedicated Management interface on the device. Multi-instance mode does not support using a data interface for chassis management or DHCP addressing for the Management interface.

You can only configure the chassis Management interface at the Firewall Threat Defense CLI (at initial setup) or FXOS CLI (after you convert to multi-instance mode). Refer to Change chassis management settings at the FXOS CLI, on page 673 to change Management interface settings in multi-instance mode.

Note By default, SSH is not allowed to this interface in multi-instance mode unless you enable the SSH server and an SSH access list. This difference means that you can connect to the application-mode threat defense Management interface using SSH, but after you convert to multi-instance mode, you can no longer connect using SSH by default. For more information, refer to Configure SSH and SSH access list, on page 654.

Instance management

All instances share the chassis management interface, and each instance has its own IP address on the Management network. After you add the instance and specify the IP address, you can make changes to the network settings at the Firewall Threat Defense CLI.

The instance Management IP address allows SSH by default.

Instance interfaces

A chassis interface is a network connection point that

- allows flexible assignment to instances through physical connections or VLAN subinterfaces,
- enables sharing (physical or VLAN) between multiple instances for efficient resource use, and
- restricts certain interface features (like subinterfaces or sharing) in multi-instance clusters, except for control links.

To provide flexible physical interface use for instances, you can create VLAN subinterfaces on the chassis and also share interfaces (VLAN or physical) between multiple instances. Refer to Shared interface scalability, on page 617 and Configure a subinterface, on page 640.

Note This chapter discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense instance. For more information, refer to Chassis interfaces vs. instance interfaces, on page 615.

Interface types

An interface type is a network configuration element that

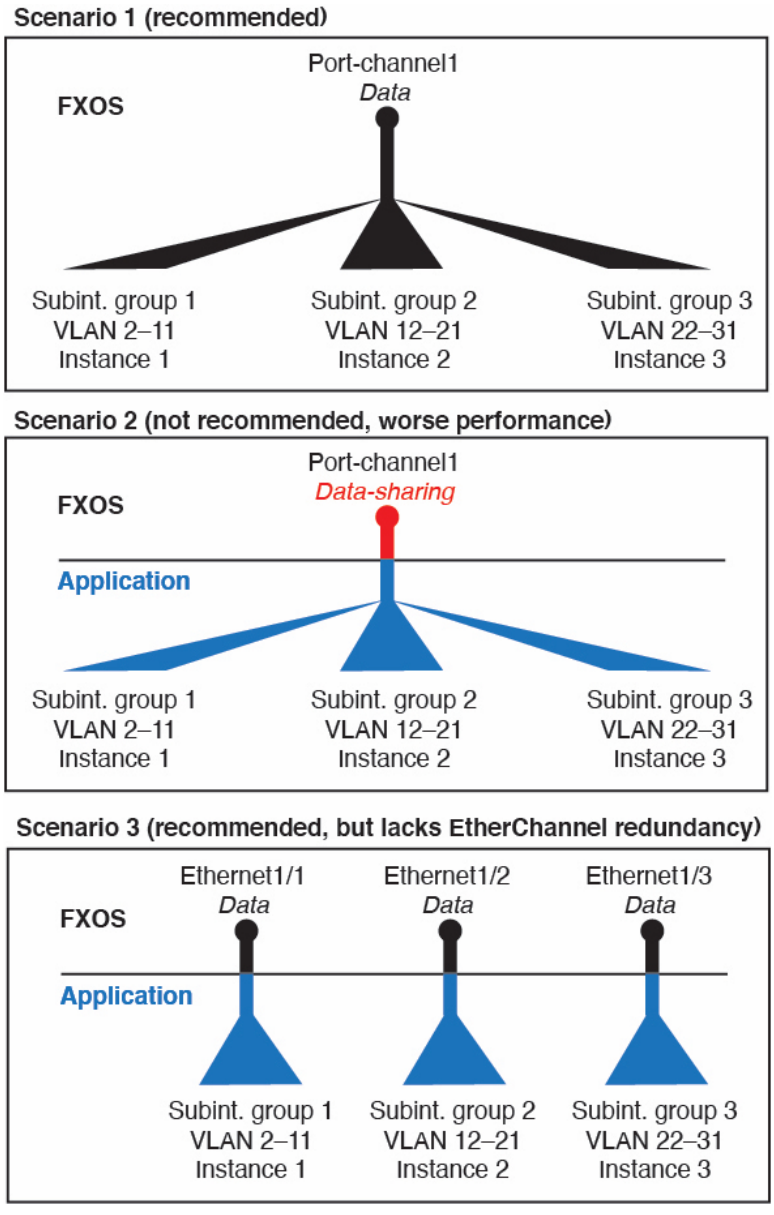
- determines how physical interfaces, VLAN subinterfaces, and EtherChannel interfaces are used in deployment, and
- defines whether interfaces can be shared among instances or dedicated to specific traffic.

Physical interfaces, VLAN subinterfaces, and EtherChannel interfaces can be one of these types:

- Data: Use for regular data or the failover link. Data interfaces cannot be shared between instances, and instances cannot communicate over the backplane to other instances. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another instance. You can add VLAN subinterfaces to a data interface to provide separate failover links per High Availability pair.
- Data-sharing: Use for regular data. These data interfaces can be shared by one or more instances. Each instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, or failover links.

Chassis interfaces vs. instance interfaces

Chassis interfaces vs. instance interfaces is an interface management model that



- manages basic Ethernet settings of physical interfaces, VLAN subinterfaces for instances, and EtherChannel interfaces at the chassis level,
- configures higher level settings within the instance, such as IP addresses for EtherChannels, and
- allows independent administrative control of interface states in both chassis and instance locations.

VLAN subinterfaces

You can create VLAN subinterfaces within the instance, just as you would for any device.

You can *also* create VLAN subinterfaces in the chassis. The instance-defined subinterfaces are not subject to the chassis limit. Choosing in which location to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface on the chassis. Another scenario that favors chassis subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces in the instance, then you would have to share the parent interface in the chassis, which may not be desirable. See this illustration that shows the three ways you can accomplish this scenario:

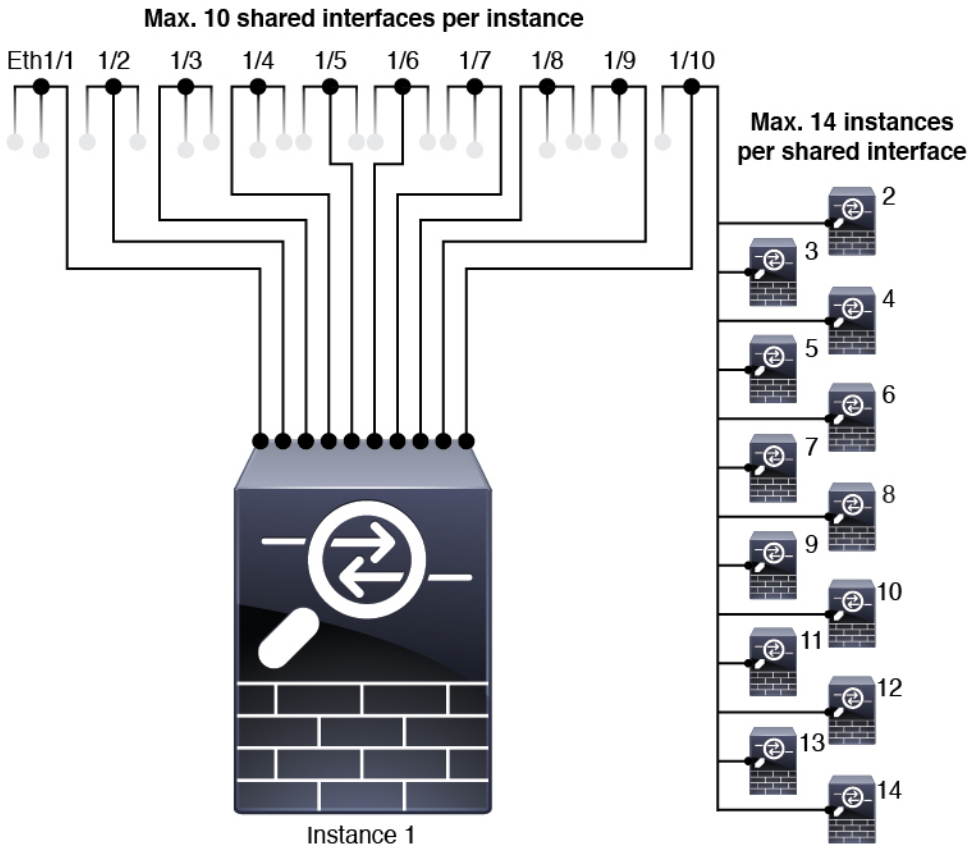
Figure 38: VLANs in the chassis vs. the instance

Independent interface states in the chassis and in the instance

You can administratively enable and disable interfaces in both the chassis and in the instance. For an interface to be operational, the interface must be enabled in both locations. Because the interface state is controlled independently, you may have a mismatch between the chassis and instance.

The default state of an interface within the instance depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the instance, but a subinterface is enabled by default.

Shared interface scalability



A shared interface is a network resource that

- allows multiple logical connections to transmit data concurrently,
- adapts bandwidth allocation based on real-time demand, and
- enhances scalability to support growing numbers of devices and traffic flows.

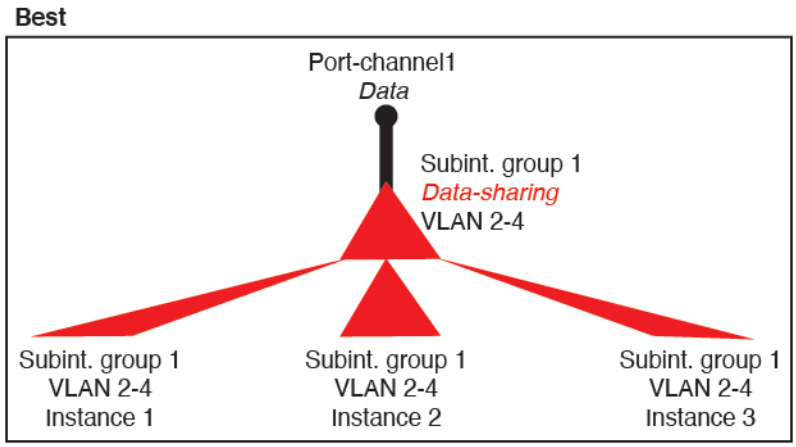
Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:

Shared interface best practices

This topic outlines the best practices to follow when configuring shared interfaces to maximize performance and security.



For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best: Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

   For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2, Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 39: Best: Shared Subinterface Group on One Parent

If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

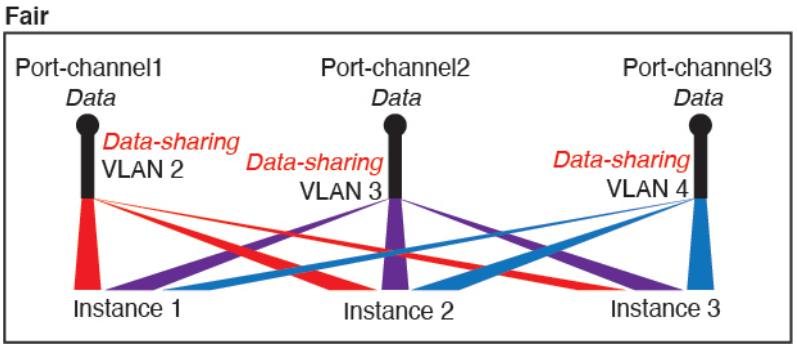


Figure 40: Good: Sharing Multiple Subinterface Groups on One Parent

2. Fair: Share subinterfaces across parents.

   For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

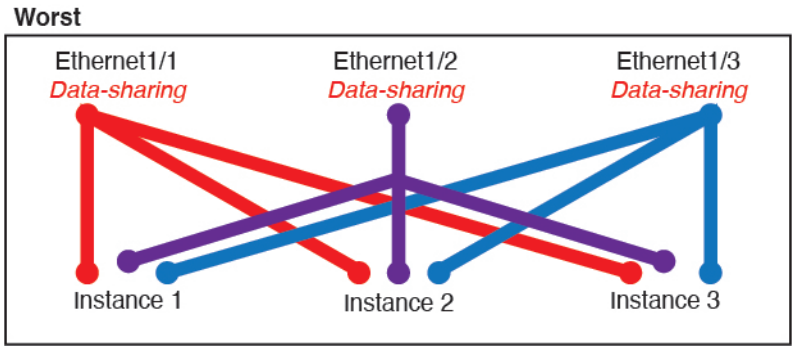

Figure 41: Fair: Shared Subinterfaces on Separate Parents

3. Worst: Share individual parent interfaces (physical or EtherChannel).

   This method uses the most forwarding table entries.

Figure 42: Worst: Shared Parent Interfaces

How the chassis classifies packets

The chassis processes incoming and outgoing packets as they pass through a device, ensuring that each packet is handled according to its type, destination, and security requirements.

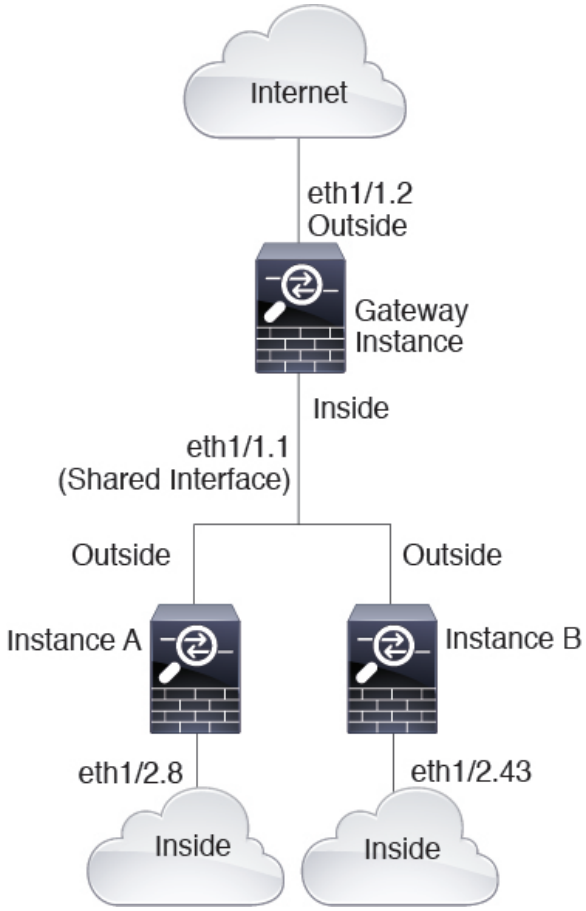
Each packet that enters the chassis must be classified so that the chassis can determine to which instance to send a packet.

- Unique Interfaces: If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- Unique MAC Addresses: The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification examples

This reference provides examples to help you understand different classification scenarios and their implementation.



Cascading container instances

Cascading instances connect one instance's outside interface to another's inside interface, simplifying configuration by sharing parameters in the top instance. Avoid using shared interfaces with High Availability to prevent MAC address conflicts; use unique interfaces and an external switch instead.

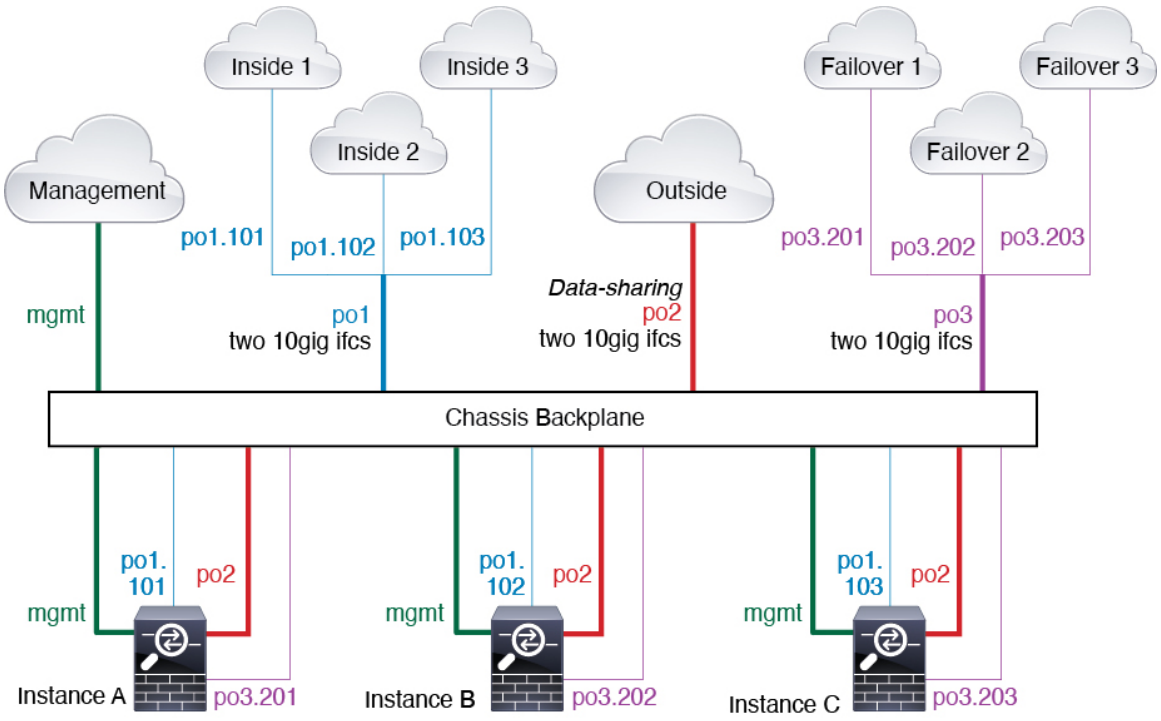
Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 43: Cascading Instances

Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

Typical multi-instance deployments



A typical multi-instance deployment is a firewall configuration that

- supports multiple container instances operating simultaneously,
- configures distinct interfaces for management, inside, outside, and failover connectivity, and
- utilizes dedicated subinterfaces and EtherChannels to enhance performance and reliability.

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- Management: All instances and the chassis use the dedicated Management interface. Within each instance (and the chassis), the interface uses a unique IP address on the same management network.
- Inside: Each instance uses a subinterface on Port-Channel1 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.
- Outside: All instances use the Port-Channel2 interface (data-sharing type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover: Each instance uses a subinterface on Port-Channel3 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

Figure 44: Typical multi-instance deployment

Automatic MAC addresses for instance interfaces

An automatic MAC address for instance interfaces is a network identifier that is automatically generated and assigned to instance interfaces in multi-instance deployments.

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or a system-defined prefix, and *zz.zzzz* is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the chassis native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

Performance scaling factors for multi-instance modes

A performance scaling factor is a throughput adjustment metric that

- enables calculation of effective throughput in multi-instance appliance modes,
- considers the percentage of CPU cores assigned to each instance, and
- accounts for efficiency reductions compared to single-instance (appliance mode) operation.

The maximum throughput (connections, VPN sessions) for a platform is calculated for an appliance mode device's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use an instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to an instance may be less than that available to an appliance.

For detailed instructions on calculating the throughput for instances, refer to https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html.

Instances and high availability

A high availability pair is a deployment option that

- uses two instances on separate chassis to ensure service continuity,
- allows for multiple high availability pairs to be created from available instances, and
- permits standalone instances to exist alongside high availability pairs within the same chassis.

You can use High Availability using an instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. You can also have standalone instances on the same chassis as High Availability instances. For more information about the requirements, refer to Requirements and prerequisites for instances, on page 625.

Note Clustering is not supported.

Licenses for instances

This reference provides information about how licenses are assigned and consumed for chassis and feature instances.

All licenses are consumed per chassis and not per instance. Refer to these details.

- Essentials licenses are assigned to the chassis as a whole, one per chassis.
- Feature licenses are assigned to each instance, but you only *consume* one license per feature per chassis.

Requirements and prerequisites for instances

This reference provides the requirements and prerequisites for deploying instances on Secure Firewall models, including supported models, upgrade paths, resource limitations per model, software requirements, high availability requirements, and management center requirements.

Model support

- Secure Firewall 3110
- Secure Firewall 3120
- Secure Firewall 3130
- Secure Firewall 3140
- Secure Firewall 4215
- Secure Firewall 4225
- Secure Firewall 4245

Note The Secure Firewall 3105 is not supported.

Maximum container instances and resources per model

For each container instance, you can specify the number of CPU cores (or more specifically, threads) to assign to the instance. We use the term "core" generically to account for different hardware architecture. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 43: Maximum container instances and resources per model

Model	Max. Container Instances	Available CPU Cores (Threads)
Secure Firewall 3110	3	22
Secure Firewall 3120	5	30
Secure Firewall 3130	7	46
Secure Firewall 3140	10	62
Secure Firewall 4215	10	62
Secure Firewall 4225	21	126
Secure Firewall 4245	34	254

Software requirements

- You can run different versions of Firewall Threat Defense software on each instance as long as they are all compatible with the version of FXOS running on the chassis.
- You cannot deploy an instance with a patch version of the Firewall Threat Defense software because it is not a complete bundle. You need to first deploy the major or maintenance version, and then patch it after deployment.

High availability requirements

- The two instances in a High Availability configuration must:
  - Be on separate chassis.
  - Be on the same model.
  - Have the same interfaces assigned. All interfaces must be preconfigured in the chassis identically before you enable High Availability.
  - Use the same resource profile attributes. The profile names can be different, but the definitions need to match.

Cloud-Delivered Firewall Management Center requirements

For chassis management and all instances on the chassis, you must use the same Cloud-Delivered Firewall Management Center due to the licensing implementation.

Guidelines and limitations for instances

This reference provides guidelines and limitations for managing instances on chassis, including general requirements, interface configurations, VLAN subinterfaces, EtherChannels, data-sharing interfaces, and MAC address considerations.

General guidelines

- A single Cloud-Delivered Firewall Management Center must manage all instances on a chassis, as well as manage the chassis itself.
- For instances, these features are not supported:
  - TLS crypto acceleration
  - Clustering
  - Cloud-Delivered Firewall Management Center UCAPL/CC mode
  - Flow offload to hardware
  - LLDP
- Primary management of the chassis by Security Cloud Control cloud-delivered Cloud-Delivered Firewall Management Center and separate analytics-only management of the chassis by an on-prem Cloud-Delivered Firewall Management Center is not supported. You can however add Security Cloud Control-managed instances to an analytics-only on-prem Cloud-Delivered Firewall Management Center.

Management interface

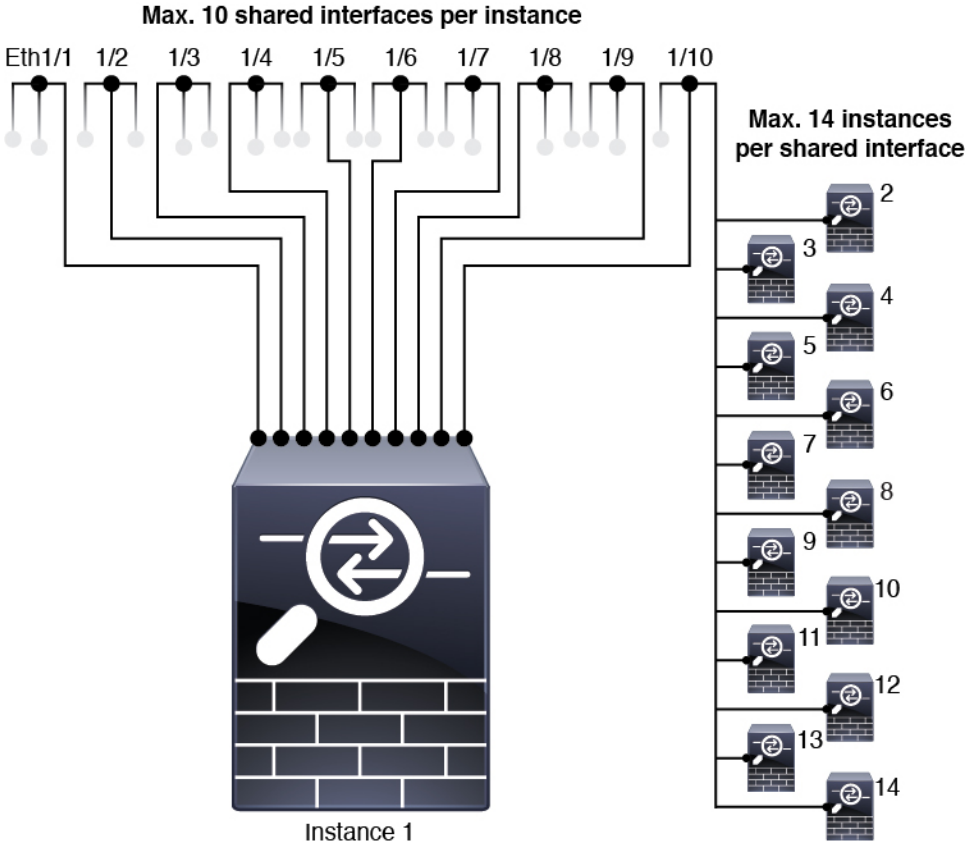
- No support for a data interface for chassis management; only the dedicated Management interface can be used
- No DHCP addressing for the Management interface
- The management connection requires TCP port 8305; do not change the value from the default.

VLAN subinterfaces

- This document discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the instance.
- If you assign a parent interface to an instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic.
- Subinterfaces are supported on Data or Data-sharing type interfaces.
- You can create up to 500 VLAN IDs.
- You cannot use subinterfaces for an inline set or as a passive interface.
- If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

EtherChannels

- You can configure up to 48 EtherChannels, limited by the number of physical interfaces.
- The EtherChannel can have up to 8 active interfaces.
- All interfaces in the EtherChannel must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface



capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.

- The chassis does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **VLAN dot1Q tag native** command, then the chassis will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch.
- In Cisco IOS software versions earlier than 15.1(1)S2, the chassis did not support connecting an EtherChannel to a switch stack. With default switch settings, if the chassis EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-MAC persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.

Data-sharing interfaces

- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

  Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.

- You cannot use a data-sharing interface with a transparent firewall mode instance.
- You cannot use a data-sharing interface with inline sets or passive interfaces.

- You cannot use a data-sharing interface for the failover link.

Default MAC addresses

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. For more information, refer to Automatic MAC addresses for instance interfaces, on page 623.

Instance configuration

Prepare the chassis and management environment to enable instance configuration on your device.

Before you configure instances, you need to enable multi-instance mode, add the chassis to the Cloud-Delivered Firewall Management Center, and configure chassis interfaces. You can also customize the chassis settings.

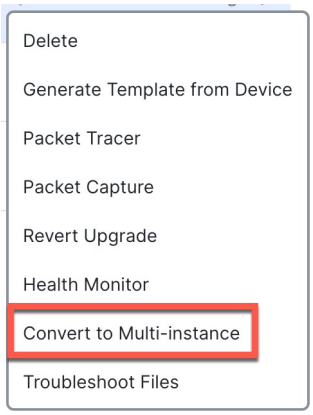
Convert a device to Multi-Instance mode

Use this procedure to convert a device in the Cloud-Delivered Firewall Management Center to multi-instance mode. The conversion takes approximately 15 minutes. The system reboots and, as part of changing the mode, erases the configuration with the exception of the Management network settings and the admin password. The chassis hostname is set to "firepower-*model*." The Management IP address is assigned to the chassis for the management connection with the Cloud-Delivered Firewall Management Center. When you add instances, they will use separate IP addresses on the Management interface and maintain their own management connections.

After you convert to multi-instance mode, you can use the Cloud-Delivered Firewall Management Center to configure all chassis settings as well as instances. The Secure Firewall Chassis Manager or configuration at the FXOS CLI is not supported.

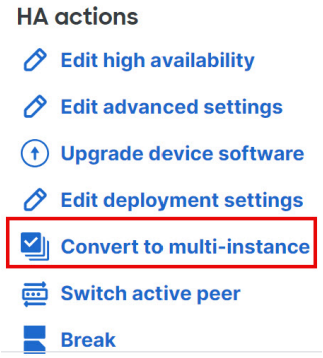
Note If you would prefer to use the CLI to convert to multi-instance mode before adding the device to the Cloud-Delivered Firewall Management Center, refer to Onboard a Chassis, on page 49.

Before you begin



Add the appliance-mode device to the Cloud-Delivered Firewall Management Center as a standalone device. This device cannot use:

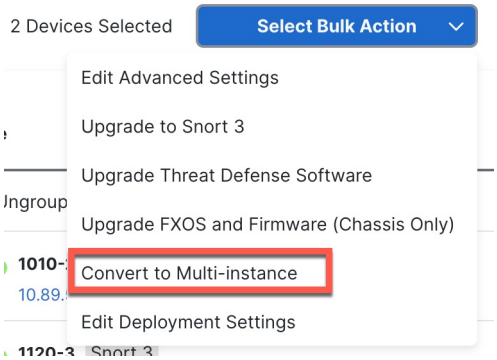
- A data interface for manager access
- DHCP for the Management interface
- Zero-Touch Provisioning



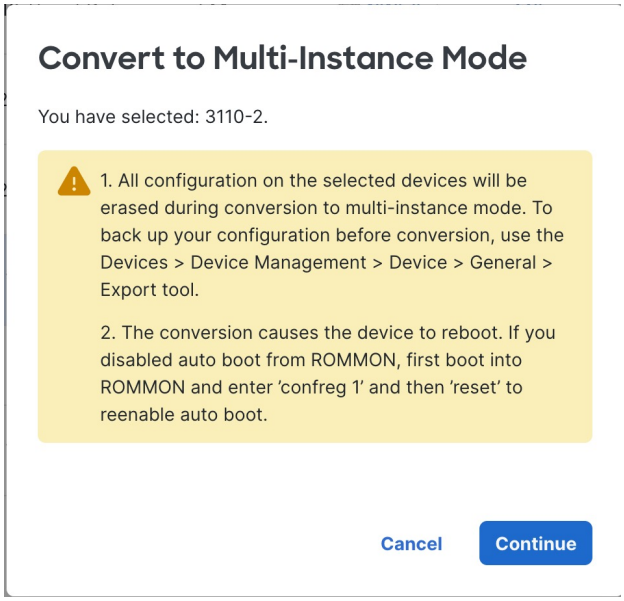
Procedure

Step 1 On **Devices** > **Device Management**, next to the device you want to convert to multi-instance mode, choose **More** (⋮) > **Convert to Multi-Instance**.

Figure 45: Convert to Multi-Instance



If you have switched to the new device management page, select your device to open the right-pane. Under **HA actions**, select **Convert to multi-instance**.

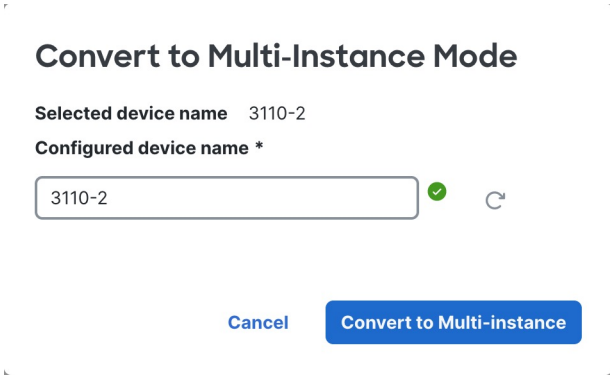


You can alternatively check the check-box next to multiple devices that you want to convert, and choose **Select Bulk Action** > **Convert to Multi-Instance**.

Figure 46: Bulk Conversion

Step 2 Confirm that you want to perform the conversion and click **Continue**.

Figure 47: Conversion Confirmation

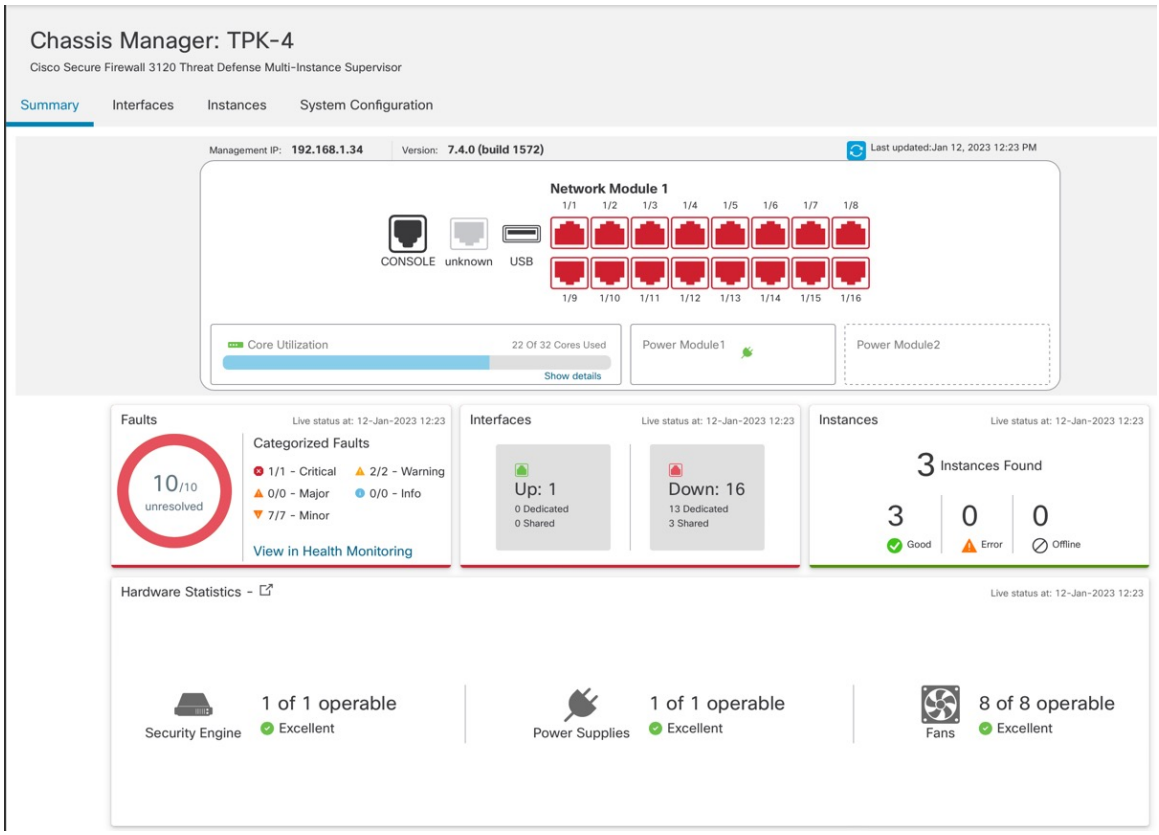


A readiness check is performed. The check might fail if, for example, a deployment is in progress.

Step 3 Optionally change the name of the chassis, and click **Convert to Multi-Instance**. By default, the device name is used, but you may want a different naming convention for multi-instance chassis.

Note
If the readiness check failed, for example because of a deployment in progress, you can wait for the process to complete and click ↻ to rerun the readiness check so you can continue.

Figure 48: Rename Chassis



Wait for approximately 15 minutes, during which the device is removed from the device list, and then after conversion, it is re-added as a chassis.

Step 4 To view and configure the chassis, click **Manage** in the **Chassis** column, or click **Edit** ( ).

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Figure 49: Chassis Summary

Chassis interface configuration

A chassis interface is a physical network interface that

- enables connection to the firewall's internal and external networks,
- supports configuration of basic Ethernet settings, VLAN subinterfaces, and EtherChannel grouping, and
- defaults to a disabled state until explicitly enabled by an administrator.

Additional information

Note To configure breakout ports and perform other network module operations, refer to Network module management for Secure Firewall 3100/4200, on page 1015.

Note For information about the **Sync Device** button, refer to Sync Interface Changes with the Cloud-Delivered Firewall Management Center, on page 1014.

Configure a physical interface

You can physically enable and disable interfaces, as well as set the interface speed and duplex and other hardware settings. To use an interface, it must be physically enabled for the chassis and logically enabled in the instance. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

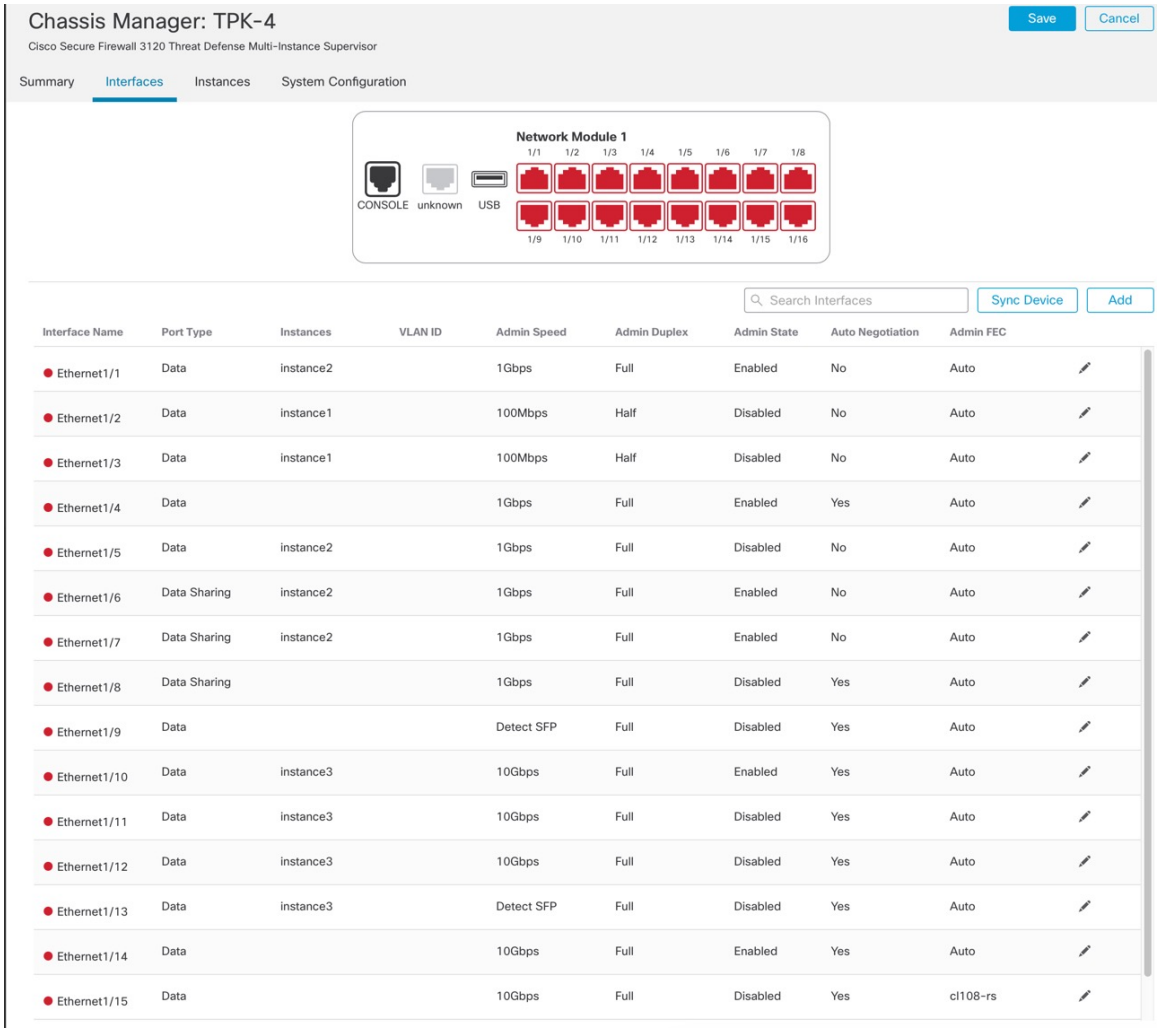


Figure 50: Manage Chassis

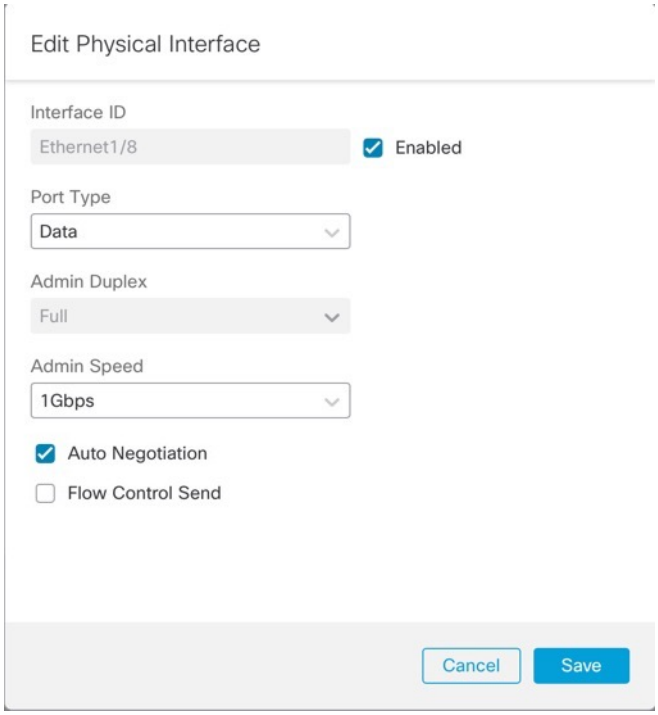
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Interfaces**.

Figure 51: Interfaces

Step 3 Click **Edit** (✎) for the interface you want to edit.

Figure 52: Edit Physical Interface

Step 4 Enable the interface by checking the **Enabled** check box.

- For the **Port Type**, choose **Data** or **Data Sharing**.

  Figure 53: Port Type

- Set the **Admin Duplex**.

  Speeds of 1Gbps and higher only support **Full** duplex. SFP interfaces only support **Full** duplex.

- Set the **Admin Speed**.

  For SFPs, Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

Step 5 (Optional) Check **Flow Control Send** to enable pause (XOFF) frames for flow control.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note
The Firewall Threat Defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flow control enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Step 6 (Optional) Check **Auto Negotiation** to set the interface to negotiate the speed, link status, and flow control. You cannot edit this setting for speeds lower than 1Gbps. For SFP interfaces, you can only disable auto-negotiation when the speed is set to 1Gbps.

Step 7 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure an EtherChannel

An EtherChannel (also known as a port channel) can include up to 8 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices. LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state when it is added to an instance.

Before you begin

Enable physical interfaces and set hardware parameters. For more information, refer to Configure a physical interface, on page 633.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

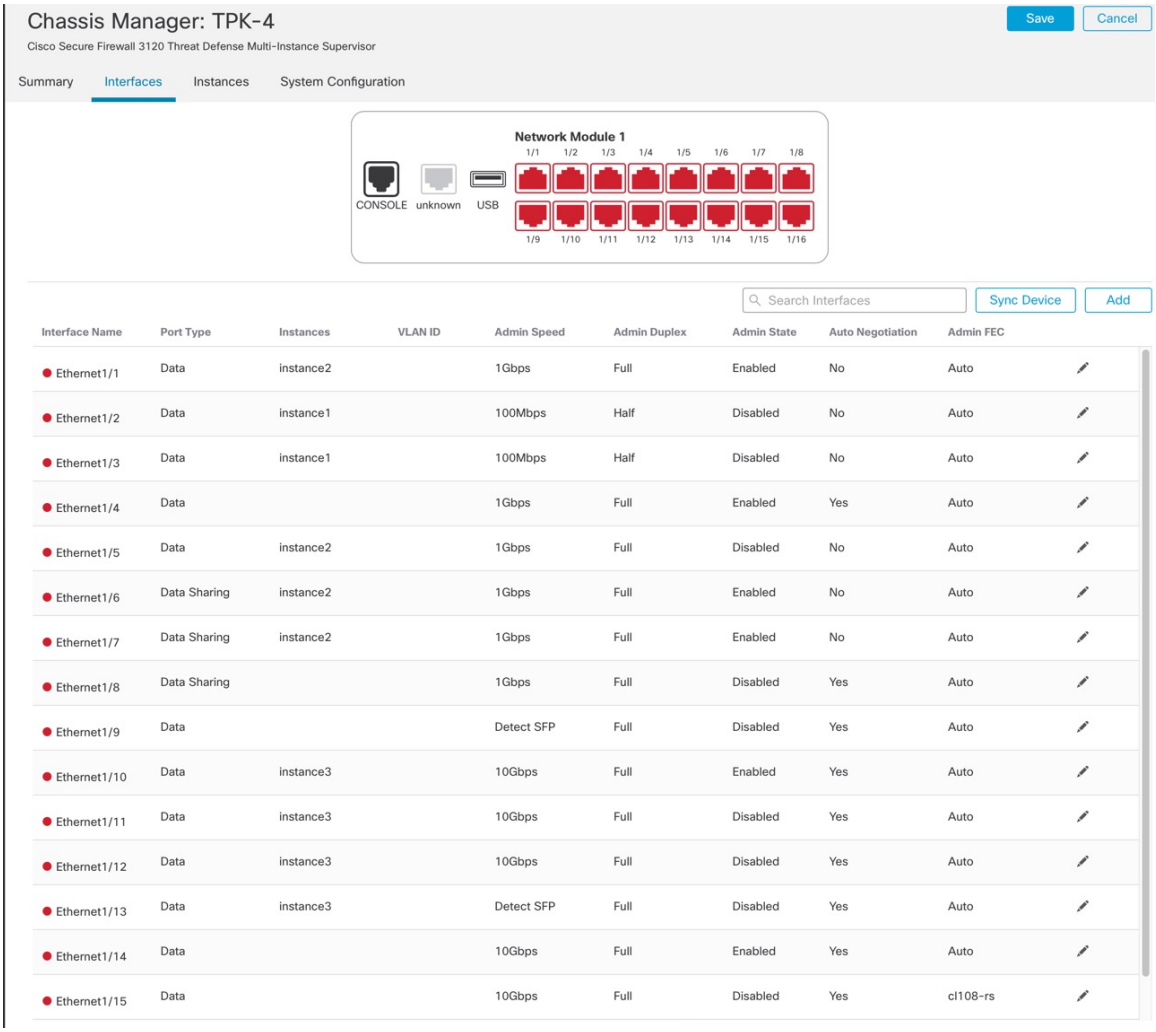


Figure 54: Manage Chassis

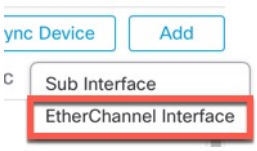
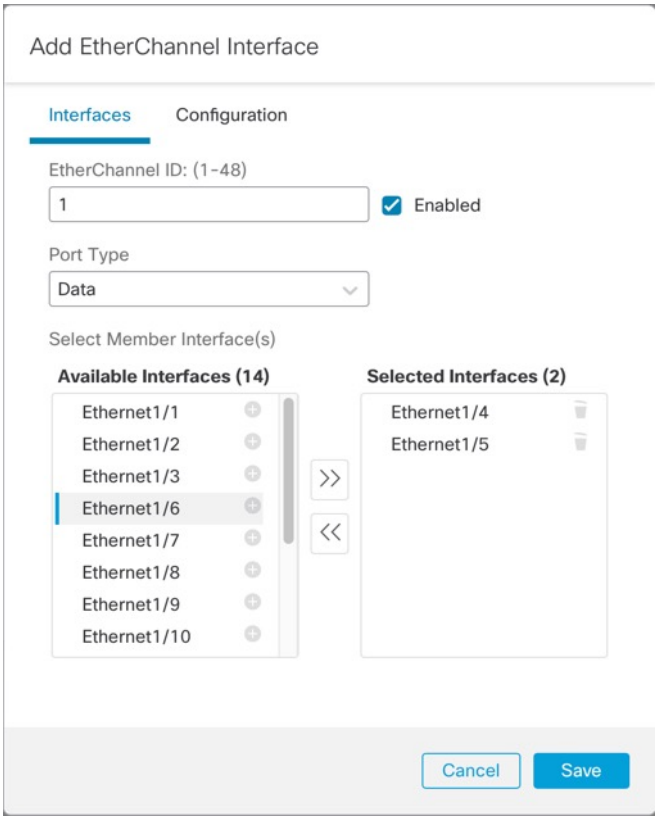
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Interfaces**.

Figure 55: Interfaces



Step 3 Click **Add** > **EtherChannel Interface**.

Figure 56: Add EtherChannel

Step 4 Set the following **Interfaces** parameters.

Figure 57: Interfaces settings

a) For the **EtherChannel ID**, specify an ID between 1 and 48.
b) Check **Enabled**.
c) For the **Port Type**, choose **Data** or **Data Shared**.

   For information about the port type, refer to Interface types, on page 615.

d) To add a physical interface to the EtherChannel, select click **Add** (⊕) in the **Available Interfaces** list to move it to the **Selected Interfaces** list.

   To add or remove all interfaces, click the double arrow button.

   Note
   You cannot add an interface that is already assigned to an instance.

Step 5 (Optional) Set the following **Configuration** parameters.

Many of these settings (excluding the LACP settings) set the requirements for interfaces to be included in the EtherChannel; they do not override the settings of member interfaces. So if you check **LLDP Transmit**, for example, you should only add interfaces that have that setting. If you set the **Admin Speed** to 1 Gbps, then only 1Gbps interfaces can be included.

Figure 58: Configuration settings

a) Choose the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.

If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.

b) Choose the required **Admin Speed** for the member interfaces from the drop-down list.

If you add a member interface that is not at the specified speed, it will not successfully join the port channel.

c) Choose the **LACP Mode**, **Active** or **On**.

- **Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- **On**—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

Note
It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

d) Choose the **LACP Rate**, **Default**, **Fast**, or **Normal**.

The default is **Fast**.

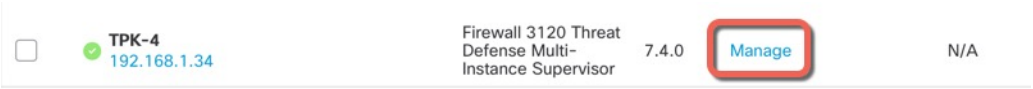
e) Choose the required Link Layer Discovery Protocol (LLDP) settings for member interfaces by checking **LLDP Transmit** and/or **LLDP Receive**.
f) Check the required **Flow Control Send** setting for member interfaces.

Step 6 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure a subinterface

You can add up to 500 subinterfaces to your chassis.



VLAN IDs per interface must be unique, and within an instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This section discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the instance. For more information, refer to Chassis interfaces vs. instance interfaces, on page 615.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

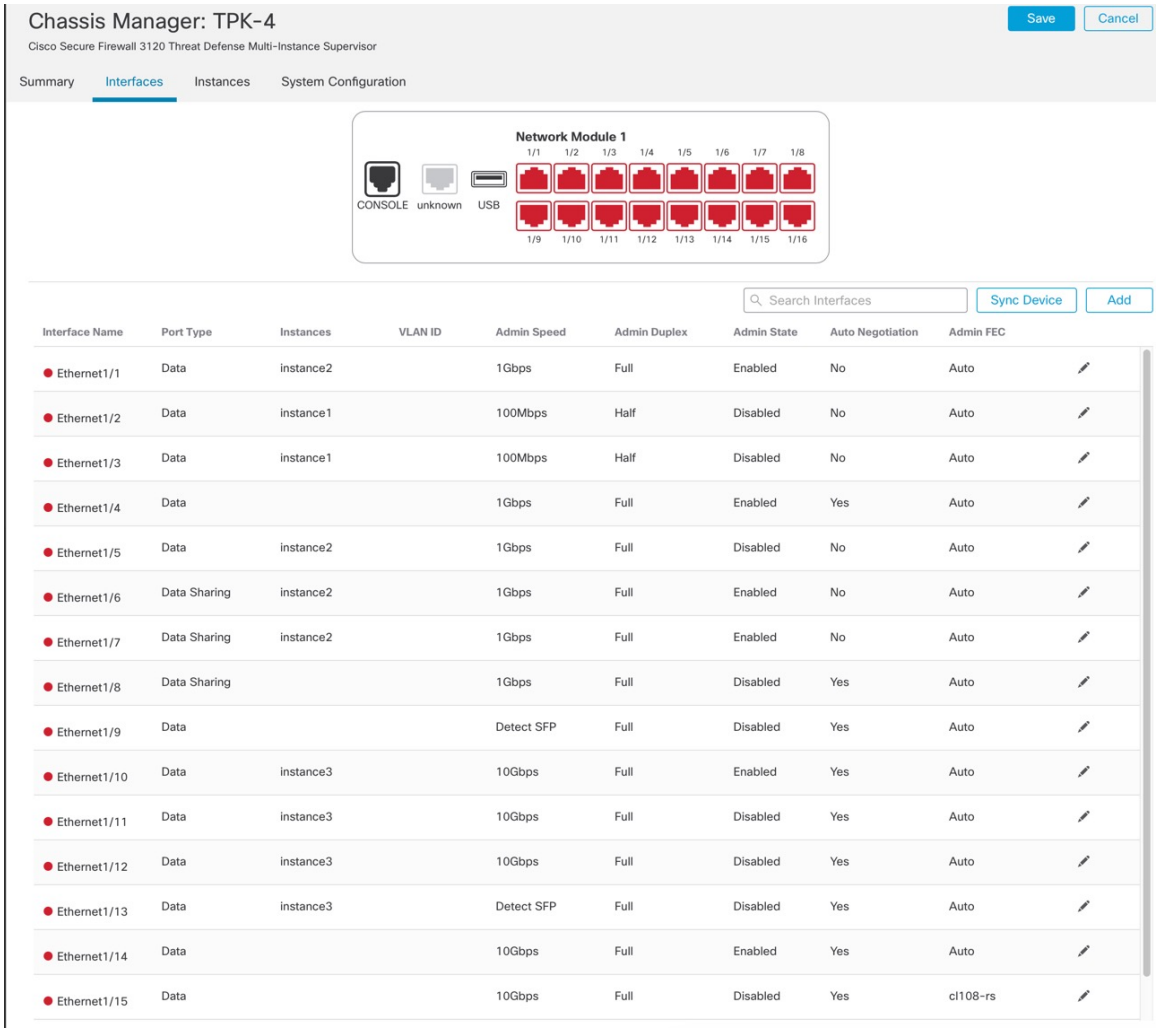


Figure 59: Manage Chassis

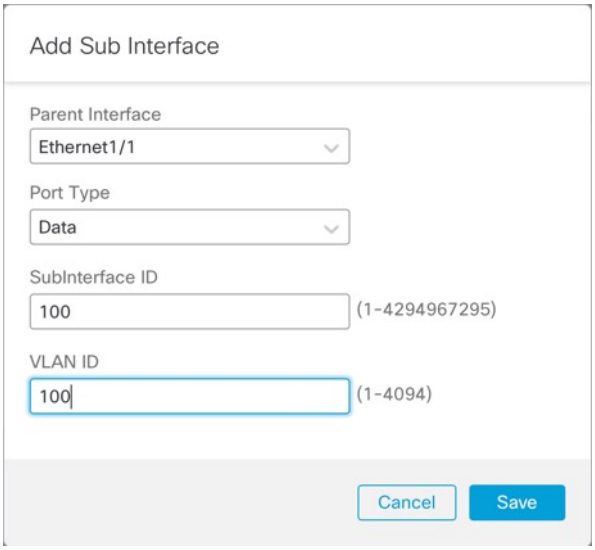
The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

Figure 60: Interfaces



Step 3 Click **Add** > **Subinterface**.

Figure 61: Add subinterface

Step 4 Set the following parameters.

Figure 62: Subinterface settings

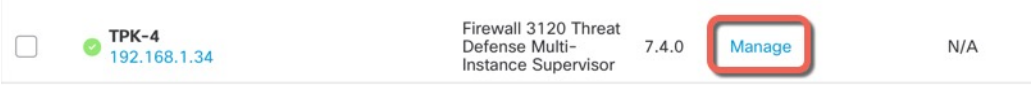
Step 5 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Add an instance

Use this task when you need to add one or more instances to a chassis already in multi-instance mode. The number of supported instances depends on your model; refer to Requirements and prerequisites for instances, on page 625.

Before you begin



Onboard the multi-instance chassis using the CLI, on page 667.

Follow these steps to add an instance to a chassis in multi-instance mode:

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

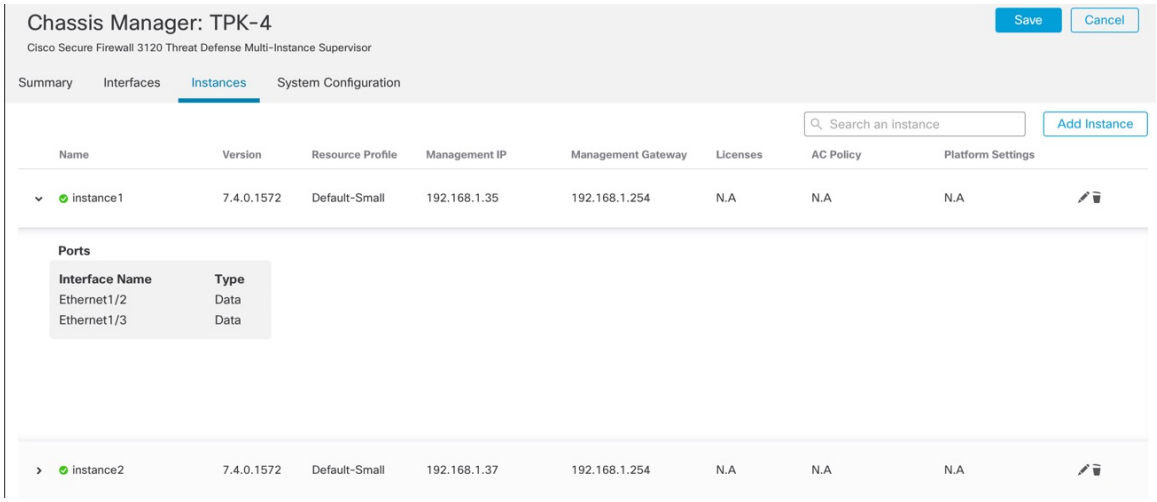


Figure 63: Manage Chassis

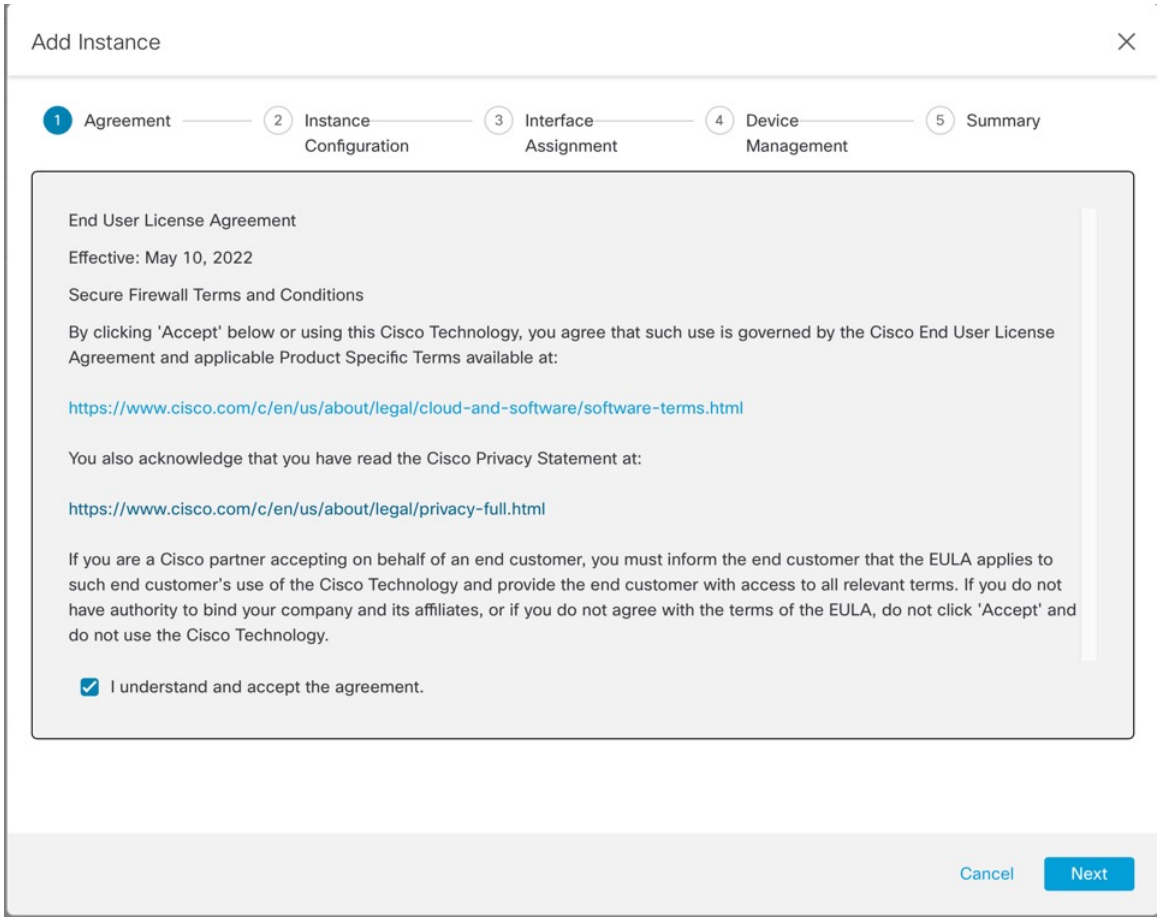
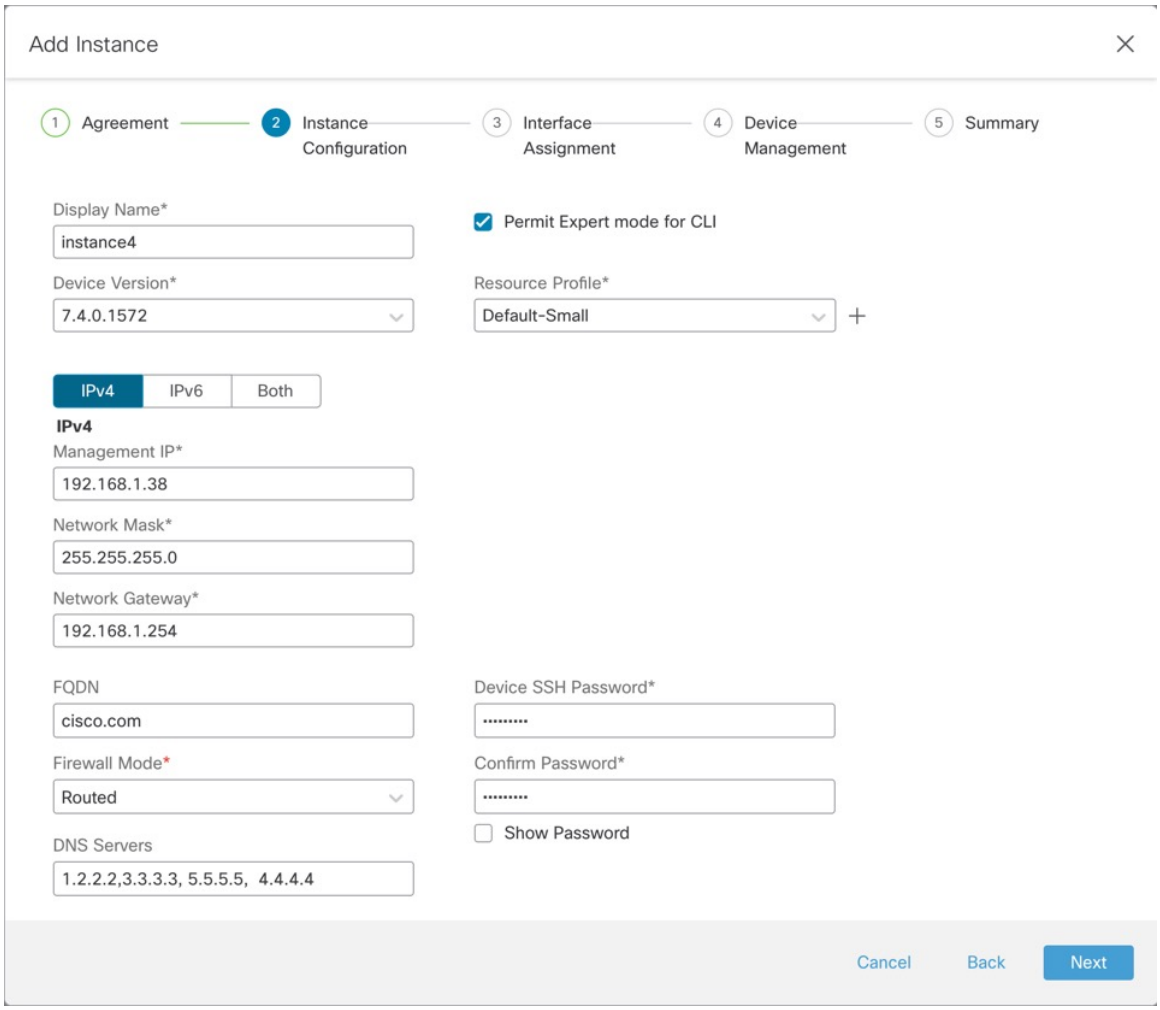
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Instances**, and click **Add Instance**.

Figure 64: Instances



Step 3 On **Agreement**, check **I understand and accept the agreement**, then click **Next**.

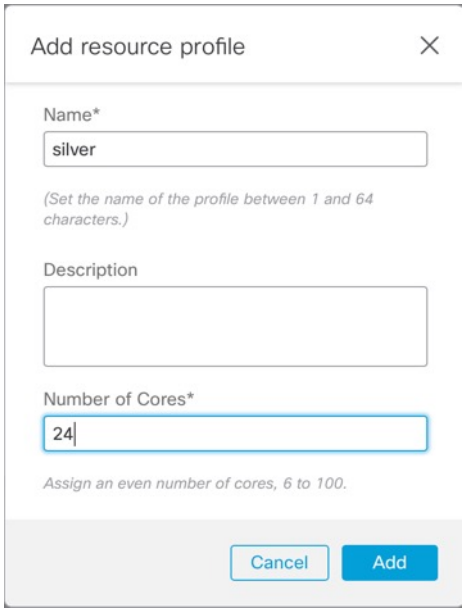
Figure 65: Agreement

Step 4 On **Instance Configuration**, set the instance parameters, then click **Next**.

Figure 66: Instance configuration

- **Display Name**
- **Device Version**: Versions listed are packages currently downloaded to the chassis. Patch versions are not listed and cannot be used because they don't contain the entire bundle. To upgrade to a new package, refer to **Devices** > **Upgrade** > **Chassis Upgrade**. When you upgrade, both the old Firewall Threat Defense version and the new Firewall Threat Defense version will be listed in the menu. To download an older package, you need to use the FXOS CLI. Note: Both FXOS and Firewall Threat Defense images are included in the same package. For more information, refer to troubleshooting guide.

  For example:



```
firepower-3110# scope firmware
firepower-3110# download image
https://10.10.7.89/Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar
Please use the command 'show download-task' or 'show download-task detail' to check
download progress.
% Download-task Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar : completed successfully.
```

- **IPv4**, **IPv6**, or **Both**: Set a **Management IP** address on the same network as the chassis Management interface. Set the **Network Mask** and gateway (likely the same gateway as the chassis). The chassis Management interface is shared with each instance, and each instance has its own IP address on the network. You can SSH to this IP address by default to reach the Firewall Threat Defense CLI.
- (Optional) **FQDN**
- **Firewall Mode**: **Routed** or **Transparent**. For more information about the firewall mode, refer to Transparent or Routed Firewall Mode, on page 153.
- **DNS Servers**: Enter a comma-separated list of DNS servers for management traffic only.
- (Optional) **Permit Expert Mode for CLI**: Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

  If you enable this option, then users who access the instance directly from an SSH session can enter Expert Mode. If you disable this option, then only users who access the instance from the FXOS CLI can enter Expert Mode. We recommend disabling this option to increase isolation between instances.

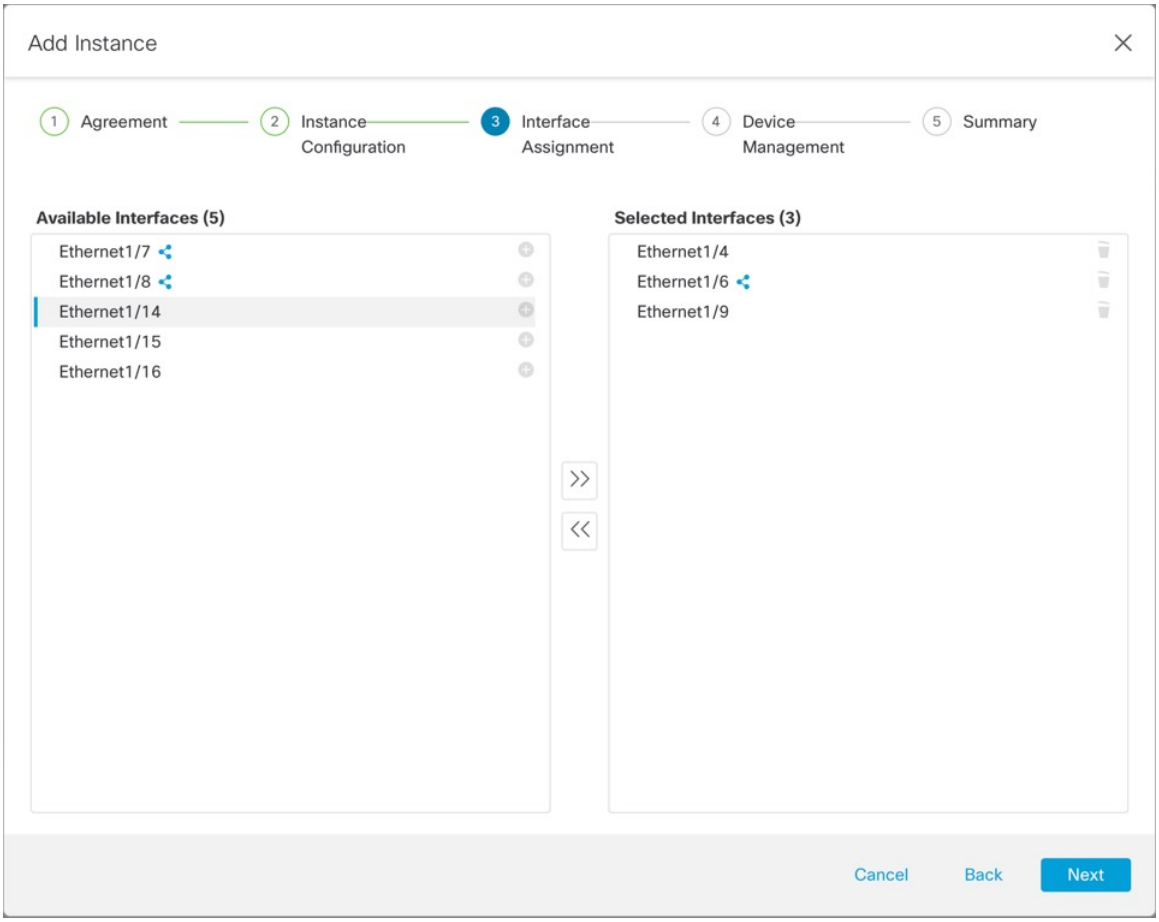
  Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.
- **Resource Profile**: The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. The chassis includes these default resource profiles: Default-Small, Default-Medium, and Default-Large. You can add additional profiles for this chassis by clicking **Add** (+). You cannot later edit the resource profile.

Figure 67: Add resource profile

  - The minimum number of cores is 6.

  Note

Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.



- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the model; refer to Requirements and prerequisites for instances, on page 625.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes. Note that for an established High Availability pair , if you assign a different-sized resource profile, be sure to make all members the same size as soon as possible.

- **Device SSH Password**: Set the Firewall Threat Defense admin user password for CLI access, either SSH or console. Repeat the password in the **Confirm Password** field.

Step 5 On **Interface Assignment**, assign the chassis interfaces to the instance, then click **Next**.

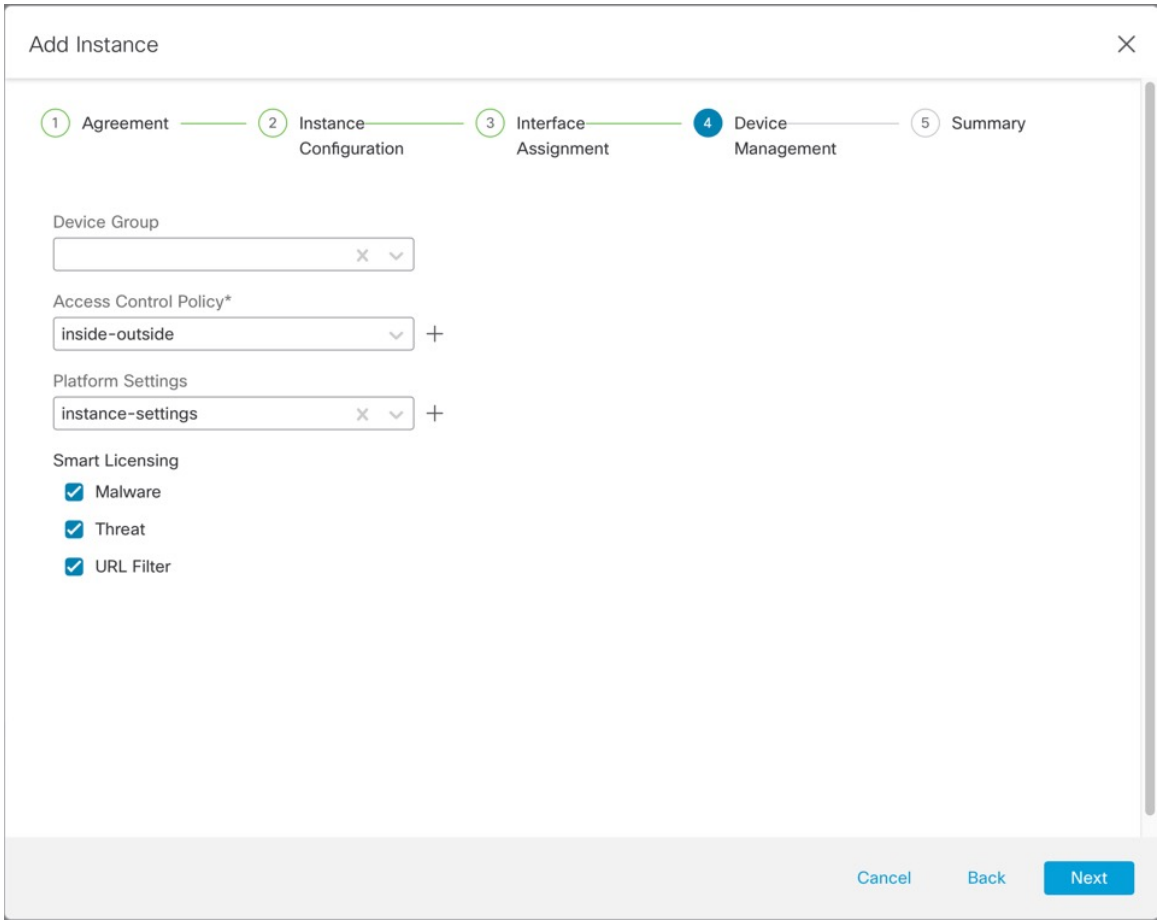


Figure 68: Interface assignment

Shared interfaces show the sharing icon ( ).

Step 6 On **Device Management**, set the device-specific settings, then click **Next**.

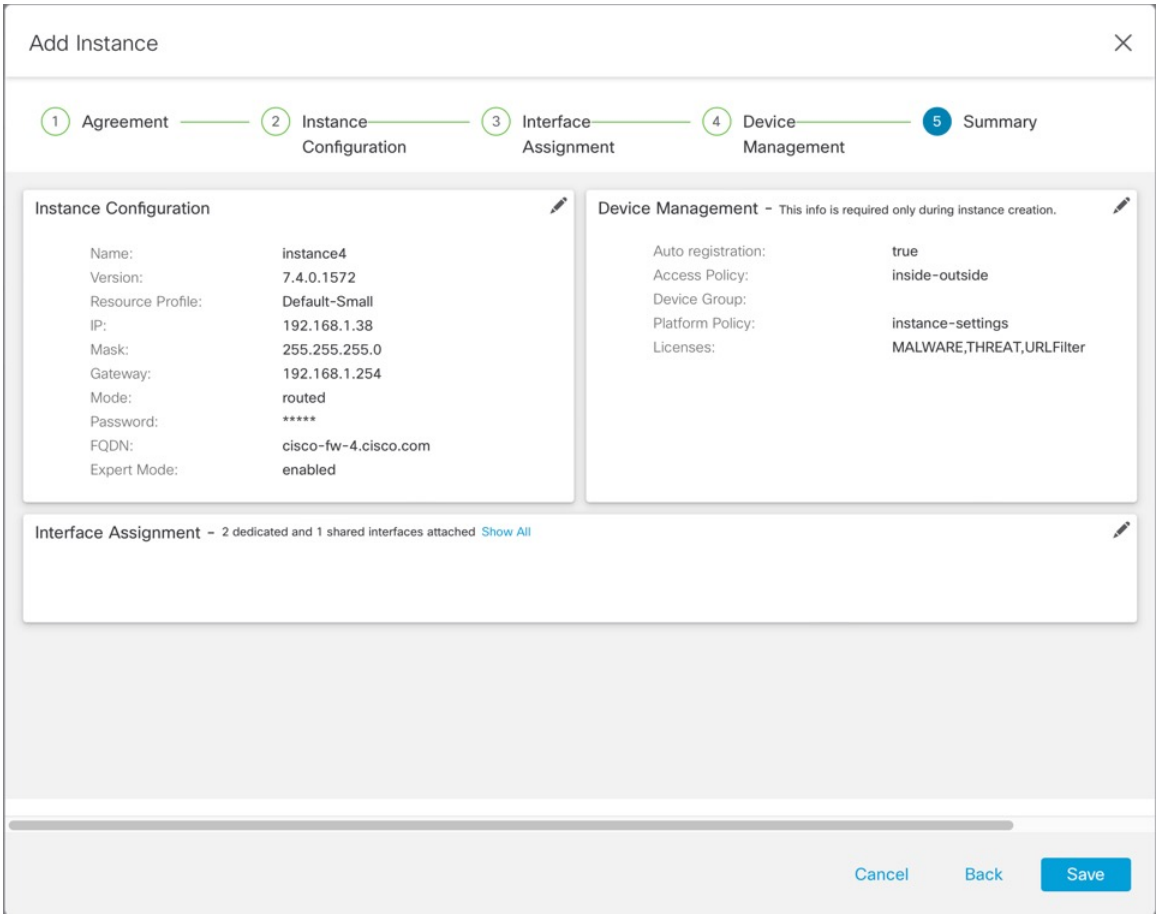

Figure 69: Device management

- **Device Group**
- **Access Control Policy**: Choose an existing access control policy, or create a new policy.
- **Platform Settings**: Choose an existing platform setting policy, or create a new policy.
- **Smart Licensing**

Step 7 On **Summary**, confirm your settings, then click **Save**.

Figure 70: Summary

You can edit any settings on this screen before saving the instance. After you save, the instance is added to the **Instances** screen.

Step 8 On the **Instances** screen, click **Save**.

Deploy the chassis configuration.

Step 9 Manually add the instance to Security Cloud Control as an FTD.

a) Add the instance **Using a CLI Registration Key**. For more information, refer to Onboard a Device with a CLI Registration Key, on page 22.

For the **Device Name**, you can use the instance name that you specified or any other name.

b) Access the chassis CLI and connect to the instance CLI. For more information, refer to Log into the Command-Line Interface on the device, on page 99.

connect FTD *name*

c) Delete the current manager; this manager needs to be deleted and reconfigured.

configure manager delete

d) Paste the generated **configure manager add** command from Security Cloud Control.

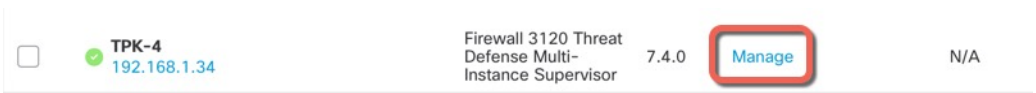
System configuration customization

You can configure chassis-level settings such as SNMP. You can also import or export the chassis FXOS configuration.

Configure SNMP

You can access chassis-level MIBs through the data interface of one of the instances, which you specify in the chassis system configuration. You can only use this instance for chassis SNMP information. You cannot access SNMP through the chassis Management interface.

Before you begin



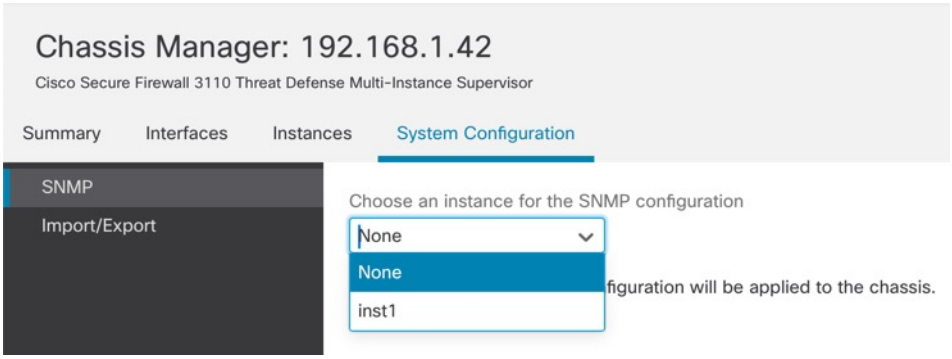
Configure SNMP for one of the instances. For more information, refer to Configure SNMP for a security device, on page 1264.

Follow these steps to configure SNMP:

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 71: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **System Configuration**.

Step 3 Click **SNMP**, and choose the instance from the drop-down list.

Figure 72: SNMP

SNMP on the chassis will be accessible from the selected instance.

Step 4 Click **Save**.

Step 5 Deploy the chassis configuration.

Import or export the chassis configuration

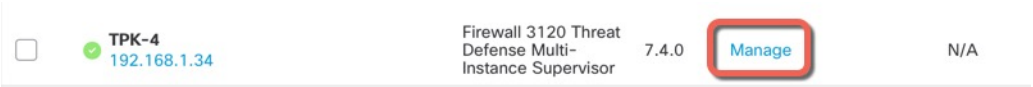
You can use the configuration export feature to export an XML file containing chassis configuration settings to your local computer. You can later import that configuration file to quickly apply the configuration settings to your chassis to return to a known good configuration or to recover from a system failure.

Note If you need to import the configuration into a new chassis of the same model, contact Cisco TAC.

When exporting, only chassis configurations are exported; instance configuration settings are not exported. Instances need to be backed up separately using the device backup/restore feature.

When importing, all existing configurations on the chassis will be replaced by the configuration in the import file.

Before you begin



When you import the configuration to the same chassis, make sure the chassis matches for the following:

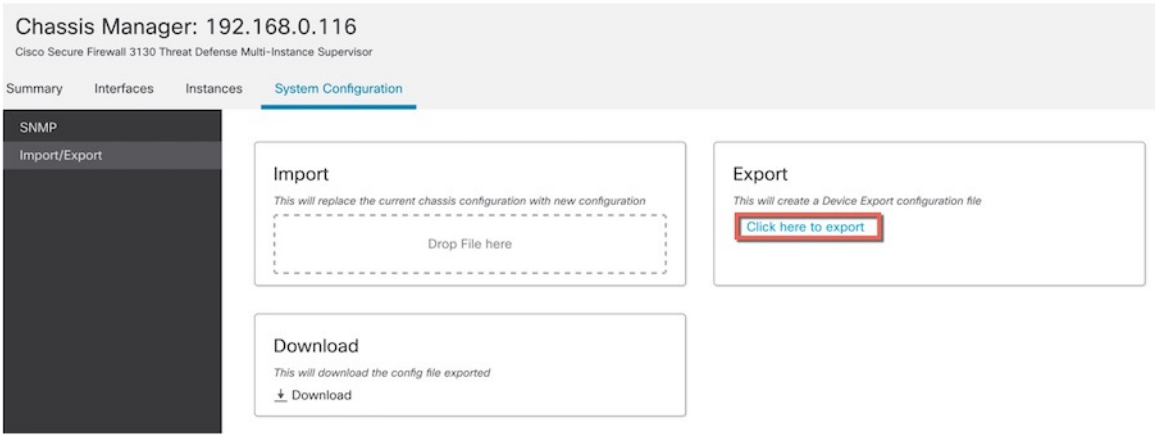
- Same chassis software version
- Same Firewall Threat Defense instance images
- Same network modules

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 73: Manage Chassis

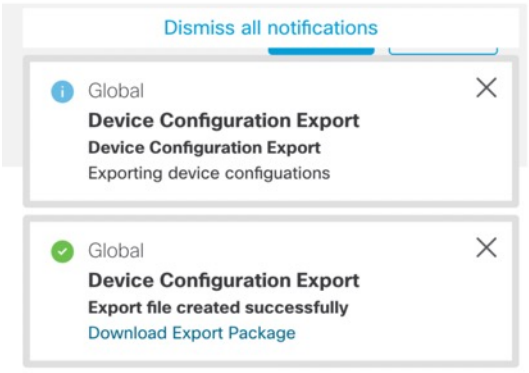
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **System Configuration**.

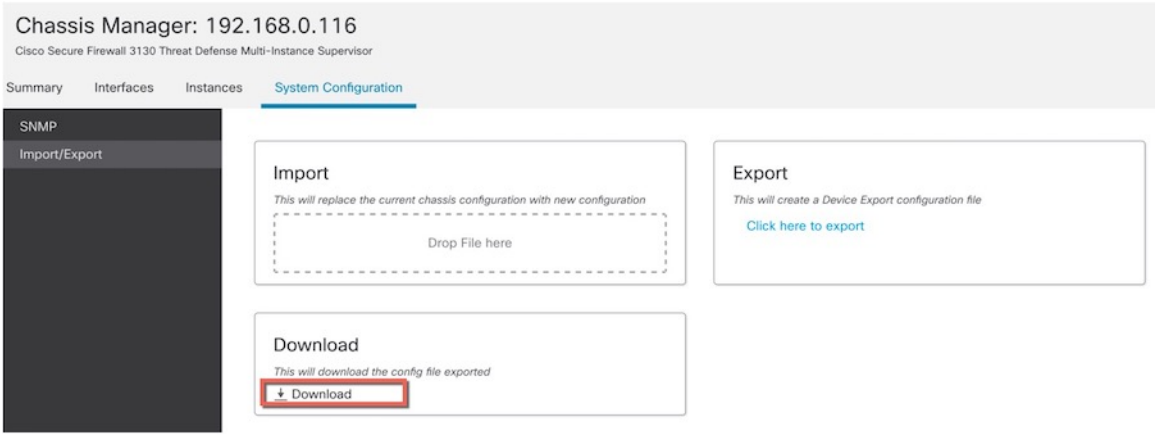
Step 3 Click **Import/Export**.

Step 4 To export the configuration, follow these steps.



a) In the **Export** area, click **Click here to export**.

Figure 74: Create Export File



b) Monitor the notifications for the **Export file created successfully** message.

Figure 75: Export File Created Successfully

c) Download the export file by clicking the notification message (**Download Export Package**) or by clicking **Download**.

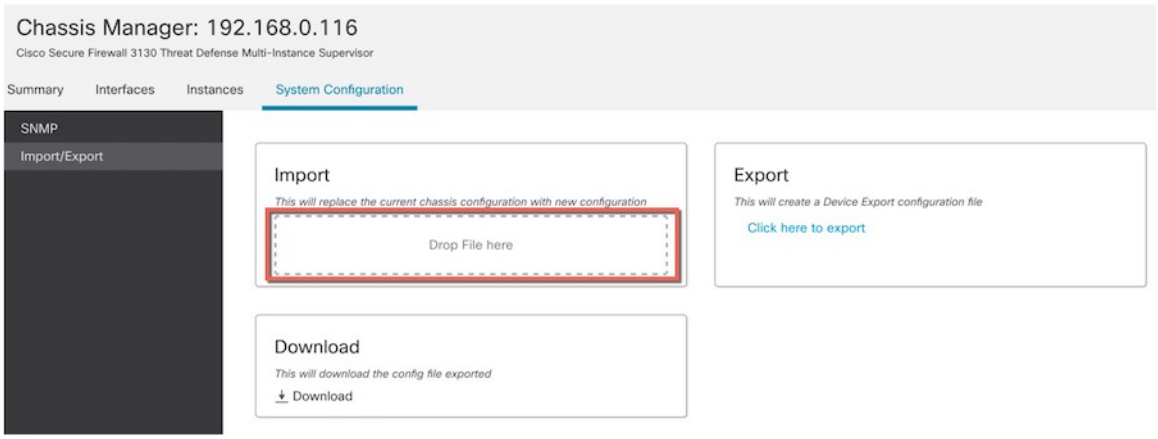


Figure 76: Download

The file is saved with the .sfo extension.

Step 5 To import a configuration, drag the **.sfo** file on the **Import** > **Drop File here** area.

Figure 77: Import

Chassis platform settings

Chassis platform settings are configuration features that configure a range of features for managing the chassis and can be shared among multiple chassis.

Chassis platform settings configure a range of features for managing the chassis. You can share the policy among multiple chassis. If you want different settings per chassis, you must create multiple policies.

Create a chassis platform settings policy

Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** ( ), **Edit** ( ), or **Delete** ( ) the policy.

Caution
You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose **Chassis Platform Settings** from the drop-down list.
b) Enter a **Name** for the new policy and optionally, a **Description**.
c) Optionally, choose the **Available Chassis** where you want to apply the policy and click **Add** to add the selected chassis.

d) Click **Save**.

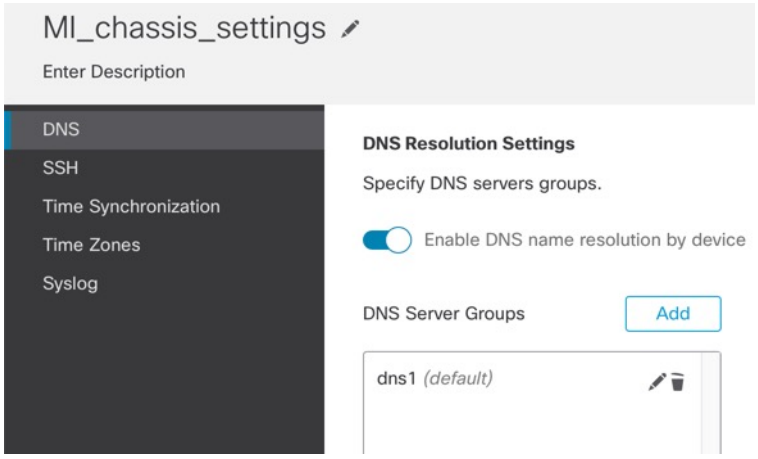
The system creates the policy and opens it for editing.

Step 4 To change the target chassis for a policy, click **Edit** ( ) next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.
b) To assign a chassis to the policy, select it in the **Available Chassis** list and click **Add**.
c) To remove a chassis assignment, click **Delete** ( ) next to a chassis in the **Selected Chassis** list.
d) Click **OK**.

Configure DNS

You need to specify a DNS server if the chassis requires resolution of hostnames to IP addresses. These chassis DNS settings are separate from the DNS settings per instance, which are configured in the device platform settings.



When you configure multiple DNS servers, the chassis uses servers in a random order. You can configure up to four servers across four DNS server groups. For example, you can configure a single server group with four servers, or you can configure four server groups with one server each.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **DNS**.

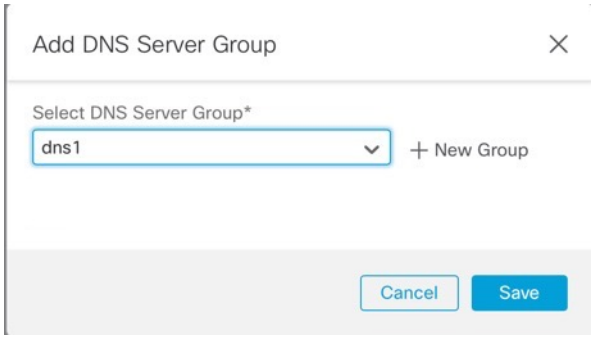


Figure 78: DNS

Step 3 Enable the **Enable DNS name resolution by device** slider.

Step 4 Click **Add** to add a DNS server group.

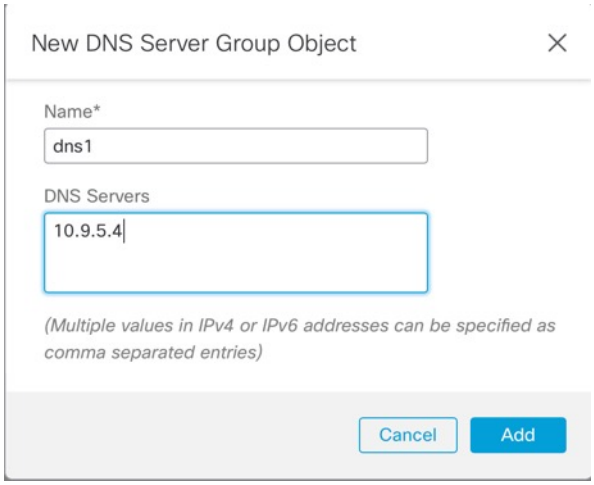

Figure 79: Add DNS server group

Step 5 Either select an existing DNS server group (refer to Create a DNS server group object, on page 2965), or click (+) **New Group**.

If you add a new group, you see this dialog box. Provide a name and up to four DNS server IP addresses as comma-separated values, and click **Add**.

Figure 80: New DNS server group object

Step 6 Click **Save** to add the DNS server to the list.

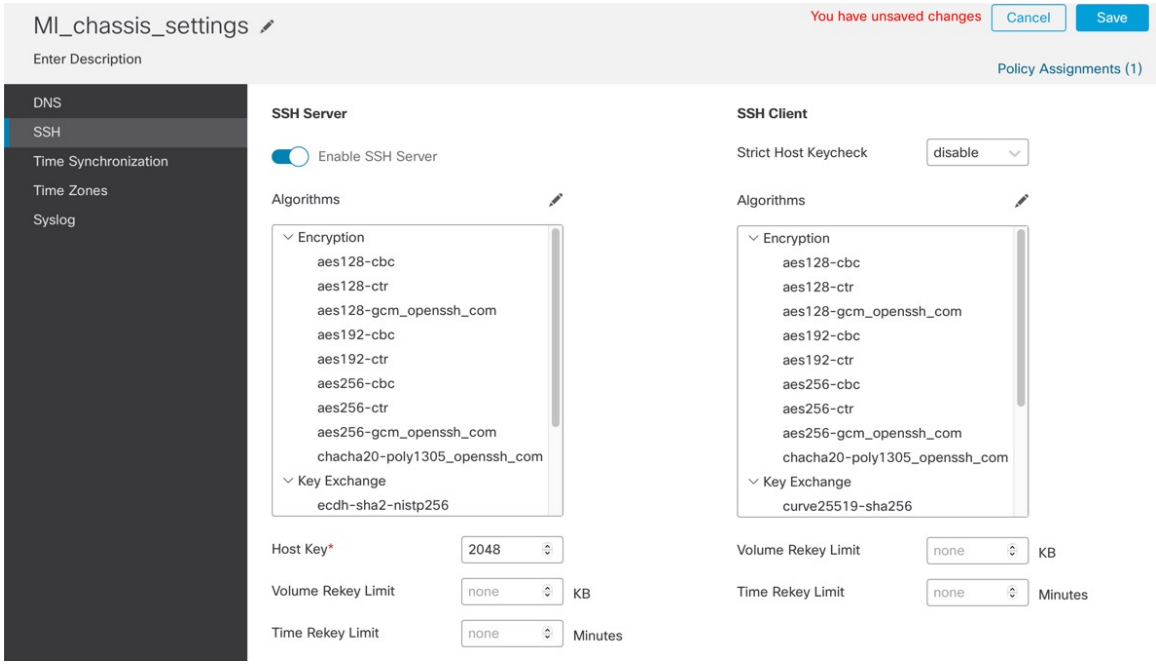
Step 7 Repeat these steps to add additional server groups.

Make sure you only identify a maximum of four DNS servers in all groups combined.

Step 8 Click **Save** to save all policy changes.

Configure SSH and SSH access list

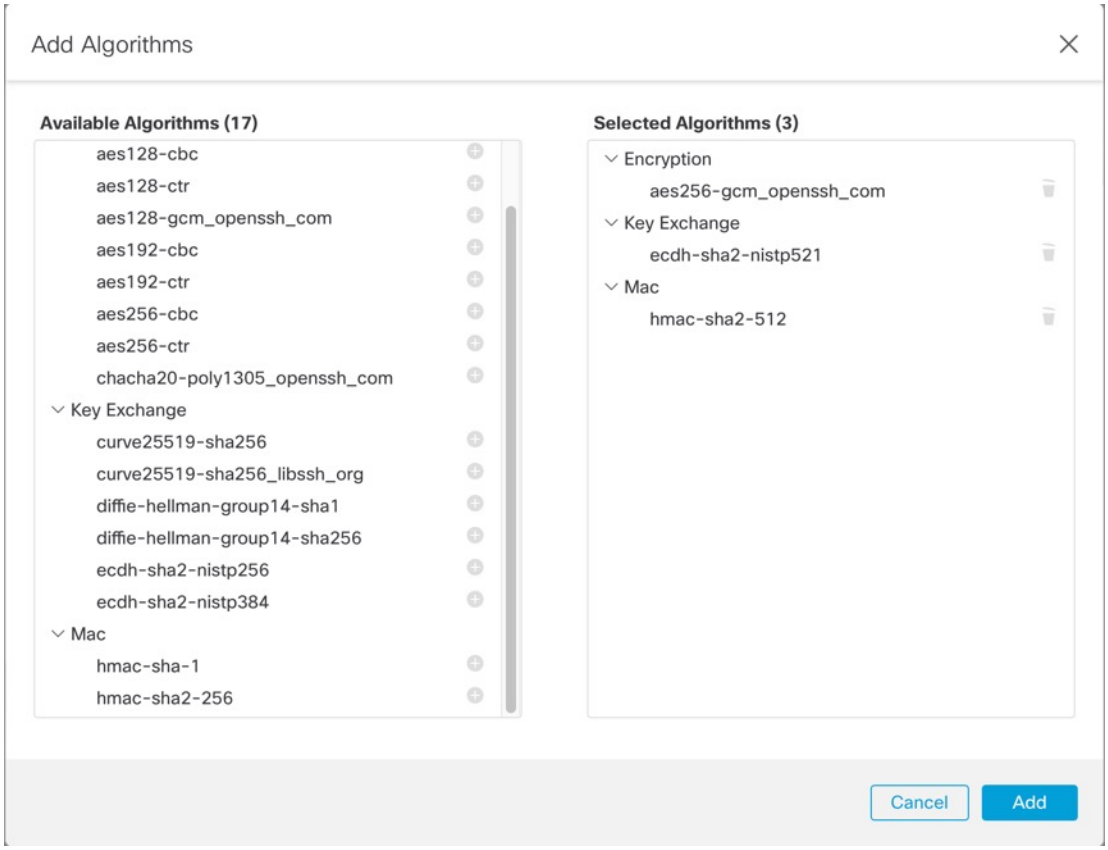
To allow SSH sessions from the admin user to the chassis on the Management interface, enable the SSH server and configure the allowed networks.



Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **SSH**.



Step 3 To enable SSH access to the chassis, enable the **Enable SSH Server** slider.

Figure 81: SSH

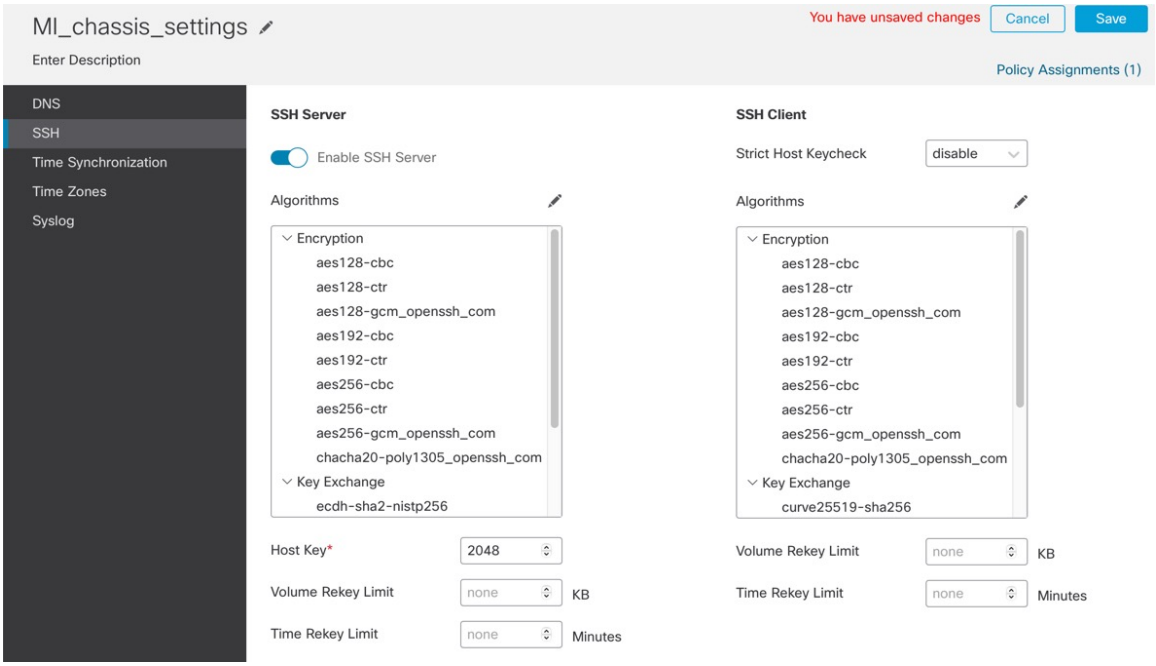
Step 4 To set the allowed **Algorithms**, click **Edit** ( ).

Figure 82: Add Algorithms

a) Select the **Encryption** algorithms.
b) Select the **Key Exchange** algorithms.

   The key exchange provides a shared secret that cannot be determined by either party alone. The key exchange is combined with a signature and the host key to provide host authentication. This key-exchange method provides explicit server authentication.

c) Select the **Mac** integrity algorithms.



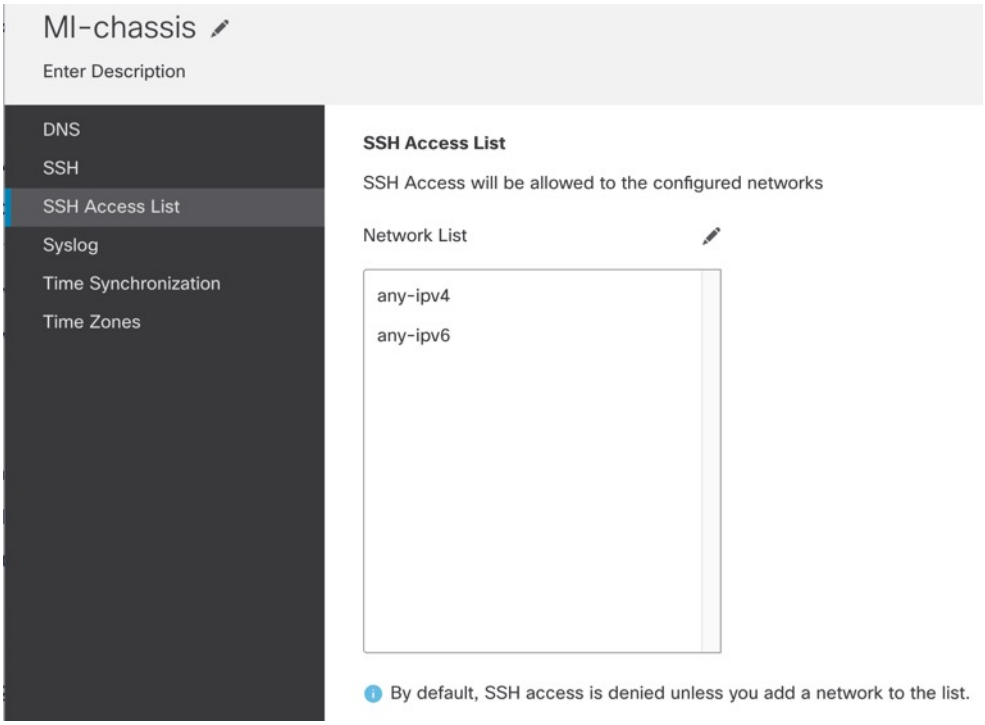
Step 5 For **Host Key**, enter the modulus size for the RSA key pairs.

The modulus value (in bits) is in multiples of 8 from 1024 to 2048. The larger the key modulus size you specify, the longer it takes to generate an RSA key pair. We recommend a value of 2048.

Step 6 For the server **Volume Rekey Limit**, set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.. For the server **Time Rekey Limit**, set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

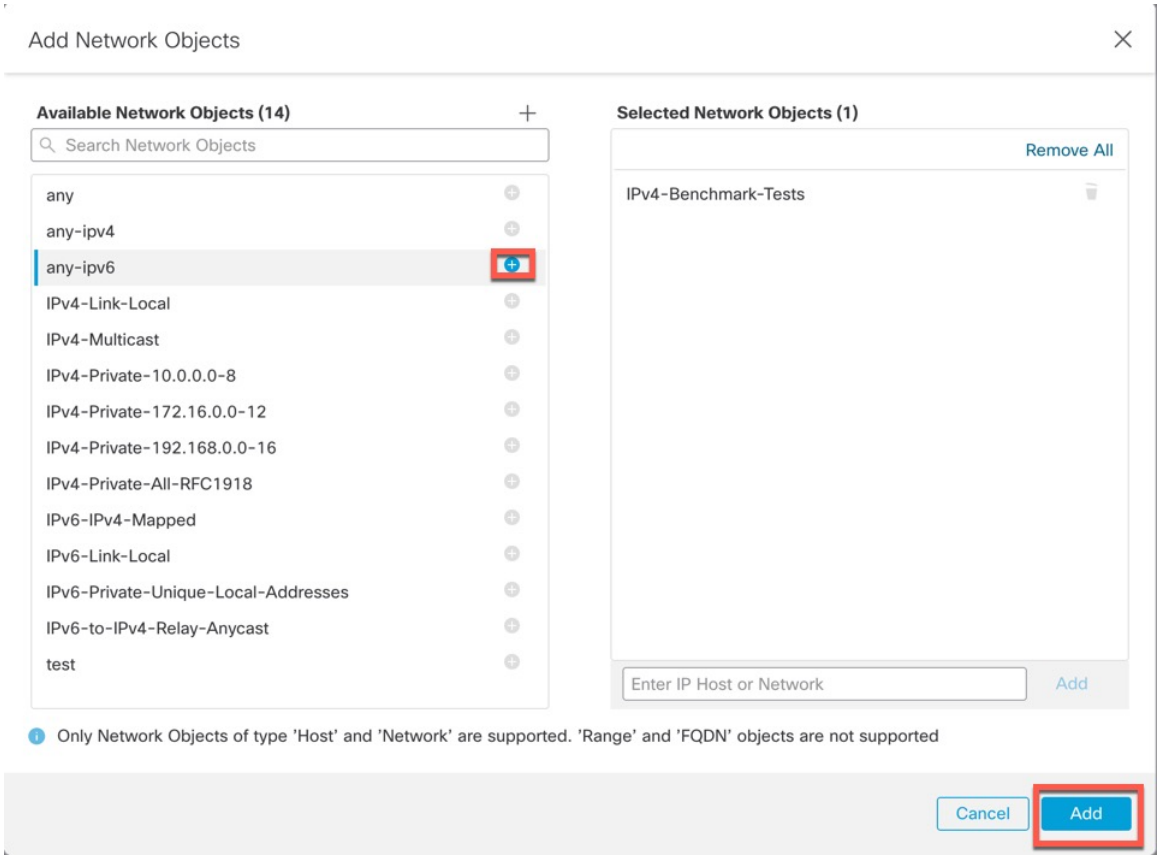
Step 7 For the **SSH Client**, configure the following settings.

Figure 83: SSH



- **Strict Host Keycheck**—Choose **enable**, **disable**, or **prompt** to control SSH host key checking.
  - **enable**—The connection is rejected if the host key is not already in the FXOS known hosts file. You must manually add hosts at the FXOS CLI using the **enter ssh-host** command in the system/services scope.
  - **prompt**—You are prompted to accept or reject the host key if it is not already stored on the chassis.
  - **disable**—(The default) The chassis accepts the host key automatically if it was not stored before.
- **Algorithms**: Click **Edit** (✎). and select the **Encryption**, **Key Exchange**, and **Mac** algorithms.
- **Volume Rekey Limit**: Set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.
- **Time Rekey Limit**: Set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

Step 8 Choose **SSH Access List**. You need to allow access to IP addresses or networks before you can use SSH.



You can add up to 25 access lists.

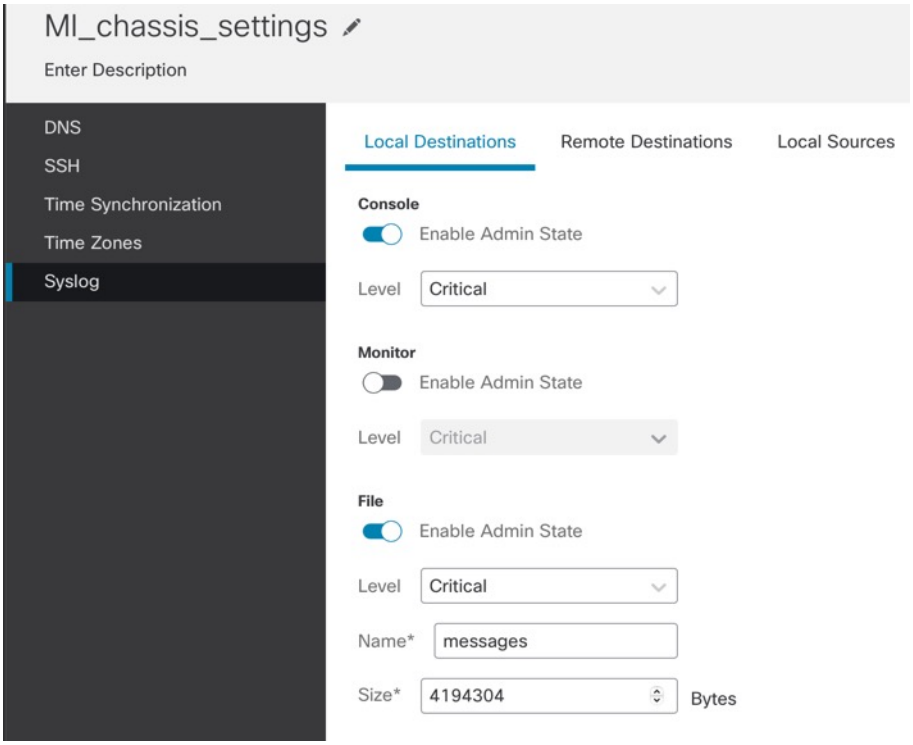
Figure 84: SSH Access List

Step 9 Click **Edit** ( ) to add network objects and click **Save**. You can also manually enter IP addresses. Click **Save** to save all policy changes.

Figure 85: Network Objects

Configure syslog

You can enable syslogs from the chassis. These syslogs come from the chassis' FXOS operating system.



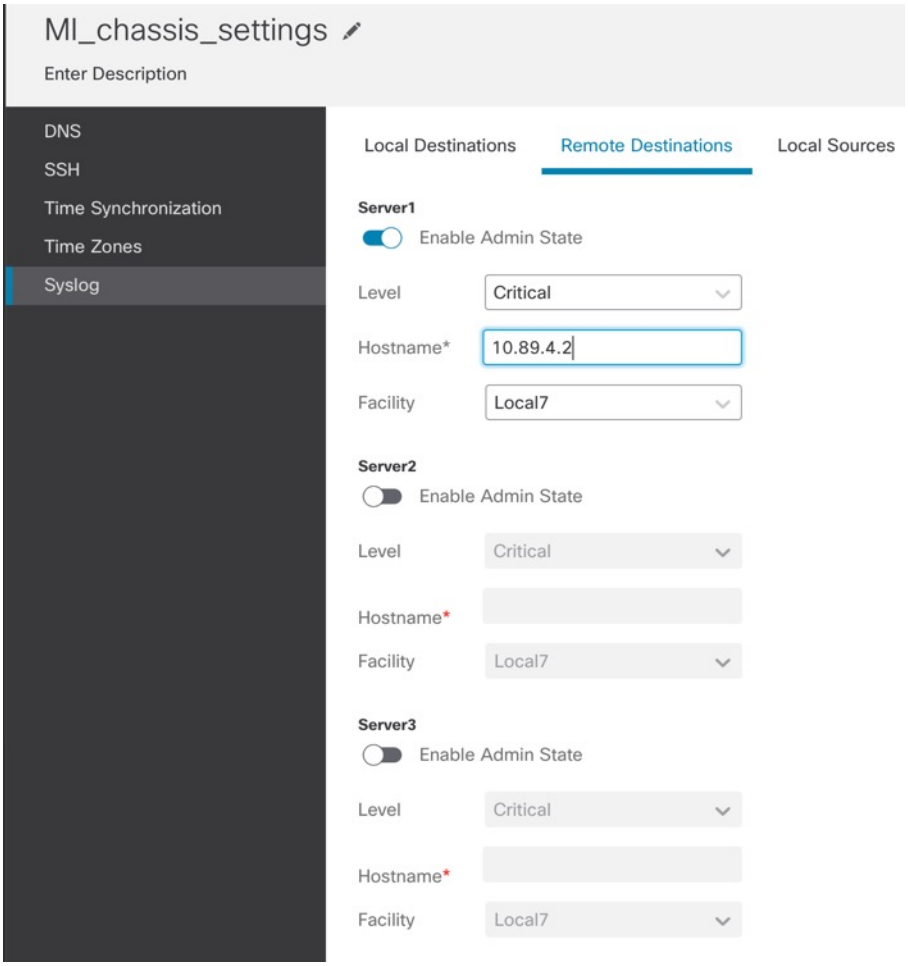
Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Syslog**.

Step 3 Click the **Local Destinations** tab, and complete the following fields.

Figure 86: Syslog local destinations

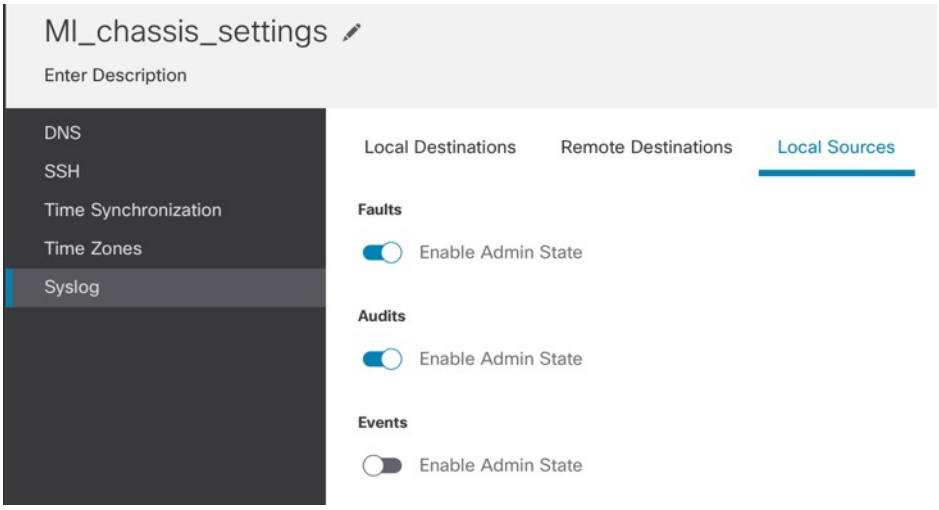


Name	Description
Console Section	
Admin State field	Whether the chassis displays syslog messages on the console. Check the **Enable** check box if you want to have syslog messages displayed on the console as well as added to the log. If the **Enable** check box is unchecked, syslog messages are added to the log but are not displayed on the console.
Level field	If you checked the **Enable** check box for **Console - Admin State**, select the lowest message level that you want displayed on the console. The chassis displays that level and above on the console. This can be one of the following: • **Emergencies** • **Alerts** • **Critical**
Monitor Section	

Name	Description
Admin State field	Whether the chassis displays syslog messages on the monitor. Check the **Enable** check box if you want to have syslog messages displayed on the monitor as well as added to the log. If the **Enable** check box is unchecked, syslog messages are added to the log but are not displayed on the monitor.
Level drop-down list	If you checked the **Enable** check box for **Monitor - Admin State**, select the lowest message level that you want displayed on the monitor. The system displays that level and above on the monitor. This can be one of the following: • **Emergencies** • **Alerts** • **Critical** • **Errors** • **Warnings** • **Notifications** • **Information** • **Debugging**

Step 4 On the **Remote Destinations** tab, complete the following fields for up to three external logs that can store messages generated by the chassis:

Figure 87: Syslog remote destinations



By sending syslog messages to a remote destination, you can archive messages according to the available disk space on the external syslog server, and manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

Name	Description
Admin State field	Check the **Enable** check box if you want to have syslog messages stored in a remote log file.

Name	Description
Level drop-down list	Select the lowest message level that you want the system to store. The system stores that level and above in the remote file. This can be one of the following: • **Emergencies** • **Alerts** • **Critical** • **Errors** • **Warnings** • **Notifications** • **Information** • **Debugging**
Hostname/IP Address field	The hostname or IP address on which the remote log file resides. **Note** You must configure a DNS server if you use a hostname rather than an IP address.
Facility drop-down list	Choose a system log facility for syslog servers to use as a basis to file messages. This can be one of the following: • **Local0** • **Local1** • **Local2** • **Local3** • **Local4** • **Local5** • **Local6** • **Local7**

Step 5 Click the **Local Sources** tab, and complete the following fields.

Figure 88: Syslog local sources

Name	Description
Faults > **Enable Admin State**	Enable system fault logging.
Audits > **Enable Admin State**	Enable audit logging.
Events > **Enable Admin State**	Enable system event logging.

Step 6 Click **Save** to save all policy changes.

Configure time synchronization

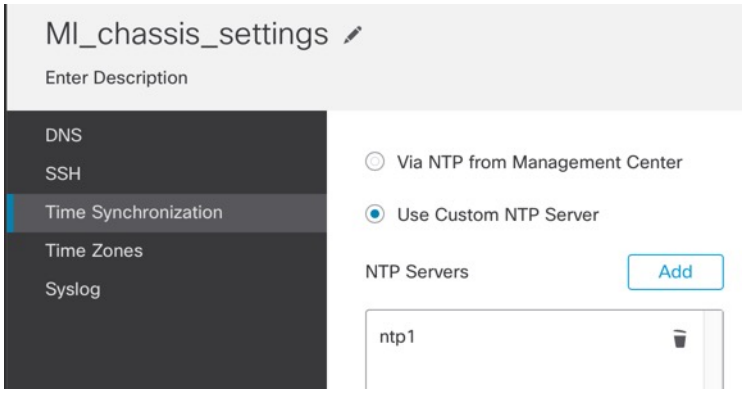
NTP is used to implement a hierarchical system of servers that provide precisely synchronized time among network systems. This kind of accuracy is required for time-sensitive operations, such as validating CRLs, which include a precise time stamp. You can configure up to four NTP servers.

Note

- FXOS uses NTP version 3.
- If the stratum value of an external NTP server is 13 or greater, the application instance cannot sync to the NTP server on the FXOS chassis. Each time a NTP client syncs to a NTP server, the stratum value increases by one.

  If you have set up your own NTP server, you can find its stratum value in the /etc/ntp.conf file on the server. If the NTP server has stratum value of 13 or greater you can either change the stratum value in the ntp.conf file and restart the server, or use a different NTP server (for example: pool.ntp.org).

Before you begin



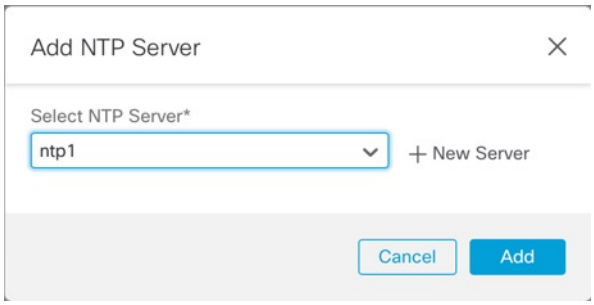
If you use a hostname for the NTP server, you must configure a DNS server. For more information, refer to Configure DNS, on page 653.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Synchronization**.

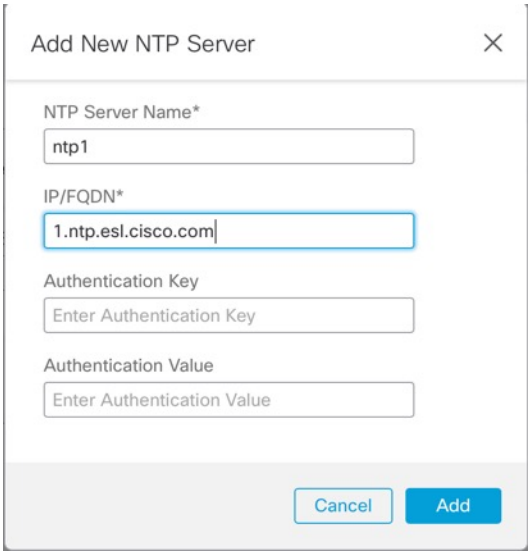
Figure 89: Time synchronization



Step 3 If you want to obtain the time from the Cloud-Delivered Firewall Management Center, click **Via NTP from Management Center**.

This option ensures both the chassis and the Cloud-Delivered Firewall Management Center have the same time.

Step 4 To use an external NTP server, click **Use Custom NTP Server**.



a) Click **Add** to add a server.

Figure 90: Add NTP server

b) Choose any already-defined servers from the drop-down menu and click **Add**, or click + **New Server** to add a new server.

Figure 91: Add new NTP server

c) For a new server, enter the following fields, and click **Add**.

- **NTP Server Name**: A name to identify this server.
- **IP/FQDN**: The IP address or hostname of the server.
- **Authentication Key** and **Authentication Value**: Obtain the key ID and value from the NTP server. For example, to generate the SHA1 key on NTP server Version 4.2.8p8 or later with OpenSSL installed, enter the **NTP-keygen -M** command, and then view the key ID and value in the NTP.keys file. The key is used to tell both the client and server which value to use when computing the message digest.

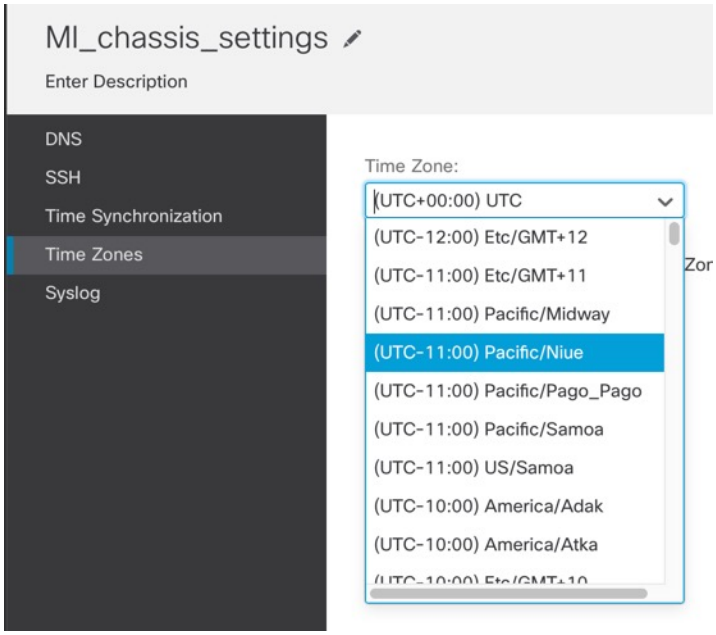
  Only SHA1 is supported for NTP server authentication.

Step 5 Click **Save** to save all policy changes.

Configure time zones

Time zone configuration is essential for maintaining accurate timestamps in system logs and ensuring proper time-based functionality across the device.

Before you begin



Follow these steps to configure the time zone for the chassis:

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Zones**.

Figure 92: Time zones

Step 3 Choose your **Time Zone** from the drop-down menu.

Step 4 Click **Save** to save all policy changes.

Multi-instance mode management

This section describes less common tasks, including changing settings at the FXOS CLI or changing interfaces assigned to the chassis.

Onboard the multi-instance chassis using the CLI

If you want to pre-configure your devices for multi-instance mode before you add them to the Cloud-Delivered Firewall Management Center, you can perform this procedure. To use the Cloud-Delivered Firewall Management Center to convert to multi-instance mode, refer to Convert a device to Multi-Instance mode, on page 629.

You need to connect to the chassis FXOS CLI at the console port to enable multi-instance mode and perform initial setup. After you configure the chassis, you can add it to the Cloud-Delivered Firewall Management Center. The management center and the chassis share a separate management connection using the chassis MGMT interface.

Note Although you can connect to SSH on the management port, we recommend using the console port to avoid multiple disconnections. If you use SSH before you switch to multi-instance mode, you connect to the Firewall Threat Defense CLI and need to connect to FXOS using **connect FXOS**. This procedure covers the console port.

Use the Cloud-Delivered Firewall Management Center to configure all chassis settings as well as instances. The Secure Firewall Chassis Manager or configuration at the FXOS CLI is not supported.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Step 2 Log in with the username **admin** and the password **Admin123**.

The first time you log in to FXOS, you are prompted to change the password.

Note
If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default. See the FXOS troubleshooting guide for the reimage procedure.

Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1

[...]

Hello admin. You must change your password.
Enter new password: ********
Confirm new password: ********
Your password was updated successfully.

[...]

firepower#
```

Step 3 Check your current mode, Native or Container. If the mode is Native, you can continue with this procedure to convert to multi-instance (Container) mode.

show system detail

Example:

```
firepower # show system detail

Systems:
    Name: firepower
    Mode: Stand Alone
    System IP Address: 172.16.0.50
    System IPv6 Address: ::
    System Owner:
    System Site:
    Deploy Mode: Native
    Description for System:
firepower #
```

Step 4 Enable multi-instance mode.

scope system

set deploymode container

You are prompted to reboot.

Example:

```
firepower# scope system
firepower /system # set deploymode container
All configuration and bootable images will be lost and system will reboot.
If there was out of band upgrade, it might reboot with the base version and need to re-image
 to get the expected running version.
Do you still want to change deploy mode? (yes/no):yes
firepower /system #
```

To change the mode back to appliance mode, enter **set deploymode native**.

Step 5 After the chassis finishes rebooting, set the Management IP address. You can use IPv4 and/or IPv6. The default address is 192.168.45.45/24 with a gateway of 192.168.45.1.

IPv4:

scope fabric-interconnect

set out-of-band static ip *ip_address* **netmask** *network_mask* **gw** *gateway_ip_address*

IPv6:

scope fabric-interconnect

scope ipv6-config

set out-of-band static ipv6 *ipv6_address* **ipv6-prefix** *prefix_length* **ipv6-gw** *gateway_address*

Example:

IPv4:

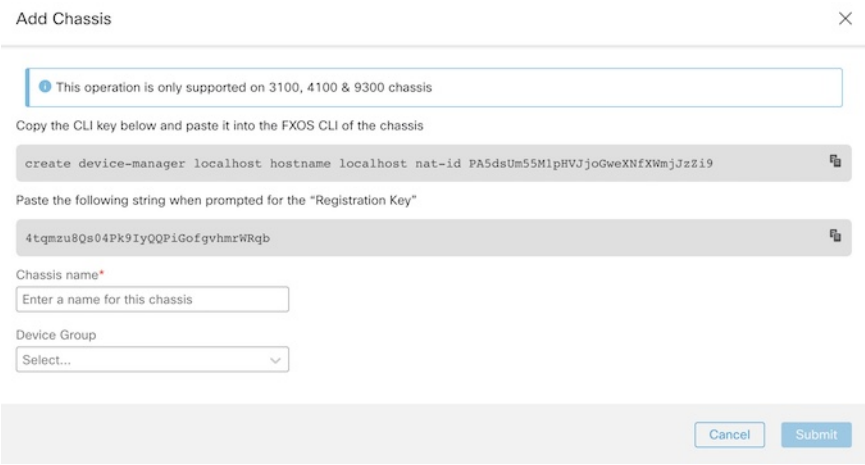
```
firepower-3110# scope fabric-interconnect
firepower-3110 /fabric-interconnect # set out-of-band static ip 10.5.23.8 netmask
255.255.255.0 gw 10.5.23.1
```

IPv6:

```
firepower-3110# scope fabric-interconnect
firepower-3110 / fabric-interconnect # scope ipv6-config
firepower-3110 / fabric-interconnect /ipv6-config # set out-of-band static ipv6 2001:DB8::34
 ipv6-prefix 64 ipv6-gw 2001:DB8::1
```

Step 6 Log in to Security Cloud Control.

Step 7 In the left pane, click **Security Devices**.



Step 8 Click **Onboard device or service** ( ) icon.

Step 9 Click the **FTD Chassis** tile to open the **Add Chassis** dialog box.

Figure 93: FTD Chassis Tile

Figure 94: Add Chassis

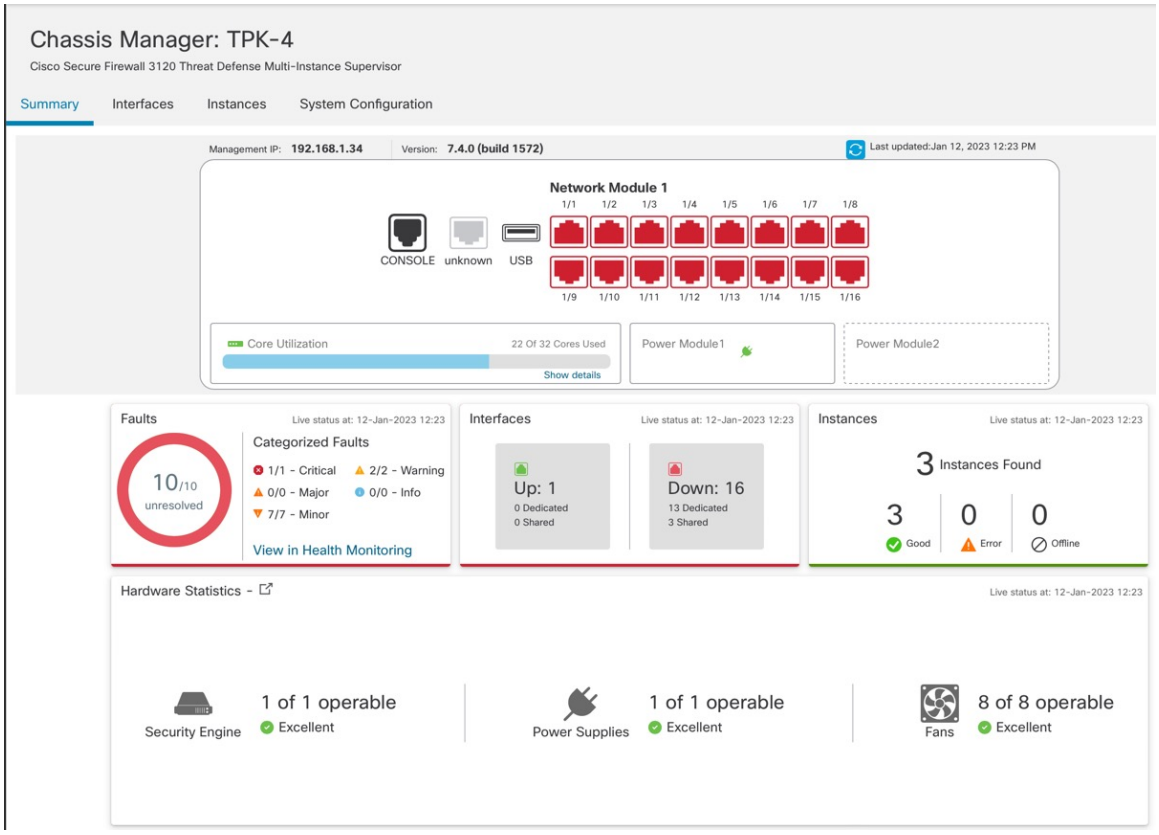
Step 10 Click **Copy** ( ) to copy the top generated command, then paste it at the FXOS CLI of your chassis.

Step 11 When prompted for the Registration Key at the FXOS CLI, click **Copy** ( ) on the **Add Chassis** dialog box for the generated registration key and paste it at the FXOS CLI.

You can disconnect from the FXOS CLI at this point.

Step 12 In the Cloud-Delivered Firewall Management Center **Chassis Name** field, enter a name for the chassis as you want it to display in the Cloud-Delivered Firewall Management Center.

Step 13 (Optional) Add the chassis to a **Device Group**.



Step 14 Click **Submit**.

The chassis is added to the **Device** > **Device Management** page.

Step 15 To view and configure the chassis, click **Manage** in the **Chassis** column, or click **Edit** ( ) .

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Figure 95: Chassis Summary

Change interfaces assigned to an instance

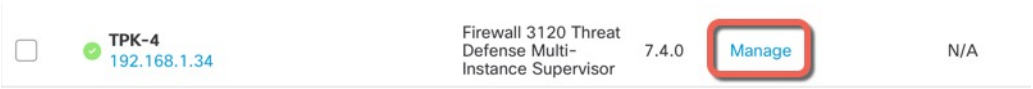
You can allocate or unallocate an interface on the instance. Adding a new interface, or deleting an unused interface, has minimal impact on the instance configuration. You can also edit the membership of an allocated EtherChannel without affecting the instance.

Deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the instance configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface.

Policies that refer to security zones are not affected.

Note For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

Before you begin



- Configure your interfaces according to Instance configuration, on page 629.

- If you plan to add an already-allocated interface to an EtherChannel, you need to unallocate the interface from the instance first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the instance.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

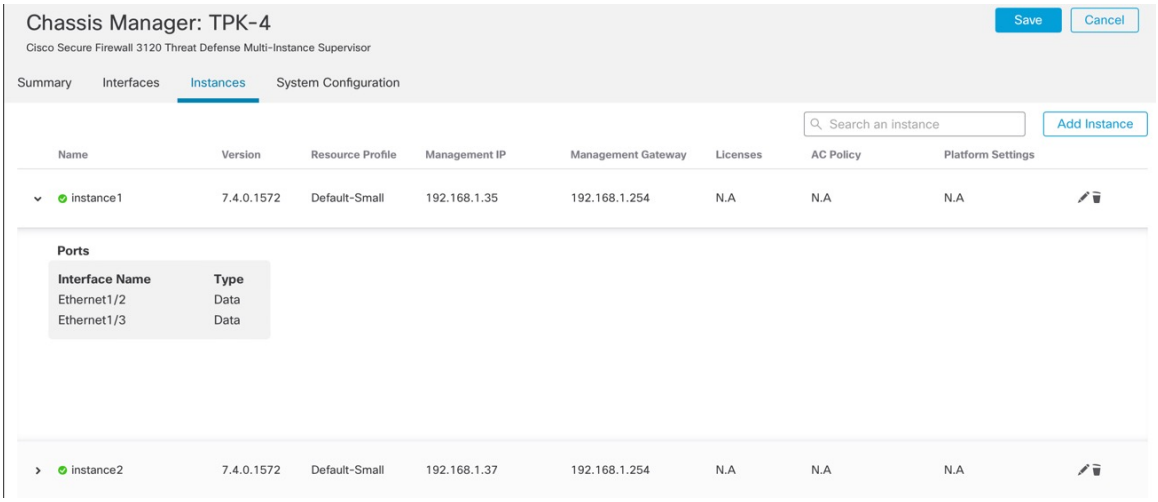


Figure 96: Manage Chassis

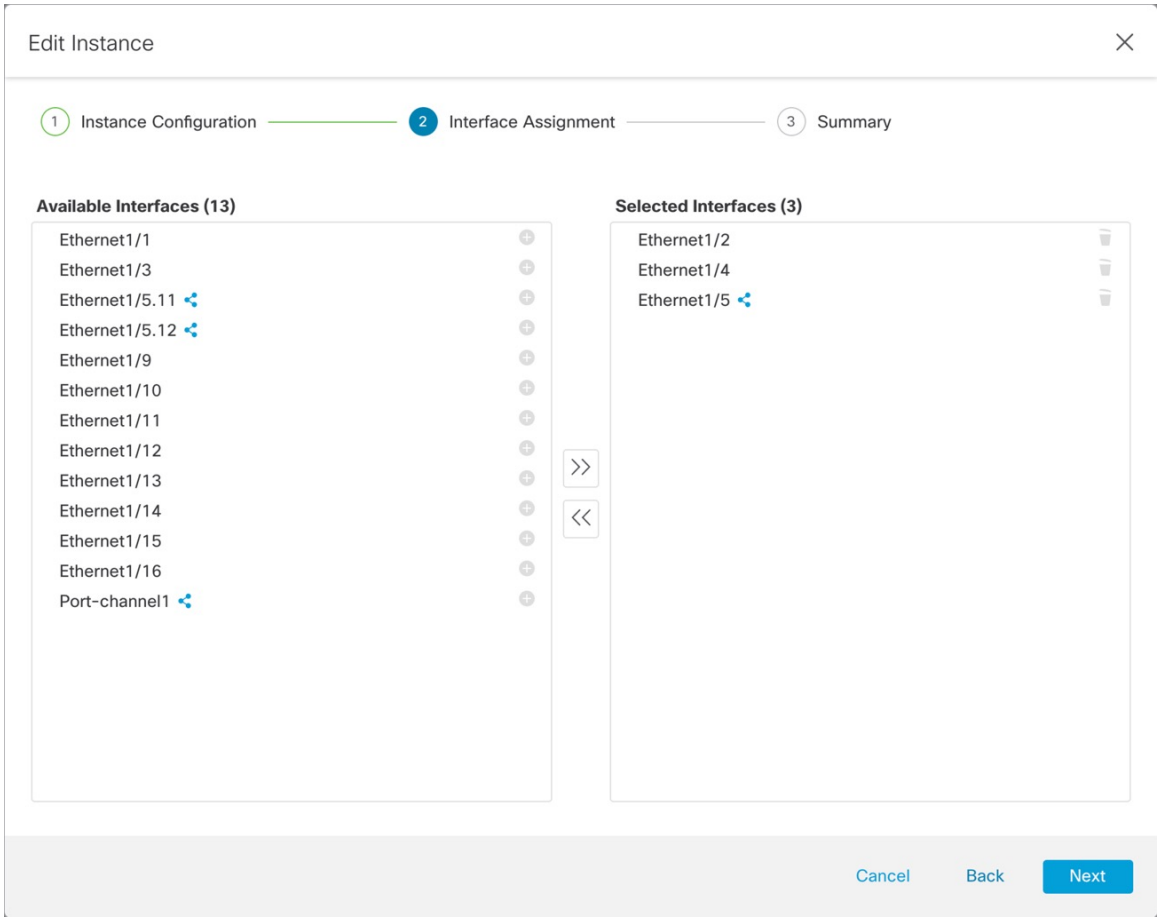
The **Chassis Manager** page opens for the chassis to the **Summary** page.



Step 2 Click **Instances**, and click **Edit** ( ) next to the instance for which you want to change interfaces.

Figure 97: Instances

Step 3 Click **Next** until you get to the **Interface Assignment** screen.

Figure 98: Interface assignment

Shared interfaces show the sharing icon ( ).

Step 4 Make your interface changes, and then click **Next**.

Step 5 Click **Save** on the **Summary** screen.

Step 6 For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

Change chassis management settings at the FXOS CLI

If you want to change the chassis management interface IP address and gateway, change the Cloud-Delivered Firewall Management Center to a new manager, change the admin password, or disable multi-instance mode, you can do so from the FXOS CLI.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Note
We recommend using the console port. You can also connect using SSH to the management interface, if configured in the chassis platform settings in the Cloud-Delivered Firewall Management Center; however, if you change the management IP address, you will be disconnected.

Step 2 Log in with the username **admin** and the password you set during initial setup.

Step 3 Change the Management IP address. You can use a static IPv4 and/or IPv6 address.

IPv4:

scope fabric-interconnect

set out-of-band static IP *ip_address* **netmask** *network_mask* **gw** *gateway_ip_address*

IPv6:

scope fabric-interconnect

scope ipv6-config

set out-of-band static ipv6 *ipv6_address* **ipv6-prefix** *prefix_length* **ipv6-gw** *gateway_address*

Example:

IPv4:

```
firepower-3110# scope fabric-interconnect
firepower-3110 /fabric-interconnect # set out-of-band static ip 10.5.23.8 netmask
255.255.255.0
gw 10.5.23.1
```

IPv6:

```
firepower-3110# scope fabric-interconnect
firepower-3110 / fabric-interconnect # scope ipv6-config
firepower-3110 / fabric-interconnect /ipv6-config # set out-of-band static ipv6 2001:DB8::34
ipv6-prefix 64 ipv6-gw 2001:DB8::1
```

Step 4 Change the Cloud-Delivered Firewall Management Center.

You should first unregister the chassis from the current Cloud-Delivered Firewall Management Center.

enter device-manager *manager_name* [**hostname** {*hostname* | *ipv4_address* | *ipv6_address*}] [**NAT-ID** *nat_id*]

You are prompted for the registration key.

You can enter this command from any scope.

- **hostname** {*hostname* | *ipv4_address* | *ipv6_address*}: Specifies either the FQDN or IP address of the Cloud-Delivered Firewall Management Center. At least one of the devices, either the Cloud-Delivered Firewall Management Center or the chassis, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you do not specify a **hostname**, then the chassis must have a reachable IP address or hostname and you must specify the **NAT-ID**.

- **NAT-ID** *nat_id*: Specifies a unique, one-time string of your choice that you will also specify on the Cloud-Delivered Firewall Management Center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a **hostname**, however we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Cloud-Delivered Firewall Management Center.
- **Registration Key:** *reg_key*: You will be prompted for a one-time registration key of your choice that you will also specify on the Cloud-Delivered Firewall Management Center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).

Example:

```
firepower-3110# enter device-manager boulder_fmc hostname 10.89.5.35 nat-id 93002
(Valid registration key characters: [a-z],[A-Z],[0-9],[-]. Length: [2-36])
Registration Key: Impala67
```

Step 5 Change the admin password.

scope security

set password

Enter a password: *password*

Confirm the password: *password*

Example:

```
firepower-3110# scope security
firepower-3110 /security # set password
Enter new password: Sw@nsong67
Confirm new password: Sw@nsong67
firepower-3110 /security #
```

Step 6 Disable multi-instance mode and set the system back to appliance mode.

scope system

set deploymode native

You are prompted to reboot.

Example:

```
firepower-3110# scope system
firepower-3110 /system # set deploymode native
All configuration and bootable images will be lost and system will reboot.
If there was out of band upgrade, it might reboot with the base version and
need to re-image to get the expected running version.
Do you still want to change deploy mode? (yes/no):yes
firepower-3110 /system #
```

To change the mode back to multi-instance mode, enter **set deploymode container**. You can check the current mode using the **show system detail** command.

Multi-instance mode

This section helps you troubleshoot and diagnose your multi-instance mode chassis and instances.

Multi-instance setups

A multi-instance setup is a system configuration approach that

- enables running multiple independent instances on a single hardware platform,
- allows flexible allocation of resources to each instance, and
- supports both container and native (appliance) operating modes.

show system detail

This FXOS command shows the current mode, Native or Container. If the mode is Native (also known as appliance mode), you can convert to multi-instance (Container) mode. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the Firewall Threat Defense (by default "firepower")

```
firepower # show system detail

Systems:
    Name: firepower
    Mode: Stand Alone
    System IP Address: 172.16.0.50
    System IPv6 Address: ::
    System Owner:
    System Site:
    Deploy Mode: Native
    Description for System:
firepower #
```

scope system > show

This FXOS command shows the current mode in a table format. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the Firewall Threat Defense.

```
firepower-3110# scope system
firepower-3110 /system # show

Systems:
    Name       Mode        Deploy Mode System IP Address System IPv6 Address
    ---------- ----------- ----------- ----------------- -------------------
```

```
    firepower-3110
               Stand Alone Container   10.89.5.42        ::

3110-1# scope system
3110-1 /system # show

Systems:
    Name       Mode        Deploy Mode System IP Address System IPv6 Address
    ---------- ----------- ----------- ----------------- -------------------
    3110-1     Stand Alone Native      10.89.5.41        ::
3110-1 /system #
```

Instance interfaces

An instance interface is a physical or virtual network interface on a device that

- enables connectivity between multiple logical instances within a system,
- facilitates assignment of interfaces to one or more instances, and
- supports configuration of forwarding rules using ECMP and multicast groups.

show portmanager switch forward-rules hardware mac-filter

This command shows the internal switch-forwarding rule for two instances with a dedicated physical interface assigned to each instance. Ethernet 1/2 is assigned to ftd1 and Ethernet 1/1 is assigned to ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

```
secfw-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN   SRC_PORT   PC_ID   SRC_ID   DST_PORT     PKT_CNT      DMAC
1        0         17       0       17         19       29164  0:0:0:0:0:0
2        0         19       0       19         17       67588  0:0:0:0:0:0
3        0          1       0      101       1541           0  a2:5b:83:0:0:15
4        0          1       0      101       1541        8181  ff:ff:ff:ff:ff:ff
5        0          2       0      102       1540           0  a2:5b:83:0:0:18
6        0          2       0      102       1540         431  ff:ff:ff:ff:ff:ff
7        0         17       0        0          0       11133  0:0:0:0:0:0
8        0         17       0        0          0           0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared physical interfaces assigned to two instances. Ethernet 1/1 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4096 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN   SRC_PORT   PC_ID   SRC_ID   DST_PORT     PKT_CNT      DMAC
1        0         17       0       17         19        2268  0:0:0:0:0:0
2        0         19       0       19         17        4844  0:0:0:0:0:0
3        0          1       0      101       1541           0  a2:5b:83:0:0:9
4        0          1       0      101       4096         546  ff:ff:ff:ff:ff:ff
5        0          1       0      101       1540           0  a2:5b:83:0:0:c
6        0         17       0        0          0        1263  0:0:0:0:0:0
7        0         17       0        0          0           0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared subinterfaces assigned to both instances. Ethernet 1/1.2452 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4097 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN   SRC_PORT   PC_ID   SRC_ID   DST_PORT     PKT_CNT      DMAC
1        0         17       0       17         19       21305  0:0:0:0:0:0
2        0         19       0       19         17       50976  0:0:0:0:0:0
3     2452          1       0      101       1541         430  a2:5b:83:0:0:f
4     2452          1       0      101       4097           0  ff:ff:ff:ff:ff:ff
5     2452          1       0      101       1540           0  a2:5b:83:0:0:12
6        0         17       0        0          0       11038  0:0:0:0:0:0
7        0         17       0        0          0           0  0:0:0:0:0:0
```

show portmanager switch ecmp-groups detail

Use this command to list each Instance Ecmp-Vport-Physical port mapping detail.

Note Physical-Port 18 is the backplane uplink interface between the internal switch and the instance.

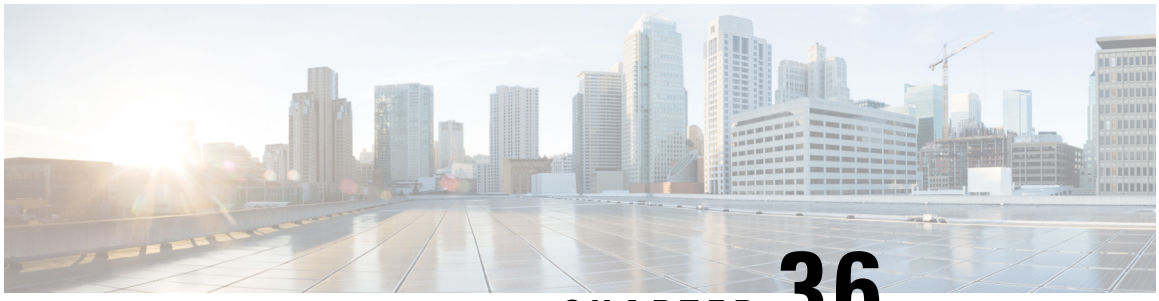
```
firepower-3140(local-mgmt)# show portmanager switch ecmp-groups detail
       ECMP-GROUP  VPORT      PHYSICAL-PORT
1      1536        256        18
2      1537        257        18
3      1538        258        18
4      1539        259        18
5      1540        260        18
6      1541        261        18
7      1542        262        18
8      1543        263        18
9      1544        264        18
10     1545        265        18
```

show portmanager switch mcast-groups detail

Use this command to list MCAST group membership details.

```
firepower-3140(local-mgmt)# show portmanager switch mcast-groups detail
       MCAST-GROUP
1      4096
       Member-ports
       Ethernet 1/1
       ECMP-ID 1541
       ECMP-ID 1540
```

show portmanager counters mcast-group



Use this command to check the MCAST group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters mcast-group 4096
PKT_CNT: 8106
```

show portmanager counters ecmp

Use this command to check the ECMP group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters ecmp 1541
PKT_CNT: 430
```

CHAPTER 36

High Availability for Devices

The following topics describe how to configure Active/Standby failover to accomplish high availability of the Firewall Threat Defense.

- Secure Firewall Threat Defense high availability, on page 681
- Config-sync optimization, on page 700
- Requirements and prerequisites for high availability, on page 702
- Guidelines for High availability, on page 702
- Add a high availability pair, on page 705
- Configure optional high availability parameters, on page 708
- Manage High availability, on page 710
- Monitoring High availability, on page 717
- High availability break troubleshooting in remote branch deployments, on page 718

Secure Firewall Threat Defense high availability

Secure Firewall Threat Defense high availability is a failover configuration that

- requires two identical Firewall Threat Defense devices connected through a dedicated failover link and optionally a state link
- supports Active/Standby failover where one unit passes traffic while the standby unit does not actively pass traffic synchronizes configuration and state information, and
- monitors the health of the active unit (hardware, interfaces, software, and environmental status) to determine if failover conditions are met.

Failover process details

When a failover occurs, the active unit fails over to the standby unit, which then becomes active. The health of the active unit (hardware, interfaces, software, and environmental status) is monitored to determine if specific failover conditions are met. If those conditions are met, failover occurs.

Note High availability is not supported on Firewall Threat Defense Virtual running in the public cloud. See the Secure Firewall Threat Defense Virtual getting started guides for more information about configuring the Firewall Threat Defense Virtual device for high availability.

High availability support on Firewall Threat Defense devices in a remote branch office deployment

High availability support on Firewall Threat Defense devices in a remote branch office deployment is a feature that

- enables Security Cloud Control to manage devices through data interfaces instead of management interfaces
- supports centralized management through outside Security Cloud Control access for single internet connection environments, and
- requires software version 7.2 or later on managed devices.

Remote branch office deployment characteristics

In a remote branch office deployment, the data interface of the Firewall Threat Defense device is used for Security Cloud Control management instead of the management interface on the device. Most remote branch offices only have a single internet connection. Outside Security Cloud Control access makes centralized management possible.

You can use *any* data interface for Security Cloud Control access, for example, the inside interface if you have an inside Security Cloud Control. However, this guide primarily covers outside interface access, because it is the most likely scenario for remote branch offices.

Security Cloud Control provides high availability support on the Firewall Threat Defense devices that it manages through the data interface. This feature is supported on devices running on software version 7.2 or later.

For more information, see *Firepower Threat Defense Deployment with a Remote FMC* in the Cisco Firepower Getting Started Guide.

High availability system requirements

High availability system requirements are specifications that define the hardware, software, and license prerequisites for Firewall Threat Defense devices to function in a High availability configuration.

Hardware requirements

Hardware requirements are specifications that ensure two units in a High availability configuration can

- maintain identical hardware configurations including model, interfaces, modules, and RAM
- support proper synchronization and failover functionality, and
- ensure reliable high availability operation.

Hardware requirement specifications

The two units in a High availability configuration must meet these requirements:

- Be the same model. In addition, for container instances, they must use the same resource profile attributes.

For the Firepower 9300, High Availability is only supported between same-type modules. However, the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.

If you change the resource profile after you add the High Availability pair to the Security Cloud Control, update the inventory for each unit on the **Devices** > **Device Management** > **Device** > **System** > **Inventory** dialog box.

If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

- Have the same number and types of interfaces.

  For the Firepower 4100/9300 chassis, all interfaces must be preconfigured in FXOS identically before you enable High availability. If you change the interfaces after you enable High availability, make the interface changes in FXOS on the Standby unit, and then make the same changes on the Active unit.

- Have these settings in a remote branch deployment:
  - Have the same data management interface to handle management traffic in a remote deployment.

    For example, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.
  - Use data management interface for management traffic.

    You cannot have one unit managed using a data interface and the other using a management interface.

If you are using units with different flash memory sizes in your High availability configuration, make sure the unit with the smaller flash memory has enough space to accommodate the software image files and the configuration files. If it does not, configuration synchronization from the unit with the larger flash memory to the unit with the smaller flash memory will fail.

Software requirements

Software requirements are configuration specifications that High availability units must meet to function properly in a failover configuration.

Required software specifications

The two units in a High availability configuration must meet these requirements:

- Be in the same firewall mode (routed or transparent).
- Have the same software version.
- Be in the same group on the Cloud-Delivered Firewall Management Center.
- Have the same NTP configuration. See Synchronize time on FTD devices, on page 1303.
- Configuration changes must be fully deployed to the devices.

- Not have DHCP or PPPoE configured in any of their interfaces.
- (Firepower 4100/9300) Have the same flow offload mode, either both enabled or both disabled.

License requirements for Firewall Threat Defense devices in a high availability pair

Both Firewall Threat Defense units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the Cloud-Delivered Firewall Management Center releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit.

For example, if the active unit has a Essentials license and a IPS license, and the standby unit has only a Essentials license, the Cloud-Delivered Firewall Management Center communicates with the Smart Software Manager to obtain an available IPS license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

Failover and stateful failover links

A failover link and stateful failover link are dedicated connections that

- establish communication between the two units in a failover configuration
- require the same interface to be used between corresponding devices for consistency, and
- transmit critical failover and state information between the paired units.

Configuration recommendations

Cisco recommends to use the same interface between two devices in a failover link or a stateful failover link. For example, in a failover link, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.

Failover link

A failover link is a communication mechanism that enables two units in a failover pair to constantly communicate to determine the operating status of each unit.

Failover link data

This below information is communicated over the failover link:

- The unit state (active or standby)
- Hello messages (keep-alives)
- Network link status
- MAC address exchange
- Configuration replication and synchronization

Interface for the failover link

A failover link interface is a dedicated communication channel that

- exists solely for failover communication between high availability units
- uses an unused data interface (physical, or EtherChannel)
- cannot be shared with normal networking interfaces or user data traffic, and
- requires specific interface sizing based on the device model.

Interface restrictions and requirements

You can use an unused data interface (physical, or EtherChannel) as the failover link; however, you cannot specify an interface that is currently configured with a name. You cannot use a data management interface if the interface is configured for communication with Security Cloud Control. You also cannot use a subinterface with the exception of a subinterface defined on the chassis for multi-instance mode. The failover link interface is not configured as a normal networking interface; it exists for failover communication only. This interface can only be used for the failover link (and also for the state link).

The Firewall Threat Defense does not support sharing interfaces between user data and the failover link. You also cannot use separate subinterfaces on the same parent for the failover link and for data (multi-instance chassis subinterfaces only). If you use a chassis subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links.

Note When using an EtherChannel as the failover or state link, you must confirm that the same EtherChannel with the same member interfaces exists on both devices before establishing high availability.

See these guidelines for the failover link:

- Firepower 4100/9300—You cannot use the management-type interface for the failover link.
- See these guidelines for sizing the link.

Table 44: Failover link size

Model	Interface Size for Combined Failover and State Link
Firewall 200	1 Gbps
Firepower 1010	1 Gbps
Firepower 1100	1 Gbps
Secure Firewall 1200	1 Gbps
Secure Firewall 3100	Secure Firewall 3105—1 Gbps Secure Firewall 3110—1 Gbps Secure Firewall 3120—1 Gbps Secure Firewall 3130—10 Gbps Secure Firewall 3140—10 Gbps

Model	Interface Size for Combined Failover and State Link
Firepower 4100	10 Gbps
Secure Firewall 4200	10 Gbps
Firepower 9300	10 Gbps

The alternation frequency is equal to the unit hold time.

Note If you have a large configuration and a low unit hold time, alternating between the member interfaces can prevent the secondary unit from joining/re-joining. In this case, disable one of the member interfaces until after the secondary unit joins.

For an EtherChannel used as the failover link, to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a failover link.

Connect the failover link

The failover link enables communication and coordination between units in a failover configuration.

You need to establish a physical connection between the failover units to enable proper failover functionality.

Procedure

Connect the failover link using one of the following methods:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the Firewall Threat Defense device.
- Using an Ethernet cable to connect the units directly, without the need for an external switch.

If you do not use a switch between the units and the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which unit has the failed interface and caused the link to come down.

The failover link is physically connected and ready for failover configuration.

Stateful failover links

A stateful failover link is a network connection that

- passes connection state information between failover units, and
- must be configured to enable stateful failover functionality.

State link configuration requirements

To use Stateful Failover, you must configure a Stateful Failover link (also known as the state link) to pass connection state information.

Shared failover links

A shared failover link is an interface conservation method that enables multiple network functions to use the same failover connection, though dedicated interfaces for state and failover links should be considered for large configurations and high traffic networks.

Dedicated interface for the stateful failover link

A dedicated interface for the stateful failover link is a data interface configuration that uses a dedicated physical or EtherChannel interface specifically for the state link in failover deployments.

Performance considerations

You can use a dedicated data interface—such as a physical or EtherChannel interface—for the state link. For requirements about a dedicated state link, refer to Interface for the failover link, on page 685. See the section on connecting the state link for additional information Connect the failover link, on page 686.

For optimum performance with long-distance failover, the state link latency should be less than 10 milliseconds but no more than 250 milliseconds. If latency exceeds 10 milliseconds, performance might degrade due to retransmission of failover messages.

Failover and data link interruption avoidance

Failover and data link interruption avoidance is a network design practice that

- ensures failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time
- prevents failover operation suspension when the failover link is down, and
- maintains network resilience by using proper connection scenarios.

Connection scenarios

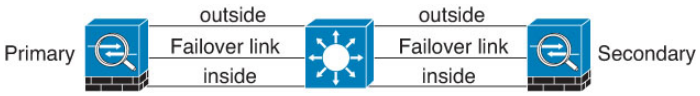
We recommend that failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time. If the failover link is down, the failover operation is suspended until the health of the failover link is restored.

These connection scenarios help design a resilient failover network.

Scenario 1—Not recommended

If a single switch or a set of switches are used to connect both failover and data interfaces between two Firewall Threat Defense devices, then when a switch or inter-switch-link is down, both Firewall Threat Defense devices become active. Therefore, the two connection methods shown in these figures are **not** recommended.

Figure 99: Connecting with a single switch—not recommended



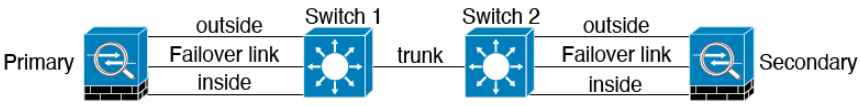


Figure 100: Connecting with a double-switch—not recommended

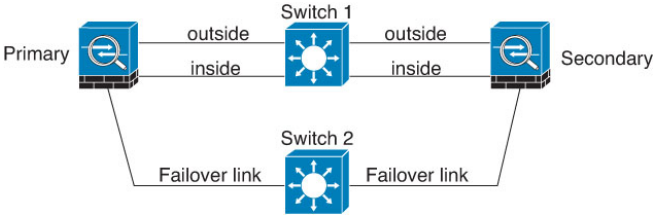
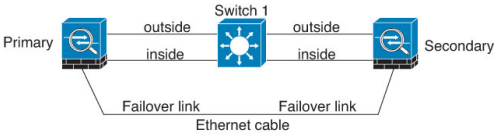
Scenario 2—Recommended

We recommend that failover links not use the same switch as the data interfaces. Instead, use a different switch or use a direct cable to connect the failover link, as shown in these figures.

Figure 101: Connecting with a different switch





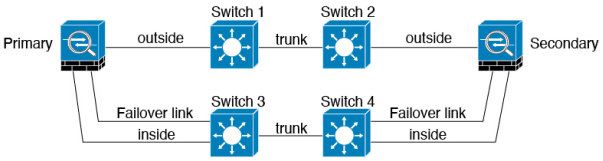


Figure 102: Connecting with a cable

Scenario 3—Recommended

If the Firewall Threat Defense data interfaces are connected to more than one set of switches, then a failover link can be connected to one of the switches, preferably the switch on the secure (inside) side of network, as shown in this figure.

Figure 103: Connecting with a secure switch

MAC addresses and IP addresses in High availability

MAC addresses and IP addresses in High availability are network addressing mechanisms that

- provide unique identification for network interfaces during failover scenarios
- maintain network connectivity when primary devices become unavailable, and
- ensure seamless traffic flow between active and standby configurations.

Address configuration types

When you configure your interfaces, you can specify an active IP address and a standby IP address on the same network. Generally, when a failover occurs, the new active unit takes over the active IP addresses and MAC addresses. Because network devices see no change in the MAC to IP address pairing, no ARP entries change or time out anywhere on the network.

Note Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state. You also cannot connect to the standby unit on that interface for management purposes.

The IP address and MAC address for the state link do not change at failover.

Active/standby configurations use specific address handling methods:

For Active/Standby High availability, see the following for IP address and MAC address usage during a failover event:

1. The active unit always uses the primary unit's IP addresses and MAC addresses.
2. When the active unit fails over, the standby unit assumes the IP addresses and MAC addresses of the failed unit and begins passing traffic.
3. When the failed unit comes back online, it is now in a standby state and takes over the standby IP addresses and MAC addresses.

However, if the secondary unit boots without detecting the primary unit, then the secondary unit becomes the active unit and uses its own MAC addresses, because it does not know the primary unit MAC addresses. When the primary unit becomes available, the secondary (active) unit changes the MAC addresses to those of the primary unit, which can cause an interruption in your network traffic. Similarly, if you swap out the primary unit with new hardware, a new MAC address is used.

If you disable high availability and set the failover configurations to a disabled state, you will need to manually resume high availability, or reboot the device. It is recommended to use the command **configure high-availability resume** and resume the high availability instead of rebooting the device. If you reload the standby unit with the failover configuration disabled, the standby unit boots up as the active unit and uses the primary unit's IP addresses and MAC addresses. This leads to duplicate IP addresses and causes network traffic disruptions. Use the command **configure high-availability resume** to enable failover and restore the traffic flow.

Note If you enable failover on a standalone device, the data interfaces go down at negotiation state of failover, interrupting traffic.

Virtual MAC addresses guard against this disruption, because the active MAC addresses are known to the secondary unit at startup, and remain the same in the case of new primary unit hardware. We recommend that you configure the virtual MAC address on both the primary and secondary units to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not configure virtual MAC addresses, you might need to clear the ARP tables on connected routers to restore traffic flow. The Firewall Threat Defense does not send gratuitous ARPs for static NAT addresses

when the MAC address changes, so connected routers do not learn of the MAC address change for these addresses.

For Active/Active failover, see the following for IP address and MAC address usage during a failover event:

1. The primary unit autogenerates active and standby MAC addresses for all interfaces in failover group 1 and 2 contexts. You can also manually configure the MAC addresses if necessary, for example, if there are MAC address conflicts.
2. Each unit uses the active IP addresses and MAC addresses for its active failover group, and the standby addresses for its standby failover group. For example, the primary unit is active for failover group 1, so it uses the active addresses for contexts in failover group 1. It is standby for the contexts in failover group 2, where it uses the standby addresses.
3. When a unit fails over, the other unit assumes the active IP addresses and MAC addresses of the failed failover group and begins passing traffic.
4. When the failed unit comes back online, and you enabled the preempt option, it resumes the failover group.

Virtual MAC addresses provide specialized functionality:

The Firewall Threat Defense has multiple methods to configure virtual MAC addresses. We recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

For multi-instance capability, the FXOS chassis autogenerates only primary MAC addresses for all interfaces. You can overwrite the generated MAC address with a virtual MAC address with both the primary and secondary MAC addresses, but predefining the secondary MAC address is not essential; setting the secondary MAC address does ensure that to-the-box management traffic is not interrupted in the case of new secondary unit hardware.

MAC address table updates occur during failover events:

During failover, the device that is designated as the new active device generates multicast packets for each MAC address entry in the MAC table and sends them to all the bridge group interfaces. This action prompts the upstream switches in the bridge group to update their routing tables with the new active device's interface to ensure accurate traffic forwarding.

The time taken to generate multicast packets and update the routing tables of the upstream switches depends on the number of entries in the MAC address table and the number of bridge group interfaces. Use the **show failover statistics state-switch-delay** command to display statistics related to the delays encountered during failover events.

Stateful failover

A stateful failover is a high availability mechanism that

- continuously passes per-connection state information from the active unit to the standby unit
- maintains connection information after a failover occurs, and
- allows supported end-user applications to continue communication sessions without reconnecting.

Stateful failover operation

During Stateful Failover, the active unit continually passes per-connection state information to the standby unit. After a failover occurs, the same connection information is available at the new active unit. Supported end-user applications are not required to reconnect to keep the same communication session.

Supported features

Supported features are high availability capabilities that

- enable state information to be passed to the standby Firewall Threat Defense device during Stateful Failover
- maintain connection states and critical information for seamless traffic flow, and
- ensure minimal disruption during failover events.

State information types

For Stateful Failover, these state information types are passed to the standby device:

- NAT translation table.
- TCP and UDP connections and states, including HTTP connection states. Other types of IP protocols, and ICMP, are not parsed by the active unit, because they get established on the new active unit when a new packet arrives.
- Snort connection states, inspection results, and pin hole information, including strict TCP enforcement.
- The ARP table
- The Layer 2 bridge table (for bridge groups)
- The ISAKMP and IPsec SA table
- GTP PDP connection database
- SIP signaling sessions and pin holes.
- Static and dynamic routing tables—Stateful Failover participates in dynamic routing protocols, like OSPF and EIGRP, so routes that are learned through dynamic routing protocols on the active unit are maintained in a Routing Information Base (RIB) table on the standby unit. Upon a failover event, packets travel normally with minimal disruption to traffic because the active secondary unit initially has rules that mirror the primary unit. Immediately after failover, the re-convergence timer starts on the newly active unit. Then the epoch number for the RIB table increments. During re-convergence, OSPF and EIGRP routes become updated with a new epoch number. Once the timer is expired, stale route entries (determined by the epoch number) are removed from the table. The RIB then contains the newest routing protocol forwarding information on the newly active unit.

Note Routes are synchronized only for link-up or link-down events on an active unit. If the link goes up or down on the standby unit, dynamic routes sent from the active unit may be lost. This is normal, expected behavior.

- DHCP Server—DHCP address leases are not replicated. However, a DHCP server configured on an interface will send a ping to make sure an address is not being used before granting the address to a DHCP client, so there is no impact to the service. State information is not relevant for DHCP relay or DDNS.
- Access control policy decisions—Decisions related to traffic matching (including URL, URL category, geolocation, and so forth), intrusion detection, malware, and file type are preserved during failover. However, for connections being evaluated at the moment of failover, there are the following caveats:
  - AVC—App-ID verdicts are replicated, but not detection states. Proper synchronization occurs as long as the App-ID verdicts are complete and synchronized before failover occurs.
  - Intrusion detection state—Upon failover, once mid-flow pickup occurs, new inspections are completed, but old states are lost.
  - File malware blocking—The file disposition must become available before failover.
  - File type detection and blocking—The file type must be identified before failover. If failover occurs while the original active device is identifying the file, the file type is not synchronized. Even if your file policy blocks that file type, the new active device downloads the file.
- User identity decisions from the identity policy, including the user-to-IP address mappings gathered passively through ISE Session Directory, and active authentication through captive portal. Users who are actively authenticating at the moment of failover might be prompted to authenticate again.
- Network AMP—Cloud lookups are independent from each device, so failover does not affect this feature in general. Specifically:
  - Signature Lookup—If failover occurs in the middle of a file transmission, no file event is generated and no detection occurs.
  - File Storage—If failover occurs when the file is being stored, it is stored on the original active device. If the original active device went down while the file was being stored, the file does not get stored.
  - File Pre-classification (Local Analysis)—If failover occurs in the middle of pre-classification, detection fails.
  - File Dynamic Analysis (Connectivity to the cloud)—If failover occurs, the system might submit the file to the cloud.
  - Archive File Support—If failover occurs in the middle of an analysis, the system loses visibility into the file/archive.
  - Custom Blocking—If failover occurs, no events are generated.
- Security Intelligence decisions. However, DNS-based decisions that are in process at the moment of failover are not completed.
- RA VPN—Remote access VPN end users do not have to reauthenticate or reconnect the VPN session after a failover. However, applications operating over the VPN connection could lose packets during the failover process and not recover from the packet loss.
- From all the connections, only established ones will be replicated on the Standby device.

Unsupported features

Unsupported features are device capabilities that

- are not passed to the standby Firewall Threat Defense in Stateful Failover
- do not maintain state information during failover events, and
- may require re-establishment after a failover occurs.

State information limitations

For Stateful Failover, the following state information is not passed to the standby Firewall Threat Defense:

- Sessions in plaintext tunnels other than GREv0 and IPv4-in-IP. Sessions inside tunnels are not replicated and the new active node will not be able to reuse existing inspection verdicts to match the correct policy rules.
- Decrypted TLS/SSL connections—The decryption states are not synchronized, and if the active unit fails, then decrypted connections will be reset. New connections will need to be established to the new active unit. Connections that are not decrypted (in other words, those that match a TLS/SSL Do Not Decrypt rule action) are not affected and are replicated correctly.
- Multicast routing.

Bridge group requirements for high availability

Bridge group requirements for high availability are special considerations that

- address traffic loss on bridge group member interfaces during failover
- prevent switch ports from entering blocking state for 30 to 50 seconds, and
- provide workarounds to maintain connectivity during topology changes.

High availability workarounds

There are special considerations for high availability when using bridge groups.

When the active unit fails over to the standby unit, the switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss on the bridge group member interfaces while the port is in a blocking state, you can configure one of the following workarounds:

- Switch port is in Access mode—Enable the STP PortFast feature on the switch:

  ```
  interface interface_id
    spanning-tree portfast
  ```

  The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, it eventually transitions into STP blocking mode.

- If the switch port is in Trunk mode, or you cannot enable STP PortFast, then you can use one of the following less desirable workarounds that impacts failover functionality or STP stability:

- Disable interface monitoring on the bridge group and member interfaces.
- Increase the interface hold time in the failover criteria to a high value that will allow STP to converge before the unit fails over.
- Decrease the STP timers on the switch to allow STP to converge faster than the interface hold time.

Failover health monitoring

Failover health monitoring is a system capability that monitors each unit for overall health and interface health.

Health monitoring tests

The Firewall Threat Defense device performs tests to determine the state of each unit. This section includes information about how the Firewall Threat Defense device performs tests to determine the state of each unit.

Unit health monitoring

Unit health monitoring is a failover mechanism that

- determines the health of peer units by monitoring the failover link with hello messages
- sends LANTEST messages on each data interface when three consecutive hello messages are missed, and
- initiates appropriate failover actions based on peer unit responsiveness.

Unit health monitoring behavior

The Firewall Threat Defense device determines the health of the other unit by monitoring the failover link with hello messages. If a unit does not receive three consecutive hello messages on the failover link, the sends LANTEST messages on each data interface, including the failover link, to validate whether the peer is responsive. The action that the Firewall Threat Defense device takes depends on the response from the other unit. These are the possible actions:

- If the Firewall Threat Defense device receives a response on the failover link, then it does not fail over.
- If the Firewall Threat Defense device does not receive a response on the failover link, but it does receive a response on a data interface, then the unit does not failover. The failover link is marked as failed. You should restore the failover link as soon as possible because the unit cannot fail over to the standby while the failover link is down.
- If the Firewall Threat Defense device does not receive a response on any interface, then the standby unit switches to active mode and classifies the other unit as failed.

Note During a high-availability failover event, the Firewall Threat Defense device device may briefly appear as **Offline** in the device's health monitoring dashboard. This happens because health alerts are cleared during the process and are only updated after the process is complete. Wait for the failover operation to finish.

Heartbeat module redundancy

Heartbeat module redundancy is a high availability feature that

- sends heartbeat messages using the data plane transport infrastructure to supplement control plane heartbeat packets
- increments a counter when the peer receives heartbeat packets in the data plane
- prevents false failover or split-brain scenarios when the control plane is congested with traffic.

Heartbeat module redundancy behavior

Each unit in the HA periodically sends a broadcast keepalive heartbeat packet over the failover link. If the control plane is too busy handling traffic, sometimes the heartbeat packets do not reach the peers, or the peers do not process the heartbeat packets due to CPU overloading. When peers cannot communicate the keepalive status within the configurable timeout period, a false failover or split-brain scenario occurs.

The heartbeat module in the data plane helps to avoid the occurrence of false failover or split-brain due to traffic congestion in the control plane.

- The additional heartbeat module works similarly to the control plane module but sends and receives heartbeat messages using the data plane transport infrastructure.
- When the peer receives heartbeat packets in the data plane, a counter gets incremented.
- If the heartbeat transfer in the control plane fails, the node checks the heartbeat counter in the data plane. If the counter is incrementing, then the peer is alive, and the cluster does not perform a failover in this situation.

Note

- The additional heartbeat module is enabled by default whenever HA is enabled. You do not have to set a poll interval for the additional heartbeat module in the data plane. This module uses the same heartbeat interval that you set for the control plane.

Interface monitoring

Interface monitoring is a failover capability that

- tracks the health of up to 1025 interfaces to detect interface failures
- performs interface tests when hello messages are not received within 15 seconds, and
- triggers failover when the number of failed interfaces meets the defined threshold.

Interface monitoring operation

When a unit does not receive hello messages on a monitored interface for 15 seconds, it runs interface tests. If one of the interface tests fails for an interface, but this same interface on the other unit continues to successfully pass traffic, then the interface is considered to be failed, and the device stops running tests.

If the threshold you define for the number of failed interfaces is met (see **Devices** > **Device Management**, and then **High Availability** > **Failover Trigger Criteria**), and the active unit has more failed interfaces than

the standby unit, then a failover occurs. If an interface fails on both units, then both interfaces go into the "Unknown" state and do not count towards the failover limit defined by failover interface policy.

An interface becomes operational again if it receives any traffic. A failed device returns to standby mode if the interface failure threshold is no longer met.

If an interface has IPv4 and IPv6 addresses configured on it, the device uses the IPv4 addresses to perform the health monitoring. If an interface has only IPv6 addresses configured on it, then the device uses IPv6 neighbor discovery instead of ARP to perform the health monitoring tests. For the broadcast ping test, the device uses the IPv6 all nodes address (FE02::1).

Interface tests

Interface tests are monitoring mechanisms that:

- evaluate interface operational status during failover scenarios
- run sequentially with approximately 1.5 second duration per test, and
- determine interface failure status on Firewall Threat Defense device units.

Interface test sequence

The Firewall Threat Defense device uses these interface tests in sequence:

1. Link Up/Down test—A test of the interface status. If the Link Up/Down test indicates that the interface is down, then the device considers it failed, and testing stops. If the status is Up, then the device performs the Network Activity test.
2. Network Activity test—A received network activity test. At the start of the test, each unit clears its received packet count for its interfaces. As soon as a unit receives any eligible packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the ARP test.
3. ARP test—A test for successful ARP replies. Each unit sends a single ARP request for the IP address in the most recent entry in its ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If the unit does not receive an ARP reply, then the device sends a single ARP request for the IP address in the *next* entry in the ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the Broadcast Ping test.
4. Broadcast Ping test—A test for successful ping replies. Each unit sends a broadcast ping, and then counts all received packets. If the unit receives any packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then testing starts over again with the ARP test. If both units continue to receive no traffic from the ARP and Broadcast Ping tests, then these tests will continue running in perpetuity.

Interface status

Interface status is a monitoring indicator that

- shows the current operational state of monitored interfaces in a failover configuration
- tracks traffic reception and hello packet communication between peer units, and
- determines whether an interface is actively monitored by the failover process.

Interface status types

Monitored interfaces can have these status types:

- **Unknown**: Initial status. This status can also mean the status cannot be determined.
- **Normal**: The interface is receiving traffic.
- **Normal (Waiting)**: The interface is up, but has not yet received a hello packet from the corresponding interface on the peer unit.
- **Normal (Not-Monitored)**: The interface is up, but is not monitored by the failover process.
- **Testing**: Hello messages are not heard on the interface for five poll times.
- **Link Down**: The interface or VLAN is administratively down.
- **Link Down (Waiting)**: The interface or VLAN is administratively down and has not yet received a hello packet from the corresponding interface on the peer unit.
- **Link Down (Not-Monitored)**: The interface or VLAN is administratively down, but is not monitored by the failover process.
- **No Link**: The physical link for the interface is down.
- **No Link (Waiting)**: The physical link for the interface is down and has not yet received a hello packet from the corresponding interface on the peer unit.
- **No Link (Not-Monitored)**: The physical link for the interface is down, but is not monitored by the failover process.
- **Failed**: No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover triggers and detection timing

Failover triggers and detection timing are high availability mechanisms that:

- initiate automatic switchover when specific failure conditions occur on the active unit,
- monitor system health through configurable detection thresholds and timing parameters, and
- ensure service continuity by transferring control to the standby unit when failures exceed defined limits.

Failover triggering events and timing parameters

These events trigger failover in a Firepower high availability pair:

- More than 50% of the Snort instances on the active unit are down.
- Disk space on the active unit is more than 90% full.

- The **no failover active** command is run on the active unit or the **failover active** command is run on the standby unit.
- The active unit has more failed interfaces than the standby unit.
- Interface failure on the active device exceeds the threshold configured.

  By default, failure of a single interface causes failover. You can change the default value by configuring a threshold for the number of interfaces or a percentage of monitored interfaces that must fail for the failover to occur. If the threshold is exceeded on the active device, failover occurs. If the threshold is exceeded on the standby device, the unit moves to **Fail** state.

  To change the default failover criteria, enter this command in global configuration mode:

Table 45: Interface policy command

Command	Purpose
failover interface-policy num [%] `hostname (config)# failover interface-policy 20%`	Changes the default failover criteria. When specifying a specific number of interfaces, the *num* argument can be from 1 to 250. When specifying a percentage of interfaces, the *num* argument can be from 1 to 100.

This table shows the failover triggering events and associated failure detection timing. If failover occurs, you can view the reason for the failover in the Message Center, along with various operations pertaining to the high availability pair. You can configure these thresholds to a value within the specified minimum-maximum range.

Table 46: Firewall Threat Defense failover times

Failover triggering event	Minimum	Default	Maximum
Active unit loses power, hardware goes down, or the software reloads or crashes. When any of these occur, the monitored interfaces or failover link do not receives any hello message.	800 milliseconds	15 seconds	45 seconds
Active unit interface physical link down.	500 milliseconds	5 seconds	15 seconds
Active unit interface up, but connection problem causes interface testing.	5 seconds	25 seconds	75 seconds

Active/standby failover

Active/standby failover is a high availability configuration that

- lets you use a standby Firewall Threat Defense device to take over the functionality of a failed unit,
- enables the standby unit to become the active unit when the active unit fails, and
- allows the failed unit to come back online as the standby unit if the problem is temporary.

The failed unit must be replaced if the problem is not temporary. Set the standby unit to primary before replacing the failed unit to retain the configuration of the secondary unit.

For multiple context mode, the ASA can fail over the entire unit (including all contexts) but cannot fail over individual contexts separately.

Primary/secondary roles and active/standby status

Primary/secondary roles and active/standby status are failover configuration concepts that

- define unit hierarchy, with primary units taking precedence during simultaneous startup
- determine IP address and MAC address usage patterns during failover operations, and
- establish traffic flow responsibilities between paired units in Active/Standby failover configurations.

Primary and secondary unit differences

When setting up Active/Standby failover, you configure one unit to be primary and the other to be secondary. During configuration, the primary unit's policies are synchronized to the secondary unit. At this point, the two units act as a single device for device and policy configuration. However, for events, dashboards, reports and health monitoring, they continue to display as separate devices.

The main differences between the two units in a failover pair are related to which unit is active and which unit is standby, namely which IP addresses to use and which unit actively passes traffic.

However, a few differences exist between the units depending on which unit is primary (as specified in the configuration) and which unit is secondary:

- The primary unit always becomes the active unit if both units start up at the same time (and are of equal operational health).
- The primary unit MAC addresses are always coupled with the active IP addresses. The exception to this rule occurs when the secondary unit becomes active and cannot obtain the primary unit MAC addresses over the failover link. In this case, the secondary unit MAC addresses are used.

Active unit determination at startup

Active unit determination at startup is a high availability process that

- sets a unit to standby if it boots and detects a peer already running as active,
- sets a unit to active if it boots and does not detect a peer, and
- sets the primary unit as active and secondary unit as standby if both units boot simultaneously.

Failover events

A failover event is a system condition that

- triggers an active unit to transfer control to a standby unit in Active/Standby failover configurations
- occurs on a unit basis, and
- follows specific failover policies that determine whether failover occurs and what actions each unit takes.

Failover event policies and actions

This table shows the failover action for each failure event. For each failure event, the table shows the failover policy (failover or no failover), the action taken by the active unit, the action taken by the standby unit, and any special notes about the failover condition and actions.

Table 47: Failover events

Failure Event	Policy	Active Unit Action	Standby Unit Action	Notes
Active unit failed (power or hardware)	Failover	n/a	Become active Mark active as failed	No hello messages are received on any monitored interface or the failover link.
Formerly active unit recovers	No failover	Become standby	No action	None.
Standby unit failed (power or hardware)	No failover	Mark standby as failed	n/a	When the standby unit is marked as failed, then the active unit does not attempt to fail over, even if the interface failure threshold is surpassed.
Failover link failed during operation	No failover	Mark failover link as failed	Mark failover link as failed	You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.
Failover link failed at startup	No failover	Become active Mark failover link as failed	Become active Mark failover link as failed	If the failover link is down at startup, both units become active.
State link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.
Interface failure on active unit above threshold	Failover	Mark active as failed	Become active	None.
Interface failure on standby unit above threshold	No failover	No action	Mark standby as failed	When the standby unit is marked as failed, then the active unit does not attempt to fail over even if the interface failure threshold is surpassed.

Config-sync optimization

Config-sync optimization is a configuration synchronization enhancement that

- compares configuration hash values between active and joining devices to determine if full synchronization is necessary

- enables faster device rejoining by skipping full configuration synchronization when hash values match, and
- reduces maintenance window and upgrade time during high availability operations.

Guidelines and limitations of configuration sync optimization

When a device reboots or rejoins after a suspend or resume high availability, the joining device clears its running configuration. The active device then sends its entire configuration to the joining device for a full configuration synchronization. If the active device has a large configuration, this process can take several minutes.

The configuration sync optimization functionality enables comparing the configuration of the joining device and the active device by exchanging configuration hash values. If the hash computed on both active and joining devices match, the joining device skips full configuration synchronization and rejoin the high availability configuration. This functionality ensures faster peering and reduces maintenance window and upgrade time.

Guidelines and limitations:

- The configuration sync optimization functionality is enabled by default.
- Firewall Threat Defense multiple context mode supports configuration sync optimization by sharing the context order during full configuration synchronization, allowing comparison of context order during subsequent node-rejoin.
- If you configure passphrase and failover IPsec key, then configuration sync optimization is not effective as the hash value computed in the active and standby devices differs.
- If you configure the device with dynamic ACL or SNMPv3, configuration sync optimization is not effective.
- Active device synchronizes full configuration with flapping LAN links as default behavior. During failover flaps between active and standby devices, configuration sync optimization is not triggered and devices perform a full configuration synchronization.
- Configuration sync optimization gets triggered when the high availability configuration recovers from an interruption or loss of network communication between the active and standby devices.

Monitoring config-sync optimization:

- Syslog messages are generated displaying whether the hash values computed on the active and joining unit match, does not match, or if the operation timeout expires.
- The syslog message also displays the time elapsed, from the time of sending the hash request to the time of getting and comparing the hash response.

Note The Configuration State in **show failover state** command displays the config sync state status during HA joining. This state does not reflect the later config deployments or changes, and replication on device until a resync has been initiated.

Requirements and prerequisites for high availability

This reference provides the requirements and prerequisites needed to implement high availability functionality.

Admin

Guidelines for High availability

Model Support

- 200/ 1010/1210/ 1220:
  - You should not use the switch port functionality when using High availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Though Cloud-Delivered Firewall Management Center allows you to configure switch ports / VLAN interfaces in HA, it may lead to misconfiguration due to network loops when connecting to external switches.
  - You can only use a firewall interface as the failover link.
- Firepower 9300—Intra-chassis High Availability is not supported.
- The Firewall Threat Defense Virtual on public cloud networks such as Microsoft Azure and Amazon Web Services are not supported with High availability because Layer 2 connectivity is required.

Additional Guidelines

- When the active unit fails over to the standby unit, the connected switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss while the port is in a blocking state, you can enable the STP PortFast feature on the switch:

  interface *interface_id* **spanning-tree portfast**

  This workaround applies to switches connected to both routed mode and bridge group interfaces. The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.
- Configuring port security on the switches connected to the Firewall Threat Defense device failover pair can cause communication problems when a failover event occurs. This problem occurs when a secure

MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.

- For Active/Standby High availability and a VPN IPsec tunnel, you cannot monitor both the active and standby units using SNMP over the VPN tunnel. The standby unit does not have an active VPN tunnel, and will drop traffic destined for the NMS. You can instead use SNMPv3 with encryption so the IPsec tunnel is not required.
- Both the peer devices go into unknown state and high-availability configuration fails if you run clish in any of the peer devices while creating a High Availability pair.
- Immediately after failover, the source address of syslog messages will be the failover interface address for a few seconds.
- For better convergence (during a failover), you must shut down the interfaces on a HA pair that are not associated with any configuration or instance.
- In high availability deployments with a shared failover and state interfaces, if the connectivity over failover interface fails while the standby unit is in sync config state, and eventually when the standby unit switches to active state, it results in a split brain. This is observed even when there is a monitored interface.

  The connectivity over failover interface can fail in the following situations:

  - After the standby unit reboots, the connectivity over failover interface fails while the standby unit is in sync config state.
  - After enabling previously disabled failover on the standby unit, the connectivity over failover interface fails while the standby unit is in sync config state.

  To avoid split brain, use failover and state interfaces. If the connectivity failures over the failover interfaces persist, isolate the new active (previously standby) unit from the network.
- If you configure failover encryption in evaluation mode, the systems use DES for the encryption. If you then register the devices using an export-compliant account, the devices will use AES after a reboot. Thus, if a system reboots for any reason, including after installing an upgrade, the peers will be unable to communicate and both units will become the active unit. We recommend that you do not configure encryption until after you register the devices. If you do configure this in evaluation mode, we recommend you remove the encryption before registering the devices.
- When using SNMPv3 with failover, if you replace a failover unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.
- The device does not share SNMP client engine data with its peer.
- If you have a very large number of access control and NAT rules, the size of the configuration can prevent efficient configuration replication, resulting in the standby unit taking an excessively long time to reach standby ready state. This can also impact your ability to connect to the standby unit during replication through the console or SSH session. To enhance configuration replication performance, enable transactional commit for both access rules and NAT, using the **asp rule-engine transactional-commit access-group** and **asp rule-engine transactional-commit nat** commands.
- A unit in a High availability pair transitioning to the standby role synchronizes its clock with the active unit.

  Example:

```
firepower#show clock
01:00:52 UTC Mar 1 2022

...
01:01:18 UTC Mar 1 2022 <======= Incorrect (previous) clock
Cold Standby               Sync Config               Detected an Active mate

19:38:21 UTC Apr 9 2022 <======= Updated clock
Sync Config                Sync File System          Detected an Active mate
...
firepower/sec/stby#show clock
19:38:40 UTC Apr 9 2022
```

- The units in High availability do not dynamically synchronize the clock. Here are some examples of events when synchronization takes place:
  - A new High availability pair is created.
  - High availability is broken and re-created.
  - Communication over the failover link was disrupted and reestablished.
  - Failover status was manually changed at the CLI using the **no failover/failover** or **configure high-availability suspend/resume** (Firewall Threat Defense) commands.
- Enabling High availability forces all routes to be deleted and are re-added after the High availability progression changes to the Active state. You could experience connection loss during this phase.
- If you replace the primary unit, then when you re-create high-availability, you should set the replacement unit as the *secondary* unit so that the configurations are replicated from the former secondary unit to the replacement unit. If you set the replacement unit as primary, you will accidentally overwrite the configuration that is present on the operational unit.
- Configure identical strong encryption on both Threat Defense devices before forming the High availability. If they are non-identical, the HA peers may enter a split-brain state.
- Deploying Firepower 1100 devices in high availability with hundreds of interfaces configured on them can result in increased delay in the failover time (seconds).
- In the High availability configuration, short-lived connections, usually using port 53, are closed quickly and never transferred or synchronized from Active to Standby, so there might be a difference in the number of connections on both High availability devices. This is expected behavior for short-lived connections. You can try to compare the connections that are long-lived (for example, more than 30-60 seconds).
- In the High availability configuration, embryonic connections—connection requests that have not yet completed the three-way handshake process—are closed quickly and not synchronized between the active and standby devices. This design ensures HA system efficiency and security. For this reason, there might be a difference in the number of connections on both High availability devices, which is to be expected.
- If the failover LAN link is not connected back-to-back and instead connected through one or more switches, a failure within the intermediate path can cause the active unit to lose connectivity with the standby unit, resulting in inconsistent active/standby states. Although this does not impact High availability functionality, it is recommended to check and recover the failover-link path between the active and standby units.

  When the failover LAN link is down, it is not recommended to deploy any configuration, as it may not be replicated to the peer unit.

- See the Secure Firewall Threat Defense Virtual getting started guides and review your Firewall Threat Defense Virtual device configurations for high availability.
- In OSPF, after a failover, the OSPF connection with the peer device becomes invalid. Terminate the invalid connection, and then establish a new OSPF connection.
- In transparent mode, if you have problems with the active unit losing the MAC address of the hot-standby router (HSRP), create a static mapping for the MAC address.
- UCAPL or CC compliance mode cannot be changed if the threat defense device is in high availability. Modify the compliance mode before forming the high availability pair.

Add a high availability pair

Establish an Active/Standby high-availability pair to ensure network protection continuity in case of device failure.

When establishing an Active/Standby high-availability pair, you designate one of the devices as primary and the other as secondary. The Cloud-Delivered Firewall Management Center deploys a merged configuration to the paired devices. If there is a conflict, the primary device setting is used.

Note The failover link and the stateful failover link are in a private IP space and are only used for communication between peers in a high-availability pair. After high availability is established, selected interface links and encryption settings cannot be modified without breaking the high-availability pair and reconfiguring it.

Caution Creating or breaking a high-availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196. The system warns you that continuing to create a high-availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Before you begin

Confirm that both devices:

- Are the same model.
- Have the same number and type of interfaces.
- Are in the same group.
- Have normal health status and are running the same software.
- Are either in routed or transparent mode.

Note Only routed mode is supported for manager access on a data interface.

- Have the same NTP configuration. See Synchronize time on FTD devices, on page 1303.
- Are fully deployed with no uncommitted changes.
- Do not have DHCP or PPPoE configured on any interfaces.
- For manager access on a data interface:
  - Use the same data interface on both devices for manager access.
  - Redundant manager access data interface is not supported.
  - You cannot use DHCP; only a static IP address is supported. Features that rely on DHCP cannot be used, including DDNS and zero-touch provisioning.

Note If you use zero-touch provisioning to register the device, when you use the outside interface for manager access, it uses DHCP by default. Before you can enable high availability, you need to change the IP address to a static address. See Change the device IP address, on page 1158. Alternatively, you can use the Management interface instead; DHCP is supported on Management with high availability.

- Have different static IP addresses in the same subnet.
- Use the same manager configuration (**configure manager add** command) to ensure that the connectivity is the same.
- You cannot use the data interface as the failover or state link.

Note The high availability formation is possible between the two Firewall Threat Defense devices when the certificate available on the primary device is not present on the secondary device. When high availability is formed, the certificate will be synched on the secondary device.

Procedure

Step 1 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 2 Click the **Devices** tab to locate your device.

Step 3 Click the **FTD** tab and select the device you want to establish as the primary device.

Step 4 In the **Management** pane, click **High Availability**.

Step 5 Enter a display **Name** for the high-availability pair.

Step 6 Under **Device Type**, choose **Firepower Threat Defense**.

Step 7 Choose the **Primary Peer** device for the high-availability pair.

Step 8 Choose the **Secondary Peer** device for the high-availability pair.

Note

In the remote deployment, the devices appearing in the **Secondary Peer** list depend on the active device selected in the **Primary Peer** list:

- If the selected primary peer uses a data interface for management, only the data interface managed devices are listed in the secondary peer list.
- If the data management interface on the primary peer has an IPv4 address configured on it, then the secondary peer lists only the data interface managed devices that have an IPv4 address configured on them. The same rule applies to IPv6-managed devices as well.
- The data management interface names of primary and secondary devices should be the same. Devices with different interface names will not be listed in the secondary peer list.

Step 9 Click **Continue**.

Step 10 Under **LAN Failover Link**, choose an **Interface** with enough bandwidth to reserve for failover communications.

Note
Only interfaces that do not have a logical name, do not belong to a security zone, and are not used for handling management traffic, will be listed in the **Interface** drop-down in the **Add High Availability Pair** dialog.

Step 11 Type any identifying **Logical Name**.

Step 12 Type a **Primary IP** address for the failover link on the active unit.

This address should be on an unused subnet.

Note
169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 13 Optionally, choose **Use IPv6 Address**.

Step 14 Type a **Secondary IP** address for the failover link on the standby unit. This IP address must be in the same subnet as the primary IP address.

Step 15 If IPv4 addresses are used, type a **Subnet Mask** that applies to both the primary and secondary IP addresses.

Step 16 Optionally, under **Stateful Failover Link**, choose the same **Interface**, or choose a different interface and enter the high availability configuration information.

Note
169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 17 (Optional) Choose **Enabled** and choose the **Key Generation** method for IPsec Encryption between the failover links.

Step 18 Click **OK**. This process takes a few minutes as the process synchronizes system data.

After a successful configuration, the high availability pair is established with one device as active and the other as standby. You can see the **FTD High Availability** label on the Firewall Threat Defense node on the Security Cloud Control **Security Devices** page. Select the node to see the active and standby devices you configured for high availability.

Note We recommend to back up the devices. You can use the backup to quickly replace the devices when they fail and to restore the high availability service without being delinked from the Cloud-Delivered Firewall Management Center.

Configure optional high availability parameters

You can view the initial High Availability Configuration on the Cloud-Delivered Firewall Management Center. You cannot edit these settings without breaking the high availability pair and then re-establishing it. To edit these settings, you must first break the high availability pair and re-establish it. You can modify the Failover Trigger Criteria to improve failover results. Interface Monitoring helps you determine which interfaces are best suited for failover.

Configure standby IP addresses and interface monitoring

Configure standby IP addresses for high availability interfaces to enable the active unit to perform network tests and check standby interface health beyond just tracking link state.

For each interface, set a standby IP address. Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state.

By default, monitoring is enabled on all named physical interfaces and, for the 200/10101210/1220, all VLAN interfaces,. You might want to exclude interfaces attached to less critical networks from affecting your failover policy. Switch ports are not eligible for interface monitoring.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Click the **High Availability** tab.

Step 4 In the **Monitored Interfaces** area, click the **Edit** ( ) next to the interface you want to edit.

Step 5 Check the **Monitor this interface for failures** check box.

Step 6 On the **IPv4** tab, enter the **Standby IP Address**.

This address must be a free address on the same network as the active IP address.

Step 7 If you configured the IPv6 address manually, on the **IPv6** tab, click the **Edit** ( ) next to the active IP address, enter the **Standby IP Address**, and click **OK**.

This address must be a free address on the same network as the active IP address. For autogenerated and **Enforce EUI 64** addresses, the standby address is automatically generated.

Step 8 Click **OK**.

Edit high availability failover criteria

This task allows you to customize failover criteria for high availability device pairs to match your specific network deployment requirements.

You can customize failover criteria based on your network deployment.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Choose **High Availability**.

Step 4 Next to **Failover Trigger Criteria**, click the **Edit** ( ).

Step 5 Under **Interface Failure Threshold**, choose the number or percentage of interfaces that must fail before the device fails over.

Step 6 Under **Hello packet Intervals**, choose how often hello packets are sent over the failover link.

Step 7 Click **OK**.

Configure virtual MAC addresses

Configure active and standby MAC addresses to minimize loss of traffic during failover and provide redundancy against IP address mapping for failover.

You can configure active and standby MAC addresses for failover using the following methods in the Cloud-Delivered Firewall Management Center:

- From the **Advanced tab** on the **Edit Interface** page during interface configuration; see Configure the MAC address, on page 1110.
- From the **Add Interface MAC Address** dialog-box which is accessed from the **High Availability** page; see this procedure.

Note To configure the MAC address in both primary and secondary units (so that the MAC address is transferred to all sub-interfaces to both the high-availability units), the recommended approach is to use the **Interfaces** tab to replicate the MAC addresses on sub-interfaces over both active and standby high-availability units.

If you configure active and standby MAC addresses in both locations, the addresses defined during interface configuration take precedence for failover.

You can minimize loss of traffic during failover by designating active and standby MAC addresses to the physical interface. This feature offers redundancy against IP address mapping for failover.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Click **High Availability**.

Step 4 Click the **Add** ( ) icon next to Interface MAC Addresses.

Step 5 Choose a **Physical Interface**.

Step 6 Enter the **Active Interface MAC Address**.

Step 7 Enter the **Standby Interface MAC Address**.

Step 8 Click **OK**.

Note
For detailed information, see Task 2, steps from 10 to 14 in Configure FTD High Availability on Firepower Appliances.

Manage High availability

This section describes how to manage High availability units after you enable High availability, including how to change the High availability setup and how to force failover from one unit to another.

Switch the Active Peer in the Firewall Threat Defense High Availability Pair

This task allows you to manually switch the active and standby units in a high availability pair, effectively forcing failover for reasons such as persistent fault or health events on the current active unit.

After you establish the Firewall Threat Defense high availability pair, you can manually switch the active and standby units, effectively forcing failover for reasons such as persistent fault or health events on the current active unit. Both units should be fully deployed before you complete this procedure.

Before you begin

Refresh node status for a single Firewall Threat Defense high availability pair, on page 711. This ensures that the status on the Firewall Threat Defense high availability device pair is in sync with the status on the Cloud-Delivered Firewall Management Center.

Follow these steps to switch the active peer in the high availability pair:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to change the active peer, click the **Switch Active Peer**.

Step 3 Choose an option:

- Click **Yes** to immediately make the standby device the active device in the high availability pair.
- Click **No** to cancel and return to the Device Management page.

Refresh node status for a single Firewall Threat Defense high availability pair

Refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair when communication issues result in out of sync data.

Whenever active or standby devices in the Firewall Threat Defense high availability pair are rebooted, the Cloud-Delivered Firewall Management Center may not display accurate high availability status for either device. This is because when the device reboots, the high availability status is immediately updated on the device and its corresponding event is sent to the Cloud-Delivered Firewall Management Center. However, the status may not be updated on the Cloud-Delivered Firewall Management Center because the communication between the device and the Cloud-Delivered Firewall Management Center is yet to be established.

Communication failures or weak communication channels between the Cloud-Delivered Firewall Management Center and devices may result in out of sync data. When you switch the active and standby devices in a high availability pair, the change may not be reflected in the Cloud-Delivered Firewall Management Center even after a significant time duration.

In these scenarios, you can refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to refresh the node status, click the **Refresh HA Node Status**.

Step 3 Click **Yes** to refresh the node status.

Suspend and resume high availability

You can suspend a unit in a high-availability pair, which is useful when:

- Both units are in an active-active situation, and fixing the communication on the failover link does not correct the problem.
- You want to troubleshoot an active or standby unit and do not want the units to fail over during that time.

When you suspend high availability, the currently active device remains active and continues handling all user connections. However, failover criteria are no longer monitored, and the system will never fail over to the now pseudo-standby device.

When using a data interface for manager access, the management connection will be broken until after you resume.

The primary difference between suspending high availability and breaking high availability is that on a suspended high-availability device, the high-availability configuration is retained. When you break high availability, the configuration is erased. Thus, you have the option to resume high availability on a suspended system, which enables the existing configuration and makes the two devices function as a failover pair again.

To suspend high availability, use the **configure high-availability suspend** command.

```
> configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

If you suspend high availability from the active unit, the configuration is suspended on both the active and standby units. The standby unit interface configuration is also erased. If you suspend it from the standby unit, it is suspended on the standby unit only, but the active unit will not attempt to fail over to a suspended unit.

To resume failover, use the **configure high-availability resume** command.

```
> configure high-availability resume
Successfully resumed high-availablity.
```

You can resume a unit only if it is in Suspended state. The unit will negotiate active/standby status with the peer unit.

Note Suspending high availability is a temporary state. If you reload a unit, it resumes the high-availability configuration automatically and negotiates the active/standby state with the peer.

Replace a unit in Firewall Threat Defense high availability pair

This reference explains the process for replacing a failed unit in a Firewall Threat Defense high availability pair, including both backup restore and manual replacement procedures.

To replace a failed unit in the Firewall Threat Defense high availability pair using a backup file, see *Restoring Cloud-Delivered Firewall Management Centers and Managed Devices* in the *Cisco Secure Firewall Management Center Administration Guide*.

If you do not have a backup of the failed device, you must break high availability. Then, register the replacement device to the Cloud-Delivered Firewall Management Center and reestablish high availability. The process varies depending on whether the device is primary or secondary:

- Replace a Primary Firewall Threat Defense HA Unit with no Backup, on page 712
- Replace a Secondary Firewall Threat Defense HA Unit with no Backup, on page 713

Replace a Primary Firewall Threat Defense HA Unit with no Backup

This task replaces a failed primary unit in a Firewall Threat Defense high availability pair to restore redundancy and maintain network protection.

Follow these steps below to replace a failed primary unit in the Firewall Threat Defense high availability pair. Failing to follow these steps can overwrite the existing high availability configuration.

Caution Creating or breaking the Firewall Threat Defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Caution Never move a disk from sensor or Cloud-Delivered Firewall Management Center to another device without reimaging the disk. This is an unsupported configuration and can cause breakage in functionality.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair; see Break a high availability pair, on page 714.

Note
The break operation removes all the configuration related to HA from Firewall Threat Defense and Cloud-Delivered Firewall Management Center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the failed primary Firewall Threat Defense device from the Cloud-Delivered Firewall Management Center.

Step 3 Register the replacement Firewall Threat Defense to the Cloud-Delivered Firewall Management CenterPrerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 21.

Step 4 Configure high availability, using the existing secondary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see Add a high availability pair, on page 705.

Replace a Secondary Firewall Threat Defense HA Unit with no Backup

This task allows you to restore high availability functionality by replacing a failed secondary unit in an Firewall Threat Defense high availability pair.

When a secondary unit fails in a high availability configuration, you need to replace it and recreate the HA pair to maintain network redundancy and protection.

Caution Creating or breaking the Firewall Threat Defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair.

See Break a high availability pair, on page 714.

Note
The break operation removes all the configuration related to HA from Firewall Threat Defense and Cloud-Delivered Firewall Management Center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the secondary Firewall Threat Defense device from the Cloud-Delivered Firewall Management Center

Step 3 Register the replacement Firewall Threat Defense to the Cloud-Delivered Firewall Management Center.

See Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 21.

Step 4 Configure high availability, using the existing primary/active unit as the primary device and the replacement device as the secondary/standby device during registration.

See Add a high availability pair, on page 705.

Break a high availability pair

Break a high availability pair to remove the high-availability configuration from both units while maintaining traffic flow on the active unit.

When you break a high-availability pair, the high-availability configuration is removed from both units.

When using the Management interface for manager access: The active unit remains up and passing traffic. The standby unit interface configuration is erased.

When using a data interface for manager access: See the following details.

- The active unit remains up and passing traffic.
- The standby unit data interfaces are shut down except for the manager access interface, which remains up using the standby IP address so it can maintain the management connection.

- In a remote branch deployment setup, all standby unit data interfaces that are assigned with a logical name are shut down except for the manager access interface, which remains up to maintain the management connection.
- If the primary unit is in the standby state:
  - The IP addresses for manager access are swapped permanently in the Cloud-Delivered Firewall Management Center configuration: the primary unit uses the standby IP address, and the secondary unit uses the active IP address.

Policies that were not deployed to the active unit prior to the break operation continue to remain un-deployed after the break operation is complete. Deploy the policies on the standalone device after the break operation is complete.

Note

- When IPsec is enabled on high availability interfaces on the Firewall Threat Defense device, the device cannot prioritize the encrypted packets into the high-priority receive queue. As a result, during high-volume data traffic scenarios, attempts to break high availability may fail as the device cannot efficiently manage and prioritize the large number of encrypted connections. To view the device's resource usage and the maximum throughput, use the `show resource usage` command.
- If you cannot reach the high-availability pair using the Cloud-Delivered Firewall Management Center, connect to the CLI on each device and enter **configure high-availability disable** to manually break high availability. See also Remove a High Availability Pair , on page 716.

Caution Breaking the Firewall Threat Defense high-availability pair immediately restarts the Snort process on the primary and secondary units, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Before you begin

- Refresh node status for a single Firewall Threat Defense high availability pair, on page 711. This ensures that the status on the high-availability pair is in sync with the status on the Cloud-Delivered Firewall Management Center.

Follow these steps to break a high availability pair:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 If you have switched to the new device management page, select the node to open the side pane, and under **HA actions**, click **Break**.

Step 3 Next to the high-availability pair you want to break, click **More** (⋮) and choose **Break**.

Step 4 If the standby peer does not respond, check **Force Break**.

Step 5 Click **Yes**.

The Break operation removes the high-availability configuration from the active and standby units.

A FlexConfig policy deployed on the active unit may show a deployment failure after the break high-availability operation. You must alter and re-deploy the FlexConfig policy on the active unit.

What to do next

If you are using a FlexConfig policy on the active unit, alter and re-deploy the FlexConfig policy to eliminate deployment errors.

Note After you break high availability, the Firewall Threat Defense device that was operating as the active unit will still have the standby unit's IP address listed in its configuration. To resolve this, do an additional deployment on the formerly active Firewall Threat Defense device to remove the standby unit's IP address from its configuration.

Remove a High Availability Pair

This task allows you to unregister a High Availability pair from the Cloud-Delivered Firewall Management Center, which keeps the High Availability pair intact. You might want to unregister the pair if you want to register it to a new Cloud-Delivered Firewall Management Center or if the Cloud-Delivered Firewall Management Center can no longer reach the pair.

Unregistering a High Availability pair:

- Severs all communication between the Cloud-Delivered Firewall Management Center and the pair.
- Removes the pair from the **Device Management** page.
- Returns the pair to local time management if the pair's platform settings policy is configured to receive time from the Cloud-Delivered Firewall Management Center using NTP.
- Leaves the configuration intact, so the pair continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the pair again to the same or a different Cloud-Delivered Firewall Management Center causes the configuration to be removed, so the pair will stop processing traffic at that point; the High Availability configuration remains intact so you can add the pair as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

- This procedure requires CLI access to the primary unit.

Procedure

Step 1 Log into Security Cloud Control and click **Security Devices**.

Step 2 Click the **FTD** tab and locate the High Availability pair you want to unregister. Select it so the device row is highlighted.

Step 3 In the **Device Actions** pane located to the right, click **Remove**.

Step 4 When prompted, select **OK** to confirm the removal of the selected device.

Monitoring High availability

Monitoring High availability is a system capability that enables you to view the High availability status.

View failover history

View the failover history of both high availability devices in a single view to understand the chronological order of failover events and their reasons.

You can view the failover history of both high availability devices in a single view. The history displays in chronological order and includes the reason for any failover.

Before you begin

Follow these steps to view failover history:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **Summary**.

Step 4 Under General, click **View** ( ).

View stateful failover statistics

This task allows you to monitor the stateful failover link statistics to assess the performance and health of your high availability configuration.

You can view the stateful failover link statistics of both the primary and secondary devices in the high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **High Availability**.

Step 4 Under Stateful Failover Link, click **View** ( ).

Step 5 Choose a device to view statistics.

High availability break troubleshooting in remote branch deployments

High availability break troubleshooting in remote branch deployments is a process that

- addresses common problems when breaking a High Availability pair in a remote deployment
- resolves active-active state issues, and
- fixes connectivity and failover link problems between devices and Security Cloud Control.

Common troubleshooting scenarios

These scenarios describe common problems you may encounter when breaking a High Availability pair in a remote deployment:

- Both Units are in Active-Active State.
- The primary or secondary device has lost connectivity with Security Cloud Control, and the failover link has become non-operational.
- The secondary device is in failed or disabled state and has lost connectivity with Security Cloud Control.

Break a high availability pair in active-active state

This task resolves the unstable network condition that occurs when both units in a high availability pair use the active IP address on their data management interface, resulting in network instability between the units and Security Cloud Control.

Both units in a remote deployment are in an active-active state because the failover interface became non-operational and they stopped receiving a response on their data interfaces. In this case, both units use the active IP address on their data management interface, which results in an unstable network between the units and Security Cloud Control.

You can determine if the units are both in active mode by logging into the device CLI and using the "show failover state" command on both units. The device status of both units shows 'active', and the same active IP address is assigned to both units.

Note You can try rectifying the failover interface to restore the communication between the two peers and then perform the **Force Break** operation.

If you cannot repair the connectivity issues of the failover interface, then perform these steps.

Procedure

Step 1 Identify a device you want to remove from the network among the two units.

Step 2 Connect to the CLI of the identified device, either from the console port or using SSH.

Step 3 Log in with the Admin username and password.

Step 4 Enter the **pmtool disablebyid sftunnel** command.

Note
Only use **pmtool** commands under the direction of the Cisco Technical Assistance Center.

Step 5 Disconnect all the interfaces from the device you want to remove from the network.

Step 6 Enter **configure network management-data-interface ipv4 manual** *ip_address ipv4_netmask gateway_ip_address* **interface***interface_id* command.

In *ip_address*specify the IP address of the standby device.

Example:

```
Configure network management-data-interface ipv4 manual 10.10.6.7 255.255.255.0 interface
gig0/0
Configuration updated successfully..!!
```

Step 7 Enter **configure high-availability suspend** to suspend HA.

```
configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

Step 8 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 9 Click the **Devices** tab to locate your device.

Step 10 Click the **FTD** tab and select the primary device.

Step 11 In the **Management** pane on the left, click **High Availability**.

Step 12 Choose **Device** > **Device Management**.

Step 13 Next to the high availability pair where you want to separate the high availability pair, click **Force Break**.

A message is displayed that the high-availability pair is separated successfully.

Step 14 Connect all the interfaces to the device.

Step 15 At the FTD CLI, enter **pmtool enablebyId sftunnel**.

The threat defense device establishes its connection with Security Cloud Control in sometime.

Note
It may take up to 5 minutes for the device to establish communication with Security Cloud Control.

Step 16 Enter the **sftunnel-status-brief** command to view the management connection status.

```
sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Wed Feb 9 09:21:57 2020 UTC
Last disconnect time : Wed Feb 9 09:19:09 2020 UTC
```

Step 17 Choose **Deploy** > **Deployment** to deploy the changes.

Before the Security Cloud Control deploys the changes, it will detect the configuration differences and stop the deployment. Security Cloud Control detects the IP address change made to the device outside of the Security Cloud Control.

Step 18 Synchronize interface changes with Security Cloud Control. See Sync Interface Changes with the Cloud-Delivered Firewall Management Center, on page 1014.

Step 19 You can now deploy the pending changes to the device. See Deploy configuration changes..

What to do next

(optional) Deploy any pending changes to the other device having the IP address of the active device.

Break a high availability pair when active or standby unit has lost connectivity

This task breaks a high availability pair when communication issues prevent normal failover operations between the active and standby units.

Problem: One of the peers has lost connectivity with Cloud-Delivered Firewall Management Center, and the failover link has become non-operational.

Table 48: Scenario:

Primary Device State	Secondary Device Stat	Primary Device Connectivity with Security Cloud Control?	Secondary Device Connectivity with ?Security Cloud Control	Failover link Operational? (Connectivity between Primary and Secondary devices)
Active	Standby	Yes	No	No
Standby	Active	No	Yes	No

Solution:

First, you can try rectifying the failover interface to restore the communication between the two peers and then perform the break or force break operation to separate the units.

If you cannot repair the connectivity issues of the failover interface, then you must complete additional steps using the device CLI after performing a high availability break operation.

Procedure

Step 1 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 2 Click the **Devices** tab to locate your device.

Step 3 Click the **FTD** tab and select the primary device.

Step 4 In the **Management** pane on the left, click **High Availability**.

Step 5 Choose **Devices** > **Device Management**.

Step 6 Next to the high-availability pair you want to break, click the **Break HA**.

Step 7 Optionally, you can also check the check box to force break as one of the peers does not respond.

Step 8 Click **Yes**.

Step 9 Delete the standby device from Security Cloud Control.

a) Choose **Devices** > **Device Management**.

b) Next to the device you want to delete, click **Delete**.

What to do next

You can onboard the device as a standalone device to Security Cloud Control if required.

Break a high availability pair when the secondary device is in a failed or disabled state

This task separates high availability devices when the secondary device cannot communicate with Security Cloud Control and allows the primary device to operate independently.

Use this procedure when the secondary device is in a failed or disabled state and has lost connectivity with Security Cloud Control. In addition, the failover link may or may not be operational.

Table 49: Scenario:

Primary Device State	Secondary Device Stat	Primary Device Connectivity with Security Cloud Control?	Secondary Device Connectivity with Security Cloud Control?	Failover link Operational? (Connectivity between Primary and Secondary devices)
Active	Failed	Yes	No	Yes or No
Active	Disabled	Yes	No	Yes or No

Perform a high availability force break to separate the units and then use the device CLI to remove the configuration from the standby unit and make the device a standalone device.

Procedure

Step 1 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 2 Click the **Devices** tab to locate your device.

Step 3 Click the **FTD** tab and select the primary device.

Step 4 In the **Management** pane on the left, click **High Availability**.

Step 5 Choose **Devices** > **Device Management**.

Step 6 Next to the high-availability pair you want to break, click the **Break HA**.

Step 7 Check the check box to force break as one of the peers does not respond.

Step 8 Click **Yes**.

Step 9 Delete the standby device from Security Cloud Control.

a) Choose **Devices** > **Device Management**.
b) Next to the device you want to delete, click **Delete**.

Step 10 Connect to the standby device's CLI, either from the console port or using SSH.

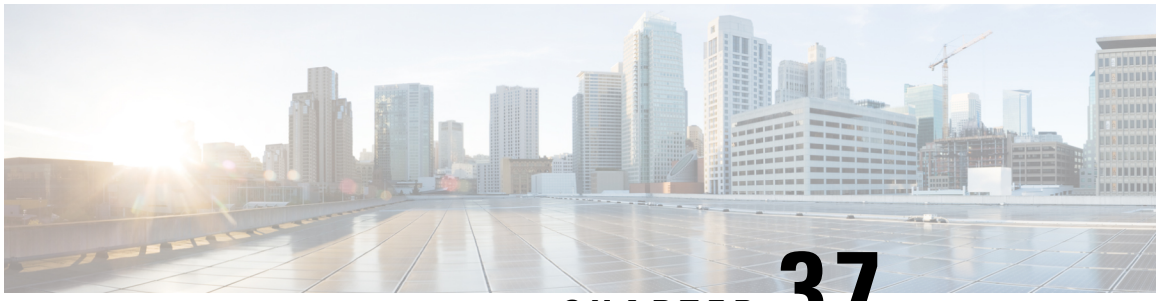
Step 11 Log in with the Admin username and password.

Step 12 Enter **configure high-availability disable** to remove the failover configuration and disable the data management interface on the device.

Step 13 Enter **configure network management-data-interface**.

Example:

```
configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:



Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.
```

The new network settings are assigned to the data device.

What to do next

You can onboard the device as a standalone device to Security Cloud Control if required.

CHAPTER 37

Clustering: Secure Firewall 3100/4200

Clustering lets you group multiple Firewall Threat Defense nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported features with clustering, on page 782.

- Clustering for the Secure Firewall 3100/4200, on page 723
- Licenses for clustering, on page 725
- Prerequisites for clustering, on page 725
- Guidelines for clustering, on page 726
- Clustering configuration, on page 731
- Cluster node management, on page 762
- Monitor the cluster, on page 772
- Troubleshoot the cluster, on page 777
- Clustering examples, on page 780
- Reference for Clustering, on page 782
- History for Clustering, on page 796

Clustering for the Secure Firewall 3100/4200

This section describes the clustering architecture and how it works.

How a cluster fits into your network

The cluster consists of multiple firewalls acting as a single unit. To act as a cluster, the firewalls need the following infrastructure:

- Isolated, high-speed backplane network for intra-cluster communication, known as the *cluster control link*.
- Management access to each firewall for configuration and monitoring.

Infrastructure requirements

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using one of these methods:

- **Spanned EtherChannel** (Recommended)—Interfaces on multiple members of the cluster are grouped into a single EtherChannel; the EtherChannel performs load balancing between units.
- **Policy-Based Routing** (Routed firewall mode only)—The upstream and downstream routers perform load balancing between units using route maps and ACLs.
- **Equal-Cost Multi-Path Routing** (Routed firewall mode only)—The upstream and downstream routers perform load balancing between units using equal cost static or dynamic routes.

Control and data node roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster interfaces

You can configure data interfaces as either Spanned EtherChannels or as Individual interfaces. All data interfaces in the cluster must be one type only. Refer Cluster interfaces, on page 731 for more information.

Interface type restrictions

- For Spanned EtherChannels: You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).
- For Individual interfaces: IPS-only interfaces are not supported.

Cluster control links

A cluster control link is a dedicated hardware interface that each unit must allocate for cluster communication. For more information, refer Cluster control link, on page 731.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for clustering

Lists the licensing requirements for clustering.

Feature license assignment

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Cloud-Delivered Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Note If you add the cluster before the Cloud-Delivered Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Cloud-Delivered Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Prerequisites for clustering

Review these prerequisites before configuring clustering on Secure Firewall devices.

Model requirements

- Secure Firewall 3100—Maximum 16 nodes
- Secure Firewall 4200—Maximum 16 nodes

User roles

- Admin
- Access Admin
- Network Admin

Hardware and software requirements

- All units in a cluster must be the same model.
- All units must include the same number of interfaces and the same network modules, and must use the same network module slot assignments.
- The Cloud-Delivered Firewall Management Center access must be from the Management interface; data interface management is not supported.
- All units must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- All units must be in the same firewall mode, routed or transparent.
- All units must use the same compliance mode.
- If core allocation is supported, all units must use the same core allocation profile.
- All units must be in the same domain and the same group, with no deployment pending or in progress.
- The control node must not have any unsupported features configured (refer Unsupported features with clustering, on page 782), and data nodes must not have any VPN configured. The control node can have site-to-site VPN configured.

Note

- Clustering is not supported for Threat Defense instances, such as instances in container mode.
- All units must use the same compliance mode.
- If core allocation is supported, all units must use the same core allocation profile.

Switch requirements

Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 100 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for clustering

Configuration requirements

Ensure that firewall mode configuration matches on all units in the cluster.

- High Availability is not supported with clustering.
- The cluster control link is only supported using IPv4.

Switch and EtherChannel configuration

Disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.

Topology change management

When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Threat Defense device or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.

Operational considerations

Expect temporary, limited packet, or connection drop when adding a unit to an existing cluster or when reloading a unit.

- In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Default clustering settings

Review the default clustering configuration settings before deployment.

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Firewall Mode

The firewall mode must match on all units.

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

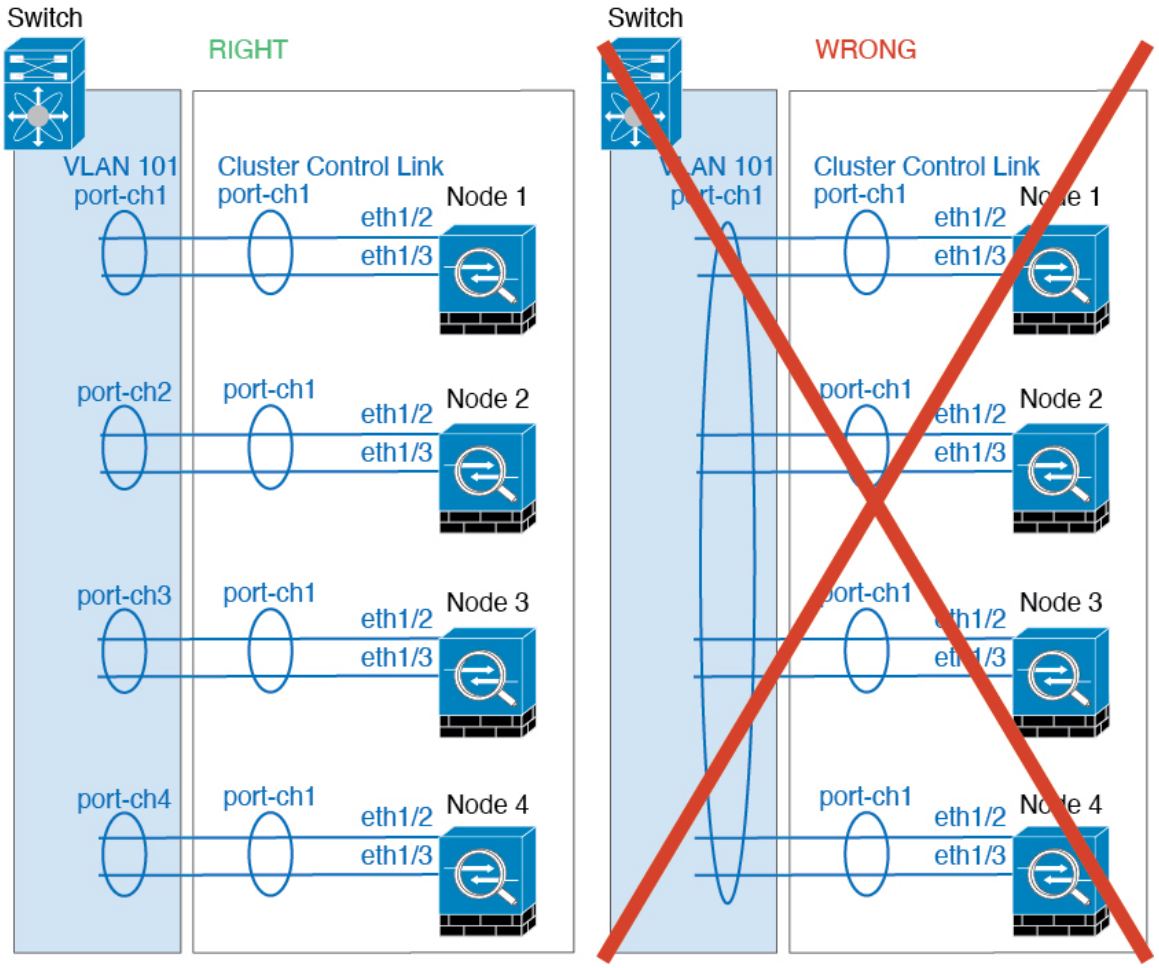
Switches

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR IPv4 MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch, we recommend that you use one of these EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command).

  Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- You should disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.



EtherChannels

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.

- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit Spanned EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

  - Device-local EtherChannels—For cluster unit Device-local EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Threat Defense or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a

new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults for clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Clustering configuration

To add a cluster to the Cloud-Delivered Firewall Management Center, add each node to the Cloud-Delivered Firewall Management Center as a standalone unit, configure interfaces on the unit you want to make the control node, and then form the cluster.

Cluster interfaces

You can configure data interfaces as either Spanned EtherChannels or as individual interfaces. All data interfaces in the cluster must be one type only. You cannot configure Ethernet 1/1 as a Spanned EtherChannel and configure Ethernet 1/2 as an Individual interface within the same cluster, for example.

For Spanned EtherChannels: You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces). For Individual interfaces: IPS-only interfaces are not supported.

Each unit must also dedicate at least one hardware interface as the cluster control link.

Cluster control link

A cluster control link is a dedicated hardware interface that enables communication between cluster units and supports cluster operation coordination.

Each unit must dedicate at least one hardware interface as the cluster control link. We recommend using an EtherChannel for the cluster control link if available.

Cluster control link traffic

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Cluster control link interfaces and network

You can use any physical interface or EtherChannel for the cluster control link. You cannot use a VLAN subinterface as the cluster control link. You also cannot use the Management interface.

Each cluster control link has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

Note For a 2-member cluster, do not directly connect the cluster control link from one node to the other node. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

If you need to directly connect the units (for testing purposes, for example), configure and enable the cluster control link interface on both nodes before forming the cluster.

Size the cluster control link

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features.

For example:

- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster control link MTU ping testing

Use Cluster control link MTU ping testing to

- verify MTU compatibility between cluster nodes during the join process
- use ping-based fragmentation tests to confirm the network path supports proper packet handling, and
- allow nodes to join even if tests fail while providing diagnostic messages for troubleshooting MTU mismatches.

Control node ping test

When a node joins the cluster, the control node sends a ping with a payload size of twice the MTU. This process tests the network's ability to handle packet fragmentation because the underlying IP layer will fragment packets that exceed the MTU limit.

A successful ping confirms that the network path supports proper fragmentation and that the cluster control link can reliably process traffic at the configured MTU size.

If the ping fails, view these messages:

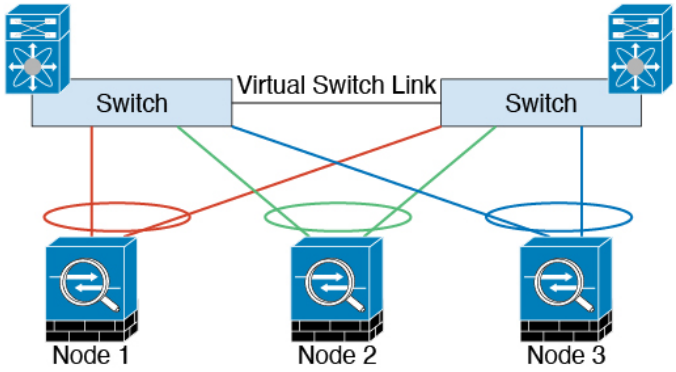
- **show cluster history**—`Event: CCL MTU test to unit name failed`
- Console WARNING—`WARNING: Unit name is not reachable in CCL jumbo frame ICMP test, please check cluster interface and switch MTU configuration`

Even if the ping fails, the node is allowed to join the cluster. In this case, you need to resolve the MTU mismatch as soon as possible.

Data node ping test

When a node joins the cluster, the joining node checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the initial ping fails, the node tries a ping using a smaller packet size (the MTU divided by 2, then by 4, then by 8) until a ping succeeds.

If the ping fails, view these messages:



- **show cluster info trace**—`Warning: CCL MTU is configured to cfg_mtu_size. However CCL MTU test to unit name failed with size larger_test_size (passed with size smaller_test_size). Please check switch MTU configuration.`

  To easily view this WARNING, filter on the **show** output using **show cluster info trace | incl MTU**.
- **show cluster history**, Cloud-Delivered Firewall Management Center notification—`Warning: MTU mismatch detected on the CCL interface. Please ensure that the MTU setting on the connected switch matches the firewall's configured MTU (cfg_mtu_size).`
- Console WARNING—`WARNING: Unit name is not reachable in CCL jumbo frame ICMP test, please check cluster interface and switch MTU configuration`

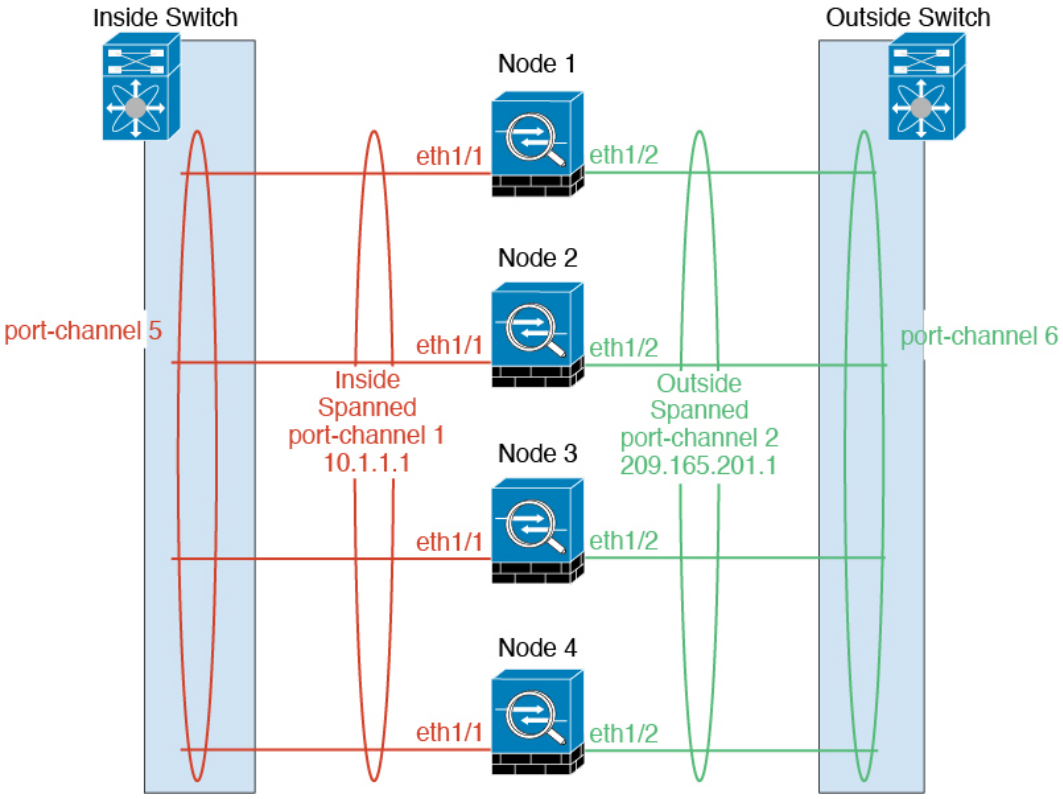
Even if the ping fails, the node is allowed to join the cluster. In this case, you need to resolve the MTU mismatch as soon as possible.

Cluster control link redundancy

The diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster control link reliability for inter-chassis clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.



The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Spanned EtherChannels (Recommended)

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

Spanned EtherChannel benefits

The EtherChannel method of load-balancing is recommended over other methods for these benefits:

- Faster failure discovery.
- Faster convergence time. Individual interfaces rely on routing protocols to load-balance traffic, and routing protocols often have slow convergence during a link failure.
- Ease of configuration.

Guidelines for maximum throughput

To achieve maximum throughput, follow these guidelines:

- Use a symmetric load-balancing hash algorithm, meaning that packets from both directions will have the same hash and will be sent to the same Firewall Threat Defense in the Spanned EtherChannel. We recommend using the source and destination IP address (the default) or the source and destination port as the hashing algorithm.
- Use the same type of line cards when connecting the Firewall Threat Defenses to the switch so that hashing algorithms applied to all packets are the same.

Load balancing

The EtherChannel link is selected using a proprietary hash algorithm, based on source or destination IP addresses and TCP and UDP port numbers.

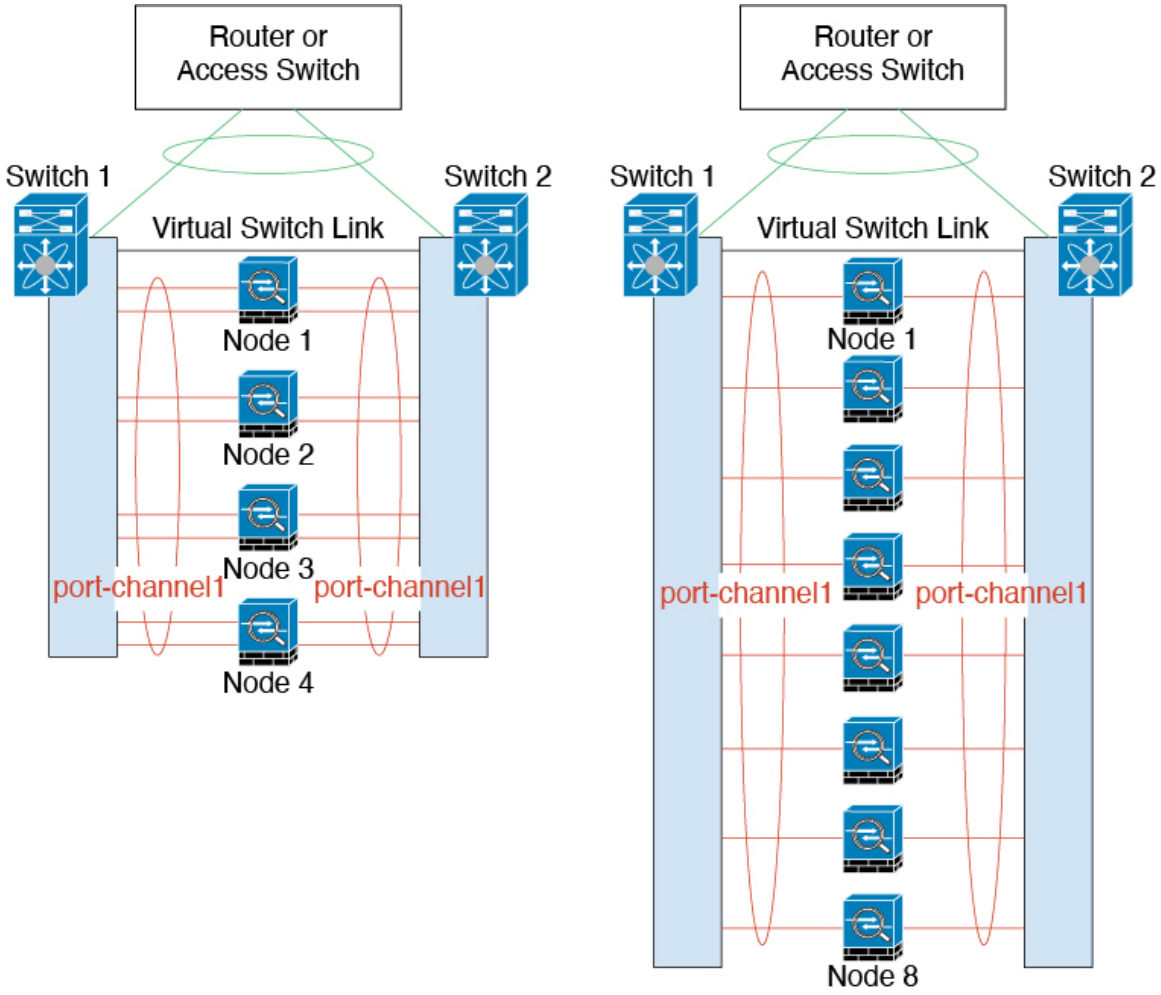
Note On the switch, we recommend that you use one of the following algorithms: **source-dest-IP** or **source-dest-IP-port** (see the Cisco Nexus OS or Cisco IOS **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the nodes in a cluster.

The number of links in the EtherChannel affects load balancing.

Symmetric load balancing is not always possible. If you configure NAT, then forward and return packets will have different IP addresses and/or ports. Return traffic will be sent to a different unit based on the hash, and the cluster will have to redirect most returning traffic to the correct unit.

EtherChannel redundancy

The EtherChannel has built-in redundancy. It monitors the line protocol status of all links. If one link fails, traffic is re-balanced between remaining links. If all links in the EtherChannel fail on a particular unit, but other units are still active, then the unit is removed from the cluster.



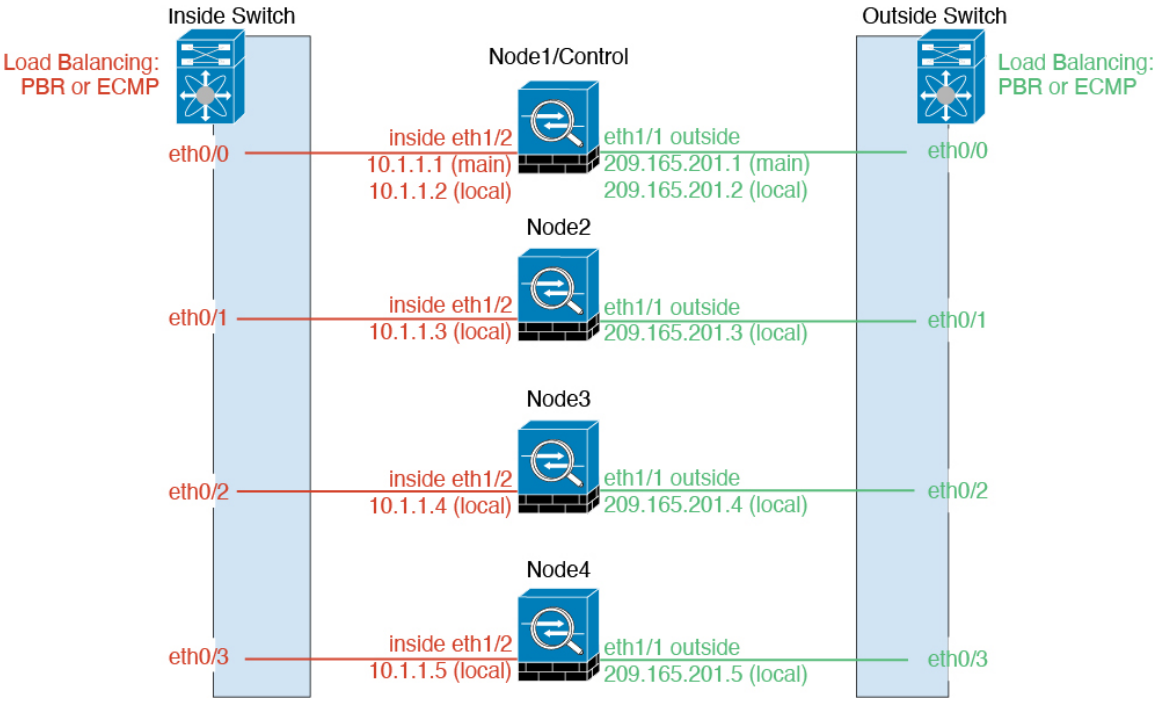
Connecting to a redundant switch system

You can include multiple interfaces per Firewall Threat Defense in the Spanned EtherChannel. Multiple interfaces per Firewall Threat Defense are especially useful for connecting to both switches in a VSS, vPC, StackWise, or StackWise Virtual system.

Depending on your switches, you can configure up to 32 active links in the spanned EtherChannel. This feature requires both switches in the vPC to support EtherChannels with 16 active links each (for example the Cisco Nexus 7000 with F2-Series 10 Gigabit Ethernet Module).

For switches that support 8 active links in the EtherChannel, you can configure up to 16 active links in the spanned EtherChannel when connecting to two switches in a redundant system.

This figure shows a 16-active-link spanned EtherChannel in a 4-node cluster and an 8-node cluster.



Individual interfaces

Individual interfaces are normal routed interfaces, each with their own *local IP address* used for routing. The *main cluster IP address* for each interface is a fixed address that always belongs to the control node. When the control node changes, the Main cluster IP address moves to the new control node, so management of the cluster continues seamlessly.

IPS-only interfaces (inline sets and passive interfaces) are not supported as Individual interfaces.

Because interface configuration must be configured only on the control node, you configure a pool of IP addresses to be used for a given interface on the cluster nodes, including one for the control node.

Load balancing must be configured separately on the upstream switch.

Policy-based routing

When using individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all Firewall Threat Defenses in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same Firewall Threat Defense.

For example, if you have a Cisco router, redundancy can be achieved by using Cisco IOS PBR with Object Tracking. Cisco IOS Object Tracking monitors each Firewall Threat Defense using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular Firewall Threat Defense.

Equal-cost multi-path routing

When using Individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure.

ECMP routing considerations

ECMP routing can forward packets over multiple best paths that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops.

If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost.

If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Cisco Intelligent Traffic Director (Routed Firewall Mode Only)

Cisco Intelligent Traffic Director (ITD) is a high-speed hardware load-balancing solution that

- supports Nexus 5000, 6000, 7000, and 9000 switch series
- fully covers the functional capabilities of traditional PBR with a simplified configuration workflow, and
- offers multiple additional features for more granular load distribution.

ITD capabilities and configuration

When using Individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address.

ITD provides these load-balancing capabilities:

- IP stickiness
- Consistent hashing for bi-directional flow symmetry
- Virtual IP addressing
- Health monitoring
- Sophisticated failure handling policies with N+M redundancy
- Weighted load-balancing
- Application IP SLA probes including DNS

Due to the dynamic nature of load-balancing, ITD achieves a more even traffic distribution across all cluster nodes as compared to PBR. To achieve bi-directional flow symmetry, configure ITD such that forward and return packets of a connection are directed to the same Firewall Threat Defense.

For more details, refer to Cisco Intelligent Traffic Director Deployment Guide with Cisco ASA.

Cable and add devices to the Cloud-Delivered Firewall Management Center

Before configuring clustering, you need to prepare your devices. In particular, the cluster will not come up unless all nodes can communicate over the cluster control link. Therefore, before you form the cluster, the cluster control link must be ready to go.

Procedure

Step 1 Cable the cluster control link network, management network, and data networks.

Step 2 Configure the upstream and downstream equipment.

a) For the cluster control link network, set the MTU to be at least 100 bytes higher than the data interface MTU.

   By default, the data interface MTU is 1500 bytes, so the cluster control link MTU on the cluster node will be set to 1600 bytes. If you use higher MTUs on your data interfaces, increase the cluster control link MTU on connecting switches accordingly.

b) Configure cluster control link interfaces on upstream and downstream equipment, including for an optional EtherChannel.

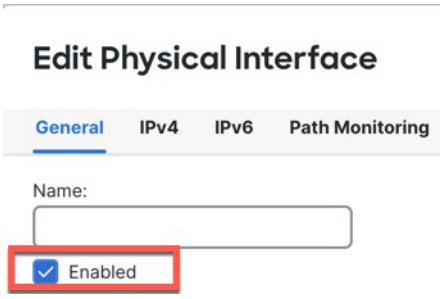
   For more information, refer to Cluster control link interfaces and network, on page 732 for cluster control link requirements.

c) Configure data interfaces on upstream and downstream equipment, including Spanned EtherChannels.

   For more information, refer to Cluster interfaces, on page 731 for information about how to cable Spanned EtherChannels.

Step 3 Add each node to the Cloud-Delivered Firewall Management Center as a standalone device in the same domain and group.

You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.



Step 4 Enable the cluster control link on the device you want to be the control node.

When you add the other nodes, they will inherit the cluster control link configuration.

Note
Do *not* configure the name or IP addressing for the cluster control link. The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU when you form the cluster, so you do not need to set it now. However, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend returning to the **Interfaces** page and manually increasing it above 8362. When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the initial ping fails, the node tries a ping using a smaller packet size (the MTU divided by 2, then by 4, then by 8) until a ping succeeds. A notification is generated so you can fix the MTU mismatch on connecting switches and try again.

a) On the device you want to be the control node, choose **Devices** > **Device Management**, and click **Edit** ().
b) Click **Interfaces**.
c) Enable the interface. If you are going to use an EtherChannel for the cluster control link, enable all members.For more information, refer to Enable the physical interface and configure Ethernet settings, on page 1003.

Figure 104: Enable the cluster control link interface

d) (Optional) Add an EtherChannel.For more information, refer to Configure an EtherChannel, on page 1011.

We recommend using the On mode for cluster control link member interfaces to reduce unnecessary traffic on the cluster control link (Active mode is the default). The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network. **Note:** We recommend setting *data* EtherChannels to Active mode.

e) Click **Save** and then **Deploy** to deploy the interface changes to the control node.

Create a Cluster

Form a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 105: Add Cluster Wizard

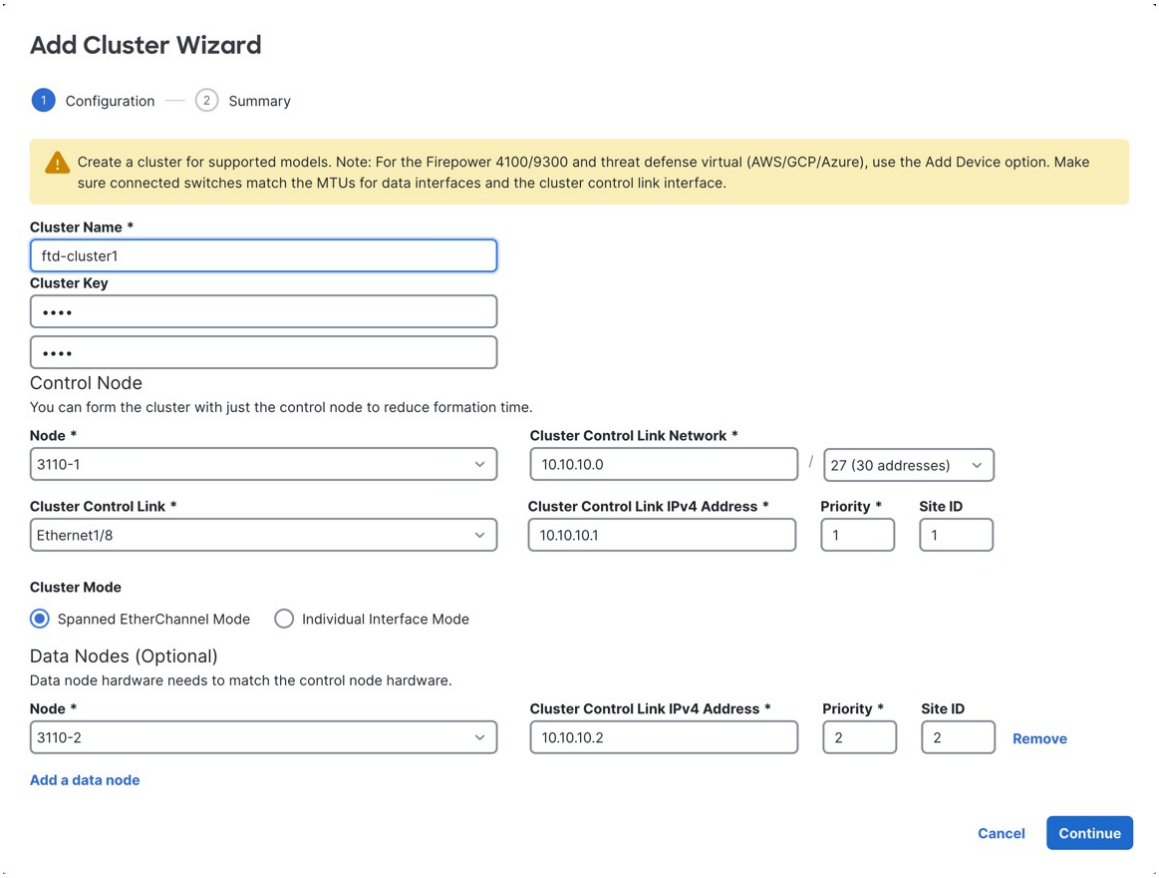


Figure 106:

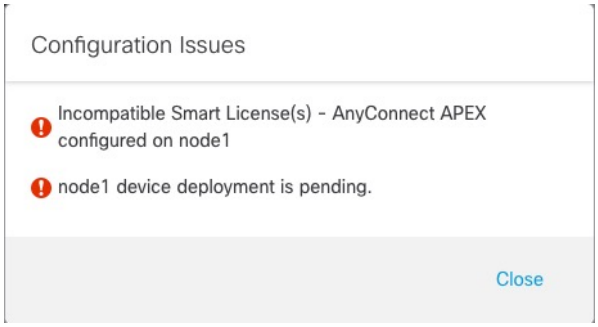
Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string of 1 to 38 characters. The cluster name can contain only letters, digits, underscores (_), and hyphens (-).
- **Cluster Key**—An ASCII string of 1 to 63 characters. The cluster key cannot be a single digit and must not contain spaces. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in clear text.



Step 3 For the **Control Node**, configure these parameters:

- **Node**—Choose the device that you want to be the control node initially. When the Cloud-Delivered Firewall Management Center forms the cluster, it will add this node to the cluster first so it will be the control node.

  Note

  If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 107: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **Cluster Control Link Network**—Specify an IPv4 subnet; IPv6 is not supported for this interface. Specify a **24**, **25**, **26**, or **27** subnet.
- **Cluster Control Link**—Choose the physical interface or EtherChannel you want to use for the cluster control link.

  Note
  The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes. We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend increasing the MTU above 8362. Choose **Devices** > **Device Management** and then click **Interfaces**.

  Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation can fail.

- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the first address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

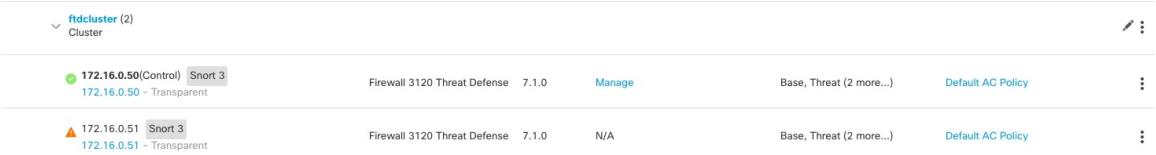
Step 4 For the **Cluster Mode**, choose **Spanned EtherChannel Mode** or **Individual Interface Mode** .

Step 5 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

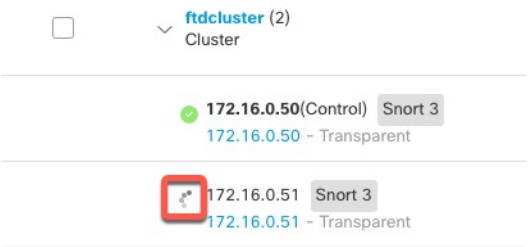
  Note



If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

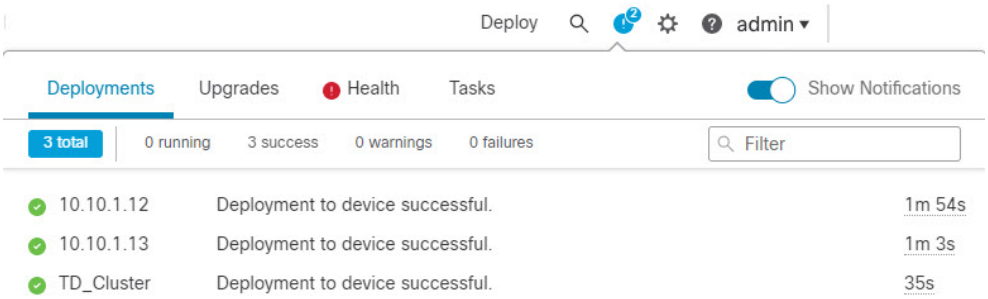
- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the next address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 6 Click **Continue**. Review the **Summary**, and then click **Save**.



The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

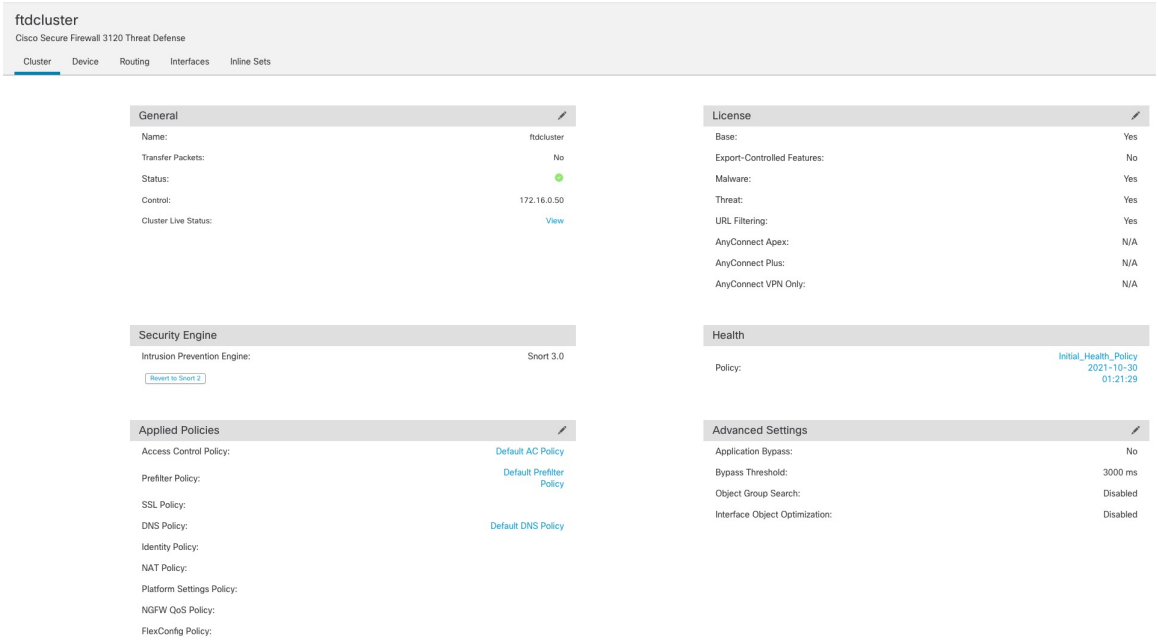
Figure 108: Cluster Management



A node that is currently registering shows the loading icon.

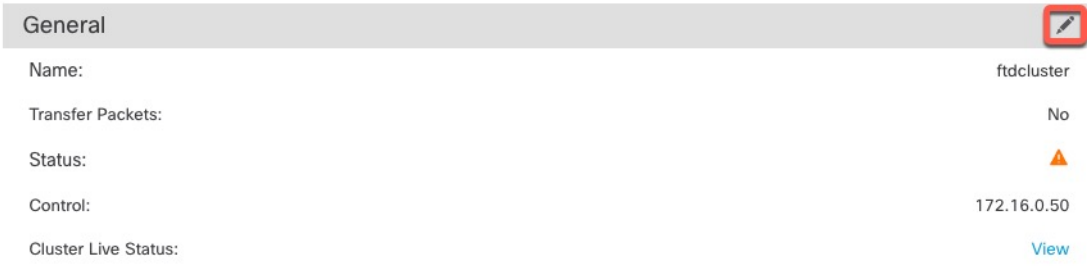
Figure 109: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The Cloud-Delivered Firewall Management Center updates the Cluster Registration task as each node registers.



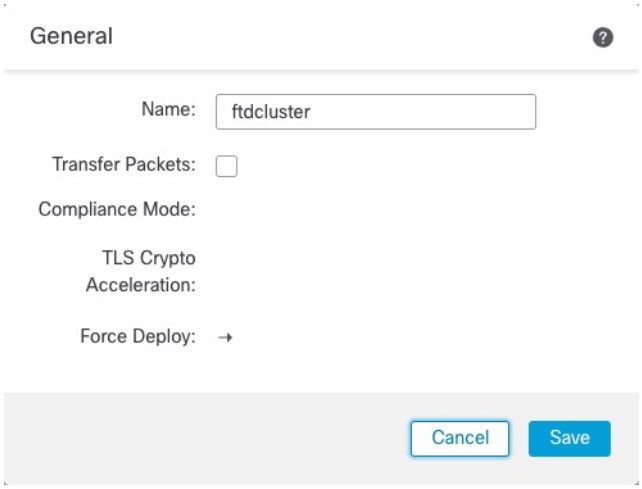
Step 7 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.



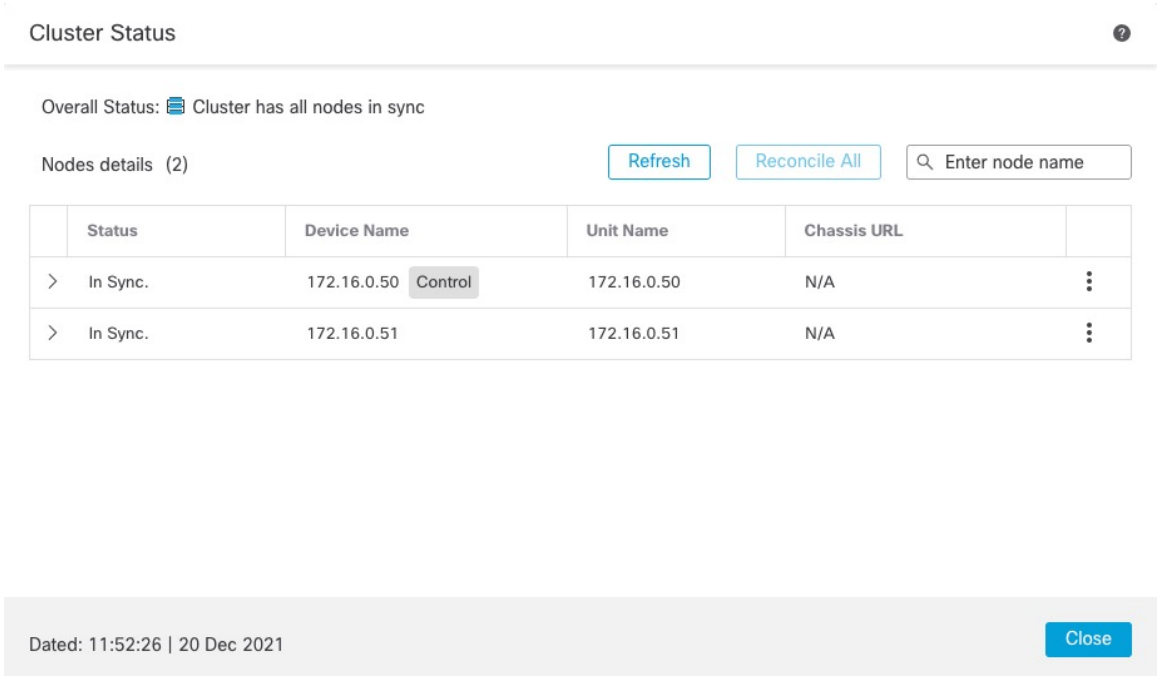
Step 8 On the **Devices** > **Device Management** and then choose **Add**, **Cluster** screen, you see **General** and other settings for the cluster.

Figure 110: Cluster Settings



See these cluster-specific items in the **General** area:

- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).



Then set the **Name** field.

- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.

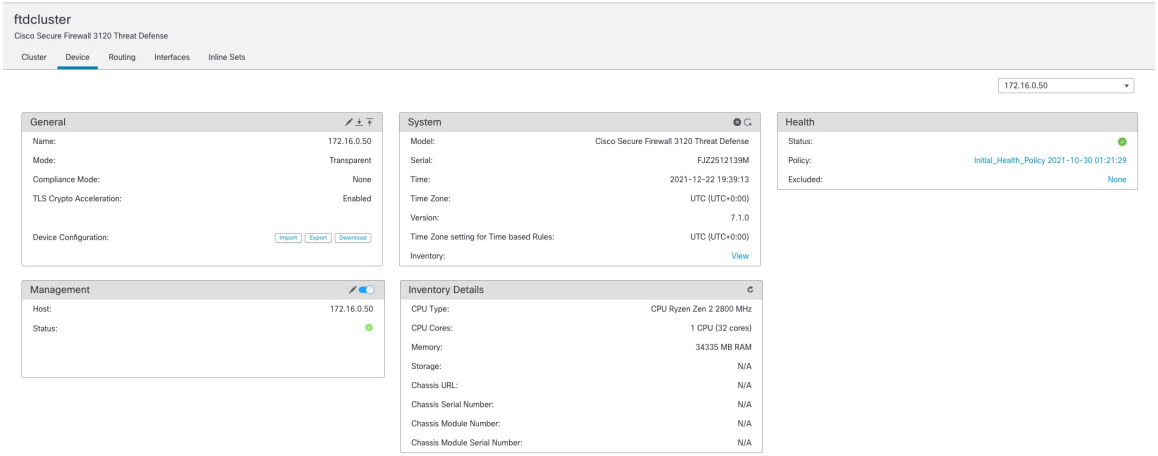
The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**.

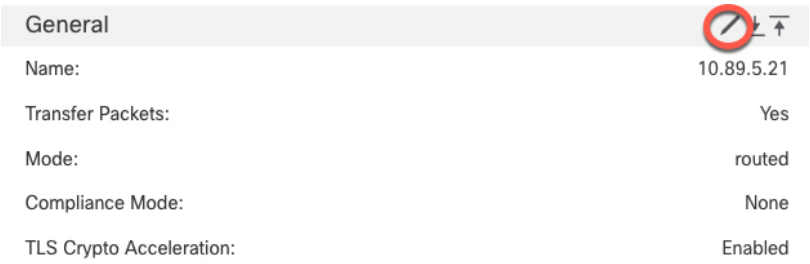
- **General > Troubleshoot**—You can generate and download troubleshooting logs, and you can view cluster CLIs. Refer Troubleshoot the cluster, on page 777 .

Figure 111: Troubleshoot

Step 9 On the **Devices** > **Device Management** and then choose **Add**, **Device**, you can choose each member in the cluster from the top right drop-down menu and configure these settings.

Figure 112: Device Settings





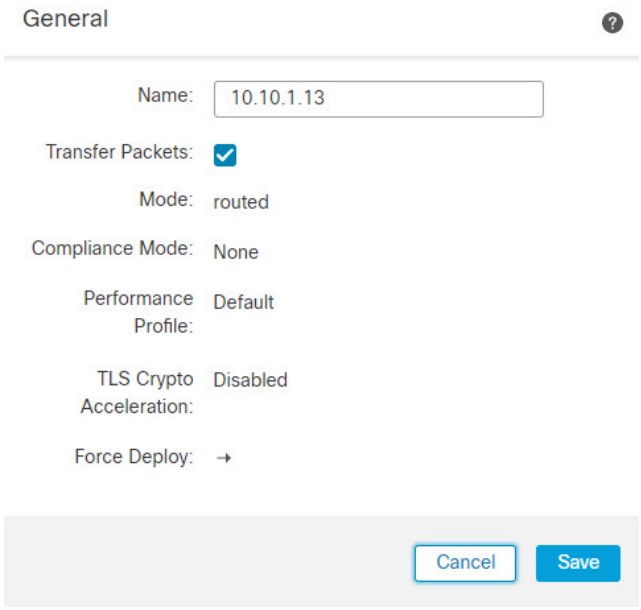


Figure 113: Choose Node

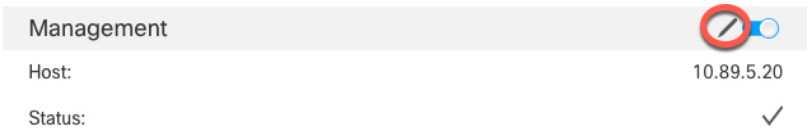


- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ) .

Then set the **Name** field.

- **Management > Host** —If you change the management IP address in the device configuration, you must match the new address in the Cloud-Delivered Firewall Management Center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Configure interfaces

You can configure data interfaces as either Spanned EtherChannels or as Individual interfaces. Each method uses a different load-balancing mechanism. You cannot configure both types in the same configuration.

Configure spanned EtherChannels

Configure data interfaces as Spanned EtherChannels.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure Spanned EtherChannel data interfaces.

a) Configure one or more EtherChannels. See Configure an EtherChannel, on page 1011.

You can include one or more member interfaces in the EtherChannel. Because this EtherChannel is spanned across all of the nodes, you only need one member interface per node; however, for greater throughput and redundancy, multiple members are recommended.

b) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the EtherChannel. The rest of this procedure applies to the subinterfaces. See Add a subinterface, on page 1060.

c) Click **Edit** ( ) for the EtherChannel interface.

d) Configure the name and other parameters. For regular firewall interfaces, see Configure routed mode interfaces, on page 1080 or, for transparent mode, Bridge group interfaces, on page 1086. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 1119.

- If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. By default, the cluster control link MTU is 1600 bytes. If you want to increase the MTU of data interfaces, first increase the cluster control link MTU. Note that we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For routed mode, DHCP, PPPoE, IPv6 autoconfig and manual link-local addresses are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.

e) Set a unique, manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby MAC Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

f) Click **OK**. Repeat the above steps for other data interfaces.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure individual interfaces

Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP addresses. The Main cluster IP address is a fixed address for the cluster that always belongs to the control node.

Individual management interfaces let you SSH directly to each unit if necessary, while a Spanned EtherChannel interface only allows connection to the control node.

IPS-only interfaces (inline sets or passive interfaces) are not supported for Individual interfaces.

Before you begin

- You must be in Individual interface mode.
- Individual interfaces require you to configure load balancing on neighbor devices. External load balancing is not required for the management interface.
- (Optional) Configure the interface as a device-local EtherChannel interface, and/or configure subinterfaces.

  For an EtherChannel, this EtherChannel is local to the unit, and is not a Spanned EtherChannel.

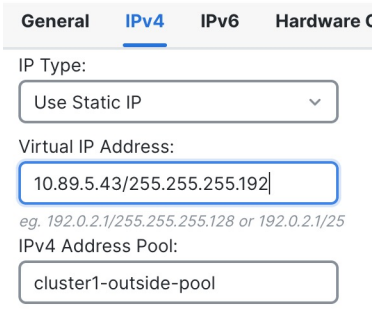
Procedure

Step 1 Choose **Objects** > **Object Management** > **Address Pools** to add an IPv4 and/or IPv6 address pool.For more information, refer to Configure address pools, on page 2954.

Include at least as many addresses as there are units in the cluster. The main IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

Figure 114: Add address pool

Note



Although not common, if you want to set the MAC addresses manually, you can also add a MAC address pool object.

Step 2 On **Devices** > **Device Management** and then choose **Interfaces**, click **Edit** (✎) for the interface you want to configure.

Step 3 On the **IPv4** page, enter the **Virtual IP Address** and mask. This main ("virtual") IP address is a fixed address for the cluster, and always belongs to the control node.

DHCP and PPPoE are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.

Figure 115: IPv4 page

Step 4 From the **IPv4 Address Pool** drop-down list, choose the address pool you created.

Step 5 On **IPv6 > Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.

IPv6 autoconfig and manual link-local addresses are not supported.

Step 6 Configure other interface settings as normal.

To set the MAC addresses manually, you can select the MAC address pool from the interface's **Advanced** page.

Note
If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. By default, the cluster control link MTU is 1600 bytes. If you want to increase the MTU of data interfaces, first increase the cluster control link MTU. Note that we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.

Configure cluster health monitor settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 116: Cluster Health Monitor Settings

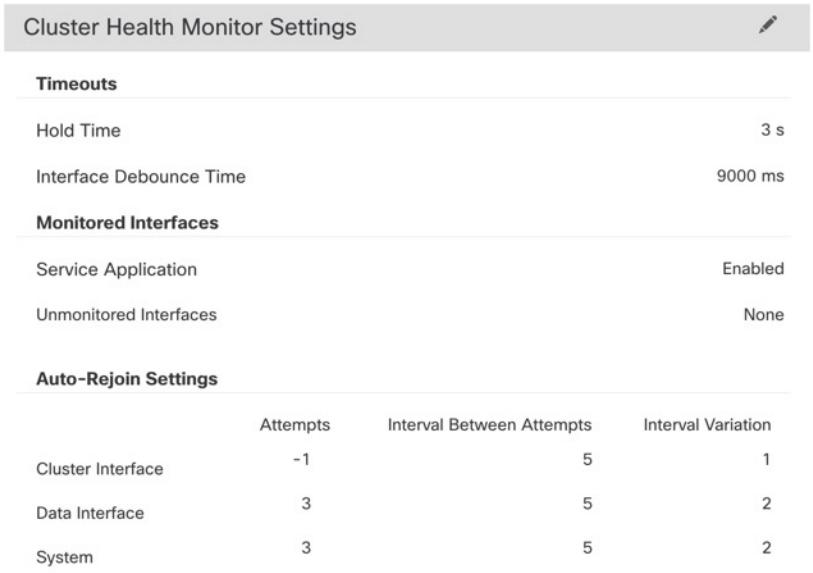


Table 50: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

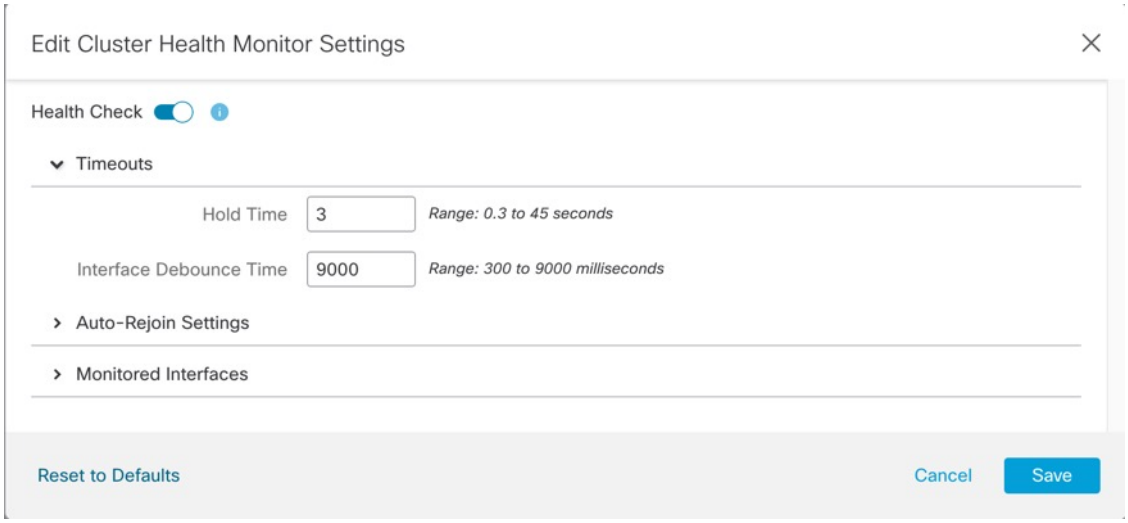
Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.



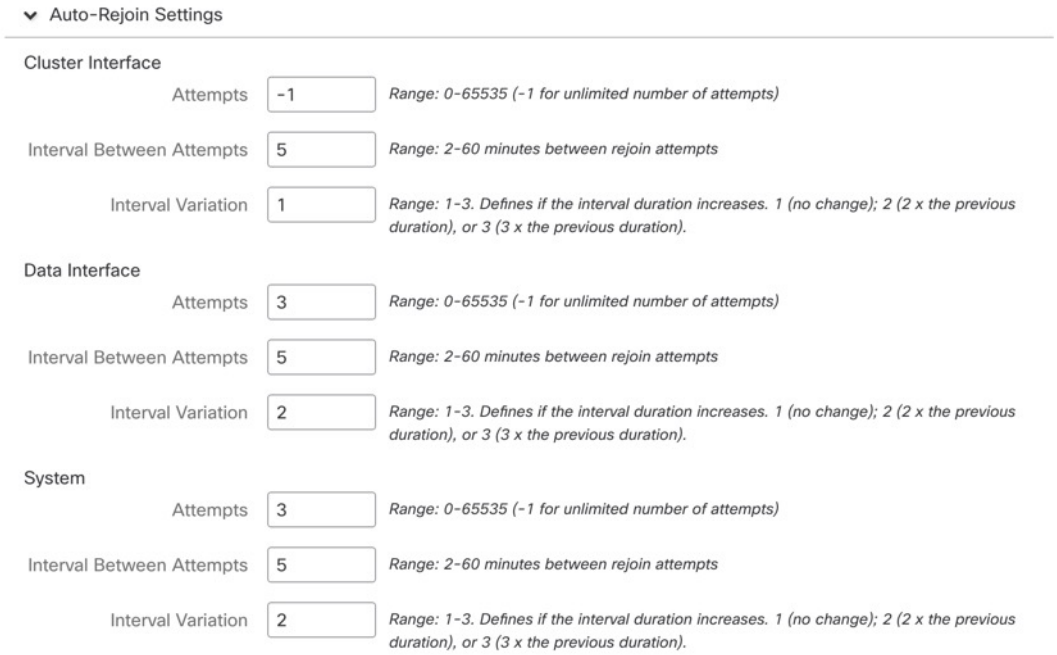
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 117: Disable the System Health Check



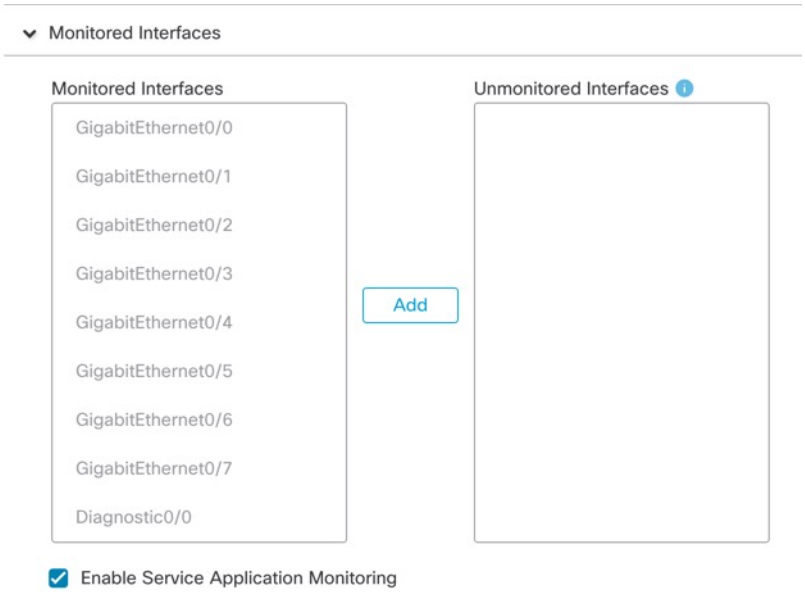
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 118: Configure Auto-Rejoin Settings



Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 119: Configure Monitored Interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save** and deploy the configuration changes.

Configure distributed Site-to-Site VPN

By default, the cluster uses centralized site-to-site VPN mode. To take advantage of the scalability of clustering, you can enable distributed site-to-site VPN mode.

Distributed site-to-site VPN

In distributed mode, site-to-site IPsec IKEv2 VPN connections are distributed across nodes of a cluster. Distributing VPN connections across the nodes of a cluster allows both the capacity and throughput of the cluster to be fully utilized, significantly scaling VPN support beyond centralized VPN capabilities.

Distributed VPN connection roles

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation. When running in distributed VPN mode, the following roles are assigned to the cluster nodes:

- **Active Session Owner**—The node that initially receives the connection or that has transitioned a backup session to an active session. The owner maintains the state and processes packets for the complete session, including the IKE and IPsec tunnels and all traffic associated with them.
- **Backup Session Owner**—The node that is handling the backup session for an existing active session. If the active session owner fails, the backup session owner becomes the active session owner, and a new backup session is established on a different node.
- **Forwarder**—If traffic associated with a VPN session is sent to a node that does not own the VPN session, that node will use the cluster control link to forward the traffic to the node that owns the VPN session.
- **Orchestrator**—The orchestrator (always the control node of the cluster) is responsible for calculating which sessions will move and where they will move to when executing an Active Session Redistribution (ASR). It sends a request to the owner node X to move N sessions to node Y. Node X will respond back to the orchestrator when complete, specifying how many sessions it was able to move.

Distributed VPN session characteristics

Distributed site-to-site VPN sessions have the following characteristics. Otherwise, VPN connections behave as they normally do if not in a cluster.

- VPN sessions are distributed across the cluster at the session level. Meaning the same cluster node handles the IKE and IPsec tunnels and all their traffic for a VPN connection. If VPN session traffic is sent to a cluster node that does not own that VPN session, traffic is forwarded to the cluster node that owns the VPN session.
- VPN sessions have a Session ID that is unique across the cluster. Using the session ID, traffic is validated, forwarding decisions are made, and IKE negotiation is completed.
- In a site-to-site VPN hub and spoke configuration, when clients connect through the cluster (called hair-pinning), the session traffic flowing in and the session traffic flowing out may be on different cluster nodes.

Distributed VPN handling of cluster events

This table lists how distributed VPN responds to different cluster events including node failures, node inactivation, and node joins.

Event	Distributed VPN
Node failure	For all active sessions on this failed node, the backup sessions (on another node) become active, and backup sessions are reallocated on another node.
Inactivate a cluster node	For all active sessions on the cluster node being inactivated, backup sessions (on another node) become active and reallocate backup sessions on another node according to the backup strategy.

Event	Distributed VPN
Cluster node join	If the VPN cluster mode on the new node is not set to distributed, the control node will request a mode change. After the VPN mode is compatible, the cluster node will be assigned active and backup sessions in the flow of normal operations.

IPsec IKEv2 modifications

IKEv2 is modified while in distributed site-to-site VPN mode in the following ways:

- An identity is used in place of IP/port tuples. This allows for proper forwarding decisions on the packets, and cleanup of previous connections that may be on other cluster members.
- The (SPI) identifiers that identify a single IKEv2 session are locally generated, random 8-byte values that are unique across the cluster. An SPI embeds a time stamp and a cluster node ID. Upon receipt of an IKE negotiation packet, if the time stamp or cluster node ID check fails, the packet is dropped and a message is logged indicating the reason.
- IKEv2 processing has been modified to prevent NAT-T negotiations from failing by being split across cluster members. A new ASP classify domain, **cluster_isakmp_redirect**, and rules are added when IKEv2 is enabled on an interface.

Certificate Management Protocol version 2

The Certificate Management Protocol version 2 (CMPv2) ID certificate and key pairs are synchronized across the cluster nodes. However, only the control node in the cluster automatically renews and rekeys the CMPv2 certificate. The control node synchronizes these new ID certificates and keys to all cluster nodes on a renewal. In this way, all nodes in the cluster utilize the CMPv2 certificates for authentication, and also any node is capable of taking over as the control node.

License for distributed site-to-site VPN

A Carrier license on each member of the cluster is required for distributed site-to-site VPN.

Prerequisites for distributed site-to-site VPN

Review these prerequisites before implementing distributed site-to-site VPN.

Model support

- Secure Firewall 4200

Cluster requirements

- Spanned EtherChannel mode.
- Routed firewall mode.

Maximum VPN sessions

Each VPN connection requires two sessions, one for the active session and one for the backup session. The maximum VPN session capacity of the cluster can be no more than half of the listed capacity due to using two licenses for each session.

Table 51: Maximum VPN sessions

Model	Maximum VPN Sessions
4215	10,000
4225	12,500
4245	15,000

Guidelines for distributed site-to-site VPN

Firewall mode

Distributed site-to-site VPN is supported in routed mode only.

Unsupported inspections

These types of inspections are not supported or are disabled in distributed site-to-site VPN mode:

- CTIQBE and DCERPC
- H323, H225, and RAS
- IPsec pass-through
- MGCP, MMP and NetBIOS
- PPTP and RADIUS
- RSH and RTSP
- SCCP (Skinny) and SUNRPC
- TFTP
- WAAS, WCCP, XDMCP

Additional Guidelines

- Only IKEv2 IPsec site-to-site VPN is supported in distributed site-to-site VPN mode. IKEv1 is not supported. IKEv1 site-to-site is supported in centralized VPN mode.
- Inter-site clustering is not supported.
- To view FlexConfig features that are also not supported with clustering, for example many inspections, refer to ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Cloud-Delivered Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 1309.

Enable distributed site-to-site VPN

Enable distributed site-to-site VPN to take advantage of the scalability of clustering for VPN sessions. This procedure requires CLI access to the control node.

Before you begin

- Configure site-to-site VPN according to Site-to-Site VPN, on page 1725.
- Apply the Carrier license to the control node.

Procedure

Step 1 Add a Spanned-EtherChannel-mode cluster according to Create a Cluster, on page 741, including all data nodes.

Step 2 After the cluster is formed and stable, remove each of the data nodes according to Disable clustering, on page 766, and then remove the control node.

Clustering needs to be disabled to change the VPN mode. The bootstrap configuration remains intact, as well as the last configuration synched from the control node, so that you can later re-add the nodes without losing your configuration.

Step 3 Connect to the control node CLI. Refer to the 'Log Into the Command-Line Interface on the Device' section in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

View the cluster on **Devices** > **Device Management** to see which device is the control node.

Step 4 Enable distributed site-to-site VPN on the control node.

cluster VPN-mode distributed

To disable distributed site-to-site VPN, use the **cluster VPN-mode centralized** command.

Example:

```
> cluster vpn-mode distributed
Cryptochecksum: ce4b0bbd 6b9252a5 7e19463d e179067d

5778 bytes copied in 0.70 secs
>
```

Step 5 In the Cloud-Delivered Firewall Management Center, reenable clustering on the control node and then for each data node. For more information, refer to Rejoin the cluster, on page 767.

The VPN mode is synched to the data nodes.

Redistribute distributed site-to-site VPN sessions

Active session redistribution redistributes the active VPN session load across the cluster nodes.

Due to the dynamic nature of beginning and ending sessions, active session redistribution is a best effort balancing of the sessions across all cluster nodes. Repeated redistribution actions will optimize the balance.

Redistribution can be run at any time, should be run after any topology change in the cluster, and is recommended after a new node joins the cluster.

To move a session, the backup session becomes the active one and another node is selected to host a new backup session. Moving sessions is dependent on the location of the active session's backup and the number of active sessions already on that particular backup node. If the backup session node is unable to host the active session for some reason, the original node remains owner of the session.

Before you begin

- Enable system logs if you would like to monitor redistribution activity.
- Enable CLI access to the control node.

Procedure

Step 1 Connect to the control node CLI. Refer to the 'Log Into the Command-Line Interface on the Device' section in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

View the cluster on **Devices** > **Device Management** to see which device is the control node.

Step 2 View how active and backup sessions are distributed across the cluster.

show cluster VPN-sessiondb distribution

Example:

Distribution information displays as follows:

```
> show cluster vpn-sessiondb distribution
Member 0 (unit-1-1): active: 209; backups at: 1(111), 2(98)
Member 1 (unit-1-3): active: 204; backups at: 0(108), 2(96)
Member 2 (unit-1-2): active: 0
```

Each row contains the member ID, member name, number of active sessions, and on which members the backup sessions reside. For the example above, one would read the information as:

- Member 0 has 209 active sessions, 111 sessions are backed up on member 1, 98 sessions are backed up on member 2
- Member 1 has 204 active sessions, 108 sessions are backed up on member 0, 96 sessions are backed up on member 2
- Member 2 has NO active sessions; therefore, NO cluster members are backing up sessions for this node. This member has recently joined the cluster.

Step 3 Redistribute sessions.

cluster redistribute VPN-sessiondb

Example:

```
> cluster redistribute vpn-sessiondb

Session redistribution initiated.
Use 'show cluster vpn-sessiondb distribution' to view distribution.
```

>

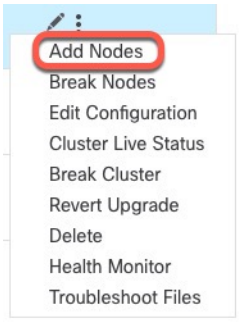
Depending on the number of sessions to redistribute and the load on the cluster, this may take some time. Syslogs containing the following phrases (and other system details not shown here) are provided as redistribution activity occurs:

Syslog Phrase	Notes
VPN session redistribution started	Control node only
Sent request to move *number* sessions from *orig-member-name* to *dest-member-name*	Control node only
Failed to send session redistribution message to *member-name*	Control node only
Received request to move *number* sessions from *orig-member-name* to *dest-member-name*	Data node only
Moved *number* sessions to *member-name*	The number of active sessions moved to the named cluster.
Failed to receive session move response from *dest-member-name*	Control node only
VPN session completed	Control node only
Cluster topology change detected. VPN session redistribution aborted.	

Step 4 Re-enter the **show cluster VPN-sessiondb distribution** command to view the results.

Cluster node management

After you deploy the cluster, you can change the configuration and manage cluster nodes.



Add a new cluster node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Add Nodes**.

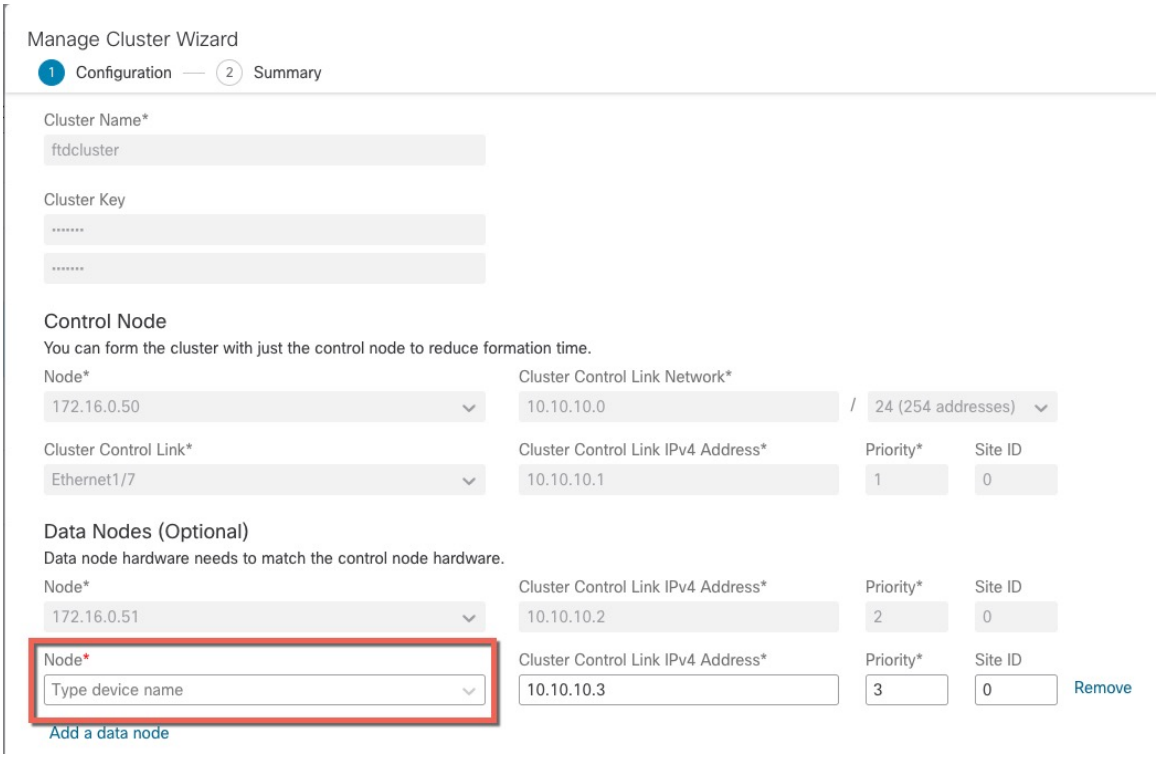


Figure 120: Add nodes

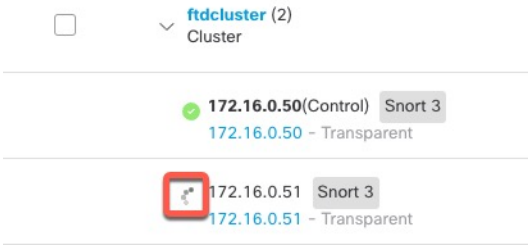
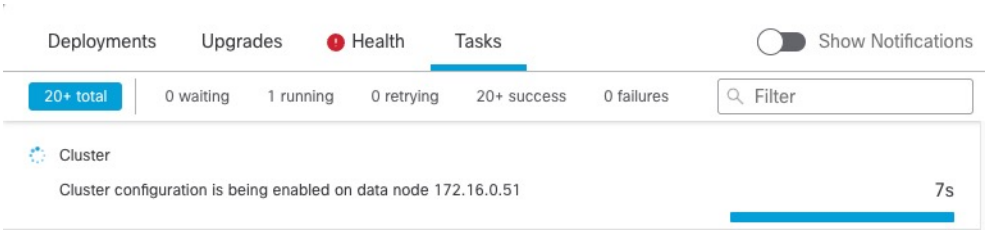
The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, adjust the IP address, priority, and Site ID if desired.

Figure 121: Manage cluster wizard



Step 3 To add additional nodes, click **Add a data node**.

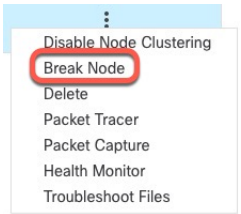


Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 122: Node registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.



Break a node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the node you want to break, and choose **Break Node**.

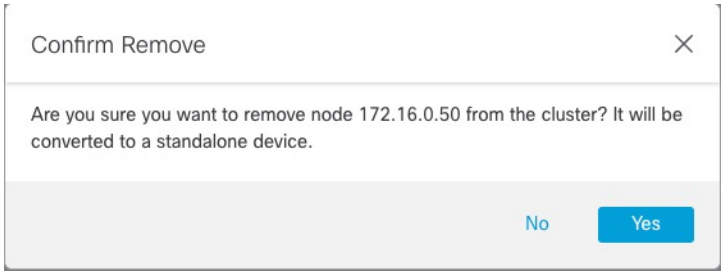


Figure 123: Break a node

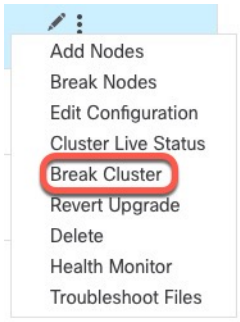
You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 124: Confirm break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

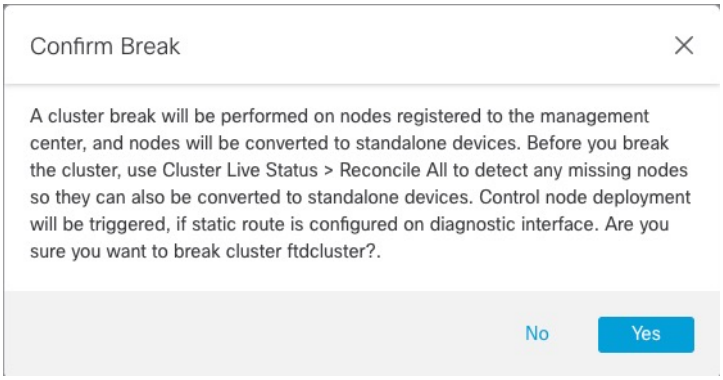
Break the cluster



You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the Cloud-Delivered Firewall Management Center by reconciling nodes. For more information, refer to Reconcile cluster nodes, on page 769.



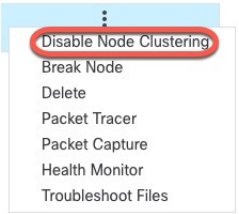
Step 2 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 125: Break cluster

Step 3 You are prompted to break the cluster; click **Yes**.

Figure 126: Confirm break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.



Disable clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Cloud-Delivered Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 127: Disable clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, refer Rejoin the cluster, on page 767.

Rejoin the cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster.

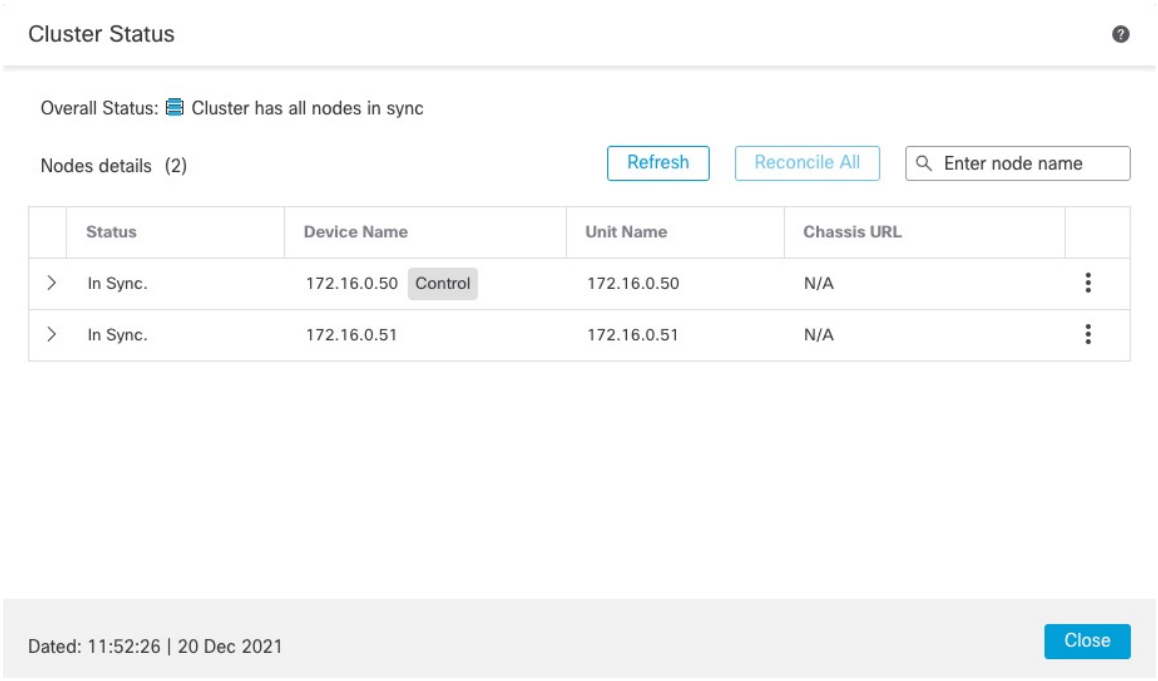
Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the unit.

Change the control node

Use this procedure when you need to specify the exact unit you want to become the control node. For centralized features, forcing a control node change will drop all connections, requiring you to re-establish the connections on the new control node.



Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

Follow these steps to change the control node:

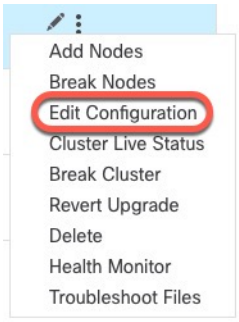
Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management More** (⋮) **Cluster Live Status**.

Figure 128: Cluster status

Step 2 For the unit you want to become the control unit, choose **More** (⋮) **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the check box, and click **OK**.



Edit the cluster configuration

You can edit the cluster configuration. If you change the cluster key, cluster control link interface, or cluster control link network, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the cluster control link IP address for a node, node priority, or site ID, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Edit Configuration**.

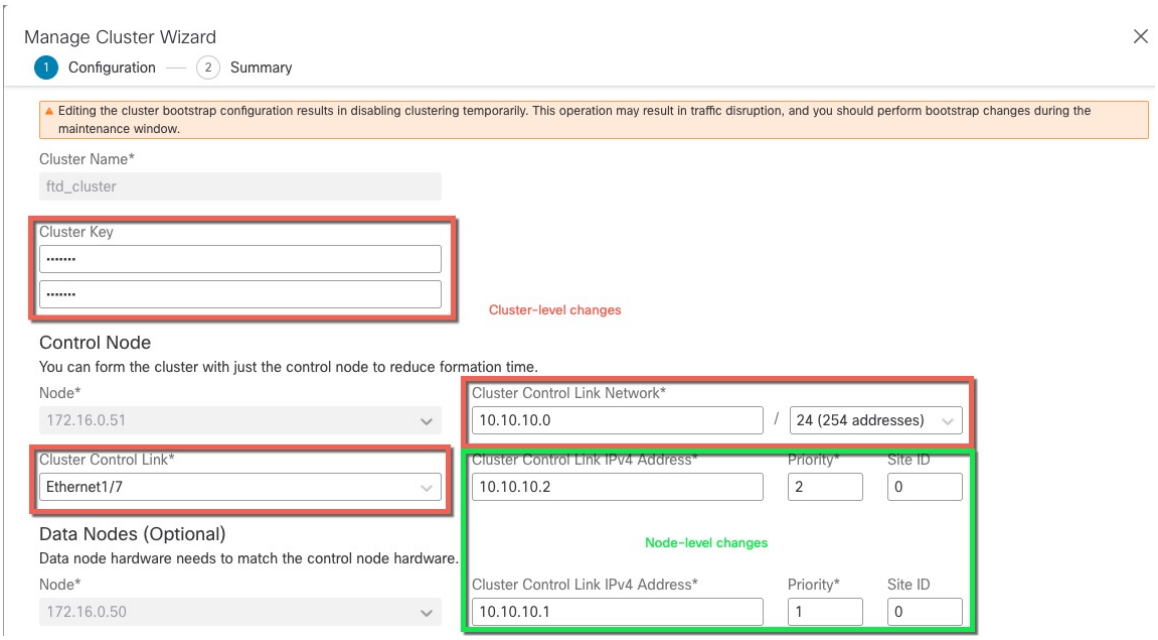


Figure 129: Edit configuration

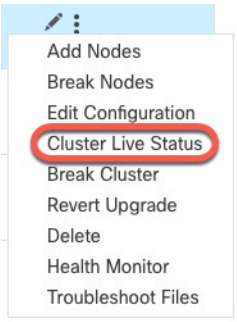
The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 130: Manage cluster wizard

If the cluster control link is an EtherChannel, you can edit the interface membership and LACP configuration by clicking **Edit** (✎) next to the interface drop-down menu.

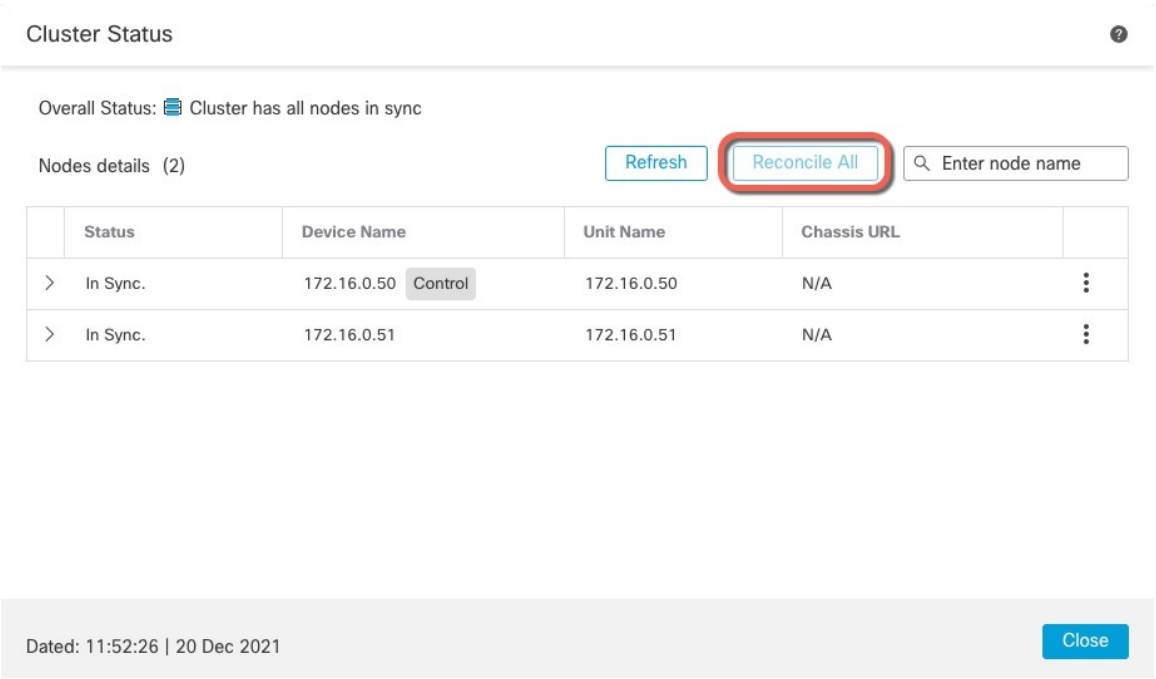
Step 3 Click **Continue**. Review the **Summary**, and then click **Save**



Reconcile cluster nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the Cloud-Delivered Firewall Management Center. For example, a data node might fail to register if the Cloud-Delivered Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure



Step 1 Choose **Devices** > **Device Management More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 131: Cluster live status

Step 2 Click **Reconcile All**.

Figure 132: Reconcile all

For more information about the cluster status, refer to Monitor the cluster, on page 772.

Unregister the Cluster or Nodes and Register to a New Cloud-Delivered Firewall Management Center

You can unregister the cluster from the Cloud-Delivered Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Cloud-Delivered Firewall Management Center.

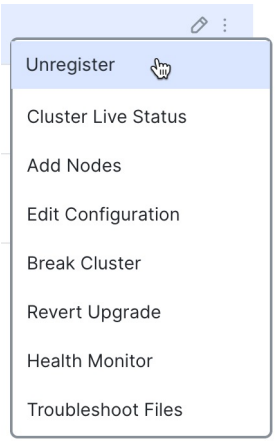
You can also unregister a node from the Cloud-Delivered Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Cloud-Delivered Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Cloud-Delivered Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Cloud-Delivered Firewall Management Center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Cloud-Delivered Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Cloud-Delivered Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.



Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

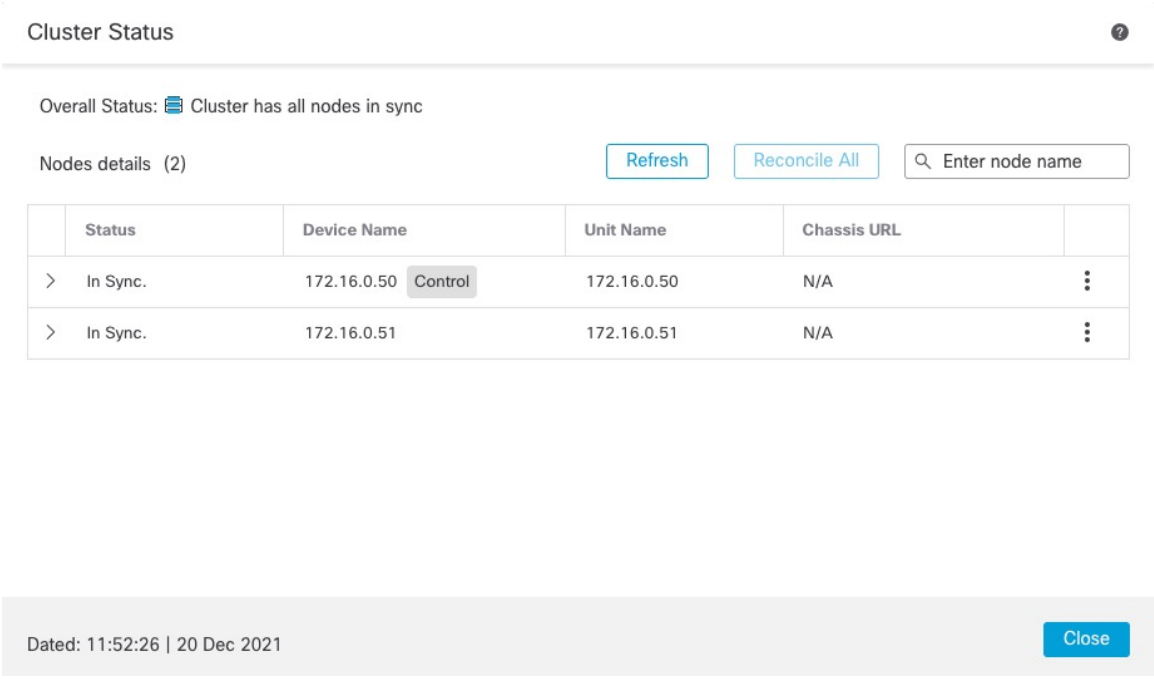
Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Unregister**.

Figure 133: Unregister cluster or node

Step 2 You are prompted to unregister the cluster or node; click **Yes**.

Step 3 You can register the cluster to a new (or the same) Cloud-Delivered Firewall Management Center by adding one of the cluster members as a new device.

You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.



Step 4 To re-add an unregistered node, refer to Reconcile cluster nodes, on page 769.

Monitor the cluster

You can monitor the cluster in the Cloud-Delivered Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management More** (⋮) icon or from the **Devices** > **Device Management** > **Cluster** page **General** area **Cluster Live Status** link.

Figure 134: Cluster status

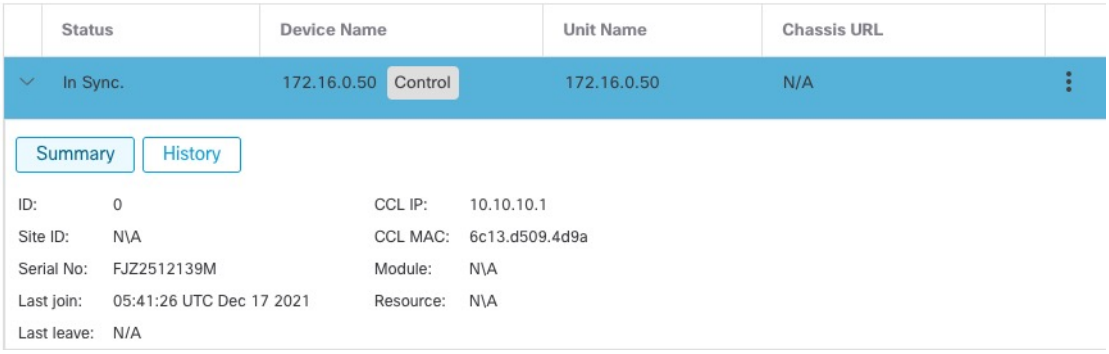
The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes these states:

- **In Sync**—The node is registered with the Cloud-Delivered Firewall Management Center.
- **Pending Registration**—The node is part of the cluster, but has not yet registered with the Cloud-Delivered Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- **Clustering is disabled**—The node is registered with the Cloud-Delivered Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- **Joining cluster**—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Cloud-Delivered Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 135: Node summary



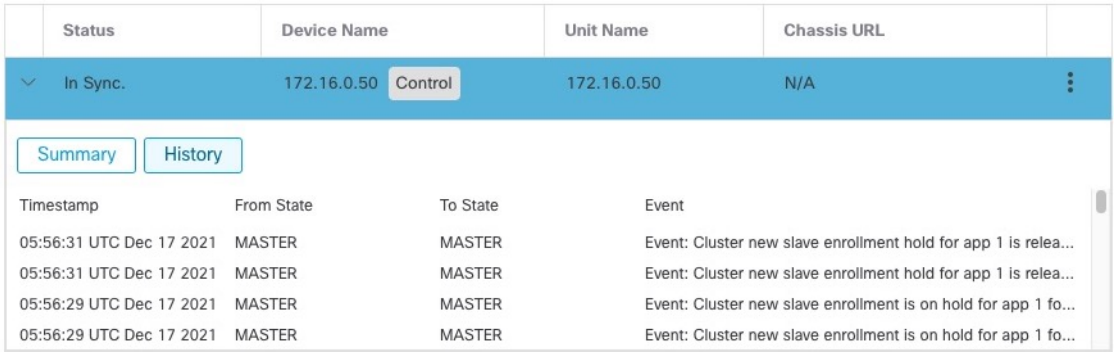


Figure 136: Node history

- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management***cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster health monitor dashboard

The cluster health monitor dashboard provides visibility into cluster status, metrics, and statistics.

View cluster health

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.
- Ensure you have created a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Procedure

	Command or Action	Purpose
Step 1	Choose **System** (⚙) > **Health** > **Monitor**.	Use the Monitoring navigation pane to access node-specific health monitors.
Step 2	In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.	
Step 3	To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:	• Overview— Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information. • Load Distribution— Traffic and packet distribution across the cluster nodes. • Member Performance— Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation. • CCL— Interface status and aggregate traffic statistics. You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.
Step 4	You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.	Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

	Command or Action	Purpose
Step 5	Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.	The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.
Step 6	(For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.	Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.
Step 7	(For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:	• Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information. • CPU — CPU utilization, including the CPU usage by process and by physical cores. • Memory — Device memory utilization, including data plane and Snort memory usage. • Interfaces — Interface status and aggregate traffic statistics. • Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts. • Snort — Statistics that are related to the Snort process. • ASP drops — Statistics related to the dropped packets against various reasons. You can navigate through the various metrics dashboards by clicking on the labels. For more information, refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.
Step 8	Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your	For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

	Command or Action	Purpose
	own variable set from the available metric groups.	

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 52: Cluster metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Troubleshoot the cluster

Use these methods to troubleshoot the devices and clusters:

- Use **Logs** to generates troubleshooting files for all nodes in the cluster. Use this option when you need one cluster-level collection instead of generating troubleshooting files from each node separately.
- Use **CLI** to run a predefined set of cluster diagnostic commands and displays the output. Use this option to check cluster configuration, member state, cluster health, control-plane transport statistics, packet drops, interface status, CPU usage, memory buffers, ARP entries, and reachability. The **CLI** option displays command output; it does not open an interactive CLI session.

Commands
show running-config cluster: Review the cluster group configuration, local unit, cluster interface, priority, health-check, auto-rejoin, and cLACP settings.

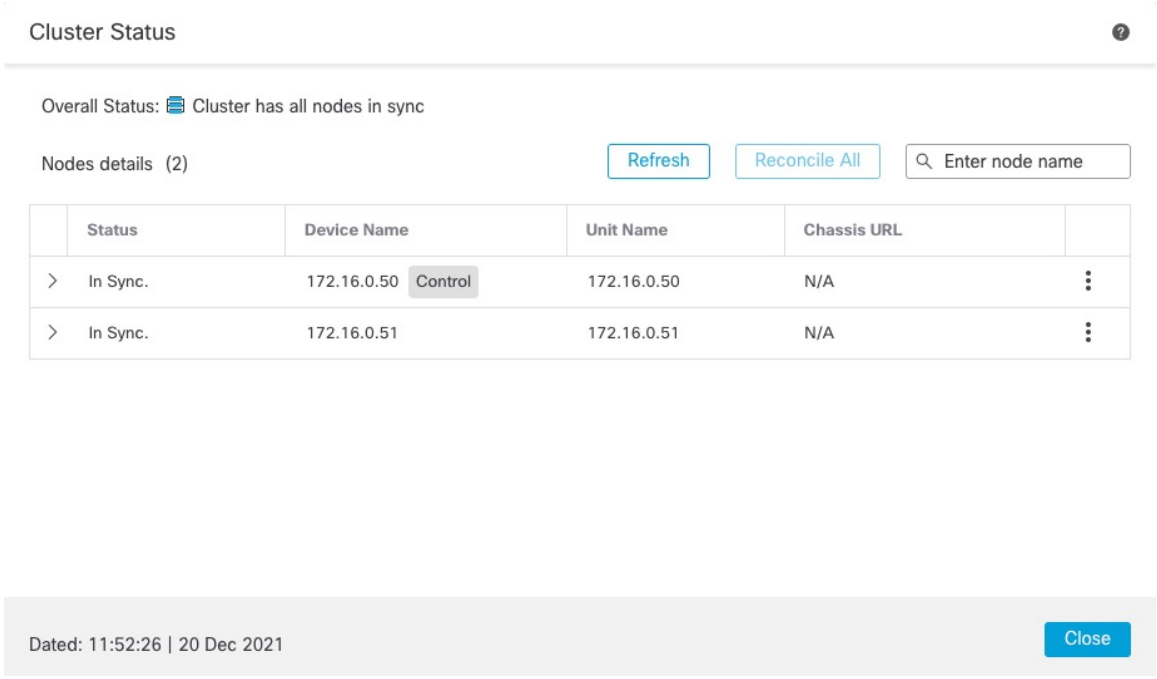
Commands
show cluster info: Confirm that clustering is enabled and identify the control node, member state, software version, serial number, CCL IP address, CCL MAC address, and last join or leave state.
show cluster info health: Check unit, interface, service, and overall cluster health.
show cluster info transport cp: Review control-plane transport counters, including reliable and unreliable message counters, errors, retransmits, drops, and buffer conditions.
show version: Capture platform, software, build, UUID, LSP, VDB, uptime, resource, and license context.
show asp drop: Identify accelerated security path packet or flow drop reasons and counters.
show counters: Review protocol, feature, and cluster CCL counters.
show arp: Verify ARP entries for interfaces that participate in cluster communication.
show int ip brief: Check interface IP addresses and administrative and line protocol status.
show blocks: Check buffer availability and failed allocations.
show cpu detailed: Check data path, control point, and total CPU usage.
show interface *ccl_interface*: Review interface state, MTU, MAC address, IP address, traffic counters, errors, and drops for the cluster-related interface.
ping *ccl_ip* **size** *ccl_mtu* **repeat 2**: Test reachability to a cluster peer by using the packet size selected by the tool.

- Use the **CCL Ping** when you need to test cluster control link connectivity between joined cluster nodes.
- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area. For more information, refer to Generate troubleshooting files.

  You can also generate files from the **Device Management** page. Click **More** (⋮) and choose **Troubleshoot Files**.
- CLI output—Choose **Devices** > **Device Management** and then choose **Add**, **ClusterGeneral** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. These commands are automatically run for the cluster:

  You can also enter any **show** command in the **Command** field.

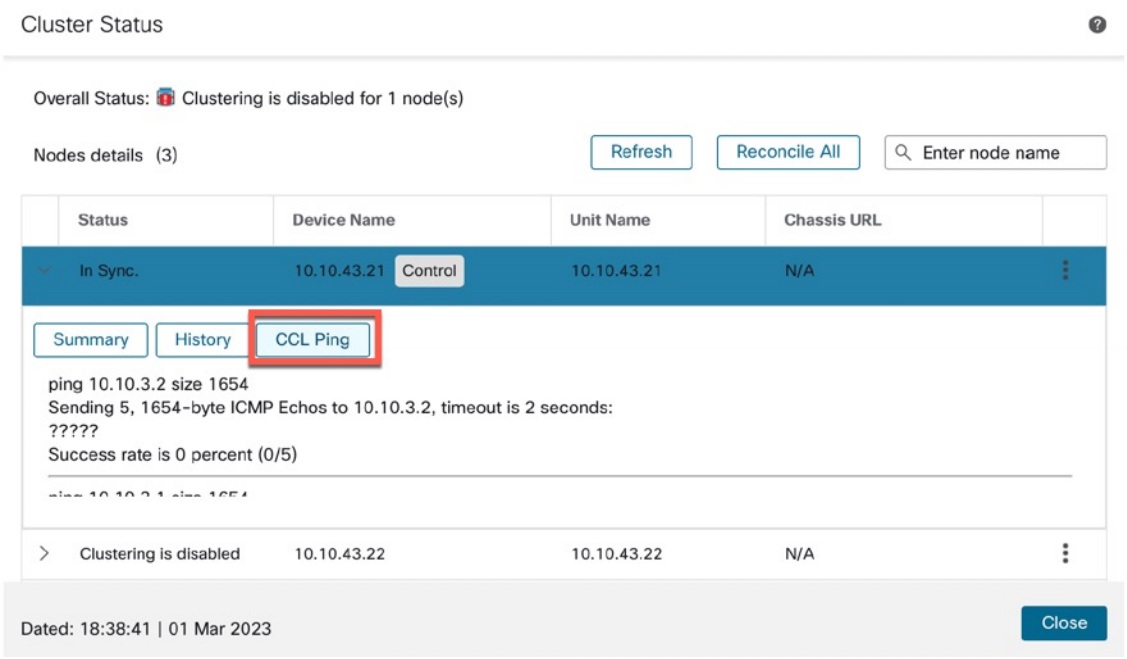
Perform a ping on the cluster control link



When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the initial ping fails, the node tries a ping using a smaller packet size (the MTU divided by 2, then by 4, then by 8) until a ping succeeds. A notification is generated so you can fix the MTU mismatch on connecting switches and try again. This tool lets you manually ping all nodes that have already joined the cluster in case you are having cluster control link connectivity problems.

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure



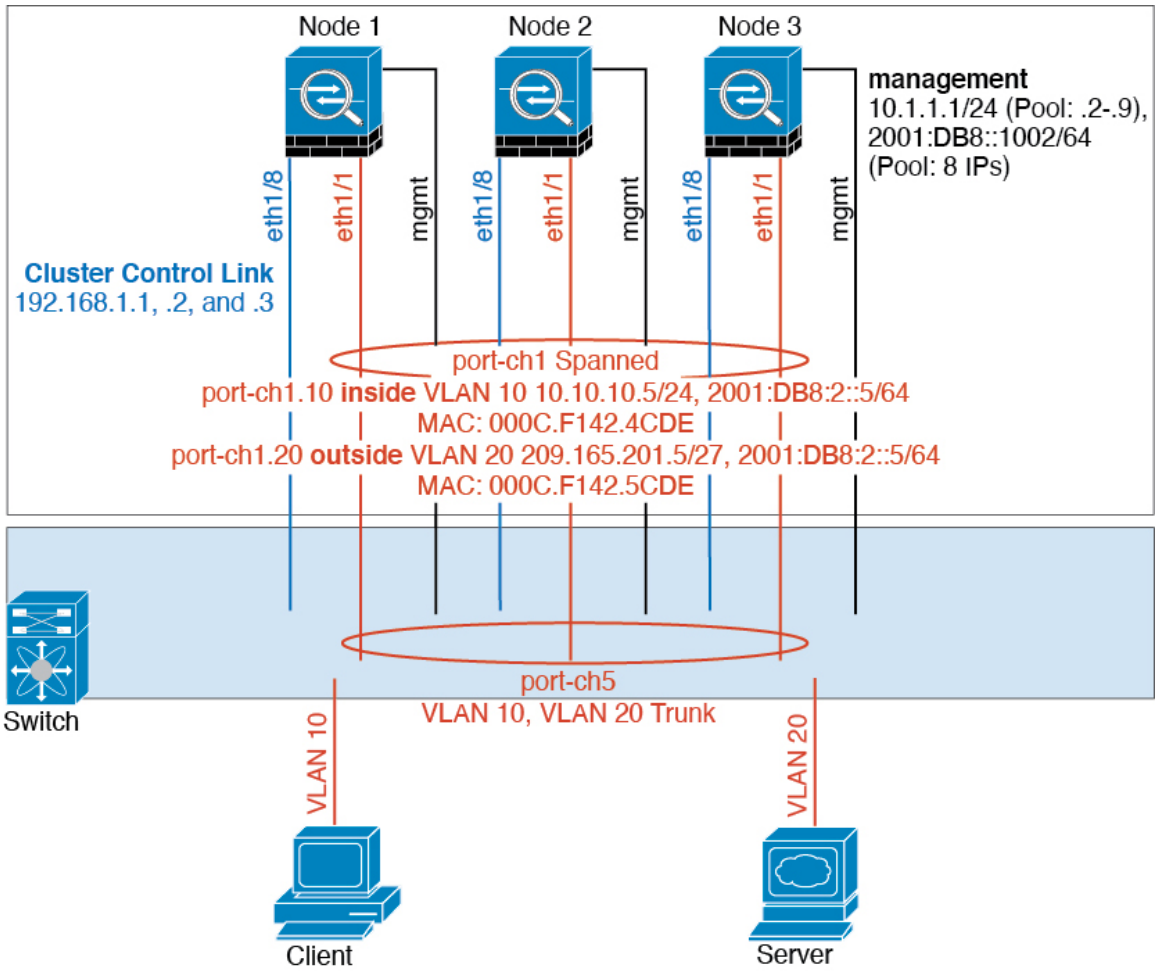
Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) icon next to the cluster, and choose **Cluster Live Status**.

Figure 137: Cluster status

Step 2 Expand one of the nodes, and click **CCL Ping**.

Figure 138: CCL ping

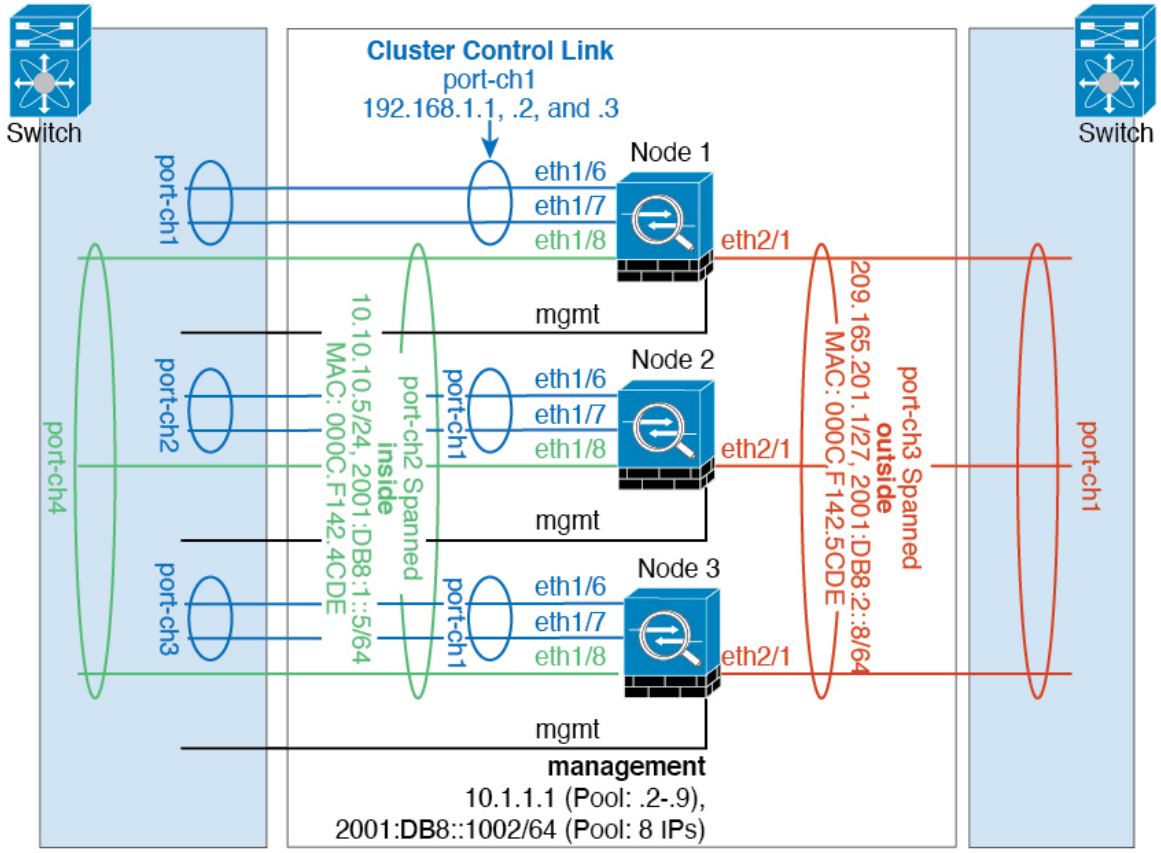
The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.



Clustering examples

These examples include examples for typical deployments.

Firewall on a stick



Data traffic from different security domains are associated with different VLANs. For example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each Threat Defense has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The Threat Defense is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the Threat Defense becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

Firewall Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features with clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, refer to the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Cloud-Delivered Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 1309.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Cloud-Delivered Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized features for clustering

These features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, refer to the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Cloud-Delivered Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 1309.

- These application inspections are supported:
  - DCERPC and ESMTP
  - NetBIOS and PPTP
  - RSH
  - SQLNET and SUNRPC
  - TFTP

- XDMCP

- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

Connection settings and clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast routing in individual interface mode

In Individual interface mode, units do not act independently with multicast. All data and routing packets are processed and forwarded by the control unit, thus avoiding packet replication.

NAT and clustering

NAT can impact the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different devices in the cluster because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the device that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link.

Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

Guidelines for NAT and clustering

General guidelines for NAT and clustering

- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number

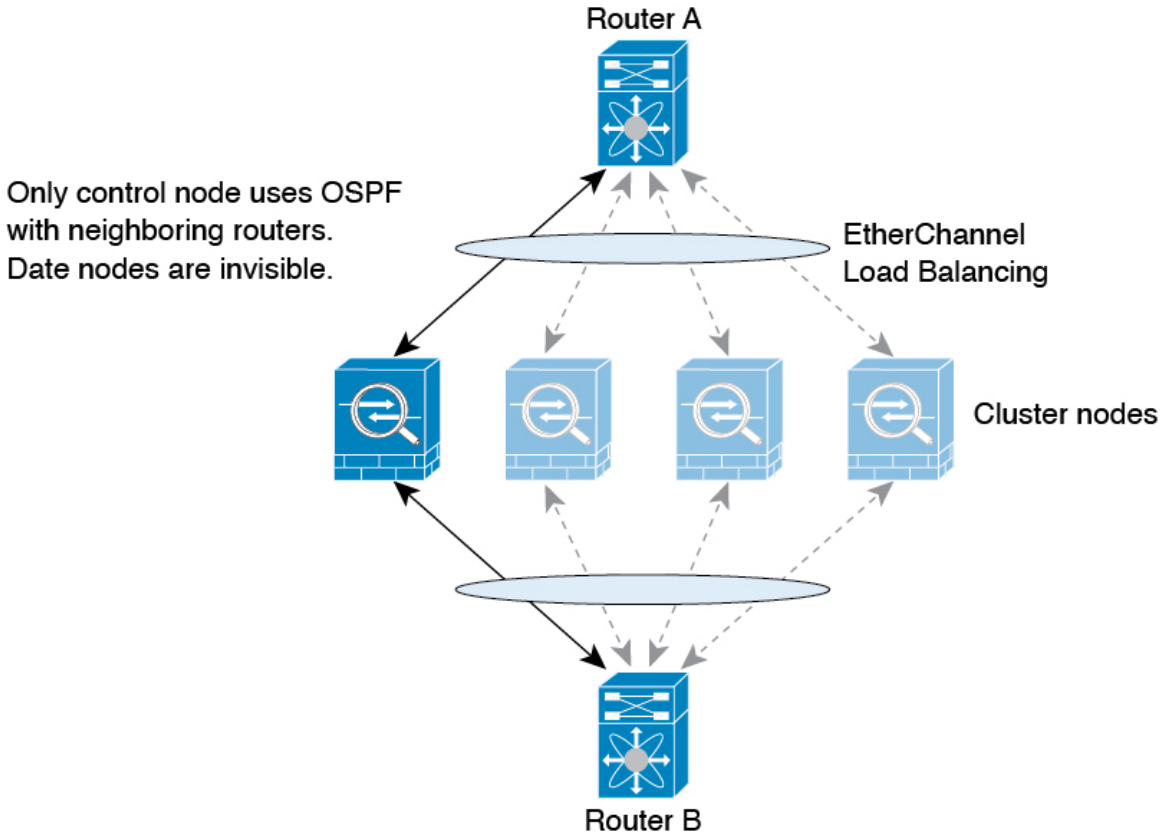
of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.

- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

PAT with port block allocation guidelines

- Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
- Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
- On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
- When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.

Limitations for NAT and Clustering



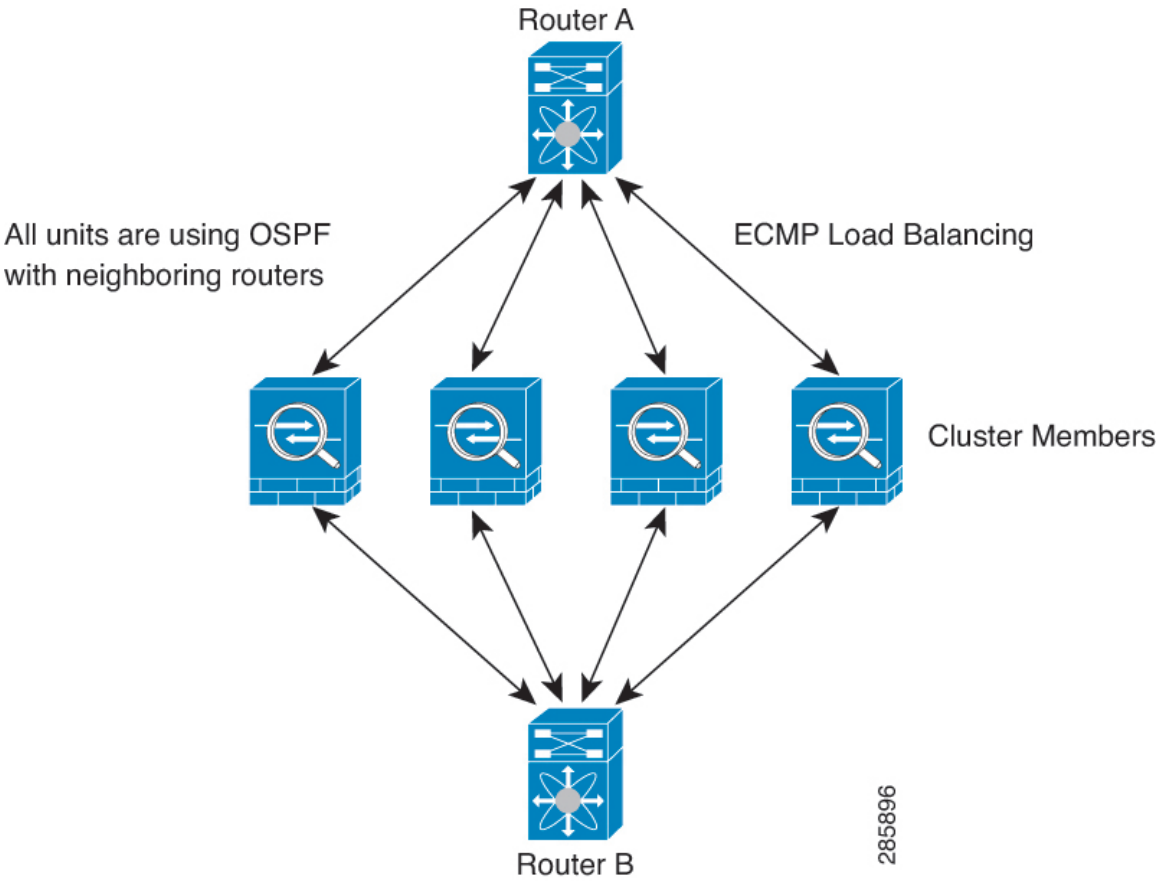
- No static PAT for these inspections:
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP

- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- No Proxy ARP—For Individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with a node that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the Main cluster IP address. This is not an issue for a Spanned EtherChannel, because there is only one IP address associated with the cluster interface.
- No interface PAT on an Individual interface—Interface PAT is not supported for Individual interfaces.

Dynamic routing

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 139: Dynamic routing in spanned EtherChannel mode



After the data node learn the routes from the control node, each node makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

Dynamic routing in individual interface mode

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 140: Dynamic routing in individual interface mode

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

EIGRP does not form neighbor relationships with cluster peers in individual interface mode.

Note If the cluster has multiple adjacencies to the same router for redundancy purposes, asymmetric routing can lead to unacceptable traffic loss. To avoid asymmetric routing, group all of these node interfaces into the same traffic zone. For more information, refer to Create an ECMP zone, on page 1433.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the local address, and not the main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

Syslog and clustering is a network management configuration that enables logging functionality within clustered network environments.

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco TrustSec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned EtherChannel address, connections are automatically forwarded to the control node. For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

Throughput calculation

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control node election

Summary

The key components involved in the control node election process are:

- Cluster nodes: Communicate over the cluster control link and participate in the election process
- Election requests: Broadcast every 3 seconds by nodes when clustering is enabled
- Priority values: Set between 1 and 100 where 1 is the highest priority
- Control node: The elected node that coordinates cluster operations

Workflow

These stages describe how cluster nodes elect a control node:

1. When clustering is enabled for a node (or when it first starts up with clustering already enabled), the node broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request. The priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node. The existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High availability within clusters

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node health monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

Split brain scenario

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

- **Spanned EtherChannel**—Uses cluster Link Aggregation Control Protocol (cLACP). Each node monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel. The status is reported to the control node.
- **Individual interfaces** (Routed mode only)—Each node self-monitors its interfaces and reports interface status to the control node.

When you enable health monitoring, all physical interfaces (including the main EtherChannel) are monitored by default; you can optionally disable monitoring per interface. Only named interfaces can be monitored. For example, the named EtherChannel must fail to be considered failed, which means all member ports of an EtherChannel must fail to trigger cluster removal.

A node is removed from the cluster if its monitored interfaces fail. The amount of time before the Firewall Threat Defense removes a member from the cluster depends on the type of interface and whether the node is an established member or is joining the cluster. For EtherChannels (spanned or not): If the interface is down on an established member, then the Firewall Threat Defense removes the member after 9 seconds. The Firewall Threat Defense does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface

status changes during this time will not cause the Firewall Threat Defense to be removed from the cluster. For non-EtherChannels, the node is removed after 500 ms, regardless of the member state.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The device automatically tries to rejoin the cluster, depending on the failure event.

Note When the device becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoin the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Cloud-Delivered Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the

connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 53: Features replicated across the cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	No	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

These roles are defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the

owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
- For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
- For other packets, both source and destination ports are 0.

- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

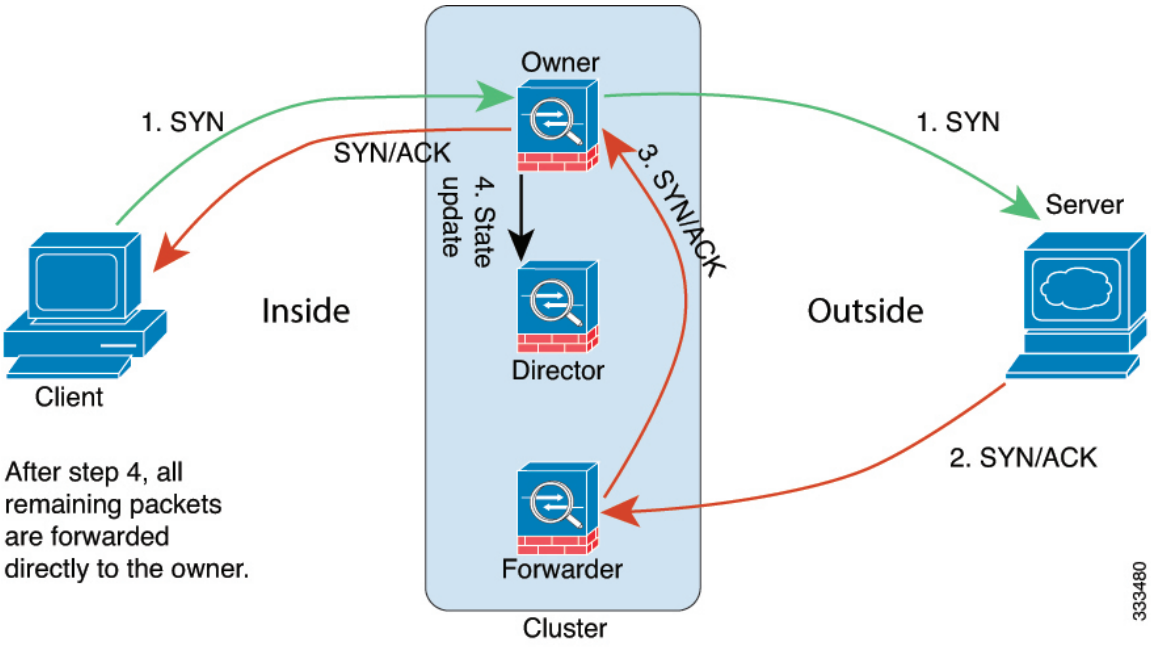
Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

New connection ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be



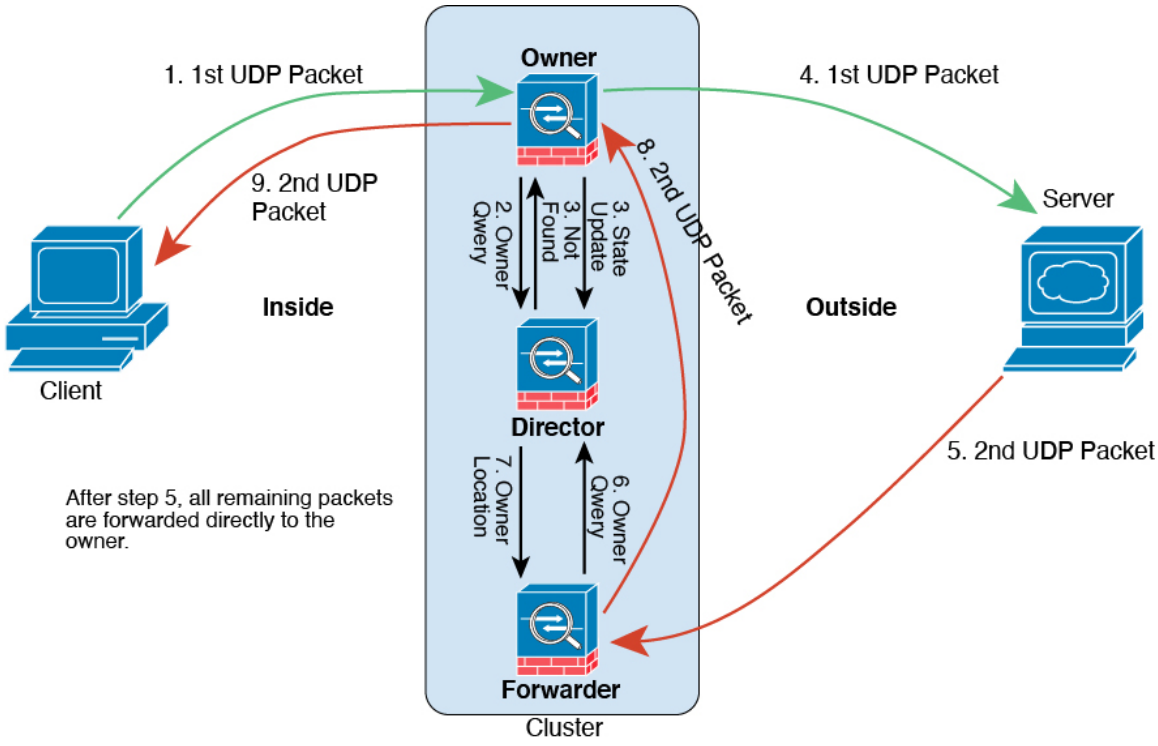
dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

Sample data flow for TCP

Summary

This example shows the establishment of a new connection.

Workflow



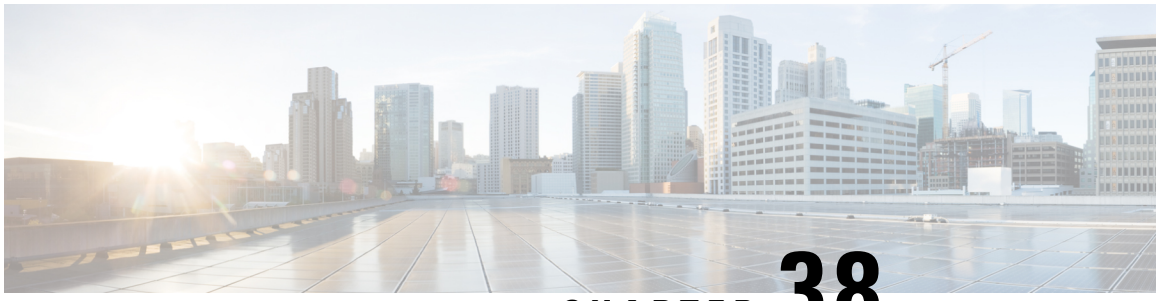
1. The SYN packet originates from the client and is delivered to one device (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different device (based on the load balancing method). This device is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample data flows for ICMP and UDP

Summary

This example shows the establishment of a new connection.

Workflow



1. The first UDP packet originates from the client and is delivered to one device (based on the load balancing method).
2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Clustering

Lists the clustering features introduced in each release.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
16-node clusters for the Secure Firewall 3100/4200.	20241030	7.6.0	For the Secure Firewall 3100 and 4200, the maximum nodes were increased from 8 to 16. See: Clustering for the Secure Firewall 3100/4200
Individual interface mode for Secure Firewall 3100/4200 clusters.	20241030	7.6.0	Individual interfaces are normal routed interfaces, each with their own local IP address used for routing. The main cluster IP address for each interface is a fixed address that always belongs to the control node. When the control node changes, the main cluster IP address moves to the new control node, so management of the cluster continues seamlessly. Load balancing must be configured separately on the upstream switch. Restrictions: Not supported for container instances. New/modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **Cluster** > **Interfaces / EIGRP / OSPF / OSPFv3 / BGP** • **Objects** > **Object Management** > **Address Pools** > **MAC Address Pool** See: Clustering for the Secure Firewall 3100/4200 and Address Pools
MTU ping test from data node on node join	20241030	7.6.0	When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size twice the cluster control link MTU. Previously, only the control node sent a ping. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again. Added/modified commands: **show cluster history**. See: Clustering for the Secure Firewall 3100/4200, Clustering for Threat Defense Virtual in a Private Cloud, Clustering for Threat Defense Virtual in a Public Cloud, Clustering for the Firepower 4100/9300
Clustering for the Secure Firewall 4200	20230929	7.4.0	The Secure Firewall 4200 supports Spanned EtherChannel clustering for up to 8 nodes.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster health monitor settings	20221213	Any	You can now edit cluster health monitor settings. New/modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard	20221213	Any	You can now view cluster health on the cluster health monitor dashboard. New/modified screens: **System** > **Health** > **Monitor**
Automatic configuration of the cluster control link MTU	20220609	7.2.0	The MTU of the cluster control link interface is now automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes.
Clustering for the Secure Firewall 3100	20220609	7.1.0	The Secure Firewall 3100 supports Spanned EtherChannel clustering for up to 8 nodes. New/modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Secure Firewall 3100

CHAPTER 38

Clustering: Private Cloud

Clustering lets you group multiple Firewall Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Firewall Threat Defense Virtual clusters in a private cloud using VMware and KVM. Only routed firewall mode is supported.

Note Some features are not supported when using clustering. See Unsupported features and clustering, on page 832.

About clustering: private cloud

This section describes the clustering architecture and how it works.

How the cluster fits into your network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the cluster control link, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Firewall Threat Defense Virtual send broadcast/multicast messages over the cluster control link.
- Management access to each firewall for configuration and monitoring. The Firewall Threat Defense Virtual deployment includes a Management 0/0 interface that you will use to manage the cluster nodes.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Layer 3 Individual interfaces and one of the following methods:

- Policy-Based Routing—The upstream and downstream routers perform load balancing between nodes using route maps and ACLs.
- Equal-Cost Multi-Path Routing—The upstream and downstream routers perform load balancing between nodes using equal cost static or dynamic routes.

Layer 2 Spanned EtherChannels are not supported.

Control and data node roles

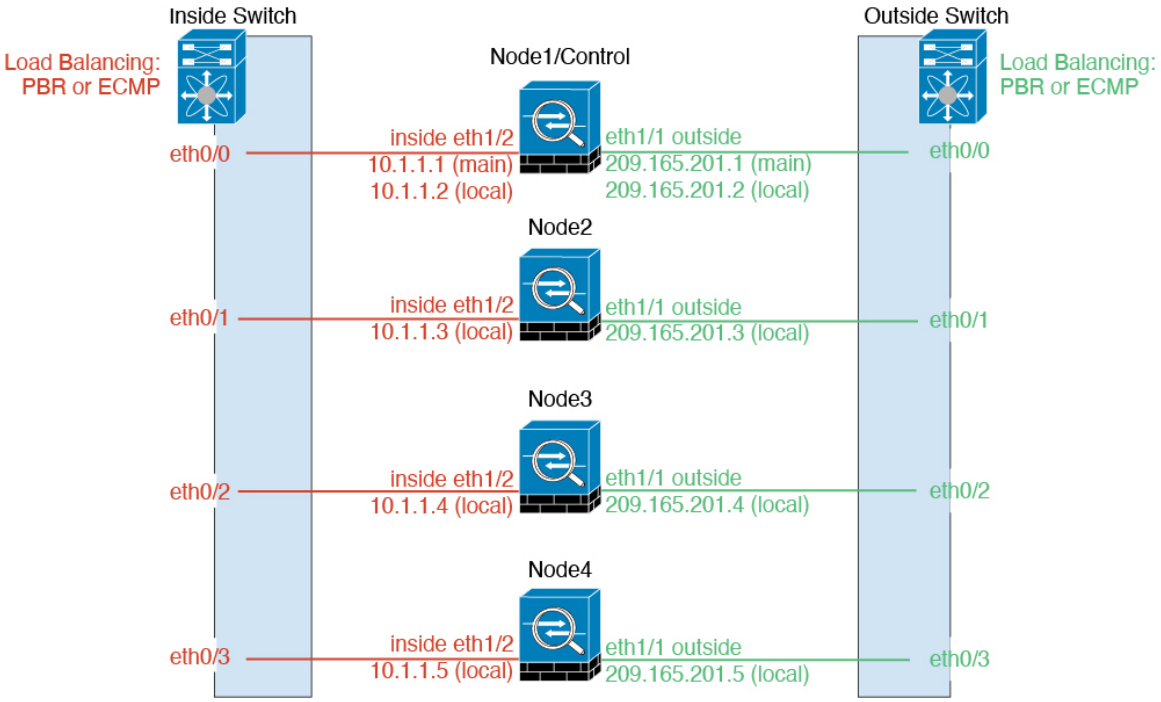
When you add a cluster in the Cloud-Delivered Firewall Management Center , you choose one firewall to be the control node, and all additional firewalls to be data nodes. When you first create the cluster, the control node you specify will become the control node simply because it is the first node added to the cluster. Later, if multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority.

When you create the cluster and deploy the cluster configuration, the Cloud-Delivered Firewall Management Center deploys a special bootstrap configuration to each node that includes fundamental settings such as the cluster control link configuration. The bootstrap configuration lets each node join the cluster. Most bootstrap settings are defined in the cluster wizard; however, you define the cluster control link interface hardware configuration (for example, creating an EtherChannel or setting the Ethernet speed) on the control node before you create the cluster. The cluster control link settings are copied to the bootstrap configuration for each node.

All nodes in the cluster share the same policy configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster. After you create the cluster, all configuration changes are made at the cluster level and are shared by all nodes.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Individual interfaces



You can configure cluster interfaces as individual interfaces.

Individual interfaces are normal routed interfaces, each with their own *local IP address* used for routing. The *main cluster IP address* for each interface is a fixed address that always belongs to the control node. When the control node changes, the main cluster IP address moves to the new control node, so management of the cluster continues seamlessly.

IPS-only interfaces (inline sets and passive interfaces) are not supported as Individual interfaces.

Because interface configuration must be done only on the control node, configure a pool of IP addresses for a given interface on the cluster nodes, including one for the control node.

Load balancing must be configured separately on the upstream switch.

Layer 2 Spanned EtherChannels are not supported.

Policy-based routing

When using individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all Firewall Threat Defenses in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same Firewall Threat Defense.

For example, if you have a Cisco router, redundancy can be achieved by using Cisco IOS PBR with Object Tracking. Cisco IOS Object Tracking monitors each Firewall Threat Defense using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular Firewall Threat Defense.

Equal-cost multi-path routing

When using Individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure.

ECMP routing considerations

ECMP routing can forward packets over multiple best paths that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops.

If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost.

If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see Configure VXLAN interfaces, on page 1071 .

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular Firewall Threat Defense Virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface. It is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, Firewall Threat Defense Virtual clustering allows you to configure multiple peers.

Cluster control link traffic overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management network

You must manage each node using the Management interface. Management from a data interface is not supported with clustering.

Licenses for clustering: Private cloud

Performance tier license requirements

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

Feature license assignment

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Cloud-Delivered Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

Note If you add the cluster before the Cloud-Delivered Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Cloud-Delivered Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Prerequisites for clustering: Private cloud

This reference provides the complete set of requirements that must be met before configuring clustering for threat defense virtual devices in private cloud deployments.

Model requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100
- VMware or KVM
- A maximum of 4 nodes in a cluster in a 2x2 configuration is supported. You can set up a maximum of two hosts with a maximum of two threat defense virtual instances in each host.

Hardware and software requirements

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the Firewall Threat Defense Virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.
- Must be the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or performance will be limited on all nodes to match the least capable node.
- Must use the management interface for Cloud-Delivered Firewall Management Center communications. Data interface management is not supported.
- Must run the same version, except during upgrade. Hitless upgrade is supported.
- Must not have any deployment pending or in progress.
- Must not have any unsupported features configured on the control node: Unsupported features and clustering, on page 832.
- Must not have VPN configured on the data nodes. The control node can have site-to-site VPN configured.

Note Devices must not be in transparent mode for cluster configuration.

Cloud-Delivered Firewall Management Center Requirements

Make sure the Cloud-Delivered Firewall Management Center NTP server is set to a reliable server that is reachable by all cluster nodes to ensure proper clock sync. By default, the device uses the same NTP server

as the Cloud-Delivered Firewall Management Center. If the time is not set to be the same on all cluster nodes, they can be removed automatically from the cluster.

Switch requirements

Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 154 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail. When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the initial ping fails, the node tries a ping using a smaller packet size (the MTU divided by 2, then by 4, then by 8) until a ping succeeds. A notification is generated so you can fix the MTU mismatch on connecting switches and try again.

Guidelines for clustering: Private cloud

High availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Additional clustering guidelines

Consider these additional guidelines when configuring clustering:

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense Virtual, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the interfaces that are affected by the topology changes. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- We do not support VXLAN for data interfaces; only the cluster control link supports VXLAN.

Default cluster configurations

Consider these default configurations when setting up clustering:

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.

- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Upgrade guidelines

Configure clustering: private cloud

To configure clustering after you deploy your Firewall Threat Defense Virtuals, perform the following tasks.

Add nodes to the Management Center

This task allows you to prepare cluster nodes for clustering configuration by adding them to the management center as individual devices.

Before configuring clustering, deploy each cluster node, then add the devices as standalone units on the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Deploy each cluster node by following the procedures given in the Secure Firewall Threat Defense Virtual getting started guides.

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the Firewall Threat Defense Virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.

Step 2 Add each node to the Cloud-Delivered Firewall Management Center as a standalone device in the same domain and group.

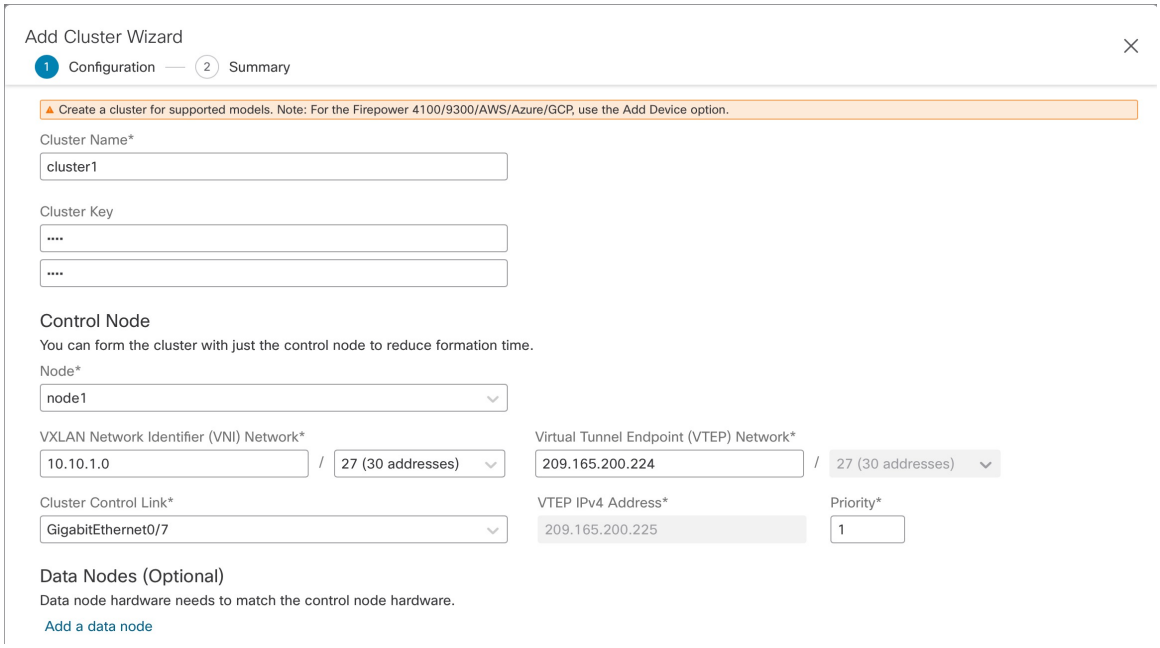
You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

Create a cluster

Creating a cluster allows multiple devices to work together as a single logical unit, providing high availability and increased throughput capacity.

Form a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Before you begin



Some features are not compatible with clustering. Wait to configure until clustering is enabled. Some features will block cluster creation if they are already configured. For example, do not configure any IP addresses on interfaces, or unsupported interface types such as BVIs.

Procedure

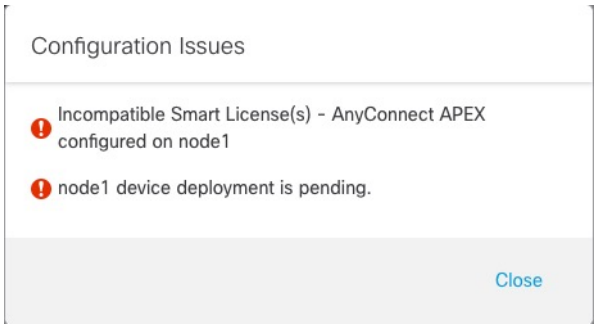
Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 141: Add Cluster Wizard

Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string of 1 to 38 characters. The cluster name can contain only letters, digits, underscores (_), and hyphens (-).
- **Cluster Key**—An ASCII string of 1 to 63 characters. The cluster key cannot be a single digit and must not contain spaces. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in clear text.



Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the Cloud-Delivered Firewall Management Center forms the cluster, it will add this node to the cluster first so it will be the control node.

  Note

If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 142: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **VXLAN Network Identifier (VNI) Network**—Specify an IPv4 subnet for the VNI network; IPv6 is not supported for this network. Specify a **24**, **25**, **26**, or **27** subnet. An IP address will be auto-assigned to each node on this network. The VNI network is the encrypted virtual network that runs on top of the physical VTEP network.
- **Cluster Control Link**—Choose the physical interface you want to use for the cluster control link.
- **Virtual Tunnel Endpoint (VTEP) Network**—Specify an IPv4 subnet for the physical interface network; IPv6 is not supported for this network. The VTEP network is a different network than the VNI network, and it is used for the physical cluster control link.
- **VTEP IPv4 Address**—This field will be auto-populated with the first address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.

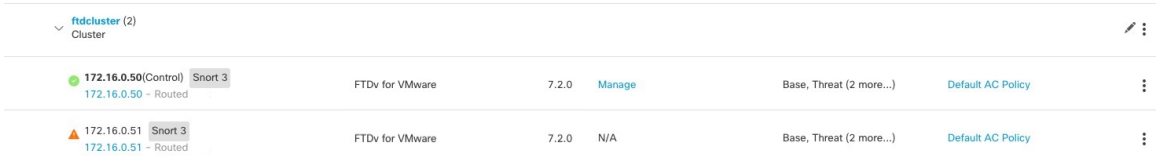
Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

  Note

  If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.



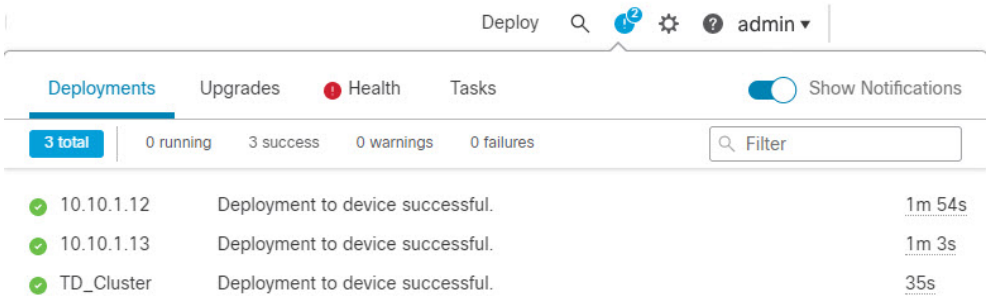
- **VTEP IPv4 Address**—This field will be auto-populated with the next address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.

The cluster bootstrap configuration is saved to the cluster nodes. The bootstrap configuration includes the VXLAN interface used for the cluster control link.

The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

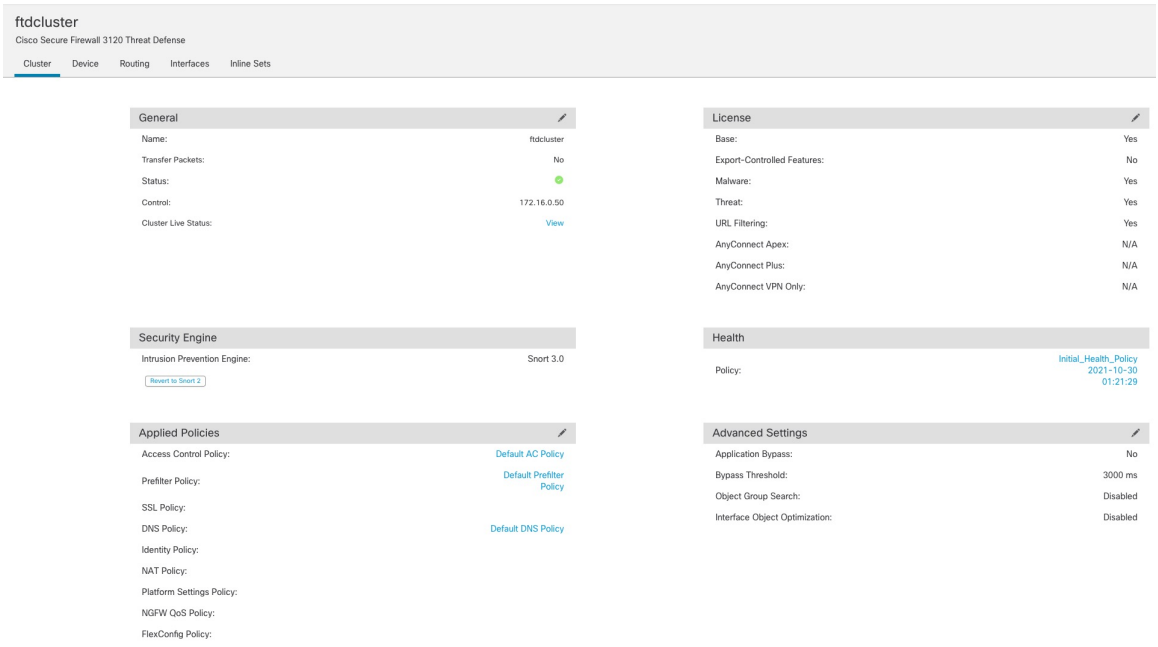
Figure 143: Cluster Management



A node that is currently registering shows the loading icon.

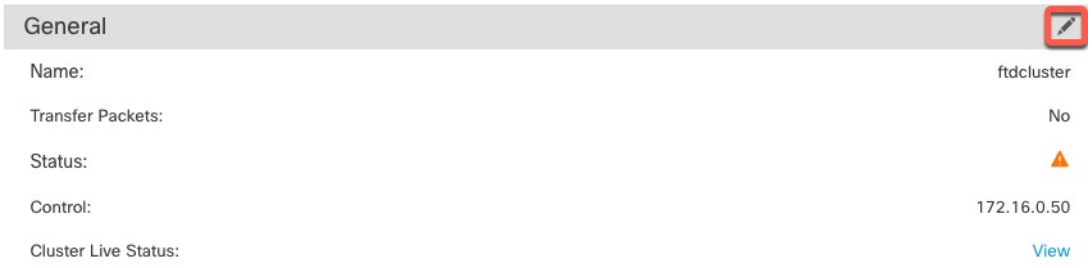
Figure 144: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The Cloud-Delivered Firewall Management Center updates the Cluster Registration task as each node registers.



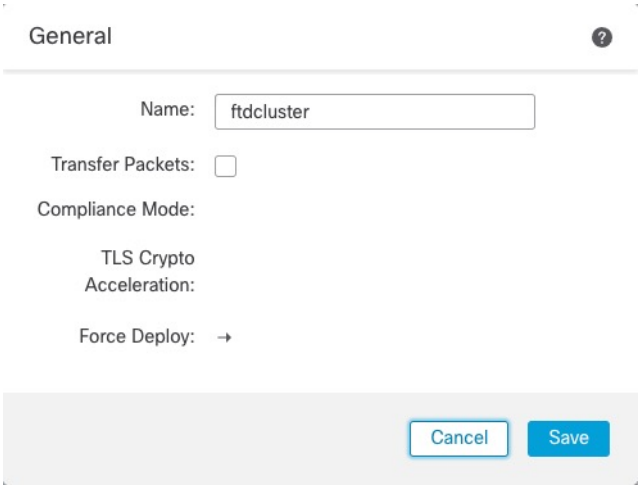
Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.



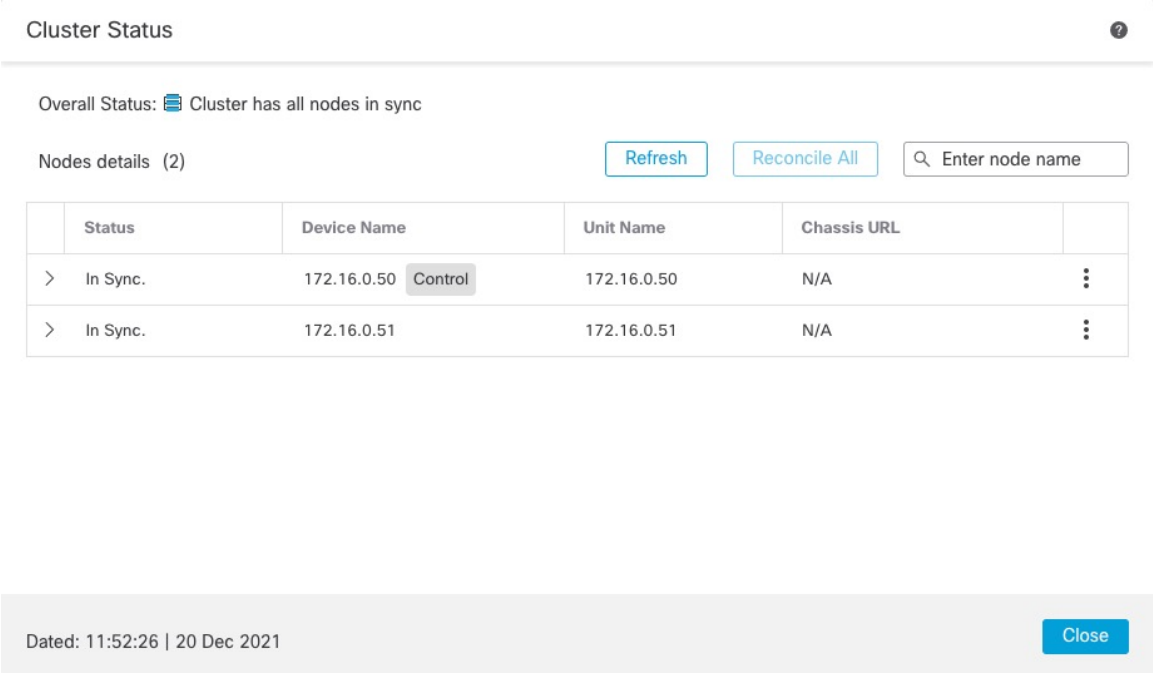
Step 7 On the **Devices** > **Device Management**, **Cluster** screen, you see **General** and other settings for the cluster.

Figure 145: Cluster Settings



See the following cluster-specific items in the **General** area:

- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).



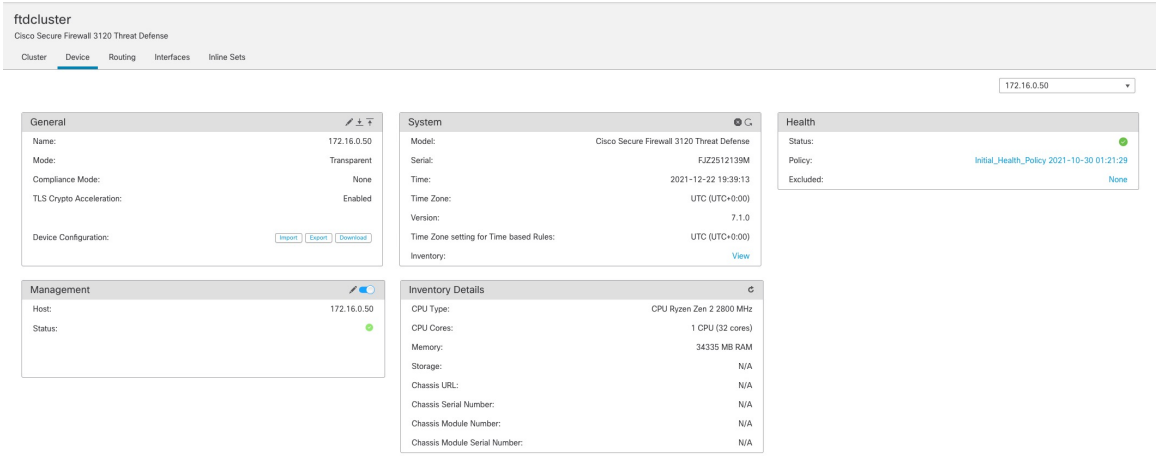
Then set the **Name** field.

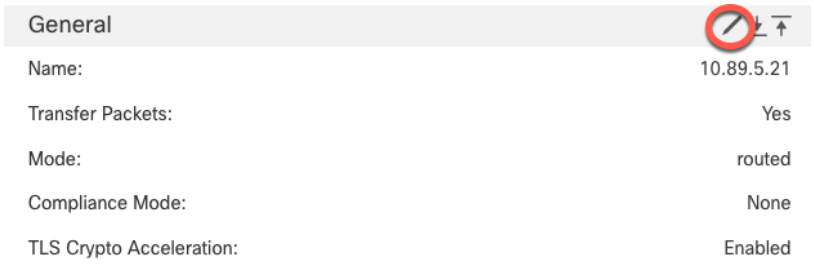
- **General > View**—Click the **View** link to open the **Cluster Status** dialog box.

The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**.

Step 8 On the **Devices** > **Device Management** and then click **Add** > **Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

Figure 146: Device Settings





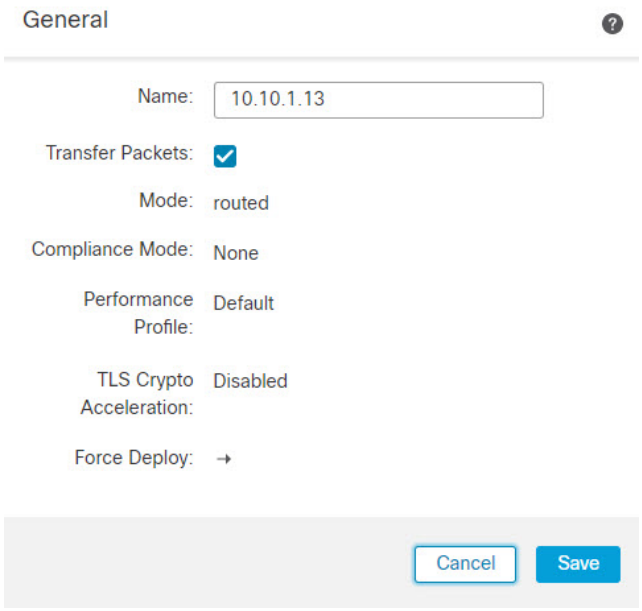


Figure 147: Choose Node

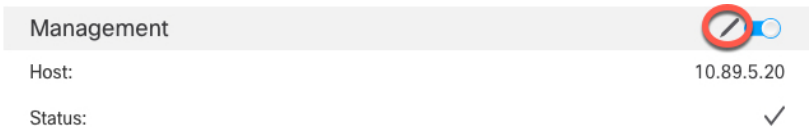


- **General** > **Name**—Change the cluster member display name by clicking the **Edit** ( ).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Cloud-Delivered Firewall Management Center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Step 9 If you deployed your cluster nodes without enabling jumbo-frame reservation, then restart all cluster nodes to enable jumbo frames, which are required for the cluster control link. See Shut down or restart the device, on page 107.

If you previously enabled jumbo-frame reservation, you can skip this step.

Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) and VXLAN overhead (54 bytes). When you create the cluster, the MTU is set to 154 bytes higher than the highest data interface MTU (1654 by default). If you later increase the data interface MTU, be sure to also increase the cluster control link MTU. For example, because the maximum MTU is 9198 bytes, then the highest data interface MTU can be 9044, while the cluster control link can be set to 9198. See Configure the MTU, on page 1109.

Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation might fail.

Configure interfaces

Configure interfaces to be compatible with clustering by setting up individual interfaces that are normal routed interfaces, each with their own IP address taken from a pool of IP addresses.

Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP addresses. The Main cluster IP address is a fixed address for the cluster that always belongs to the current control node. All data interfaces must be Individual interfaces.

Note You cannot use subinterfaces.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Address Pools** to add an IPv4 address pool, an IPv6 address pool, or both. See Configure address pools, on page 2954.

Include at least as many addresses as there are units in the cluster. The Virtual IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

Step 2 Choose **Devices** > **Device Management**, and click **Edit** ( ) next to the cluster.

Step 3 Click **Interfaces**, and then click **Edit** ( ) for a data interface.

Step 4 On the **IPv4**, enter the **IP Address** and mask. This IP address is a fixed address for the cluster, and always belongs to the current control unit.

Step 5 From the **IPv4 Address Pool** drop-down list, choose the address pool you created.

Note
If you want to manually assign a MAC address to this interface, you need to create a **MAC-address pool** using FlexConfig.

Step 6 On **IPv6** > **Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.

Step 7 Configure other interface settings as normal.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Cluster Health Monitor Settings

This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

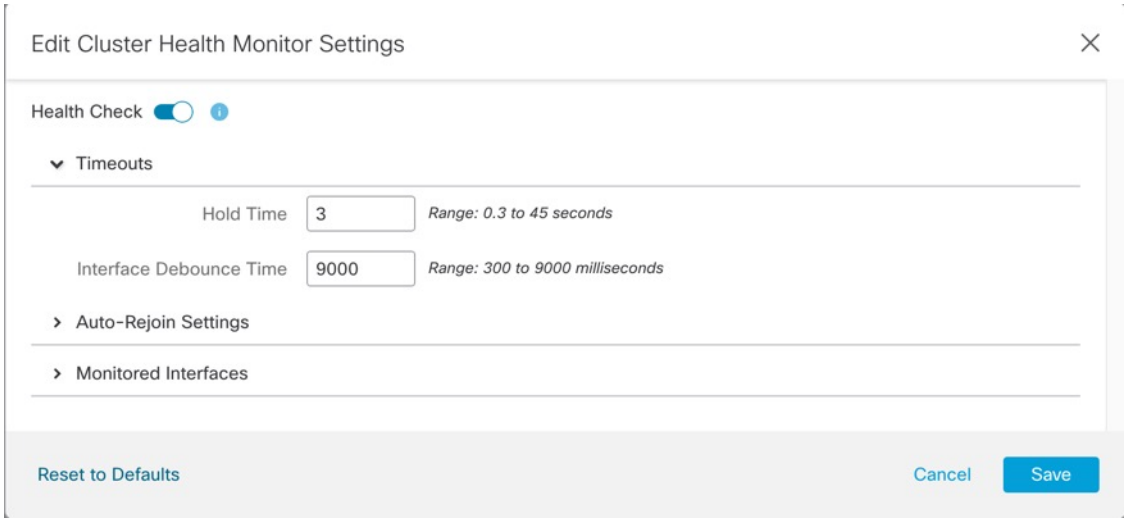
The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When

the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



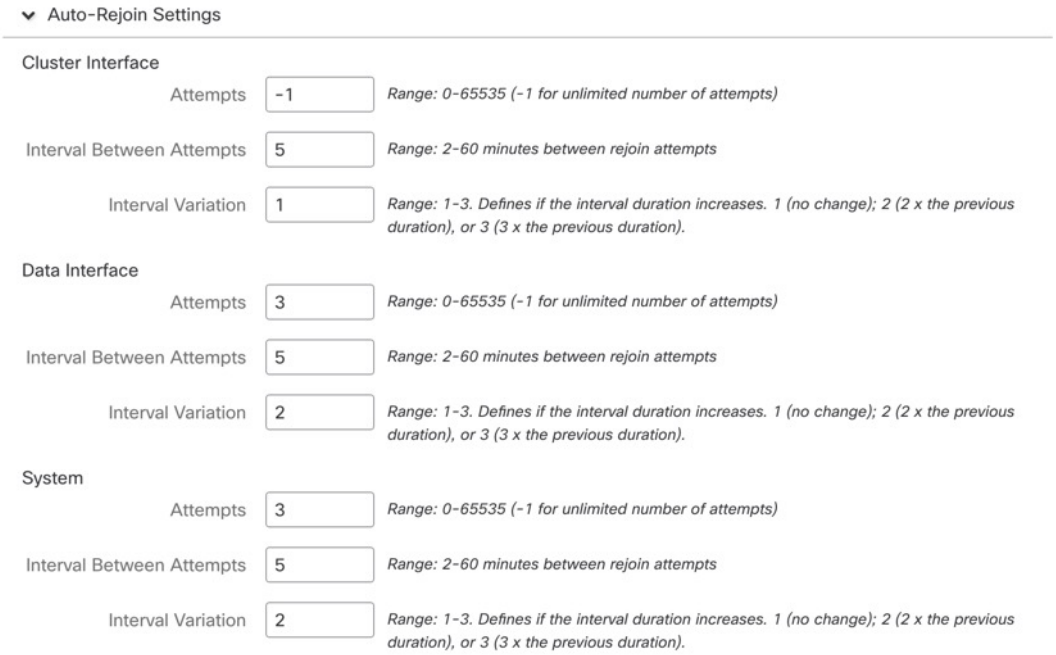
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 148: Disable the system health check



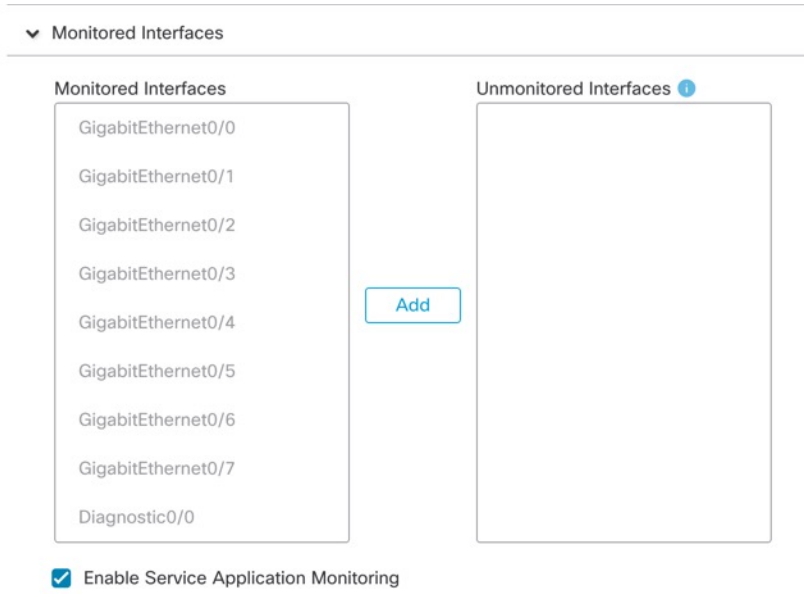
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 149: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 150: Configure monitored interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

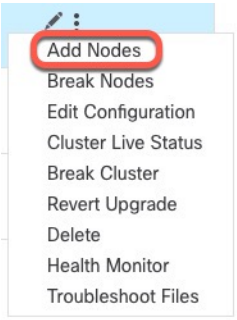
Step 9 Click **Save**.

Deploy configuration changes.

Manage cluster nodes

Describes how to manage cluster nodes to maintain high availability and optimal performance across your Cisco Secure Firewall cluster deployment.

Add a new cluster node



Adding new cluster nodes expands cluster capacity and provides additional redundancy for your security infrastructure.

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Add Nodes**.

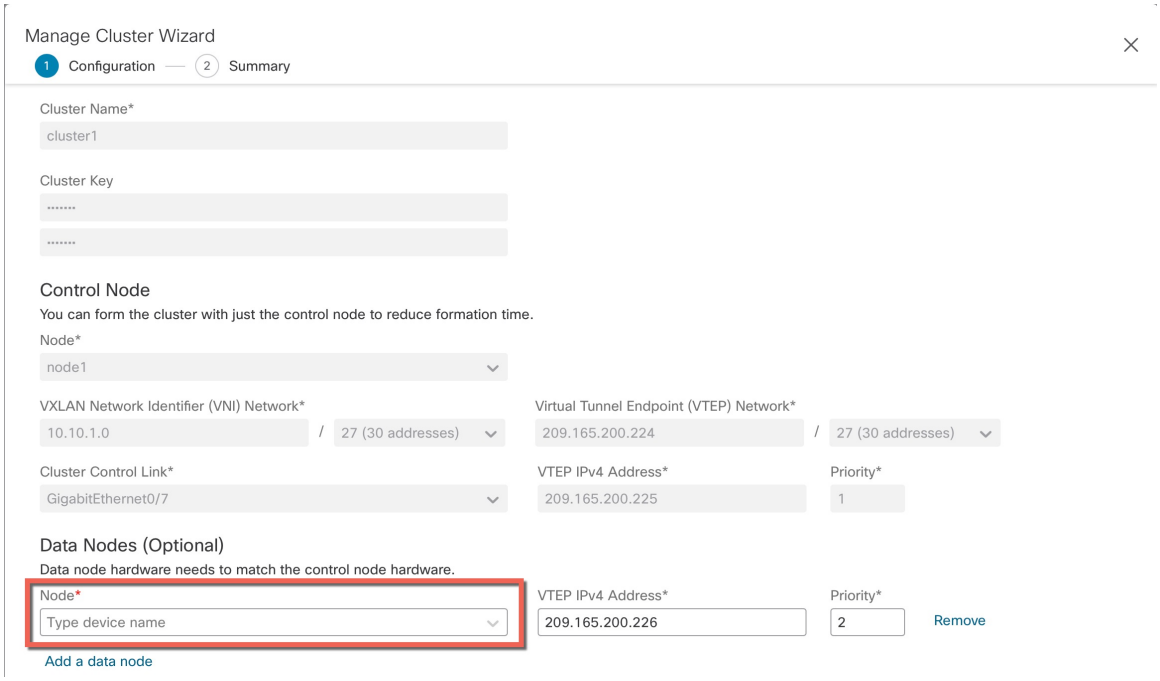


Figure 151: Add nodes

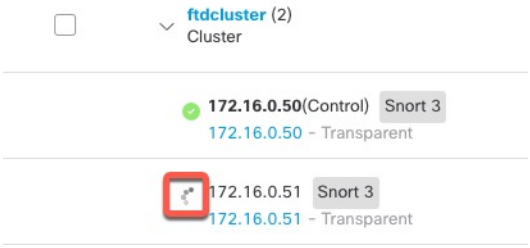
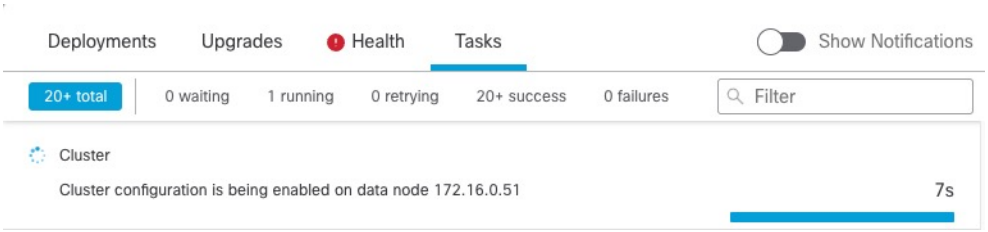
The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, and adjust the IP address and priority if desired.

Figure 152: Manage cluster wizard



Step 3 To add additional nodes, click **Add a data node**.



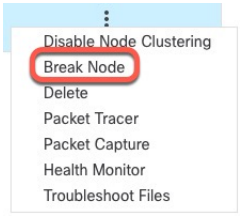
Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 153: Node registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.

Break a node



Breaking a node removes it from the cluster configuration, converting it to a standalone device.

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the node you want to break, and choose **Break Node**.

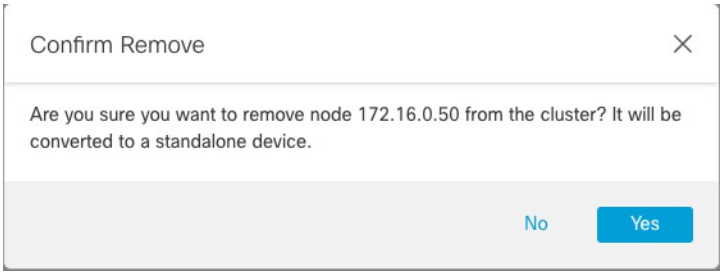


Figure 154: Break a node

You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

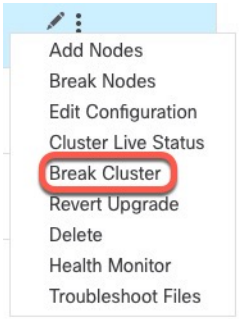
Step 2 You are prompted to confirm the break. Click **Yes**.

Figure 155: Confirm break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

Break the cluster

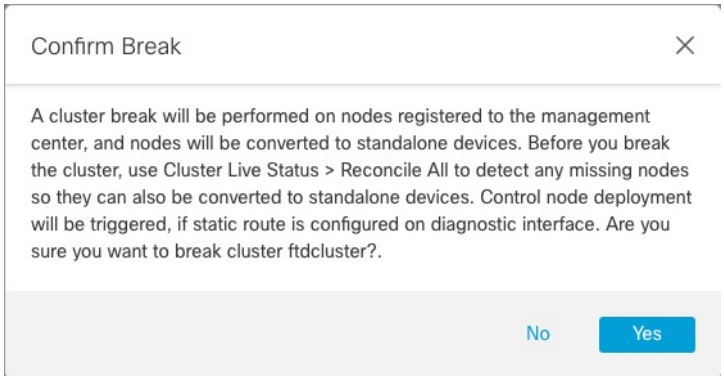
Break the cluster to convert all nodes to standalone devices when clustering is no longer needed.



You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the Cloud-Delivered Firewall Management Center by reconciling nodes. Refer to Reconcile cluster nodes, on page 824.



Step 2 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Break Cluster**.

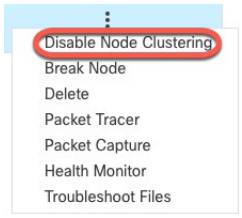
Figure 156: Break cluster

Step 3 You are prompted to break the cluster. Click **Yes**.

Figure 157: Confirm break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.

Disable clustering



Temporarily deactivate a node in a cluster while keeping it visible in the device list.

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Cloud-Delivered Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 158: Disable clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to reestablish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, refer to Rejoin the cluster, on page 822.

Rejoin the cluster

Rejoin a node to the cluster after it was removed because of failure or when clustering was manually disabled.

If a node was removed from the cluster, for example, due to a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

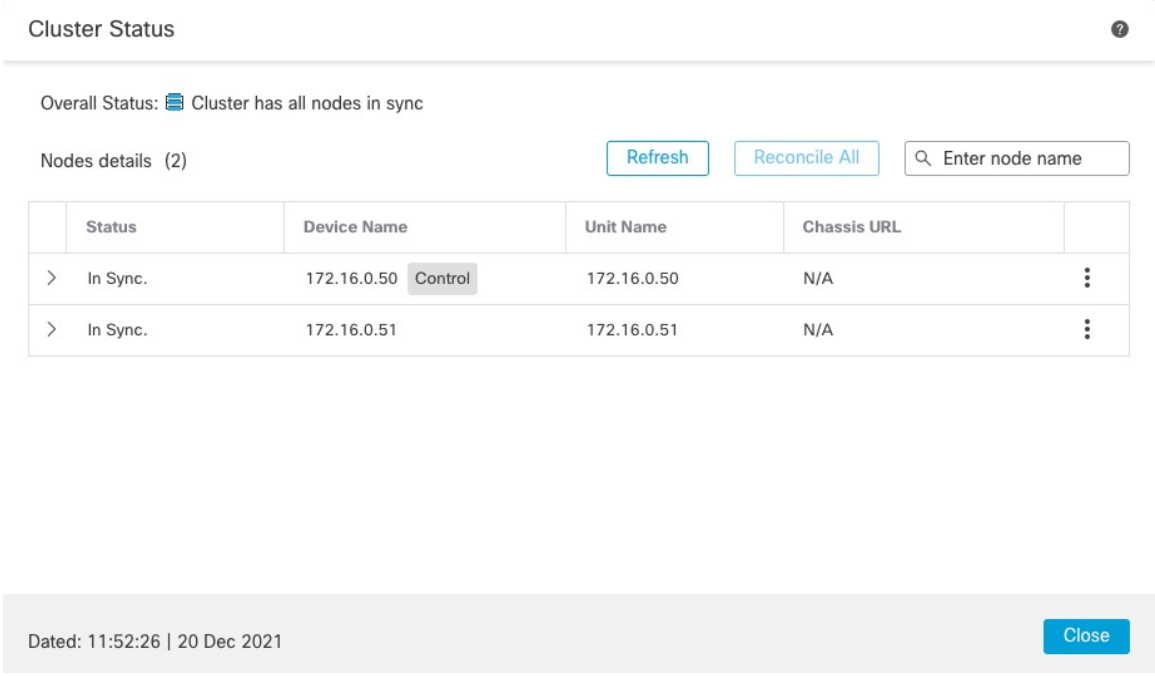
Step 2 Confirm that you want to enable clustering on the node.

Change the control node

This task changes the control node in a cluster when you need to specify the exact unit you want to become the control node.

The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. Use this procedure when you must specify the exact unit you want to become the control node.

Caution If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.



Before you begin

Follow these steps to change the control node:

Procedure

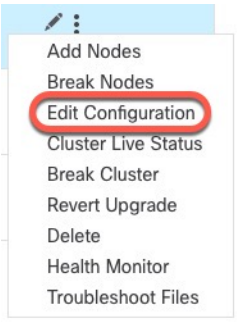
Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**.

Figure 159: Cluster status

Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Select the checkbox and click **OK**.

Edit the cluster configuration



Edit the cluster configuration to modify cluster settings and parameters as needed for your network environment.

You can edit the cluster configuration. If you change any values other than the VTEP IP address for a node or node priority, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the VTEP IP address for a node or node priority, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Edit Configuration**.

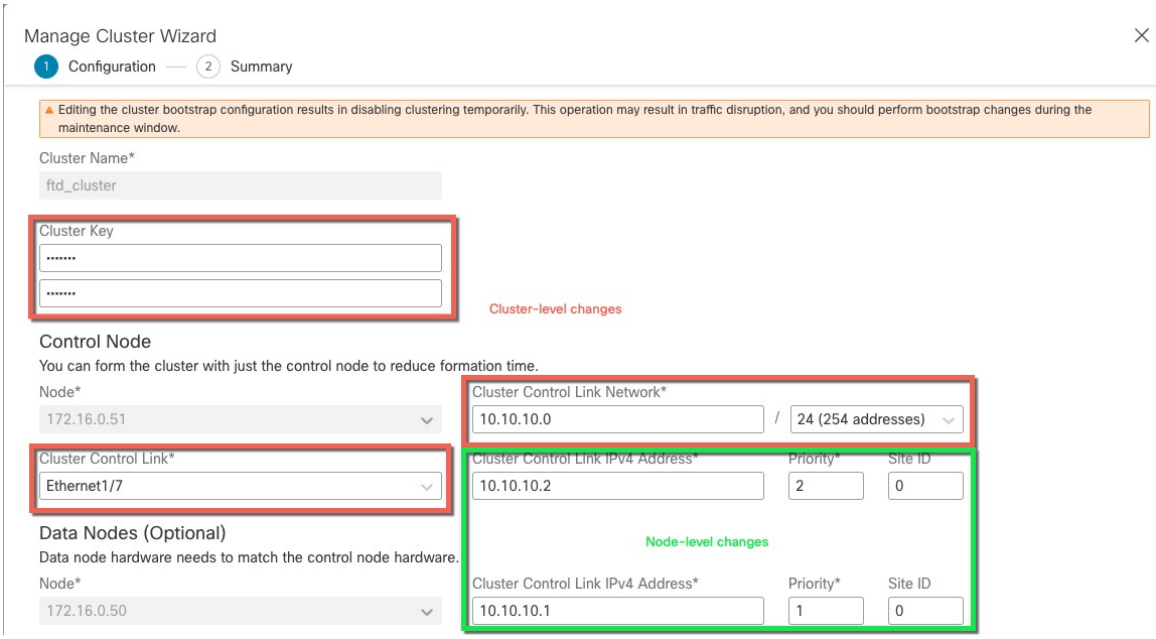


Figure 160: Edit configuration

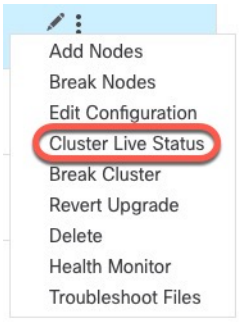
The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 161: Manage cluster wizard

Step 3 Click **Continue**. Review the **Summary**, and then click **Save**.

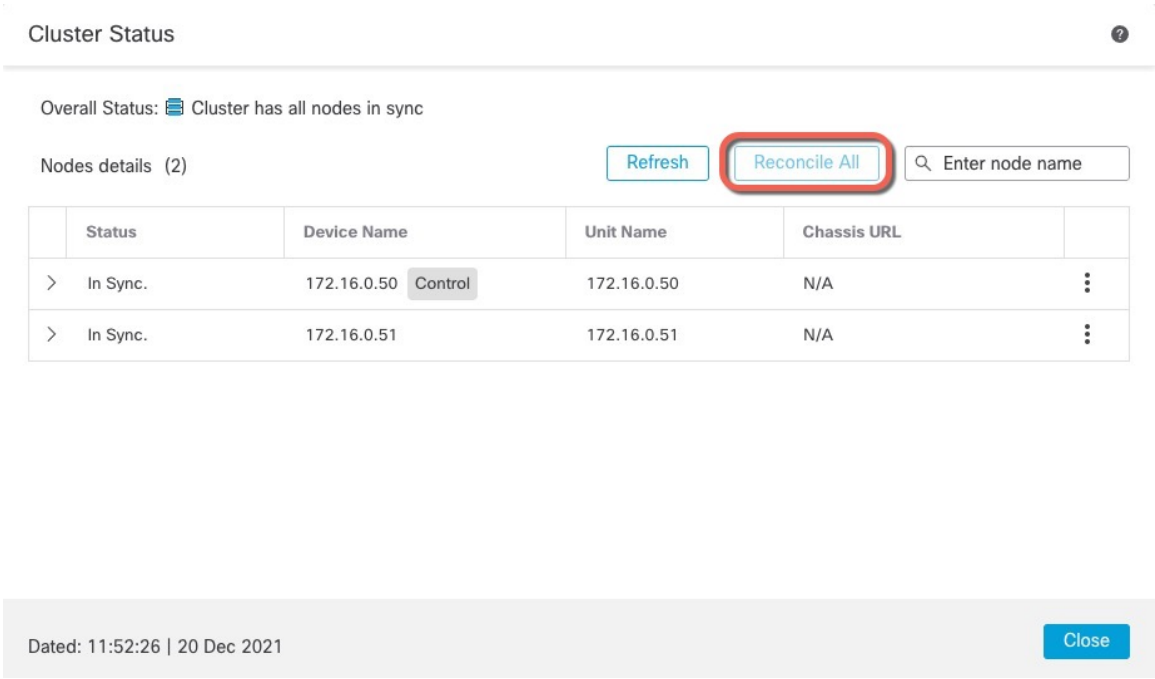
Reconcile cluster nodes



Use this procedure to reconcile cluster membership when a cluster node fails to register with the Cloud-Delivered Firewall Management Center.

If a cluster node fails to register, you can reconcile the cluster membership from the device to the Cloud-Delivered Firewall Management Center. For example, a data node might fail to register if the Cloud-Delivered Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure



Step 1 Choose **Devices** > **Device Management**, **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 162: Cluster live status

Step 2 Click **Reconcile All**.

Figure 163: Reconcile all

Delete the cluster or nodes from the Management Center

Delete clusters or nodes from Security Cloud Control to manage cluster membership and device visibility.

You can delete the cluster from the Security Cloud Control, which keeps the cluster intact. You might want to delete the cluster if you want to add the cluster to a new Security Cloud Control.

You can also delete a node from the Security Cloud Control without breaking the node from the cluster. Although the node is not visible in the Security Cloud Control, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot delete the current control node. You might want to delete the node if it is no longer reachable from the Security Cloud Control, but you still want to keep it as part of the cluster.

Procedure

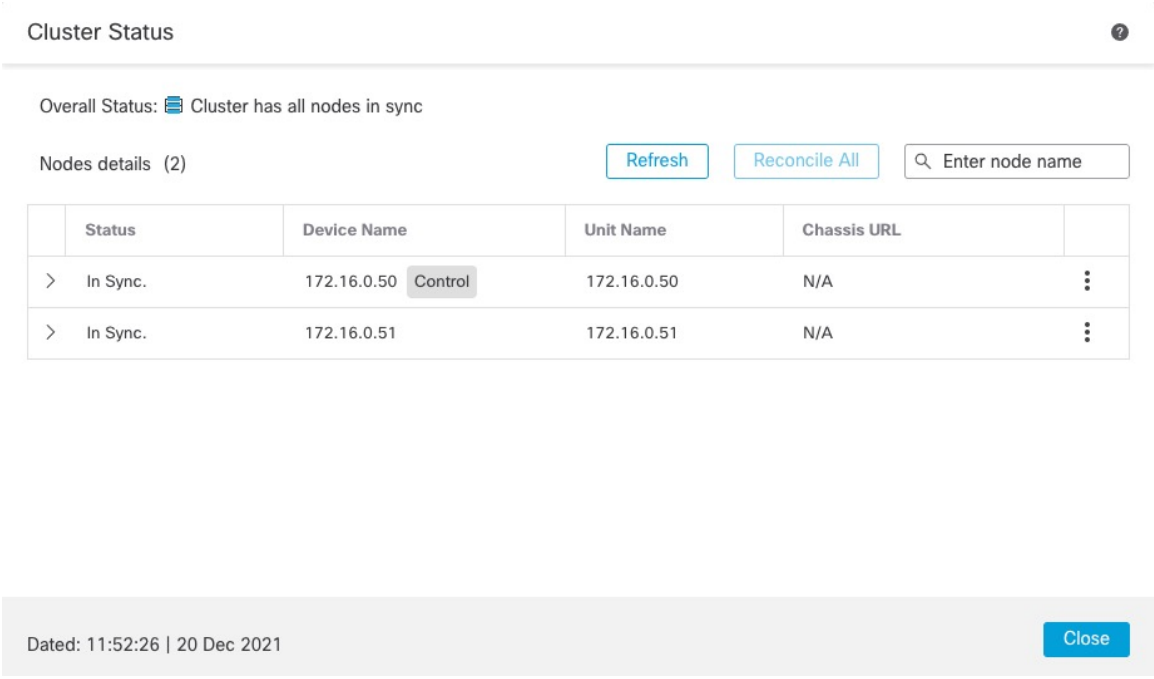
Step 1 Log into Security Cloud Control and click **Security Devices**.

Step 2 Click the **FTD** tab and locate the cluster you want. Select it so the device row is highlighted.

Step 3 Do the following:

- To delete a node within the cluster, in the **Cluster** pane on the right, click the delete icon next to the device you want to delete.
- To delete the cluster, in the **Device Actions** pane on the right, click **Remove**.

Step 4 When prompted, select **OK** to confirm the removal of the selected device.



Monitor cluster status

You can monitor the cluster in the Cloud-Delivered Firewall Management Center and at the Firewall Threat Defense CLI.

Monitor cluster status through these methods:

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management**, click **Add**, choose the **Cluster** page **General** area **Cluster Live Status** link.

Figure 164: Cluster status

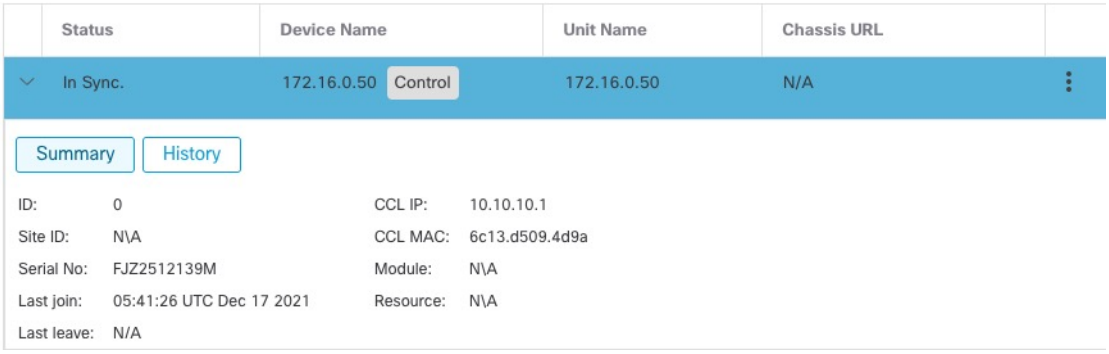
The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes these states:

- In Sync—The node is registered with the Cloud-Delivered Firewall Management Center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the Cloud-Delivered Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Cloud-Delivered Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Cloud-Delivered Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 165: Node summary



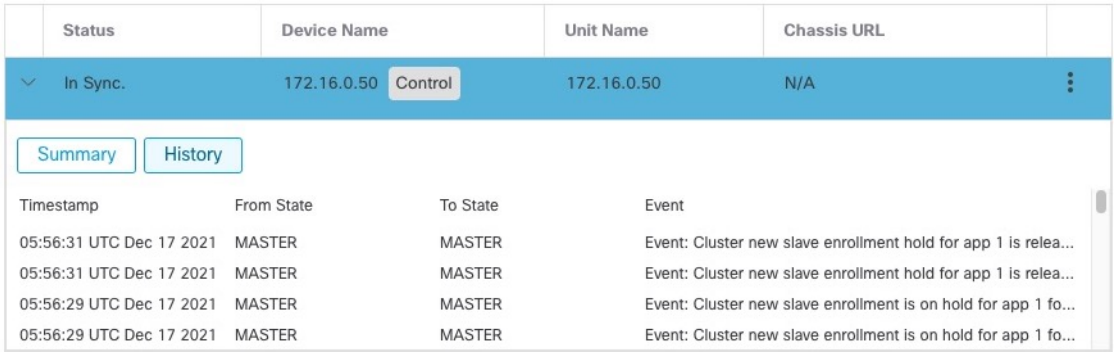


Figure 166: Node history

- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** and then click **Add** > **Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster health monitor

When a Firewall Threat Defense is the control node of a cluster, the Cloud-Delivered Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Cloud-Delivered Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

View the cluster health monitor

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.
- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.

- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 54: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Reference for clustering

This section includes more information about how clustering operates.

Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features and clustering

Centralized features for clustering

These features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, refer to the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Cloud-Delivered Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 1309.

- These application inspections are supported:
  - DCERPC and ESMTP
  - NetBIOS and PPTP
  - RSH
  - SQLNET and SUNRPC
  - TFTP
  - XDMCP
- Static route monitoring
- Site-to-site VPN

- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

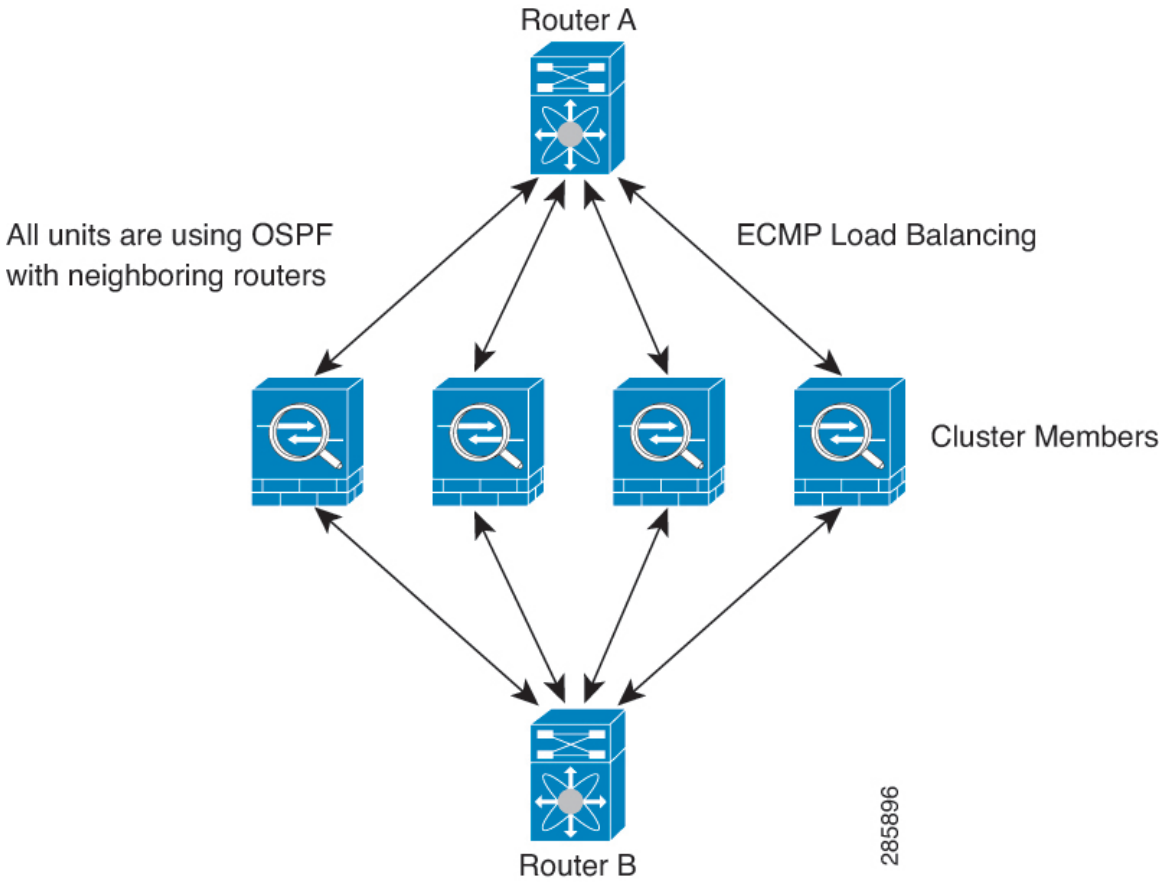
Connection settings and clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic routing and clustering

Dynamic routing and clustering are network configuration approaches that

- enable each node to run the routing protocol as a standalone router in Individual interface mode,
- allow routes to be learned by each node independently, and
- require separate router IDs for each node when communicating with external routers.



Routing behavior and load balancing

In Individual interface mode, ECMP is used to load balance traffic between multiple equal-cost paths. External routers can discover multiple paths to destinations through different cluster nodes.

Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when communicating with external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

Figure 167: Dynamic routing in individual interface mode

FTP and clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and clustering

Provides information about NAT behavior and limitations in clustering deployments.

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router requires a static route or policy-based routing (PBR) with Object Tracking for the mapped addresses, which must point to the main cluster IP address.
- No interface PAT on an individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP

- RSH
- SQLNET
- TFTP
- XDMCP
- SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco trustsec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and clustering

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an individual interface when using Policy-Based Routing (PBR) or Equal-Cost Multi-Path (ECMP), you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Note Remote access VPN is not supported with clustering.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

Throughput calculation

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control node election

The key components involved in the control node election process are:

- Cluster nodes: Communicate over the cluster control link and participate in the election process
- Election requests: Broadcast every three seconds by nodes when clustering is enabled
- Priority values: Set between 1 and 100 where 1 is the highest priority
- Control node: The elected node that coordinates cluster operations

These stages describe how cluster nodes elect a control node:

1. When clustering is enabled for a node (or when it first starts up with clustering already enabled), the node broadcasts an election request every three seconds.
2. Any other nodes with a higher priority respond to the election request. The priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node. The existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split-brain" scenario where multiple control nodes exist temporarily, the node with the highest priority retains the role, while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High availability within the cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node health monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

Split brain scenario

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 milliseconds.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Cloud-Delivered Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 55: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—

Traffic	State Support	Notes
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

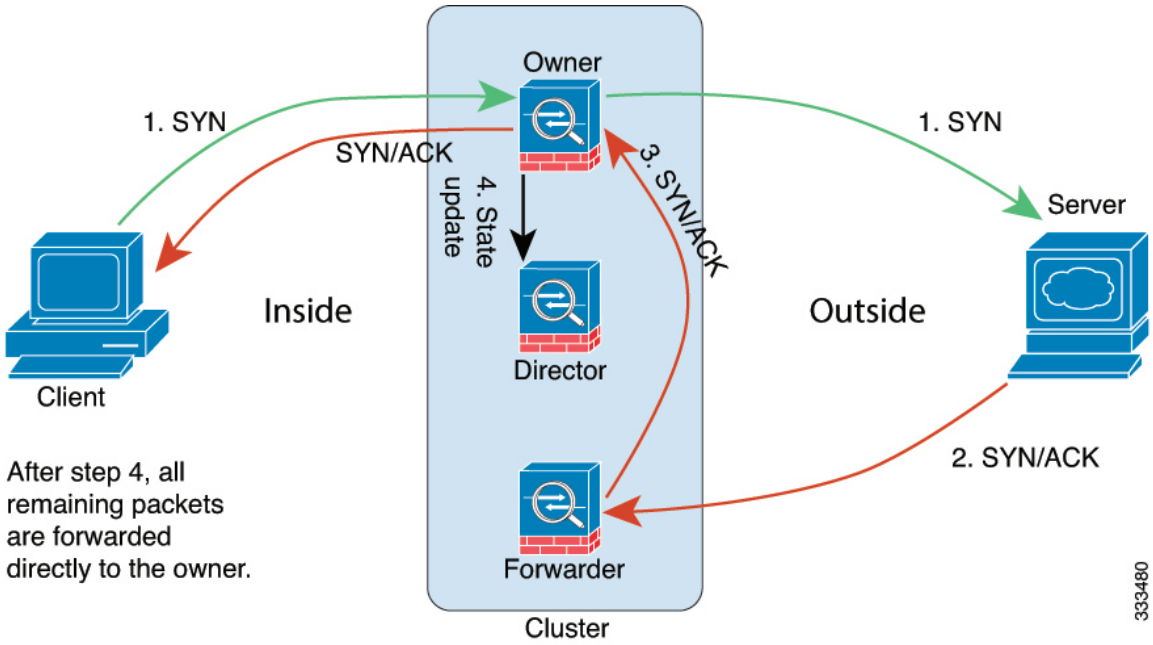
  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not

used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

Port Address Translation Connections



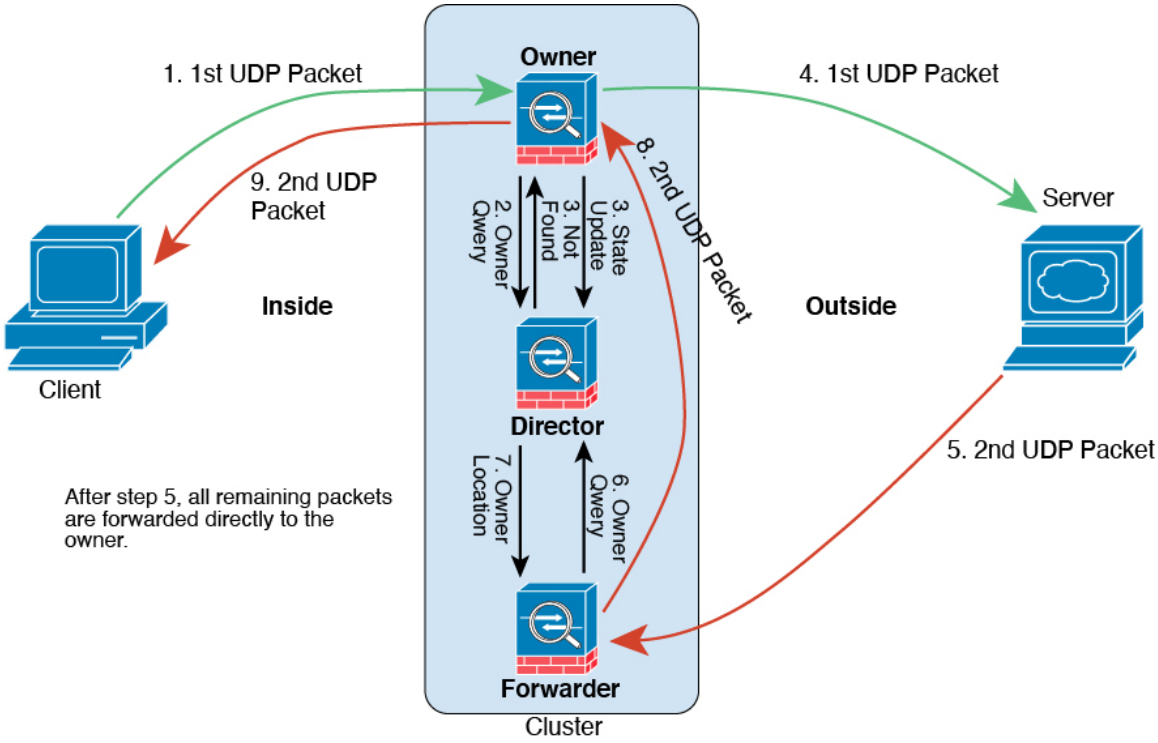
New connection ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

Sample data flow for TCP

The following example shows the establishment of a new connection.

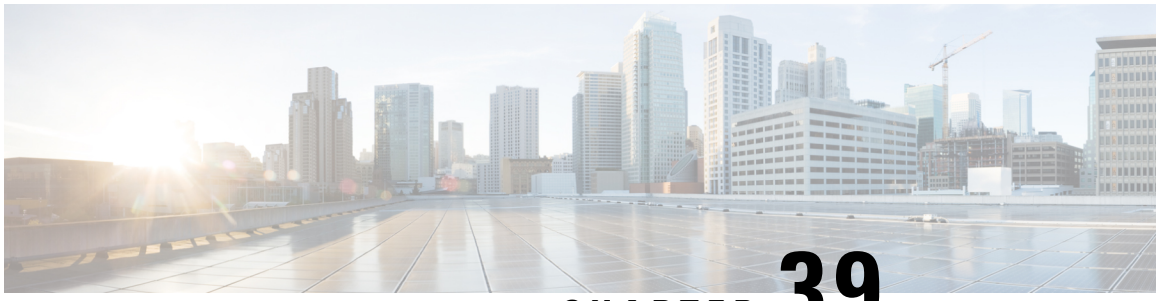


1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample data flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 168: ICMP and UDP Data Flow*



The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for clustering: private cloud

This reference provides the feature history for clustering functionality in private cloud environments, including version information, platform compatibility, and detailed descriptions of enhancements and new capabilities.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
MTU ping test from data node on node join	20241030	7.6.0	When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size twice the cluster control link MTU. Previously, only the control node sent a ping. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again. Added/modified commands: **show cluster history**. See: Clustering for the Secure Firewall 3100/4200, Clustering for Threat Defense Virtual in a Private Cloud, Clustering for Threat Defense Virtual in a Public Cloud, Clustering for the Firepower 4100/9300
Cluster health monitor settings	20221213	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard	20221213	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**
Clustering for the Firewall Threat Defense Virtual on VMware and KVM	Any	7.2.0	The Firewall Threat Defense Virtual supports Individual interface clustering for up to 4 nodes on VMware and KVM. New/Modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Firewall Threat Defense Virtual on VMware and KVM

CHAPTER 39

Clustering: Public Cloud

Clustering lets you group multiple Firewall Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Firewall Threat Defense Virtual clusters in a public cloud using the following public cloud platforms:

- Amazon Web Services (AWS)
- Microsoft Azure
- Google Cloud Platform (GCP)

Currently, only routed firewall mode is supported.

Note Some features are not supported when using clustering. See Unsupported Features and Clustering.

About Threat Defense Virtual clustering in the public cloud

This section describes the clustering architecture and how it works.

How the cluster fits into your network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the cluster control link, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Firewall Threat Defense Virtual send broadcast or multicast messages over the cluster control link.
- Load Balancer(s)—For external load balancing, you have the following options depending on your public cloud:
  - AWS Gateway Load Balancer

    The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Firewall Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint) using a Geneve interface single-arm proxy.
  - Azure Gateway Load Balancer

    In an Azure service chain, Firewall Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.
  - Native GCP load balancers, internal and external
  - Equal-Cost Multi-Path Routing (ECMP) using inside and outside routers such as Cisco Cloud Services Router

    ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses or source and destination ports, or both, can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Note Layer 2 Spanned EtherChannels are not supported for load balancing.

Individual interfaces

You can configure cluster interfaces as individual interfaces.

Individual interfaces are normal routed interfaces, each with their own local IP address. The IP address for the interface will be configured automatically via DHCP. Static IP configuration is not supported.

Control and data node roles

When you add a cluster in the Cloud-Delivered Firewall Management Center , you choose one firewall to be the control node, and all additional firewalls to be data nodes. When you first create the cluster, the control node you specify will become the control node simply because it is the first node added to the cluster. Later, if multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority.

When you create the cluster and deploy the cluster configuration, the Cloud-Delivered Firewall Management Center deploys a special bootstrap configuration to each node that includes fundamental settings such as the cluster control link configuration. The bootstrap configuration lets each node join the cluster. Most bootstrap settings are defined in the cluster wizard; however, you define the cluster control link interface hardware configuration (for example, creating an EtherChannel or setting the Ethernet speed) on the control node before you create the cluster. The cluster control link settings are copied to the bootstrap configuration for each node.

All nodes in the cluster share the same policy configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster. After you create the cluster, all configuration changes are made at the cluster level and are shared by all nodes.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see Configure VXLAN interfaces, on page 1071 .

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular Firewall Threat Defense Virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface. It is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, Firewall Threat Defense Virtual clustering allows you to configure multiple peers.

Cluster control link traffic overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management network

You must manage each node using the management interface. Management from a data interface is not supported with clustering.

Licenses for Threat Defense Virtual clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

Performance tier license requirements

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

When you add the control node to the Cloud-Delivered Firewall Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management**, **Cluster** > **License** area.

Note If you add the cluster before the Cloud-Delivered Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Cloud-Delivered Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and prerequisites for Threat Defense Virtual clustering

This reference provides the requirements and prerequisites for Threat Defense Virtual clustering, including model specifications, user roles, hardware and software requirements, and MTU configuration.

Model requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100

Note FTDv5 and FTDv10 do not support Amazon Web Services (AWS) Gateway Load Balancer (GWLB) and Azure GWLB.

- Supported public cloud services:
  - Amazon Web Services (AWS)
  - Microsoft Azure
  - Google Cloud Platform (GCP)
- Maximum of 16 nodes

See also the general requirements for the Firewall Threat Defense Virtual in the Secure Firewall Threat Defense Virtual getting started guides.

User roles

- Admin
- Access Admin
- Network Admin

Hardware and software requirements

All units in a cluster:

- Must be in the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or else performance will be limited on all nodes to match the least capable node.

- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- The Cloud-Delivered Firewall Management Center access must be from the Management interface. Data interface management is not supported.
- Multiple Availability Zone deployment is supported from Firewall Threat Defense Virtual version 7.6.0 and later. The earlier versions supports only single Availability Zone deployment.
- Cluster requires a minimum of *four* interfaces: Management, Diagnostics, Data (Geneve), and CCL (Cluster Control Link).
- Cluster control link interfaces of all units must be in the same subnet.

MTU

Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. If there is an MTU mismatch, the cluster formation will fail. When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the initial ping fails, the node tries a ping using a smaller packet size (the MTU divided by 2, then by 4, then by 8) until a ping succeeds. A notification is generated so you can fix the MTU mismatch on connecting switches and try again.

The cluster control link MTU should be 154 bytes higher than the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) plus VXLAN overhead (54 bytes).

For AWS with GWLB, the data interface uses Geneve encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the source interface MTU to be the network MTU + 326 bytes. So for the standard 1500 MTU network path, the source interface MTU should be 1826, and the cluster control link MTU should be +154, 1980.

For Azure with GWLB, the data interface uses VXLAN encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the cluster control link MTU to be the source interface MTU + 80 bytes.

The table shows the default values for the cluster control link MTU and the data interface MTU.

Note

- We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Threat Defense Virtual clusters on Azure, modifying the cluster control link (CCL) MTU via FlexConfig in Management Center is not recommended, as it may cause cluster stability issues.

Table 56: Default MTU

Public Cloud	Cluster Control Link MTU	Data Interface MTU
AWS with GWLB	1980	1826
AWS	1654	1500
Azure with GWLB	1454	1374

Public Cloud	Cluster Control Link MTU	Data Interface MTU
Azure	1454	1300
GCP	1554	1400

Guidelines for Threat Defense Virtual clustering

High availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Multi-zone clustering

Multi-zone clustering is supported for up to three zones.

Additional guidelines

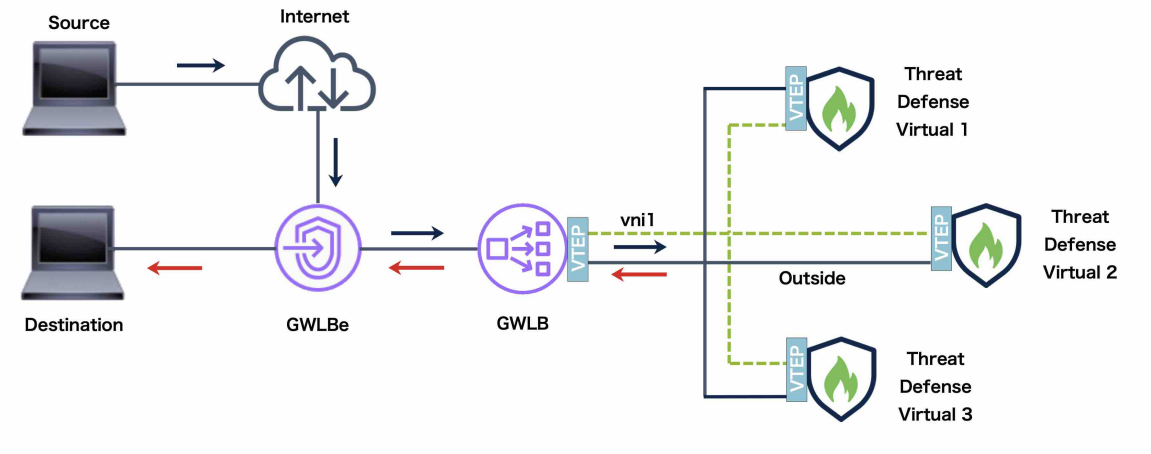
- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense or the switch, adding an additional switch to form a VSS or vPC or VNet) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a node to an existing cluster, or when reloading a node, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- Do not power off a node without first disabling clustering on the node.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new node. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- Dynamic scaling is supported from Secure Firewall version 7.3.
- Stateful Target Failover is not supported when you deploy the cluster on AWS.
- Perform a global deployment after the completion of each maintenance window.
- Ensure that you do not remove more than one device at a time from the auto scale group (AWS) / instance group (GCP) / scale set (Azure). We also recommend that you run the **cluster disable** command on the device before removing the device from the auto scale group (AWS) / instance group (GCP) / scale set (Azure).
- If you want to disable data nodes and the control node in a cluster, we recommend that you disable the data nodes before disabling the control node. If a control node is disabled while there are other data nodes

in the cluster, one of the data nodes has to be promoted to be the control node. Note that the role change could disturb the cluster.

- In the customized day 0 configuration scripts given in this guide, you can change the IP addresses as per your requirement, provide custom interface names, and change the sequence of the CCL-Link interface.
- If you experience CCL instability issues, such as intermittent ping failures, after deploying a Threat Defense Virtual cluster on a cloud platform, we recommend that you address the reasons that are causing CCL instability. Also, you can increase the hold time as a temporary workaround to mitigate CCL instability issues to a certain extent. For more information on how to change the hold time, see Edit Cluster Health Monitor Settings.
- When you are configuring your security firewall rule or security group for the Management Center virtual, you must include both Private and Public IP addresses of the Firewall Threat Defense Virtual in the Source IP address range. Also, ensure to specify the Private and Public IP addresses of the Firewall Management Center Virtual in the security firewall rule or security group of the Firewall Threat Defense Virtual. This is important to ensure proper registration of nodes during clustering deployment.

Defaults for clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.



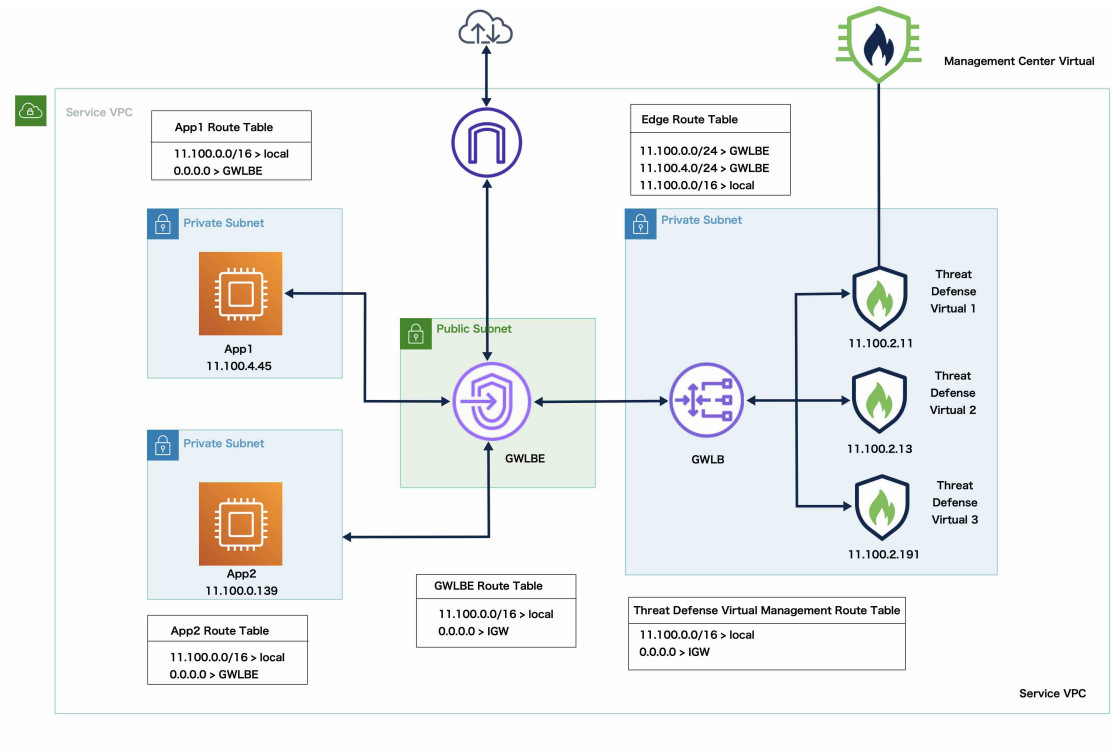
Deploy the cluster in AWS

You can deploy a cluster in AWS manually or by using CloudFormation templates to deploy a stack. You can use the cluster with AWS Gateway Load Balancer, or with a non-native load balancer such as the Cisco Cloud Services Router.

AWS gateway load balancer and Geneve single-arm proxy

This use case is the only currently supported use case for Geneve interfaces. The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Figure 169: Geneve Single-Arm Proxy



Note Transport Layer Security (TLS) Server Identity Discovery is not supported with Geneve single-arm setup on AWS.

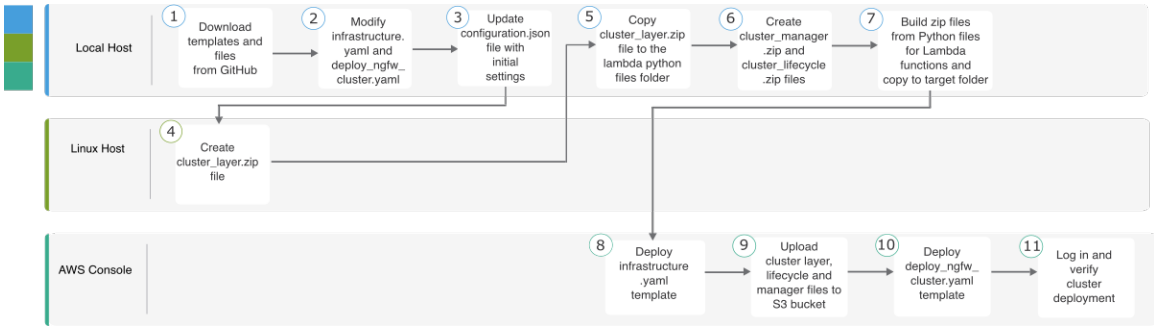
Sample topology

The sample topology provided below

- depicts both inbound and outbound traffic flow through security appliances,
- includes three Threat Defense Virtual instances in a cluster connected to a GWLB, and
- uses a Management Center Virtual instance to manage the cluster.

Traffic flow

Inbound traffic from the internet goes to the GWLB endpoint which then transmits the traffic to the GWLB. Traffic is then forwarded to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application VM, App1 /App2.



Outbound traffic from App1/App2 is transmitted to the GWLB endpoint which then sends it out to the internet.

End-to-end process for deploying Threat Defense Virtual cluster on AWS

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on AWS using either template-based or manual deployment processes.

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Clone the repository from GitHub
2	Local Host	Modify *infrastructure.yaml* and *deploy_ngfw_cluster.yaml* templates.
3	Local Host	Update the *Configuration.json* file with FMC object names.
4	Linux Host	Create *cluster_layer.zip* file.
5	Local Host	Copy *cluster_layer.zip* file to the Lambda python files folder.
6	Local Host	Create *cluster_manager.zip*, *custom_metrics_publisher.zip*, and *cluster_lifecycle.zip* files.
7	Local Host	Build zip files from Python files for Lambda functions and copy to target folder.
8	AWS Console	Deploy *infrastructure.yaml* template.
9	AWS Console	Upload *cluster_layer.zip*, *cluster_lifecycle.zip*, *custom_metrics_publisher.zip*, and *cluster_manager.zip* to the S3 bucket.
10	AWS Console	Deploy *deploy_ngfw_cluster.yaml* template.
11	AWS Console	Log in and verify cluster deployment.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Create day 0 configuration script.
2	AWS Console	Deploy Threat Defense Virtual instance.
3	AWS Console	Attach interfaces to instance.
4	AWS Console	Verify if nodes have joined cluster.
5	AWS Console	Create target group and GWLB; attach target group to the GWLB.
6	AWS Console	Register instances with the target group using data interface IP.
7	Management Center	Register control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names, default values, allowed values, and description, given in the template.

- infrastructure.yaml – Template for infrastructure deployment.
- deploy_ngfw_cluster.yaml – Template for cluster deployment.

Note Ensure that you check the list of supported AWS instance types before deploying cluster nodes. This list is found in the *deploy_ngfw_cluster.yaml* template, under allowed values for the parameter InstanceType.

Deploy the Stack in AWS Using a CloudFormation template

Deploy the stack in AWS using the customized CloudFormation template.

Before you begin

- You need an Amazon Linux virtual machine with Python 3.
- To allow the cluster to auto-register with the Cloud-Delivered Firewall Management Center , you need to create two users with administrative privileges on the Cloud-Delivered Firewall Management Center that can use the REST API. See the *Cisco Secure Firewall Management Center Administration Guide* .
- Add an access policy in the Cloud-Delivered Firewall Management Center that matches the name of the policy that you specified in `Configuration.json` .

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/aws .

b) Modify **infrastructure.yaml** and **deploy_ngfw_cluster.yaml** with the required parameters.

c) Modify **cluster/aws/lambda-python-files/Configuration.json** with initial settings.

For example:

```
{
  "licenseCaps": ["BASE", "MALWARE", "THREAT"],
  "performanceTier": "FTDv50",
  "fmcIpforDeviceReg": "DONTRESOLVE",
  "RegistrationId": "cisco",
  "NatId": "cisco",
  "fmcAccessPolicyName": "AWS-ACL"
}
```

- Keep the fmcIpforDeviceReg setting as DONTRESOLVE.
- The fmcAccessPolicyName needs to match an access policy on the Cloud-Delivered Firewall Management Center .

Note
FTDv5 and FTDv10 tiers are not supported.

d) Create a file named **cluster_layer.zip** to provide essential Python libraries to Lambda functions.

We recommend using Amazon Linux with Python 3.9 installed to create the cluster_layer.zip file.

Note
If you need an Amazon Linux environment, you can create an EC2 instance using Amazon Linux 2023 AMI or use AWS Cloudshell, which runs the latest version of Amazon Linux.

For creating the cluster-layer.zip file, you need to first create requirements.txt file that consists of the python library package details and then run the shell script.

1. Create the requirements.txt file by specifying the python package details.

   The following is the sample package details that you provide in the requirements.txt file:

   ```
   $ cat requirements.txt
   pycryptodome
   paramiko
   requests
   scp
   jsonschema
   cffi
   zipp
   importlib-metadata
   ```

2. Run the following shell script to create cluster_layer.zip file.

   ```
   $ pip3 install --platform manylinux2014_x86_64
   --target=./python/lib/python3.9/site-packages
   --implementation cp --python-version 3.9 --only-binary=:all:
   ```

```
--upgrade -r requirements.txt
$ zip -r cluster_layer.zip ./python
```

Note
If you encounter a dependency conflict error during installation, such as urllib3 or cryptography, it is recommended that you include the conflicting packages along with their recommended versions in the requirements.txt file. After that, you can run the installation again to resolve the conflict.

e) Copy the resulting **cluster_layer.zip** file to the lambda python files folder - `cluster/aws/lambda-python-files` .

f) Create the **cluster_layer.zip** , **custom_metrics_publisher.zip** , **cluster_manger.zip** and **lifecycle_ftdv.zip** files.

A make.py file can be found in the cloned repository (`cluster/aws/make.py`). This will zip the python files into a Zip file and copy to a target folder.

python3 make.py build

Note
If you are using a private IP address for the Management Center Virtual registration, then make sure that you set USE_PUBLIC_IP_FOR_FMC_CONN to False in the `cisco-ftdv/cluster/aws/lambda-python-files/constant.py` file.

Step 2 Deploy **infrastructure.yaml** and note the output values for cluster deployment. Before deploying the infrastructure stack, it is important to identify the AWS region and the availability zones that will be used. Each AWS region has a different set of availability zones and VPC infrastructure. Therefore, it is essential to select the correct region and availability zones for your deployment.

a) On the AWS Console, go to **CloudFormation** and click **Create stack** ; select **With new resources(standard)** .

b) Select **Upload a template file** , click **Choose file** , and select **infrastructure.yaml** from the target folder.

c) Click **Next** and provide the required information.

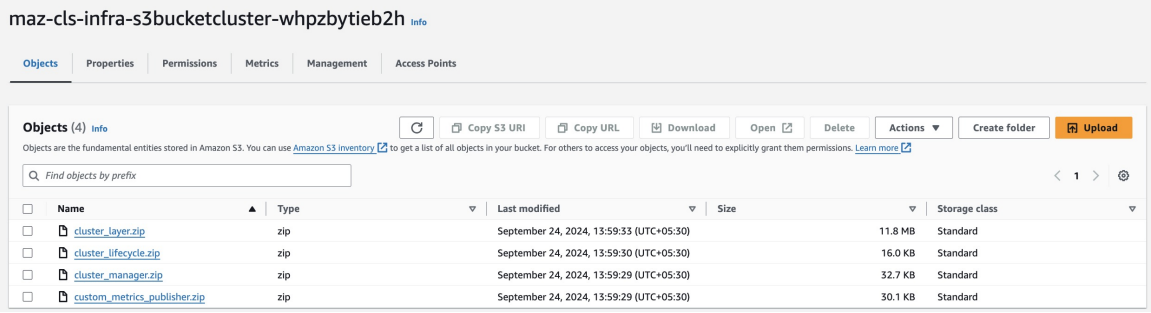
e

Parameter	Allowed Values/Type	Description
ClusterName	String	Enter unique Cluster name.
ClusterNumber	Number	Enter unique Cluster number.
VpcCidr	String	Enter the CIDR block for a new VPC
NoOfAZs	Number	Select 2 or 3 Availability Zones (AZs) for releases 7.6.0 and above; for lower releases, Select 1AZ. Management, Inside, Outside and CCL subnets will be distributed across the chosen AZs accordingly.
ListOfAZs	List	Select Availability Zones (Count should match with Number of Availability Zones)
MgmtSubnetNames	CommaDelimitedList	Management subnets name (With Internet GW as Route)

Parameter	Allowed Values/Type	Description
MgmtSubnetCidrs	CommaDelimitedList	Management subnets Cidr list
InsideSubnetNames	CommaDelimitedList	Inside subnets name (With Private Route)
InsideSubnetCidrs	CommaDelimitedList	Inside subnets Cidr list
CCLSubnetNames	CommaDelimitedList	Enter CCL subnet name
CCLSubnetCidrs	CommaDelimitedList	Enter CCL subnet CIDR
LambdaAZs	List	Select 2 Availability Zones for Lambda
LambdaSubnetNames	CommaDelimitedList	Enter Lambda Subnets name (With NAT GW as Route), for Lambda Functions
LambdaSubnetCidrs	CommaDelimitedList	Enter Lambda Subnet CIDRs

d) Enter a unique **Cluster Name** and **Cluster Number** for the cluster.
e) Select the availability zone from the **Availability Zone** list. This field lists only availability zones based on the AWS region that you select for deploying the infrastructure stack using the ClusterFormation template.
f) Click **Next** , then **Create stack** .
g) After the deployment is complete, go to **Outputs** and note the S3 **BucketName** .

Figure 170: Output of infrastructure.yaml



Outputs (13)

Search outputs

Key	Value	Description	Export name
BucketName	maz-cls-infra-s3bucketcluster-whpzbytieb2h	Name of the Amazon S3 bucket	-
BucketUrl	http://maz-cls-infra-s3bucketcluster-whpzbytieb2h.s3-website-us-east-1.amazonaws.com	URL of S3 Bucket Static Website	-
CCLSubnetIds	subnet-0bc04e2cc9e53e5c0,subnet-0d7d046a0fca25615,subnet-03ef42bf527551569	List of CCL subnet IDs (comma seperated)	-
EIPforNATgw	3.218.44.132	EIP reserved for NAT GW	-
FmcInstanceSGID	sg-076880aa64df2db5c	Security Group ID for FMC if user would like to launch in this VPC itself	-
InInterfaceSGId	sg-06ed933d6624fe51b	Security Group ID for Inside Interfaces	-
InsideSubnetIds	subnet-03d12cab8ee0eafff,subnet-0be9158b0970aebab,subnet-0b53c96fceb7c1f4d	List of Inside subnet IDs (comma seperated)	-
InstanceSGId	sg-0680b74be473186aa	Security Group ID for Instances Management Interface	-
LambdaSecurityGroupId	sg-057da2a9954e0d204	Security Group ID for Lambda Functions	-
LambdaSubnetIds	subnet-03439803d989e6bdf,subnet-087488a9d6ffc95cd	List of lambda subnet IDs (comma seperated)	-
ListOfAZs	us-east-1a,us-east-1b,us-east-1c	Availability zones for NGFWv instances	-
MgmtSubnetIds	subnet-06f0bbbd3f207a504,subnet-0c339dc43688cddc9,subnet-0a67629632a655de7	List of Mangement subnet IDs (comma seperated)	-
VpcName	vpc-09c2b0ad995e2fb24	Name of the VPC created	-

Step 3 Upload **cluster_layer.zip** , **cluster_manager.zip** , **custom_metrics_publisher.zip** , and **cluster_lifecycle.zip** to the S3 bucket created by **infrastructure.yaml** .

Figure 171: S3 Bucket

Note
Make sure that the Elastic IP address of the Lambda NAT Gateway is added to the security group associated with the Management Center Virtual.

Step 4 Deploy **deploy_ngfw_cluster.yaml** .

a) Go to **CloudFormation** and click on **Create stack** ; select **With new resources(standard)** .
b) Select **Upload a template file** , click **Choose file** , and select **deploy_ngfw_cluster.yaml** from the target folder.
c) Click **Next** and provide the required information.
d) Provide the following cluster and infrastructure configuration information.

Parameter	Allowed Values/Type	Description
Cluster Configuration		
ClusterGrpNamePrefix	String	This is the cluster name Prefix. The cluster number will be added as a suffix.
ClusterNumber	String	This is the cluster number. This will be suffixed to the cluster name (msa-ftdv-infra). For example, if this value is 1 , the group name will be msa-ftdv-infra-1. It should be at least 1 digit, but not more than 3 digits. Default: 1.
ClusterSize	Numbers	This is the total number of Firewall Threat Defense Virtual nodes in a cluster. Minimum: 1 Maximum:16
Infrastructure Details		
NoOfAZs	String	This is the total number of availability zones into which Firewall Threat Defense Virtual is deployed. (The number of availability zones varies from a Minimum 1 to Maximum 3 depending on a region). The subnet will be created in these availability zones.

Parameter	Allowed Values/Type	Description
		The availability zones available in this list is based on the region selected for deploying the cluster. **Note** Management, Inside, and Cluster Control Link (CCL) subnets are created across three availability zones based on this parameters.
AZ	String	The availability zone list is based on the region you plan to deploy. In Availability Zone list, select the valid availability zone (1 availability zone or 2 availability zones or 3 availability zones). Count should match with the value of Number of Availability Zones parameter.
NotifyEmailID	String	Email address to which cluster events email will be sent. You must accept a subscription email request to receive this email notification. For example, admin@company.com.
VpcId	String	The VPC ID for the cluster group. Type: AWS::EC2::VPC::Id
S3BktName	String	The S3 Bucket that contains the uploaded Lambda zip files. You must specify correct bucket name.
MgmtSubnetIds	List	Enter only one subnet per availability zone. If you select multiple subnets from a same availability zone, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
InsideSubnetIds	List	Enter at least one subnet per availability zone. If multiple subnets from the same Availability Zone are selected, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
LambdaSubnets	List	Enter at least two subnets for the Lambda functions. The two subnets you enter must have a NAT gateway to enable the Lambda functions to communicate with AWS services, which are public DNS. Type: List<AWS::EC2::Subnet::Id>

Parameter	Allowed Values/Type	Description
CCLSubnetIds	String	Enter at least one subnet per availability zone. If multiple subnets from the same Availability Zone are selected, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
CCLSubnetRanges	String	Enter IP addresses range of CCL subnets for different availability zones. Exclude first 4 reserved IP addresses. IP address pool for Cluster Control Link (CCL). IP address is allocated to the CCL interfaces of the Firewall Threat Defense Virtual instance from CCL IP address pool.
MgmtInterfaceSG	List	Select security group ID for the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::SecurityGroup::Id>
InsideInterfaceSG	List	Select security group ID for the inside interface of Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::SecurityGroup::Id>
LambdaSG	List	Select a security group for the Lambda functions. Ensure outbound connections are set to ANYWHERE . Type: List<AWS::EC2::SecurityGroup::Id>
CCLInterfaceSG	List	Select a security group ID for CCL interface of the Firewall Threat Defense Virtual instances.
GWLB Configuration		
DeployGWLBE	String	Click Yes to deploy the GWLB endpoint. By default, the value is set to No .
VpcIdLBE	String	Enter VPC to deploy Gateway Load Balancer Endpoint. **Note** Do not enter any value in this field if you are not deploying the GWLB endpoint.
GWLBESubnetId	String	Enter only one subnet ID. **Note** Do not enter any value in this field if you are not deploying the GWLB endpoint.

Parameter	Allowed Values/Type	Description
		Ensure that the subnet belongs to the correct VPC, and the availability zones that you have specified.
TargetFailover	String	Enable Target Failover support when a target fails or deregisters. (By default, the value of this parameter is set to rebalance). • no_rebalance : Directs existing flows to failed targets and new flows to healthy targets, ensuring backward compatibility. • rebalance : Redistributes existing flows while ensuring that new flows go to healthy targets. rebalance is supported from Firewall Threat Defense Virtual Version 7.4.1 and later.
TgHealthPort	String	Enter Health Check Port for GWLB. **Note** By default, this port must not be used for traffic. Ensure the value you provide is a valid TCP port. Default: 8080
Cisco NGFWv Instance Configuration		
InstanceType	String	Cisco Firewall Threat Defense Virtual EC2 instance type. Ensure that the AWS Region supports Instance Type you select. By default, **c5.xlarge** is selected.
LicenseType	String	Choose Cisco Firewall Threat Defense Virtual EC2 instance license type. Ensure that the AMI ID that you enter in **AMI-ID** parameter is of the same licensing type. By default, **BYOL** is selected.
AssignPublicIP	String	Set the value as **true** to assign a public IP address for Firewall Threat Defense Virtual from the AWS IP address pool.
AmiID	String	Choose the correct AMI ID as per the region, version, and license type (BYOL or PAYG). Firewall Threat Defense Virtual 7.2 and later support clustering, and Firewall Threat Defense Virtual Version 7.6 and later support the autoscaling and multiple availability zone enhancements. Type: AWS::EC2::Image::Id

Parameter	Allowed Values/Type	Description
ngfwPassword	String	Firewall Threat Defense Virtual instance password. All Firewall Threat Defense Virtual instances come up with a default password, which is in the Userdata field of the Launch Template (Cluster Group). The password is activated after Firewall Threat Defense Virtual is accessible. Minimum length must be 8 characters. The password can either be a plain text password or a KMS encrypted password.
KmsArn	String	Enter ARN of an existing KMS (AWS KMS key to encrypt at rest). If you specify a value in this field, then the Firewall Threat Defense Virtual instance's admin password must be an encrypted password. Example of generating an encrypted password: " aws kms encrypt --key-id <KMS ARN> --plaintext <password> " The password encryption must be done using only the specified ARN.
FMC Automation Configuration		
fmcDeviceGrpName	String	Enter a unique name for the cluster group in management center.
fmcPublishMetrics	String	Select **`true`** to create a Lambda Function to poll management center and publish specific device group metrics to AWS CloudWatch. Allowed values: • true • false By default, the value is set to true .
fmcMetricsUsername	String	Enter a unique internal user name for polling memory metrics from management center. The user must have privileges of Network Admin and Maintenance User or more .
fmcMetricsPassword	String	Enter the password. If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password.

Parameter	Allowed Values/Type	Description
		Ensure to enter the correct password because entering incorrect password may result in failure of metrics collection.
fmcServer	String	The IP address can be an external IP address or the IP address reachable in Firewall Threat Defense Virtual management subnet in the VPC. Minimum length: 7 Maximum length:15
fmcOperationsUsername	String	Provide a unique internal user name for Firewall Management Center Virtual for CloudWatch. The user must have Administrator privileges.
fmcOperationsPassword	String	Enter the password. If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password.
Scaling Configuration		
CpuThresholds	CommaDelimitedList	(Optional) Specifying non-zero lower and upper thresholds will create scale policies. If (0,0) is selected, no CPU scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values. By default, autoscaling is enabled in this template. Autoscale can be disabled after deployment.
MemoryThresholds	CommaDelimitedList	Specifying non-zero lower and upper threshold will create scale policies. If (0,0) is selected, no memory scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values.

e) Click **Next** , then **Create stack** .

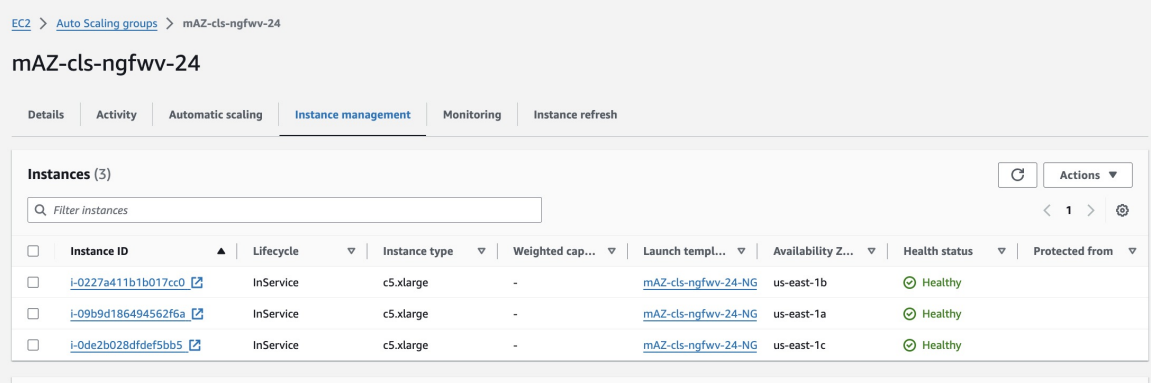
The Lambda functions manage the rest of the process, and the Firewall Threat Defense Virtual s will automatically register with the Cloud-Delivered Firewall Management Center .

Figure 172: Deployed Resources

The status changes from CREATE_IN_PROGRESS to CREATE COMPLETE, indicating successful deployment.

Step 5 Verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 173: Cluster Nodes



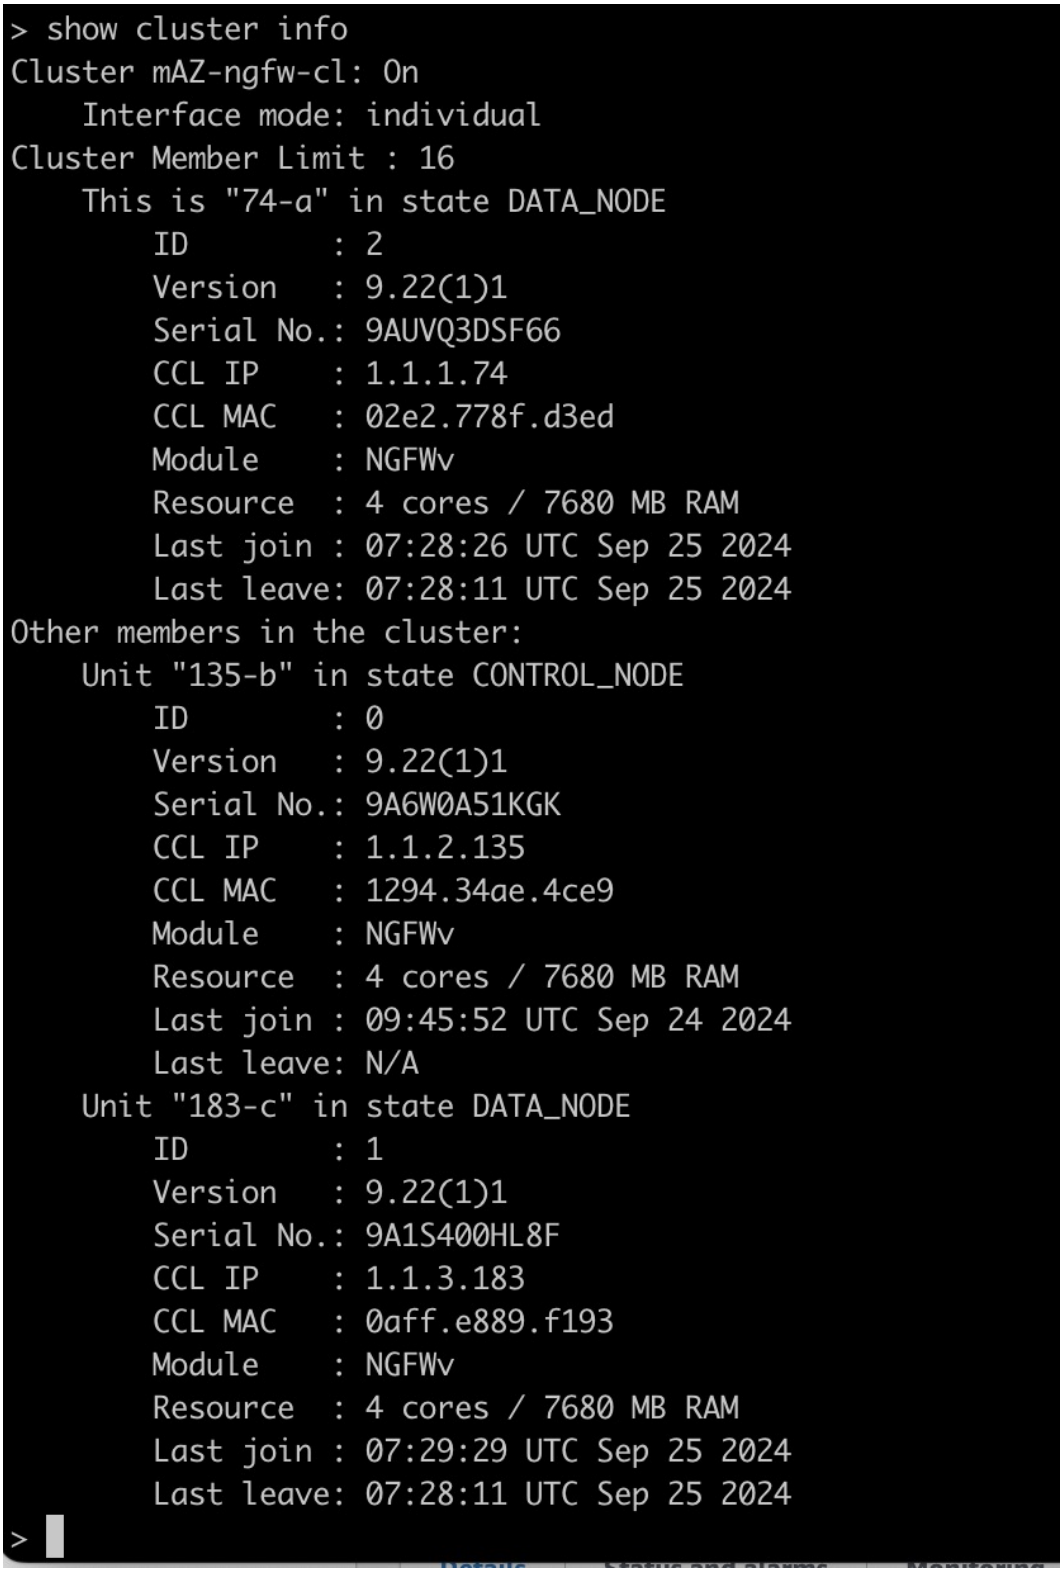


Figure 174: show cluster info

Manual cluster deployment in AWS

To deploy the cluster manually, prepare the day 0 configuration, deploy each node, and then add the control node to the Cloud-Delivered Firewall Management Center.

On version 7.6.4-69 and from 10.0.0, each cluster node requires a unique AWS instance tag "cluster-node-id" with a value ranging from 1 to 16 for internal cluster configuration. Please ensure that the tag is added before the device boots up.

For example: key "cluster-node-id" -> value "1"

Additionally, make sure that "Allow tags in instance metadata" is set to "Enabled."

Create the Day0 configuration for AWS

You can use either a fixed configuration or a customized configuration. We recommend using the fixed configuration.

Create the Day0 configuration with a fixed configuration for AWS

The fixed configuration will auto-generate the cluster bootstrap configuration.

Single availability zone - Day0 configuration with a fixed configuration for AWS

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "Cluster": {
        "CclSubnetRange": "ip_address_start ip_address_end",
        "ClusterGroupName": "cluster_name",
        [For Gateway Load Balancer] "Geneve": "{Yes | No}",
        [For Gateway Load Balancer] "HealthProbePort": "port"
    }
}
```

For example:

```
{
 "AdminPassword": "Sup3rnatural",
 "Hostname": "ciscoftdv",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "Cluster": {
              "CclSubnetRange": "10.5.90.4 10.5.90.30",
  "ClusterGroupName": "ftdv-cluster",
  "Geneve": "Yes",
  "HealthProbePort": "7777"
 }
}
```

Configure the cluster infrastructure subnet range

Use a cluster infrastructure subnet range to allocate IP addresses within a /27 CIDR block. This range provides the usable IP addresses for your cluster infrastructure.

Before you begin

- Review the table to determine valid start and end IP addresses for the /27 CIDR blocks you plan to use.
- The first four IP addresses in each subnet (including the network address) are reserved by AWS. Configure the **CclSubnetRange** to begin with the fifth IP address in the subnet.

The table shows the valid start and end IP addresses for each /27 CIDR allocation.

Table 57: CclSubnetRange mapping

CIDR	Start IP Address	End IP Address
x.y.z.0/27	x.y.z.4	x.y.z.30
x.y.z.32/27	x.y.z.36	x.y.z.62
x.y.z.64/27	x.y.z.68	x.y.z.94
x.y.z.96/27	x.y.z.100	x.y.z.126
x.y.z.128/27	x.y.z.132	x.y.z.158
x.y.z.160/27	x.y.z.164	x.y.z.190
x.y.z.192/27	x.y.z.196	x.y.z.222
x.y.z.224/27	x.y.z.228	x.y.z.254

Complete these steps to configure the cluster infrastructure subnet range.

Procedure

Step 1 Identify the /27 CIDR block assigned to your cluster infrastructure subnet.

Step 2 Find the matching CIDR in the mapping table.

Step 3 Replace "x.y.z" with the first three octets of your subnet. For example, 172.20.10 or 10.100.5.

Step 4 Configure the range by entering the start and end IP addresses from the mapping table for your subnet.

- Example 1:
  - CIDR: 172.20.10.64/27
  - Subnet range: 172.20.10.68 to 172.20.10.94
- Example 2:
  - CIDR: 10.100.5.128/27

- Subnet range: 10.100.5.132 to 10.100.5.158

Deploy cluster nodes

Deploy cluster nodes to form a functional cluster that can handle traffic distribution and provide high availability for network security services.

Deploy the cluster nodes so they form a cluster.

Procedure

Step 1 Deploy the Threat Defense Virtual instance by using the cluster day 0 configuration with the required number of interfaces - four interfaces if you are using Gateway Load Balancer (GWLB), or five interfaces if you are using non-native load balancer. To do this, in the **Configure Instance Details** > **Advanced Details** section, paste the cluster day 0 configuration.

Note
Ensure that you attach interfaces to the instances in the order given below.

- AWS Gateway Load Balancer - four interfaces - management, diagnostic, inside, and cluster control link.
- Non-native load balancers - five interfaces - management, diagnostic, inside, outside, and cluster control link.

For more information on deploying Threat Defense Virtual on AWS, refer to Deploy the Threat Defense Virtual on AWS.

Step 2 Repeat Step 1 to deploy the required number of additional nodes.

Step 3 Use the **show cluster info** command on the Threat Defense Virtual console to verify if all nodes have successfully joined the cluster.

Step 4 Configure the AWS Gateway Load Balancer.

a) Create a target group and GWLB.

b) Attach the target group to the GWLB.

Note
Ensure that you configure the GWLB to use the correct security group, listener configuration, and health check settings.

c) Register the data interface (inside interface) with the Target Group using IP addresses.

For more information, refer to Create a Gateway Load Balancer.

Step 5 Add the control node to the Management Center. Refer to Onboard a Secure Firewall Threat Defense Cluster.

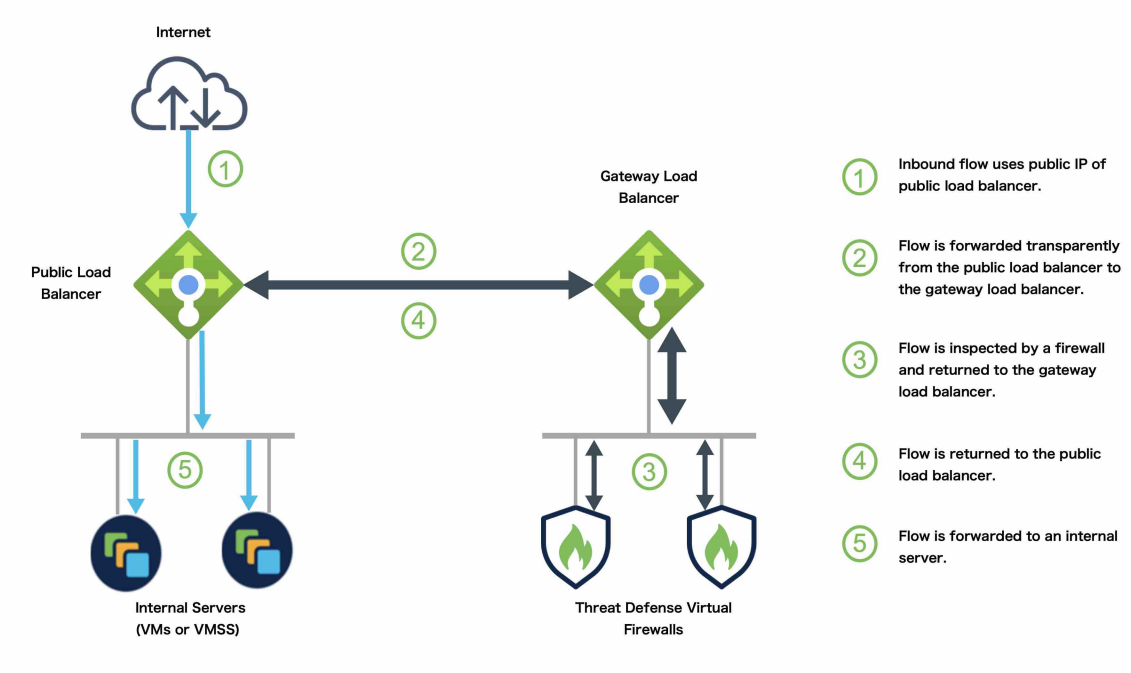
Deploy the cluster in Azure

You can use the cluster with the Azure Gateway Load Balancer (GWLB), or with a non-native load balancer. To deploy a cluster in Azure, use Azure Resource Manager (ARM) templates to deploy a Virtual Machine Scale Set.

Sample topology for GWLB-based cluster deployment

Sample topologies for deploying Gateway Load Balancer (GWLB) clusters are given below.

Figure 175: Inbound traffic use case and topology with GWLB



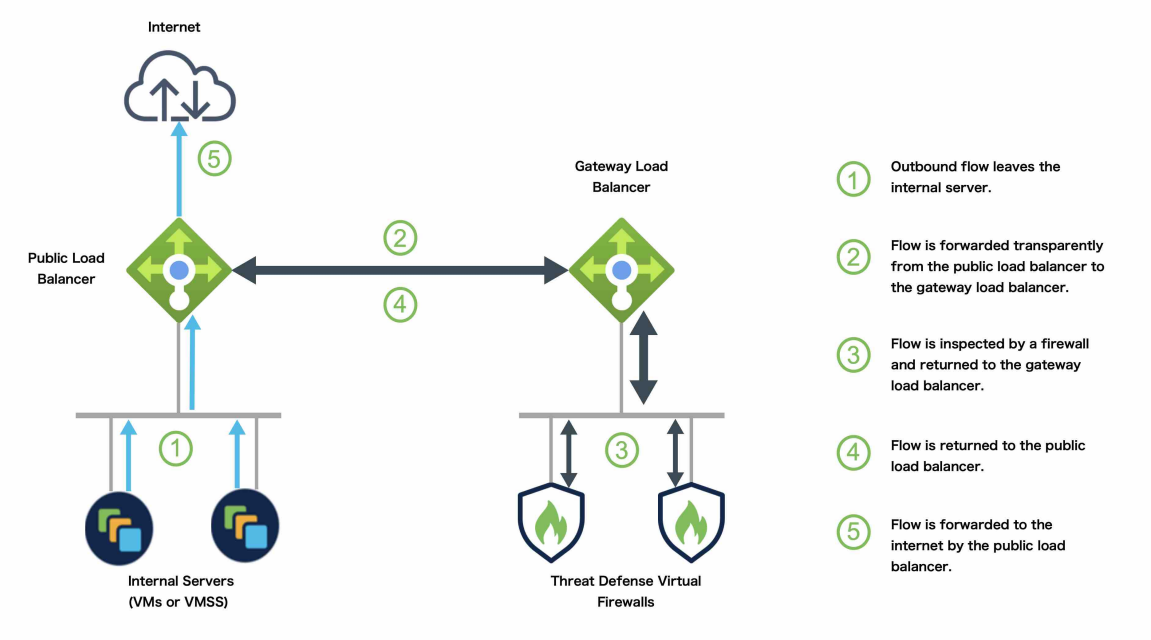


Figure 176: Outbound traffic use case and topology with GWLB

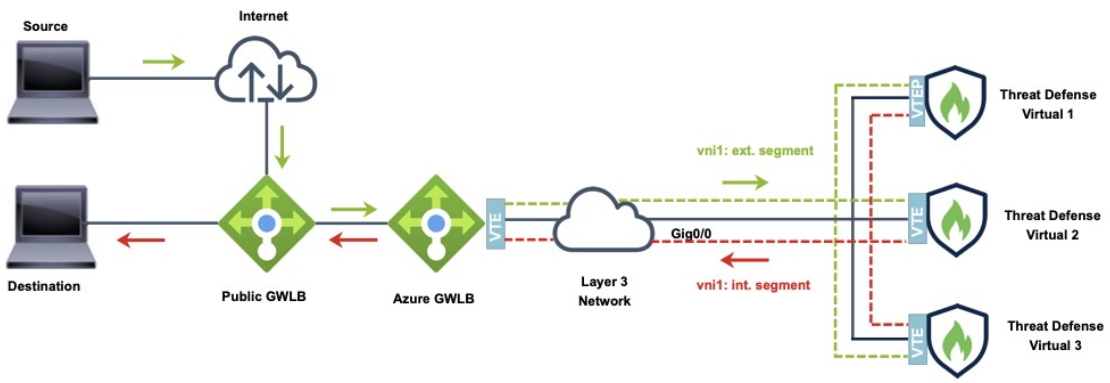
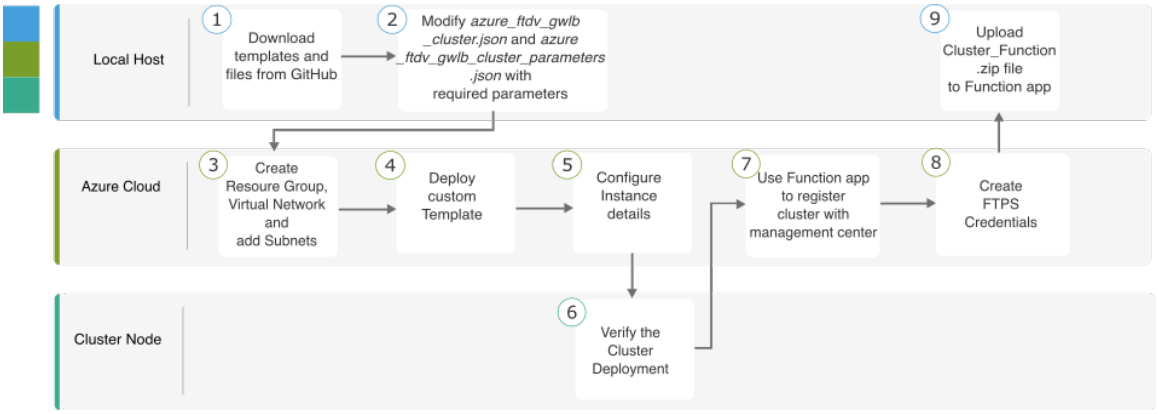


Azure gateway load balancer and paired proxy

In an Azure service chain, Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 177: Azure gateway load balancer with paired proxy



Traffic flow between GWLBe to GWLB (Geneve Single-Arm Proxy) in Azure

End-to-end process for deploying Threat Defense Virtual cluster in Azure with GWLB

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on Azure with GWLB using either template-based or manual deployment processes.

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Modify *azure_ftdv_gwlb_cluster.json* and *azure_ftdv_gwlb_cluster_parameters.json* with the required parameters.

	Workspace	Steps
3	Azure Cloud	Create the resource group, virtual network, and subnets.
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.
9	Local Host	Upload *Cluster_Function.zip* file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.
4	Local Host	Update scaling instance count.
5	Local Host	Configure GWLB.

	Workspace	Steps
6	Management Center	Add control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names and values given in the template.

Prerequisites for Azure GWLB cluster deployment

Complete these prerequisite tasks before deploying the Azure GWLB cluster.

- To allow the cluster to auto-register to the management center, create a user with Network Admin & Maintenance User privileges on the management center. Users with these privileges can use REST API. Refer to the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the management center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- Perform these steps after the cluster is added to the Management Center Virtual:
  1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, see Platform Settings.
  2. Create a static route for data traffic. For more information on creating a static route, see Add a Static Route.

     Sample static route configuration:

```
Network: any-ipv4
Interface: vxlan_tunnel
Leaked from Virtual Router: Global
Gateway: vxlan_tunnel_gw
Tunneled: false
Metric: 2
```

Note *vxlan_tunnel_gw* is the data subnet's gateway IP address.

Deploy cluster on Azure with GWLB using an Azure resource manager template

This task creates a clustered deployment of Firewall Threat Defense Virtual instances on Azure using Gateway Load Balancer (GWLB) through Azure Resource Manager templates.

Deploy the Virtual Machine Scale Set for Azure GWLB using the customized Azure Resource Manager (ARM) template. The templates mentioned in the steps below are available on GitHub.

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure.

b) Modify azure_ftdv_gwlb_cluster.json and azure_ftdv_gwlb_cluster_parameters.json with the required parameters.

Step 2 Log in to the Azure Portal: https://portal.azure.com.

Step 3 Create a Resource Group.

a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b) Choose the required **Region**.

Step 4 Create a virtual network with three subnets: Management, Data, and Cluster Control Link (CCL).

a) Create the virtual network.

1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
2. Choose the required **Region**. Click **Next: IP addresses**.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Data, and Cluster Control Link.

b) Add the subnets.

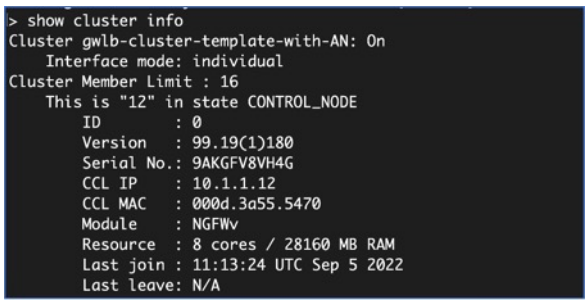
Step 5 Deploy the custom template.

a) Click **Create** > **Template deployment (deploy using custom templates)**.

b) Click **Build your own template in the editor**.

c) Click **Load File**, and upload **azure_ftdv_gwlb_cluster.json**.

d) Click **Save**.



Step 6 Configure the Instance details.

a) Enter the required values and then click **Review + create**.

b) Click **Create** after the validation is passed.

c) After the instance is running, verify the cluster deployment by logging into any one of the nodes and entering the **show cluster info** command.

Figure 178: Show cluster info

Step 7 In the Azure Portal, click the Function app to register the cluster with the Cloud-Delivered Firewall Management Center.

Note
If you do not want to use the Function app, you can alternatively register the control node to the Cloud-Delivered Firewall Management Center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 8 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 9 Upload the Cluster_Function.zip file to the Function app by executing the following **curl** command in the local terminal.

curl -X POST -u *username* **--data-binary @"Cluster_Function.zip" https://** *Function_App_Name***.scm.azurewebsites.net/api/zipdeploy**

Note
The **curl** command might take few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Figure 179: Functions

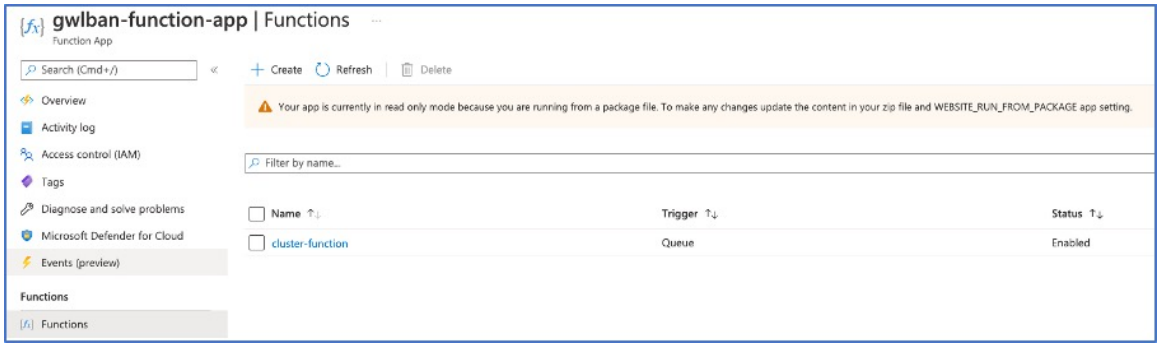


Figure 180: Queues

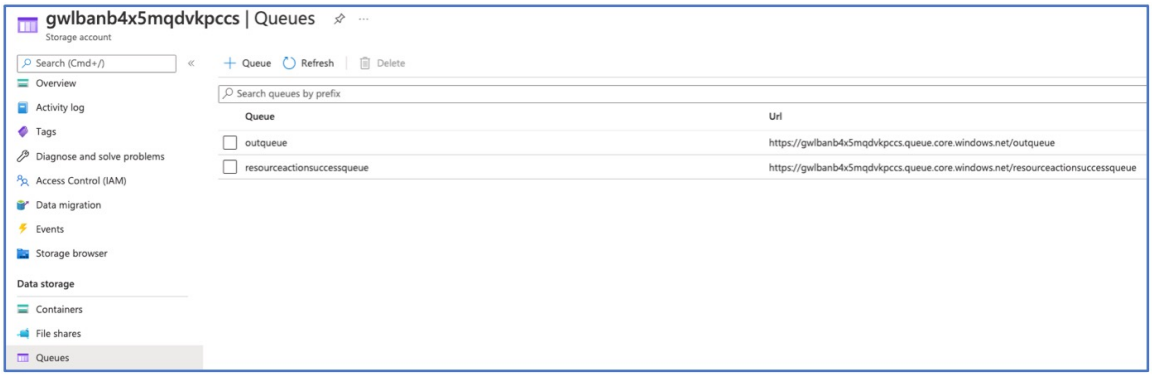

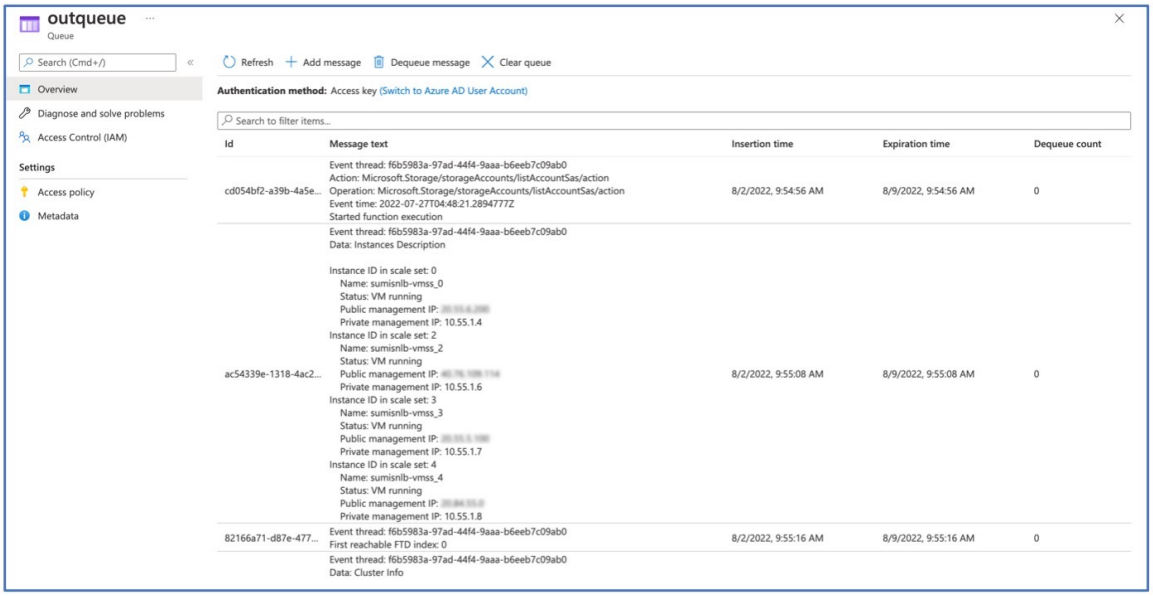

Figure 181: Outqueue

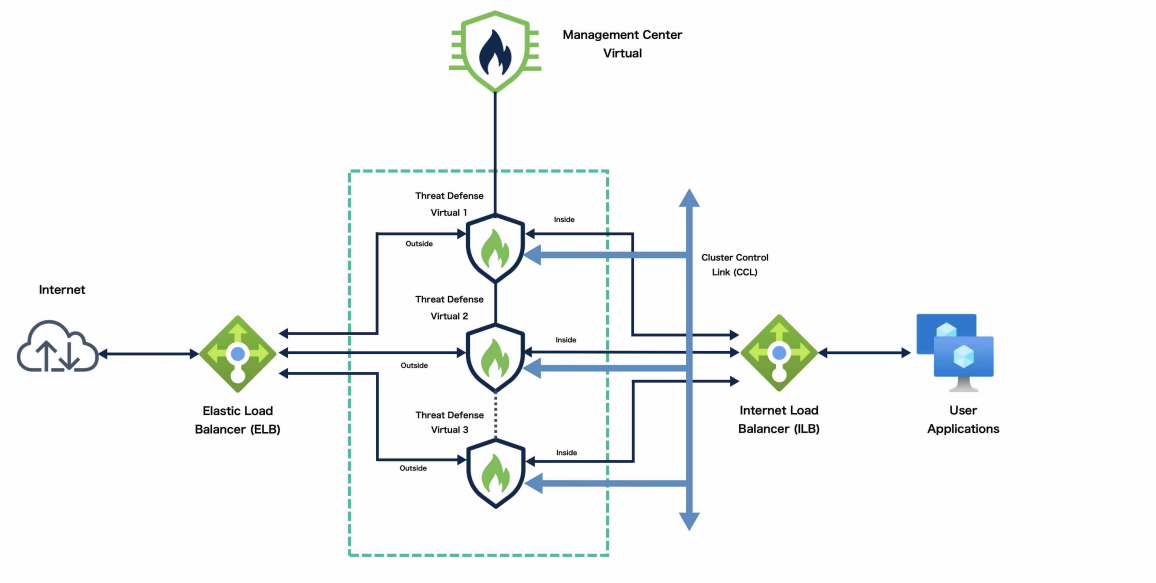
Sample topology for NLB-based cluster deployment



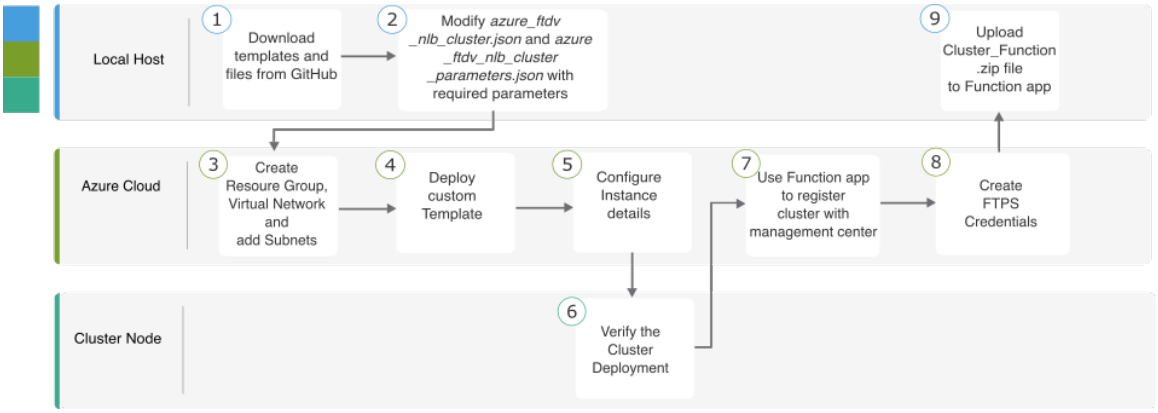
The sample topology provided here

- places the Threat Defense Virtual cluster between internal and external load balancers,
- uses a Management Center Virtual instance to manage the cluster, and
- depicts both inbound and outbound traffic flow patterns.

Traffic flow patterns

This topology shows how traffic moves through the network components:

- **Inbound traffic**: Traffic from the internet goes to the external load balancer, which transmits the traffic to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application virtual machine (VM).
- **Outbound traffic**: Traffic from the application VM is transmitted to the internal load balancer. Traffic is then forwarded to the Threat Defense Virtual cluster and then sent out to the internet.



End-to-end process for deploying Threat Defense Virtual cluster in Azure with NLB

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on Azure with NLB using either template-based or manual deployment processes.

Template-based Deployment

The following flowchart illustrates the workflow of template-based deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.

	Workspace	Steps
2	Local Host	Modify *azure_ftdv_nlb_cluster.json* and *azure_ftdv_nlb_cluster_parameters.json* with the required parameters.
3	Azure Cloud	Create the resource group, virtual network, and subnets.
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.
9	Local Host	Upload *Cluster_Function.zip* file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.
4	Local Host	Update scaling instance count.

	Workspace	Steps
5	Local Host	Configure NLB.
6	Management Center	Add control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names and values given in the template.

These templates provide the necessary components for cluster deployment:

Prerequisites for Azure NLB cluster deployment

Before deploying an Azure Network Load Balancer cluster, ensure that you complete these prerequisite tasks.

- To allow the cluster to auto-register with the Management Center, create a user with Network Admin & Maintenance User privileges on the Management Center. Users with these privileges can use REST API. Refer to the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the Management Center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- After the cluster is added to the Management Center Virtual, complete these configuration steps:
  1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, refer to Platform Settings.
  2. Create static routes for traffic from outside and inside interfaces. For more information on creating a static route, refer to Add a Static Route.

Important Configure static routes for both interface gateway paths when Azure Load Balancer health probes are enabled on both inside and outside interfaces of FTDv cluster nodes. Do not rely on a single default route. Azure health probes may arrive on either interface, so FTDv must respond using the correct interface path. Missing routing configuration can cause probe drops and load balancer health check failures. If SSH on port 22 is used as the health probe and SSH is enabled on both interfaces through Platform Settings, verify return path routing for both interfaces. Similarly, if HTTP is used as the health probe and HTTP or HTTPS is enabled on both interfaces through Platform Settings, verify return path routing for both interfaces.

Note Ensure that you do not configure your virtual network using the Microsoft-owned IP address range that includes 168.63.129.16. This configuration causes a conflict with the health probe's IP address. For more information, refer to Microsoft Azure design guidance.

Sample static route configuration for the outside interface:

```
Network: any-ipv4
Interface: outside
Leaked from Virtual Router: Global
Gateway: ftdv-cluster-outside
Tunneled: false
Metric: 10
```

Note *ftdv-cluster-outside* is the outside subnet's gateway IP address.

Sample static route configuration for the inside interface:

```
Network: any-ipv4
Interface: inside
Leaked from Virtual Router: Global
Gateway: ftdv-cluster-inside-gw
Tunneled: false
Metric: 11
```

Note *ftdv-cluster-inside-gw* is the inside subnet's gateway IP address.

3. Configure NAT rule for data traffic. For more information on configuring NAT rules, refer to Network Address Translation.

Deploy cluster on Azure with NLB using an Azure resource manager template

This task enables you to deploy a cluster for Azure NLB using the customized Azure Resource Manager (ARM) template for scalable network security.

Deploy the cluster for Azure NLB using the customized Azure Resource Manager (ARM) template. Note that the templates mentioned in the steps below are available on GitHub.

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure.

b) Modify azure_ftdv_nlb_cluster.json and azure_ftdv_nlb_cluster_parameters.json with the required parameters.

Step 2 Log in to the Azure Portal: https://portal.azure.com.

Step 3 Create a Resource Group.

a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
b) Choose the required **Region**.

Step 4 Create a virtual network with 5 subnets: Management, Diagnostic, Inside, Outside, and Cluster Control Link.

a) Create the virtual network.

1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
2. Choose the required **Region**. Click **Next: IP addresses**.

b) Add the subnets.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Diagnostic, Inside, Outside, and Cluster Control Link.

Step 5 Deploy the custom template.

a) Click **Create** > **Template deployment (deploy using custom templates)**.
b) Click **Build your own template in the editor**.
c) Click **Load File**, and upload **azure_ftdv_nlb_cluster.json**.
d) Click **Save**.

Step 6 Configure the instance details.

a) Enter the required values and then click **Review + create**.

Note
For the cluster control link starting and ending addresses, specify only as many addresses as you need (up to 16). A larger range can affect performance.

b) Click **Create** after the validation is passed.
c) After the instance is running, verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 182: Show cluster info

```
> show cluster info
Cluster gwlb-cluster-template-with-AN: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "12" in state CONTROL_NODE
        ID          : 0
        Version     : 99.19(1)180
        Serial No.: 9AKGFV8VH4G
        CCL IP      : 10.1.1.12
        CCL MAC     : 000d.3a55.5470
        Module      : NGFWv
        Resource    : 8 cores / 28160 MB RAM
        Last join : 11:13:24 UTC Sep 5 2022
        Last leave: N/A
```

Step 7 In the Azure Portal, click the Function app to register the cluster to the Cloud-Delivered Firewall Management Center.

Note

If you do not want to use the Function app, you can alternatively register the control node with the Management Center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 8 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 9 Upload the Cluster_Function.zip file to the Function app by executing the **curl** command in the local terminal.

curl -X POST -u *username* **--data-binary @"Cluster_Function.zip" https://** *Function_App_Name***.scm.azurewebsites.net/api/zipdeploy**

Note
The **curl** command might take a few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Manual cluster deployment in Azure

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the Cloud-Delivered Firewall Management Center .

Create the Day0 configuration for Azure

You can use either a fixed configuration or a customized configuration.

Create the Day0 configuration with a fixed configuration for Azure

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end",
"ClusterGroupName": "cluster_name",
"HealthProbePort": "port_number",
"GatewayLoadBalancerIP": "ip_address",
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Example

A sample day 0 configuration is given below.

```
"Cluster": {
"CclSubnetRange": "10.45.3.4 10.45.3.30",     //mandatory user input
"ClusterGroupName": "ngfwv-cluster",          //mandatory user input
"HealthProbePort": "7777",                    //mandatory user input
"GatewayLoadBalancerIP": "10.45.2.4",         //mandatory user input
"EncapsulationType": "vxlan",
"InternalPort": "2000",
```

```
"ExternalPort": "2001",
"InternalSegId": "800",
"ExternalSegId": "801"
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration

For the Azure health check settings, be sure to specify the **HealthProbePort** you set here.

For the **CclSubnetRange** variable, specify a range of IP addresses starting from x.x.x.4. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Note All cluster infrastructure subnets must use /27 CIDR

Table 58: Examples of start and end IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.4	10.1.1.30
10.1.1.32/27	10.1.1.36	10.1.1.62
10.1.1.64/27	10.1.1.68	10.1.1.94
10.1.1.96/27	10.1.1.100	10.1.1.126
10.1.1.128/27	10.1.1.132	10.1.1.158
10.1.1.160/27	10.1.1.164	10.1.1.190
10.1.1.192/27	10.1.1.196	10.1.1.222
10.1.1.224/27	10.1.1.228	10.1.1.254

Create the Day0 configuration with a customized configuration for azure

You can enter the entire cluster bootstrap configuration using commands.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end",
"ClusterGroupName": "cluster_name",
"HealthProbePort": "port_number",
"GatewayLoadBalancerIP": "ip_address",
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Deploy cluster nodes manually - GWLB-based deployment

This task allows you to deploy cluster nodes so they form a cluster in Azure using Gateway Load Balancer-based deployment.

Deploy the cluster nodes so they form a cluster.

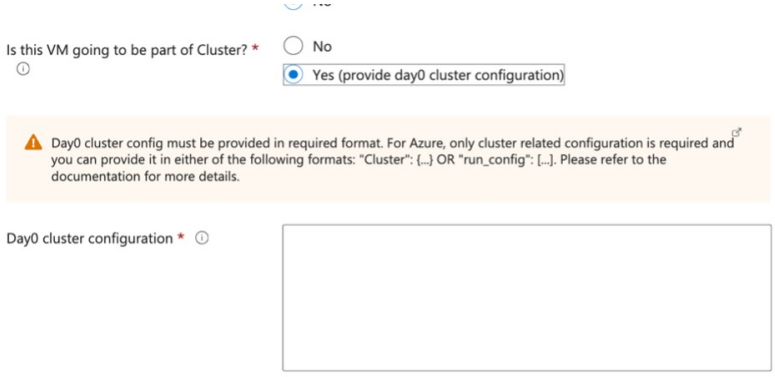
Procedure

Step 1 Log in to the Azure Portal: https://portal.azure.com

Step 2 Create a Resource Group.

a. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b. Choose the required **Region**.



Step 3 Create a Virtual Network with the necessary subnets: Management, Data and Cluster Control Link (CCL).

Note
Configure the CCL with the smallest subnet mask as required. Wider subnets can impact performance.

Refer to the Azure document for creating the Virtual Network and subnet: https://learn.microsoft.com/en-us/azure/virtual-network/quickstart-create-virtual-network?tabs=portal

Step 4 Go to the Marketplace and search for **Cisco Secure Firewall Threat Defense Virtual – BYOL and PAYG** and click **Create**.

Step 5 Fill the required details and choose **Yes** for **Is this VM going to be part of Cluster?**

Paste the following cluster-related configuration in the text box.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end", //mandatory user input
"ClusterGroupName": "cluster_name", //mandatory user input
"HealthProbePort": "port_number", //mandatory user input
"GatewayLoadBalancerIP": "ip_address",  //mandatory user input
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

a) Click **Next** and select the **Virtual Network & Subnets**.
b) Click **Review + create**. Wait for the Threat Defense Virtual deployment to complete.

Step 6 Connect to the Threat Defense Virtual device and use the **show cluster info** command to confirm the cluster formation is successful.

```
> show cluster info
Cluster ngfwv-cluster: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "4" in state CONTROL_NODE
        ID        : 0
        Version   : 9.23(1)
        Serial No.: 9AC1VMGJKAQ
        CCL IP    : 169.254.200.4
        CCL MAC   : 6045.bda8.e07b
        Module    : NGFWv
        Resource  : 4 cores / 14336 MB RAM
        Last join : 05:22:55 UTC Jul 14 2025
        Last leave: N/A
Other members in the cluster:
    There is no other unit in the cluster
>
```

Step 7 Configure the Azure Gateway Load Balancer. Refer to Auto Scale with Azure Gateway Load Balancer Use Case for more information.

Step 8 Add the control node to the Cloud-Delivered Firewall Management Center. See Onboard a Secure Firewall Threat Defense Cluster.

Deploy cluster nodes manually - NLB-based deployment

Deploy cluster nodes manually to establish a functional cluster configuration in Azure using NLB-based deployment.

Deploy the cluster nodes so they form a cluster.

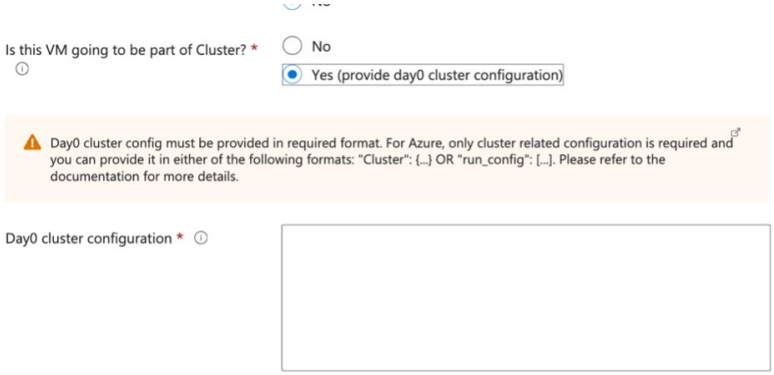
Procedure

Step 1 Log in to the Azure Portal: https://portal.azure.com

Step 2 Create a Resource Group.

a. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b. Choose the required **Region**.



Step 3 Create a Virtual Network with the necessary subnets: Management, Inside, Outside and Cluster Control Link (CCL).

Note
Configure the CCL with the smallest subnet mask as required. Wider subnets can impact performance.

Refer to the Azure document for creating the Virtual Network and subnet: https://learn.microsoft.com/en-us/azure/virtual-network/quickstart-create-virtual-network?tabs=portal

Step 4 Go to the Marketplace and search for **Cisco Secure Firewall Threat Defense Virtual – BYOL and PAYG** and click **Create**.

Step 5 Fill the required details and choose **Yes** for **Is this VM going to be part of Cluster?**

Paste the following cluster-related configuration in the text box.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end", //mandatory user input
"ClusterGroupName": "cluster_name" //mandatory user input
}
```

Step 6 Click **Next** and select the **Virtual Network & Subnets**.

Step 7 Click **Review + create**. Wait until the Threat Defense Virtual deployment is completed.

Step 8 Connect to the Threat Defense Virtual device and use the **show cluster info** command to confirm the cluster formation is successful.

```
> show cluster info
Cluster ngfwv-cluster: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "4" in state CONTROL_NODE
        ID          : 0
        Version     : 9.23(1)
        Serial No.: 9AC1VMGJKAQ
        CCL IP      : 169.254.200.4
        CCL MAC     : 6045.bda8.e07b
        Module      : NGFWv
        Resource    : 4 cores / 14336 MB RAM
        Last join : 05:22:55 UTC Jul 14 2025
        Last leave: N/A
Other members in the cluster:
    There is no other unit in the cluster
>
```

Step 9 Add the control node to the Management Center. Refer to Onboard a Secure Firewall Threat Defense Cluster.

Troubleshoot cluster deployment in Azure

This reference provides troubleshooting guidance for resolving common issues that may occur during cluster deployment in Azure, including traffic flow problems, cluster formation failures, and role assignment errors.

- Issue: No traffic flow

Troubleshooting:

- Check if the health probe status of the Threat Defense Virtual instances deployed with a GWLB is healthy.
- If the Threat Defense Virtual instance's health probe status is unhealthy-
  - Check if the static route is configured in the Management Center Virtual.
  - Check if the default gateway is the data subnet's gateway IP address.
  - Check if the Threat Defense Virtual instance is receiving health probe traffic.
  - Check if the access list configured in the Management Center Virtual allows health probe traffic.

- Issue: Cluster is not formed

  Troubleshooting:

  - Check the IP address of the NVE-only cluster interface. Ensure that you can ping the NVE-only cluster interface of other nodes.
  - Check the IP address of the NVE-only cluster interfaces are part of the object group.
  - Ensure that the NVE interface is configured with the object group .
  - Ensure that the cluster interface in the cluster group has the right VNI interface. This VNI interface has the NVE with the corresponding object group.
  - Ensure that the nodes are pingable from each other. Since each node has its own cluster interface IP, these should be pingable from each other.
  - Check if the CCL subnet's start and end address mentioned during template deployment is correct. The start address should begin with the first available IP address in the subnet. For example, if the subnet is 192.168.1.0/27. The start address should be 192.168.1.4 (the three IP addresses at the start are reserved by Azure).
  - Check if the Management Center Virtual has a valid license.

- Issue: Role-related error while deploying resources again in the same resource group.

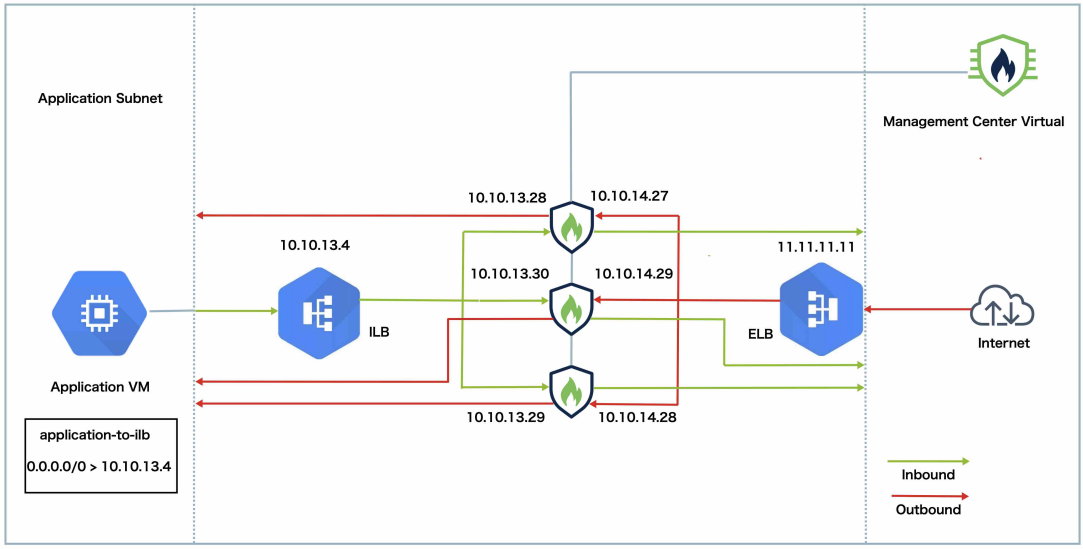
  Troubleshooting: Remove the roles given below by using these commands on the terminal.

  Error message:

```
"error": {
"code": "RoleAssignmentUpdateNotPermitted",
"message": "Tenant ID, application ID, principal ID, and scope are not allowed to be
updated."}
```

  - **az role assignment delete --resource-group** <*Resource Group Name*> **--role "Storage Queue Data Contributor"**
  - **az role assignment delete --resource-group** <*Resource Group Name*> **--role "Contributor"**

Deploy the cluster in GCP



To deploy a cluster in GCP, you can either manually deploy or use an instance template to deploy an instance group. You can use the cluster with native GCP load balancers or non-native load balancers such as the Cisco Cloud Services Router.

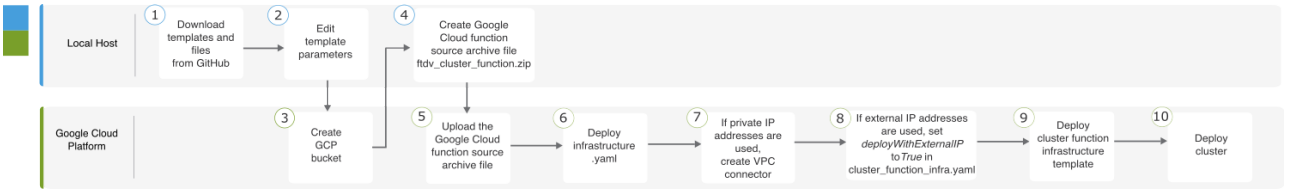
Note Outbound traffic requires interface NAT and is limited to 64,000 connections.

Sample topology for GCP clustering autoscale solution

Understand the architecture and traffic flow of a typical GCP clustering autoscale deployment.

Figure 183: Sample Topology

The topology shows both inbound and outbound traffic flow.

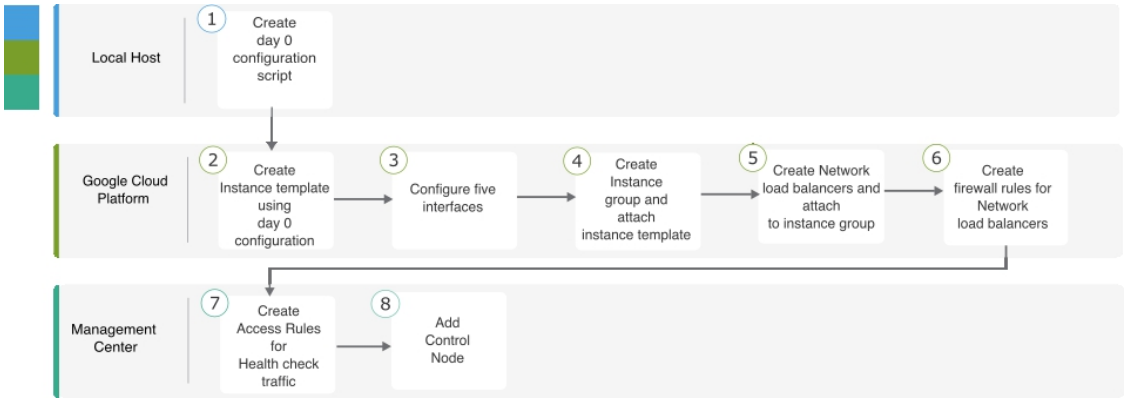


1. The Threat Defense Virtual cluster is placed between the internal and external load balancers. A Management Center Virtual instance is used to manage the cluster.
2. Inbound traffic from the internet goes to the external load balancer, which then transmits the traffic to the Threat Defense Virtual cluster.
3. The Threat Defense Virtual instance in the cluster inspects the traffic, and after inspection, forwards the traffic to the application VM.
4. Outbound traffic from the application VM goes to the internal load balancer. The load balancer forwards this traffic to the Threat Defense Virtual cluster, which sends it to the internet.

End-to-end process for deploying Threat Defense Virtual cluster in GCP

Provides a workflow to help users successfully deploy and verify a Threat Defense Virtual cluster on GCP using either template-based or manual deployment processes.

Template-based Deployment



The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Edit template parameters.
3	Google Cloud Platform	Create GCP bucket.
4	Local Host	Create Google Cloud function source archive file *ftdv_cluster_function.zip*.
5	Google Cloud Platform	Upload the Google function source archive file.
6	Google Cloud Platform	Deploy infrastructure.yaml.
7	Google Cloud Platform	If private IP addresses are used, create VPC connector.
8	Google Cloud Platform	If external IP addresses are used, set *deployWithExternalIP* to *True* in *cluster_function_infra.yaml*.
9	Google Cloud Platform	Deploy cluster function infrastructure template.
10	Google Cloud Platform	Deploy cluster.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Create day 0 configuration script.
2	Google Cloud Platform	Create instance template using day 0 configuration.
3	Google Cloud Platform	Configure the interfaces.
4	Google Cloud Platform	Create instance group and attach instance template.
5	Google Cloud Platform	Create NLB and attach to instance group.
6	Google Cloud Platform	Create firewall rules for NLB.
7	Management Center	Create access rules for health check traffic.
8	Management Center	Add control node.

Templates

The templates are available in GitHub. The parameter values are self-explanatory with the parameter names and values given in the template.

- Cluster deployment template for East-West traffic - deploy_ngfw_cluster_yaml
- Cluster deployment template for North-South traffic - deploy_ngfw_cluster.yaml

Deploy the instance group in GCP using an instance template

Deploy a scalable instance group in Google Cloud Platform using pre-configured instance templates to establish a Secure Firewall cluster with automated management capabilities.

Deploy the instance group in GCP using an instance template.

Before you begin

- Download the templates from GitHub to your local folder.
- Use Google Cloud Shell for deployment. Alternatively, you can use Google SDK on any macOS/Linux/Windows machine.
- To allow the cluster to auto-register with the Management Center, you need to create a user with administrative privileges on the Management Center that can use the REST API. See the *Cisco Secure Firewall Management Center Administration Guide*.
- Add an access policy in the Management Center that matches the name of the policy that you specified in *cluster_function_infra.yaml*.

Procedure

Step 1 Edit the **infrastructure.yaml**, **cluster_function_infra.yaml** and **deploy_ngfw_cluster.yaml** templates with the required *resourceNamePrefix* parameter (for example, ngfwvcls) and other required user inputs.

Note that there is a **deploy_ngfw_cluster.yaml** file in both the **east-west** and **north-south** folders in GitHub. Download the appropriate template as per your traffic flow requirement.

Step 2 Create a bucket using Google Cloud Shell to upload the Google cloud function source archive file *ftdv_cluster_function.zip*.

gsutil mb --pap enforced gs://*resourceNamePrefix***-ftdv-cluster-bucket/**

Ensure that the *resourceNamePrefix* variable here matches the *resourceNamePrefix* variable that you specified in **cluster_function_infra.yaml**.

Step 3 Create an archive file for the cluster infrastructure.

Example:

```
zip -j ftdv_cluster_function.zip ./cluster-function/*
```

Step 4 Upload the Google source archive that you created earlier.

gsutil cp ftdv_cluster_function.zip gs://*resourceNamePrefix***-ftdv-cluster-bucket/**

Step 5 Deploy infrastructure for the cluster.

gcloud deployment-manager deployments create *cluster_name* **--config infrastructure.yaml**

Step 6 If you are using private IP addresses, perform the steps given below:

a) Launch and set up the Management Center Virtual with a Threat Defense Virtual management VPC.

b) Create a VPC connector to connect the Google Cloud functions with the Threat Defense Virtual management VPC.

gcloud compute networks VPC-access connectors create *VPC-connector-name* **--region us-central1 --subnet** *resourceNamePrefix***-ftdv-mgmt-subnet28**

Step 7 If the Management Center is remote from the Threat Defense Virtual, and the Threat Defense Virtual needs an external IP address, ensure that you set **deployWithExternalIP** to **True** in **cluster_function_infra.yaml**.

Step 8 Deploy the cluster function infrastructure.

gcloud deployment-manager deployments create *cluster_name* **--config cluster_function_infra.yaml**

Step 9 Deploy the cluster.

a. For North-South topology deployment:

gcloud deployment-manager deployments create *cluster_name* **--config north-south/deploy_ngfw_cluster.yaml**

b. For East-West topology deployment:

gcloud deployment-manager deployments create *cluster_name* **--config east-west/deploy_ngfw_cluster.yaml**

Manual cluster deployment in GCP

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the Cloud-Delivered Firewall Management Center .

Create the Day0 configuration with a fixed configuration for GCP

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
                "Diagnostic": "OFF",
    "Cluster": {
        "CclSubnetRange": "ip_address_start ip_address_end",
        "ClusterGroupName": "cluster_name"
    }
}
```

For example:

```
{
    "AdminPassword": "DeanW1nche$ter",
    "Hostname": "ciscoftdv",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "Cluster": {
        "CclSubnetRange": "10.10.55.2 10.10.55.253",     //mandatory user input
        "ClusterGroupName": "ftdv-cluster"               //mandatory user input
    }
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

For the **CclSubnetRange** variable, note that you cannot use the first two IP addresses and the last two IP addresses in the subnet. See Reserved IP addresses in IPv4 subnets for more information. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Note All cluster infrastructure subnets must use /27 CIDR.

Table 59: Examples of start and end IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.2	10.1.1.29
10.1.1.32/27	10.1.1.34	10.1.1.61
10.1.1.64/27	10.1.1.66	10.1.1.93
10.1.1.96/27	10.1.1.98	10.1.1.125
10.1.1.128/27	10.1.1.130	10.1.1.157
10.1.1.160/27	10.1.1.162	10.1.1.189
10.1.1.192/27	10.1.1.194	10.1.1.221
10.1.1.224/27	10.1.1.226	10.1.1.253

Deploy cluster nodes manually

Deploy cluster nodes to form a functional cluster on Google Cloud Platform (GCP) with proper network load balancing and management integration.

Deploy the cluster nodes so they form a cluster. For clustering on GCP, you cannot use the 4 vCPU machine type. The 4 vCPU machine type only supports four interfaces, and five are needed. Use a machine type that supports five interfaces, such as c2-standard-8.

Procedure

Step 1 Create an instance template using the day 0 configuration (in the **Metadata** > **Startup Script** section) with 5 interfaces: outside, inside, management, diagnostic, and cluster control link.

See Secure Firewall Threat Defense Virtual getting started guides.

Step 2 Create an instance group, and attach the instance template.

Step 3 Create GCP network load balancers (internal and external), and attach the instance group.

Step 4 For GCP network load balancers, allow health checks in your security policy on the Management Center. Refer to Allow health checks for GCP network load balancers, on page 897.

Step 5 Add the control node to the Management Center. Refer to Onboard a Secure Firewall Threat Defense Cluster.

Allow health checks for GCP network load balancers

Google Cloud provides health checks to determine if backends respond to traffic. This configuration allows health check traffic through firewall rules and access rules, redirects health check traffic to the Google metadata server using dynamic manual NAT rules, and sets up routing for GCP health checks across all interfaces used for health probes.

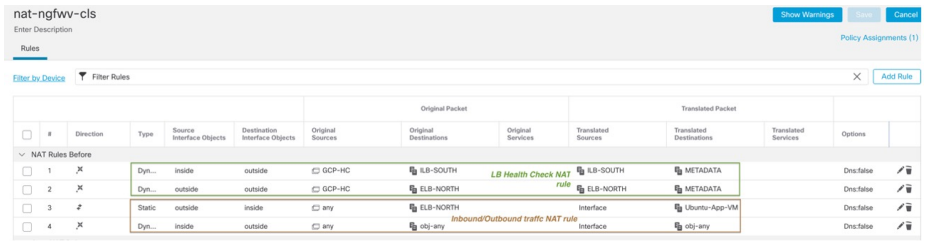
Configuration requirements

Refer to https://cloud.google.com/load-balancing/docs/health-checks to create firewall rules for network load balancers. Then in the Cloud-Delivered Firewall Management Center, create access rules to allow the health check traffic. See https://cloud.google.com/load-balancing/docs/health-check-concepts for the required network ranges. See Access Control Rules, on page 2041.

You also need to configure dynamic manual NAT rules to redirect the health check traffic to the Google metadata server at 169.254.169.254. See Configure dynamic manual NAT, on page 1596.

You can set up a route for GCP health checks across all interfaces that are used to configure their health probes. You can achieve this by creating a route with a higher metric on interfaces where a route for GCP health checks is not already available.

North-South NAT rules sample configuration



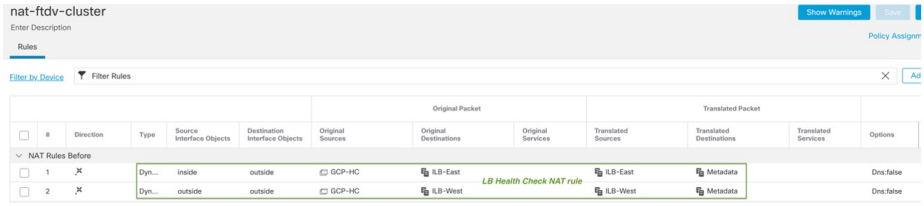
```
nat (inside,outside) source dynamic GCP-HC ILB-SOUTH destination static ILB-SOUTH METADATA
nat (outside,outside) source dynamic GCP-HC ELB-NORTH destination static ELB-NORTH METADATA

nat (outside,inside) source static any interface destination static ELB-NORTH Ubuntu-App-VM
nat (inside,outside) source dynamic any interface destination static obj-any obj-any

object network Metadata
 host 169.254.169.254

object network ILB-SOUTH
host <ILB_IP>
object network ELB-NORTH
host <ELB_IP>

object-group network GCP-HC
 network-object 35.191.0.0 255.255.0.0
 network-object 130.211.0.0 255.255.252.0
 network-object 209.85.204.0 255.255.252.0
 network-object 209.85.152.0 255.255.252.0
```



East-West NAT rules sample configuration

```
nat (inside,outside) source dynamic GCP-HC ILB-East destination static ILB-East Metadata
nat (outside,outside) source dynamic GCP-HC ILB-West destination static ILB-West Metadata
```

```
object network Metadata
 host 169.254.169.254

object network ILB-East
host <ILB_East_IP>
object network ILB-West
host <ILB_West_IP>

object-group network GCP-HC
 network-object 35.191.0.0 255.255.0.0
 network-object 130.211.0.0 255.255.252.0
 network-object 209.85.204.0 255.255.252.0
 network-object 209.85.152.0 255.255.252.0
```

North-South and East-West traffic routing configuration sample

```
route outside 0.0.0.0 0.0.0.0 <Outside_Gateway> 1
route inside 35.191.0.0 255.255.0.0 <Inside_Gateway> 1
route inside 130.211.0.0 255.255.252.0 <Inside_Gateway> 1
route inside 209.85.152.0 255.255.252.0 <Inside_Gateway> 1
route inside 209.85.204.0 255.255.252.0 <Inside_Gateway> 1
```

If a default route is not available, then policy-based routing can be used to route the traffic for health checks.

Note Set the NAT > Translated destination port to 80.

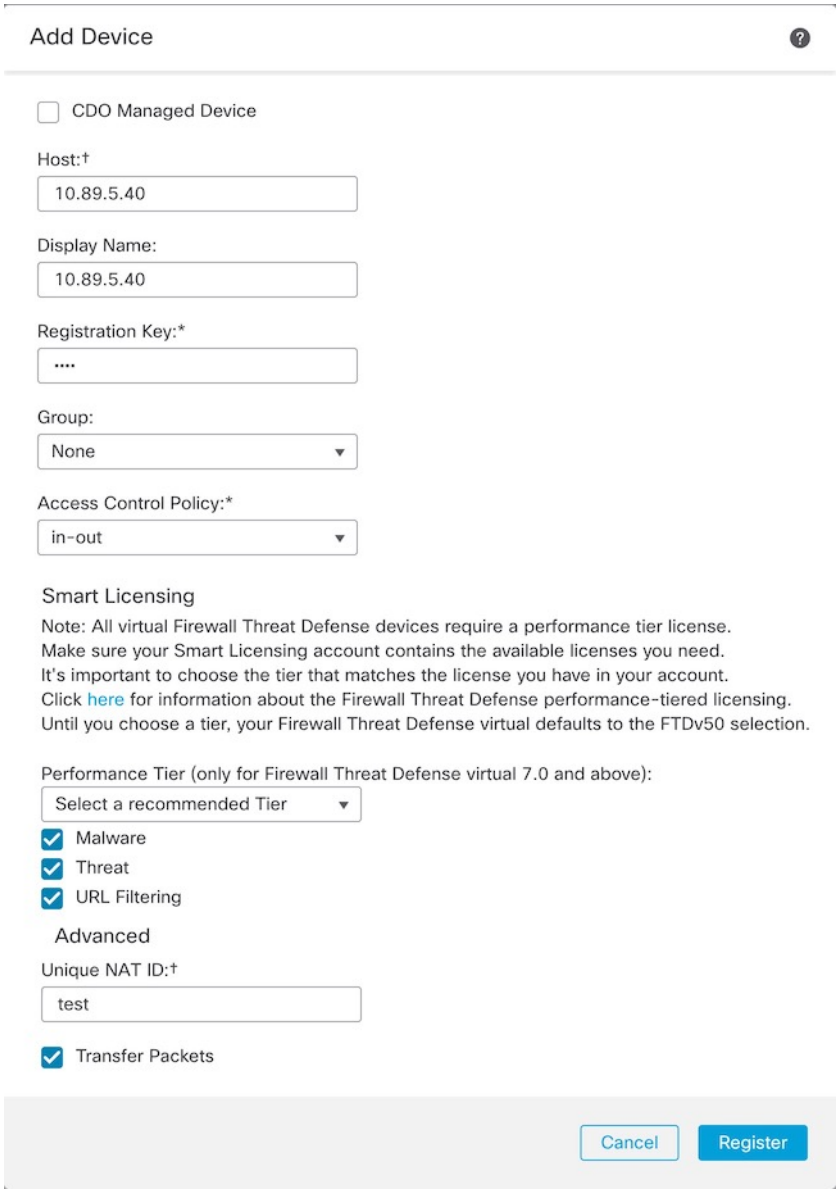
Add the cluster to the Management Center (manual deployment)

This task registers a manually deployed cluster with the Cloud-Delivered Firewall Management Center to enable centralized management and configuration of the cluster units.

Use this procedure to add the cluster to the Cloud-Delivered Firewall Management Center if you manually deployed the cluster. If you used a template, the cluster will auto-register on the Cloud-Delivered Firewall Management Center.

Add one of the cluster units as a new device to the Cloud-Delivered Firewall Management Center; the Cloud-Delivered Firewall Management Center automatically detects all other cluster members.

Before you begin



- All cluster units must be in a successfully formed cluster before adding the cluster to the Cloud-Delivered Firewall Management Center. You should also check which unit is the control unit. Use the Firewall Threat Defense **show cluster info** command.

Follow these steps to add the cluster to the Management Center for manual deployment:

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address.

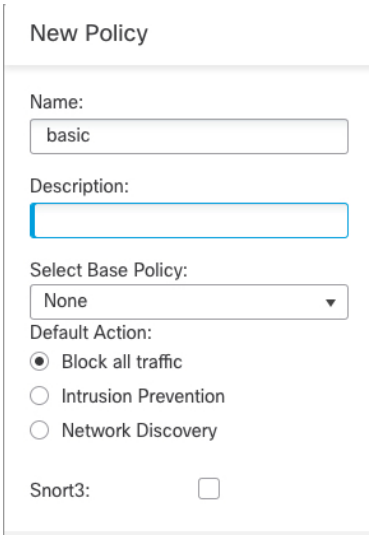
Figure 184: Add device

a) In the **Host** field, enter the IP address or hostname of the control unit.

We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

If you used a NAT ID during device setup, you may not need to enter this field.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the Cloud-Delivered Firewall Management Center.



This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used during device setup. The registration key is a one-time-use shared secret.

d) (Optional) Add the device to a device **Group**.

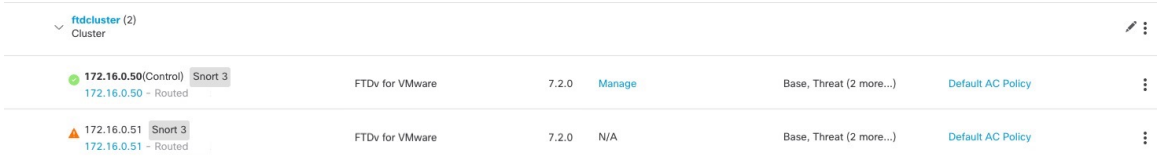
e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

f) Choose licenses to apply to the device.

g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.

h) Check the **Transfer Packets** check box to allow the device to transfer packets to the Cloud-Delivered Firewall Management Center.



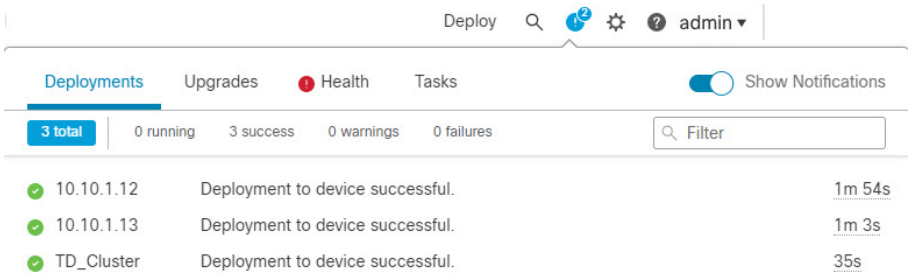
This option is enabled by default. When events such as IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the Cloud-Delivered Firewall Management Center for inspection. If you disable it, only event information will be sent to the Cloud-Delivered Firewall Management Center, but packet data is not sent.

i) Click **Register**.

The Cloud-Delivered Firewall Management Center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.

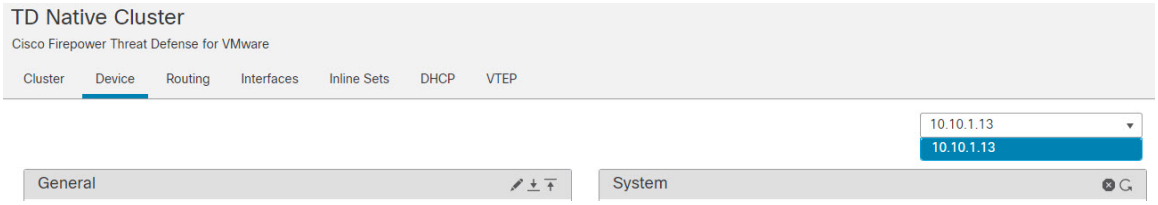
The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

Figure 185: Cluster management



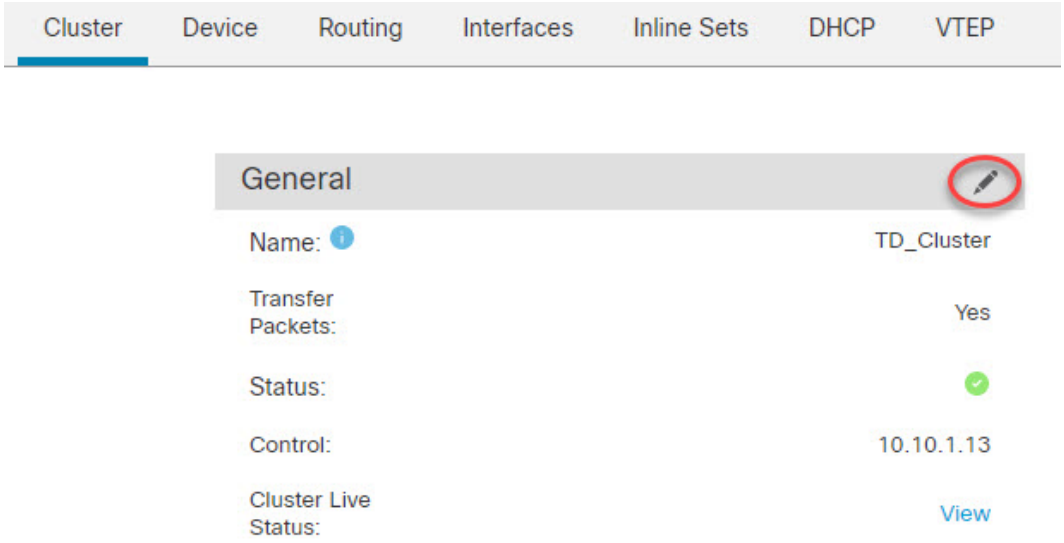
A unit that is currently registering shows the loading icon.

Figure 186: Node registration



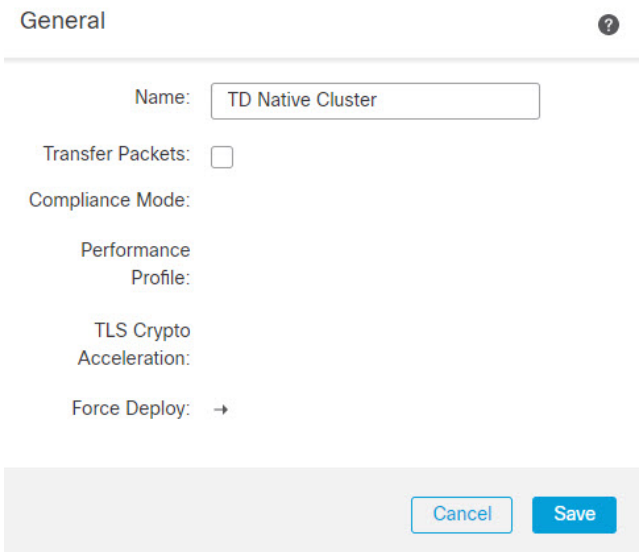
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The Cloud-Delivered Firewall Management Center updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile Cluster Nodes, on page 911.

Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

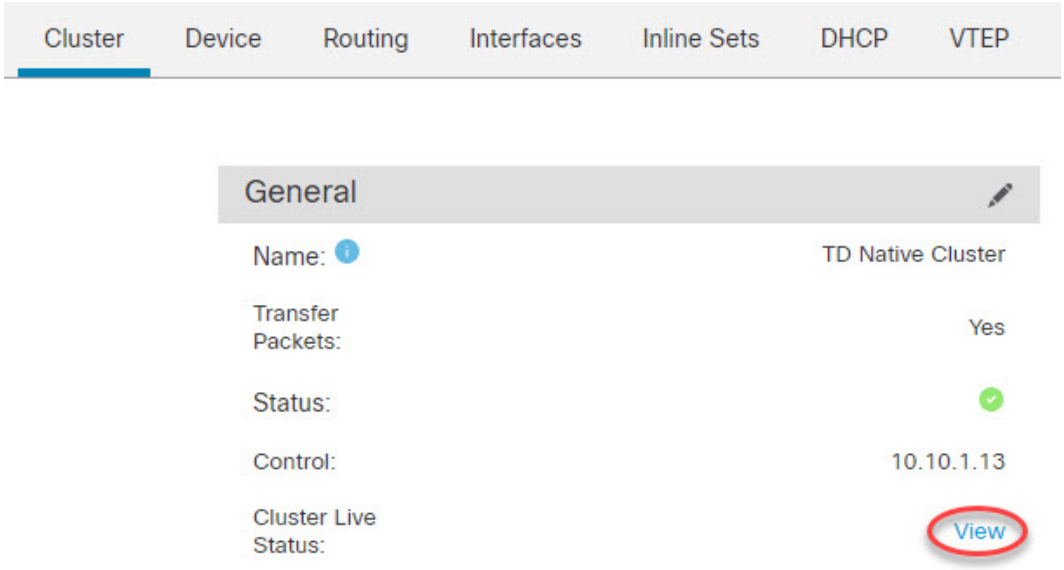


Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

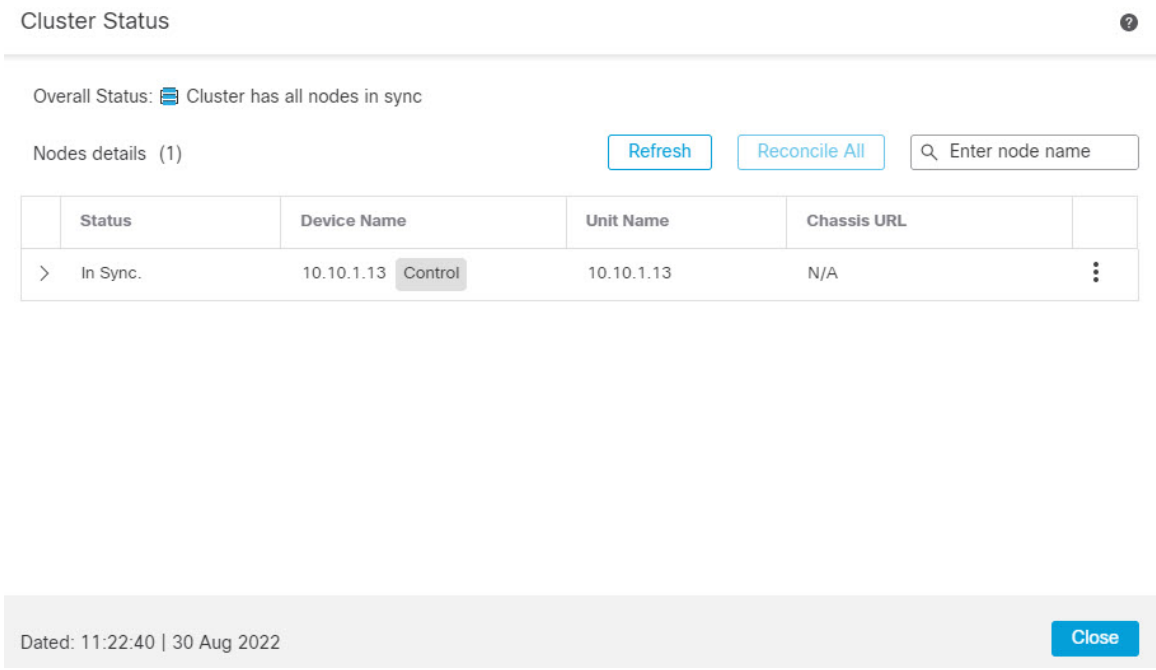
Step 3 On the **Devices** > **Device Management** and then choose **Add**, **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.



See these cluster-specific items:

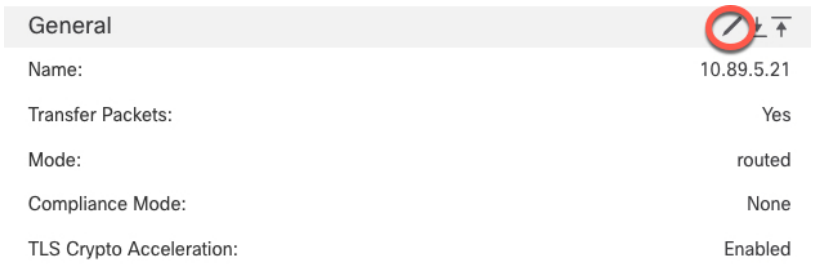


- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).

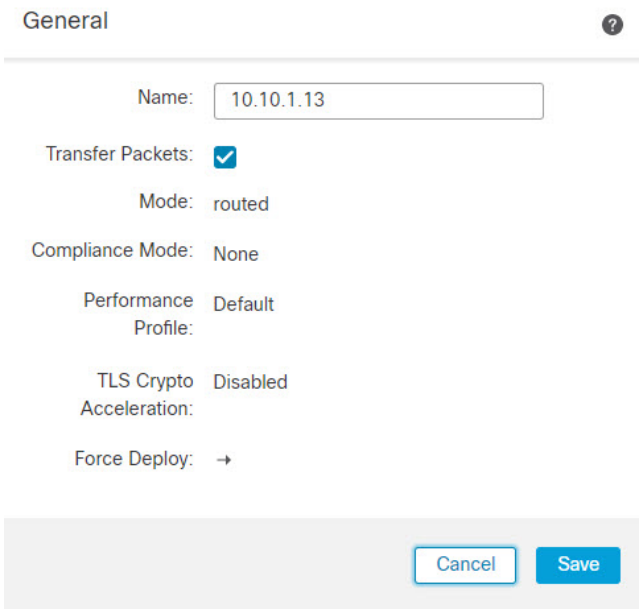


Then set the **Name** field.

- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.

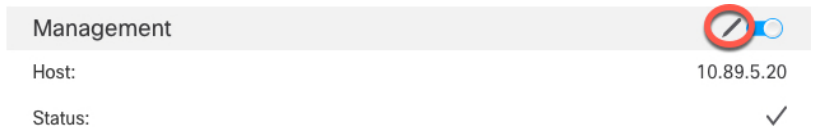


The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.



- **License**—Click **Edit** (✎) to set license entitlements.

Step 4 On the **Devices** > **Device Management** and then click **Add** > **Device**, you can choose each member in the cluster from the top right drop-down menu and configure these settings.



- **General > Name**—Change the cluster member display name by clicking the **Edit** (✎).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Cloud-Delivered Firewall Management Center so that it can reach the device on the network; edit the **Host** address in the **Management** area.

Onboard a Secure Firewall Threat Defense Cluster

This task enables you to register a Secure Firewall Threat Defense cluster with Cloud-Delivered Firewall Management Center for centralized management and policy enforcement.

The following table provides information about device models that support cluster onboarding and creation on the Cloud-Delivered Firewall Management Center:

Secure Firewall Threat Defense Platforms	Minimum Secure Firewall Threat Defense Version for Cluster Management	Support cluster creation from Cloud-Delivered Firewall Management Center?
VMware, KVM	7.2.1	Yes
AWS, GCP	7.2.1	No
Azure	7.3	No
Secure Firewall 3100	7.2.1	Yes
Firepower 4100	7.2.x	No
Secure Firewall 4200	7.4	Yes
Firepower 9300	7.2.x	No

Note When you onboard a Secure Firewall Threat Defense cluster to Cloud-Delivered Firewall Management Center, you register only the cluster CONTROL NODE. After the CONTROL NODE registers, Cloud-Delivered Firewall Management Center discovers the DATA nodes in the cluster.

Before you begin

Review these limitations:

- Firepower 4100 and Firepower 9300 devices must be clustered through the device's Firewall Chassis Manager.
- Secure Firewall 3100 devices, Secure Firewall 4200 devices, KVM, and VMware environments must be clustered through the Cloud-Delivered Firewall Management Center UI.
- Azure, AWS, and GCP environment clusters must be created through their own environment and onboarded to Cloud-Delivered Firewall Management Center.
- Verify that the Secure Firewall Threat Defense virtual devices are successfully configured as a cluster before you register the cluster with Cloud-Delivered Firewall Management Center.

  For example, in the Secure Firewall Threat Defense CLI, enter the `show cluster info` command. Confirm that the output shows the cluster as `On`, one unit in `CONTROL_NODE` state, and the remaining units in `DATA_NODE` state.

```
> show cluster info
Cluster mAZ-ngfw-cl: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "74-a" in state DATA_NODE
        ID        : 2
        Version   : 9.22(1)1
        Serial No.: 9AUVQ3DSF66
        CCL IP    : 1.1.1.74
        CCL MAC   : 02e2.778f.d3ed
        Module    : NGFWv
        Resource  : 4 cores / 7680 MB RAM
        Last join : 07:28:26 UTC Sep 25 2024
        Last leave: 07:28:11 UTC Sep 25 2024
Other members in the cluster:
    Unit "135-b" in state CONTROL_NODE
        ID        : 0
        Version   : 9.22(1)1

```

Follow these steps to onboard a Secure Firewall Threat Defense cluster:

Procedure

Step 1 In the left pane, click **Security Devices**.

Step 2 Click **Onboard device or service** ( ) icon.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Select **Use CLI Registration Key**.

Step 6 Enter the device name in the **Device Name** field and click **Next**.

Step 7 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 8 Specify whether the device you are onboarding is a physical or virtual device. If you are onboarding a virtual device, you must select the device's performance tier from the drop-down menu.

Step 9 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 10 Security Cloud Control generates a command with the registration key. Paste the entire registration key into the device's CLI without making changes.

Step 11 (Optional) Add labels to your device to help sort and filter the **Security Devices** page. Enter a label and select the blue plus button. Labels are applied to the device after it's onboarded to Security Cloud Control.

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Edit cluster health monitor settings

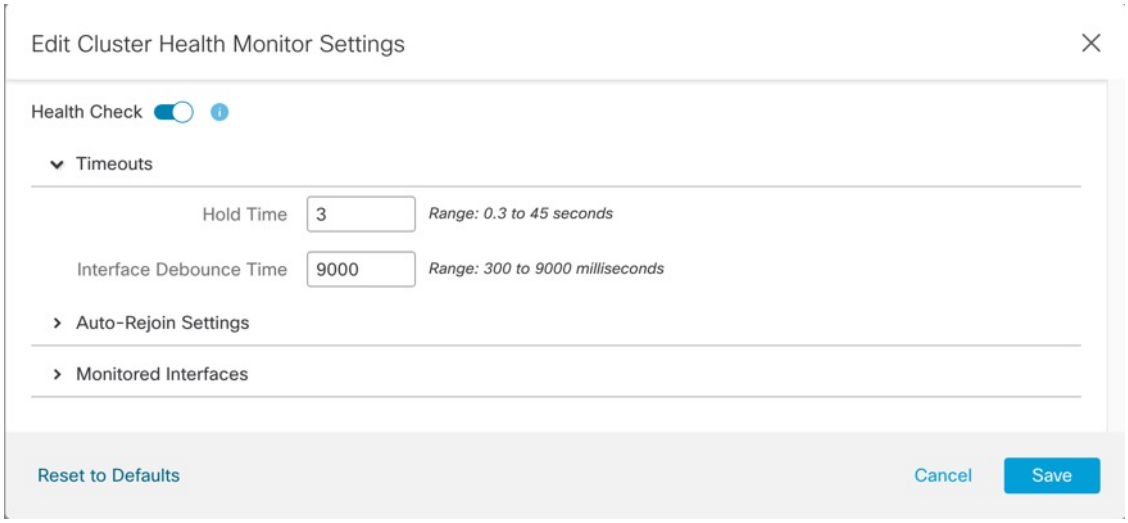
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



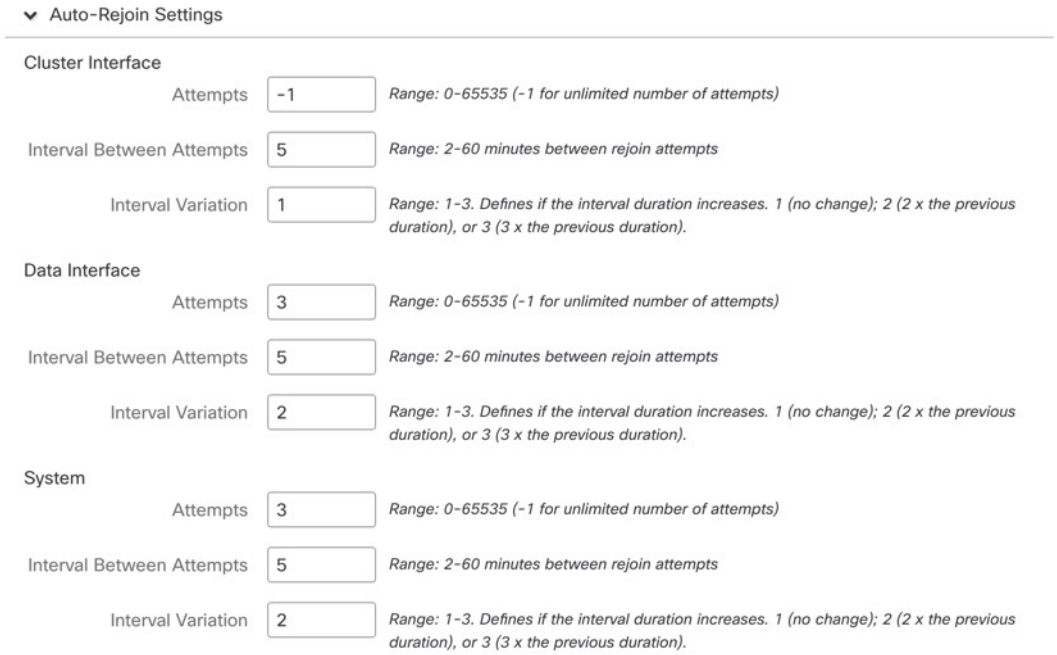
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 187: Disable the system health check



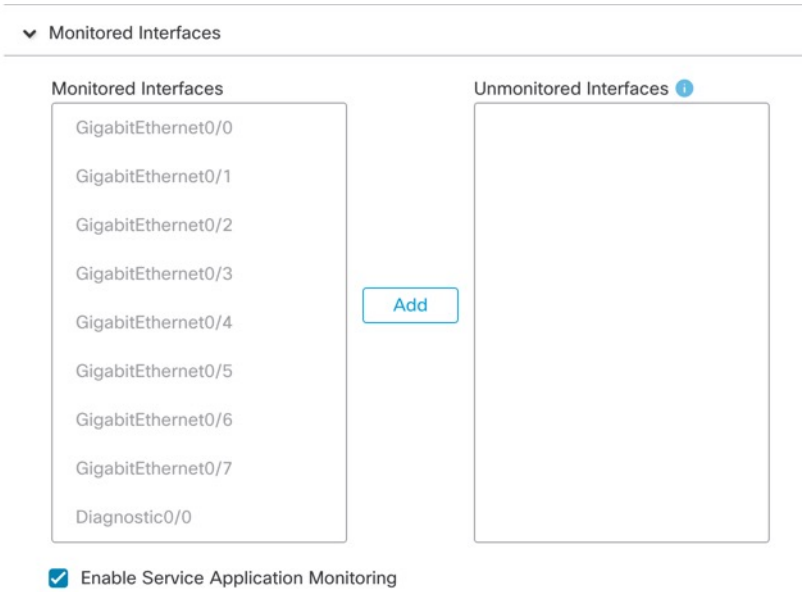
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 188: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 189: Configure monitored interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Deploy configuration changes.

Manage cluster nodes

Explains how to add, remove, and configure cluster nodes in your deployment.

Disable clustering

Disable clustering to temporarily deactivate a node in preparation for deleting the node or for maintenance purposes.

You may want to deactivate a node to delete it or for temporary maintenance. This procedure temporarily deactivates a node, but the node will still appear in the Cloud-Delivered Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Note Do not power off the node without first disabling clustering.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click the **More** (⋮), and choose **Disable Node Clustering**.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, refer to Rejoin the Cluster.

Rejoin the cluster

Rejoin a node to the cluster after it was removed because of failure or when clustering was manually disabled.

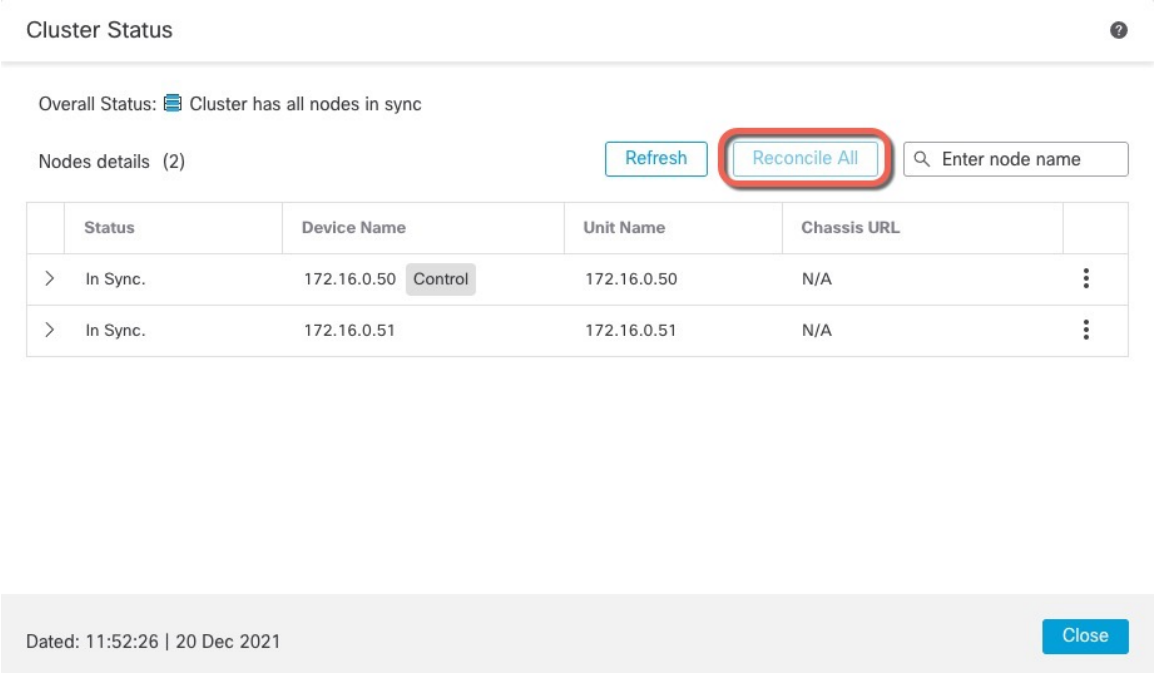
If a node was removed from the cluster, for example, due to a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the node.

Reconcile Cluster Nodes



If a cluster node fails to register, you can reconcile the cluster membership from the device to the Cloud-Delivered Firewall Management Center. For example, a data node might fail to register if the Cloud-Delivered Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Step 2 Click **Reconcile All**.

Figure 190: Reconcile All

Unregister the cluster or nodes and register with a new Cloud-Delivered Firewall Management Center

This task allows you to move cluster nodes from one management center to another by safely removing them from their current management center and re-registering them with a new one.

You can unregister the cluster from the Cloud-Delivered Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Cloud-Delivered Firewall Management Center.

You can also unregister a node from the Cloud-Delivered Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Cloud-Delivered Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Cloud-Delivered Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Cloud-Delivered Firewall Management Center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Cloud-Delivered Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Cloud-Delivered Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

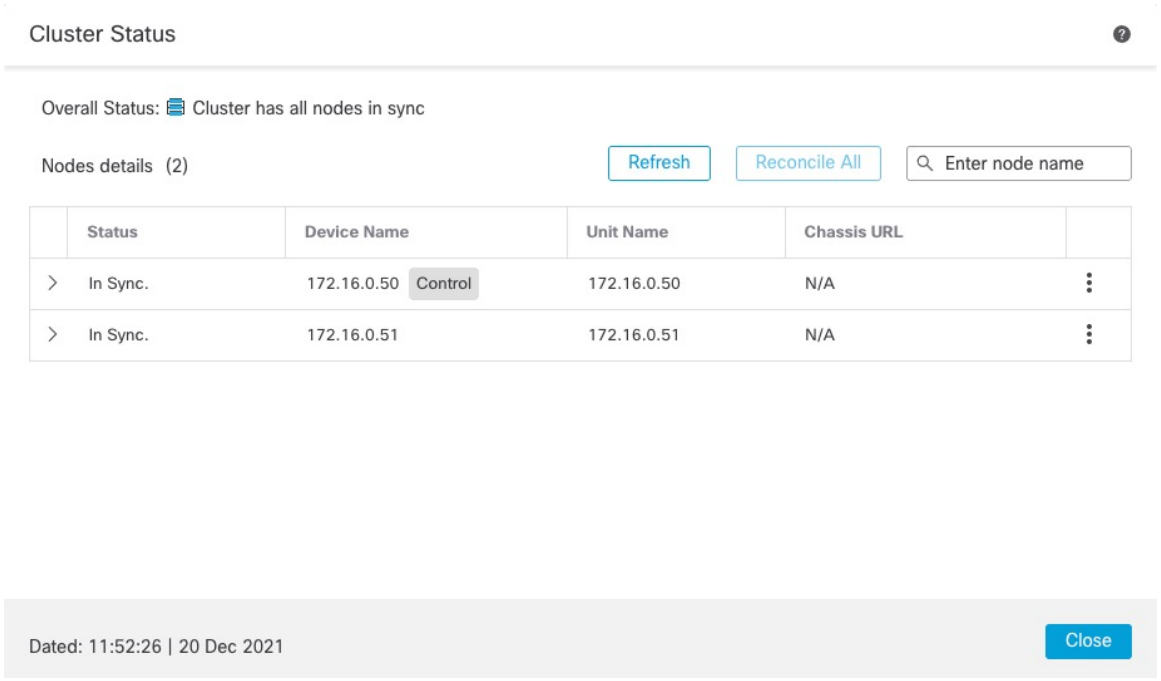
Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Unregister**.

Step 2 You are prompted to unregister the cluster or node; click **Yes**.

Step 3 You can register the cluster with a new (or the same) Cloud-Delivered Firewall Management Center by adding one of the cluster members as a new device.

Add one of the cluster nodes as a device. The system will discover the remaining nodes.

Step 4 To re-add a deleted node, refer to Reconcile Cluster Nodes, on page 911.



Monitor cluster status

You can monitor the cluster in the Cloud-Delivered Firewall Management Center and at the Firewall Threat Defense CLI.

Monitor cluster status through these methods:

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management**, click **Add**, choose the **Cluster** page **General** area **Cluster Live Status** link.

Figure 191: Cluster status

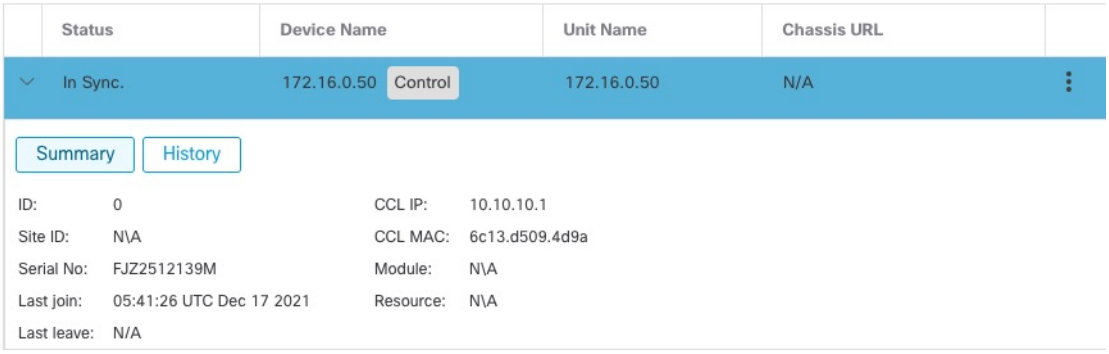
The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes these states:

- In Sync—The node is registered with the Cloud-Delivered Firewall Management Center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the Cloud-Delivered Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Cloud-Delivered Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Cloud-Delivered Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 192: Node summary



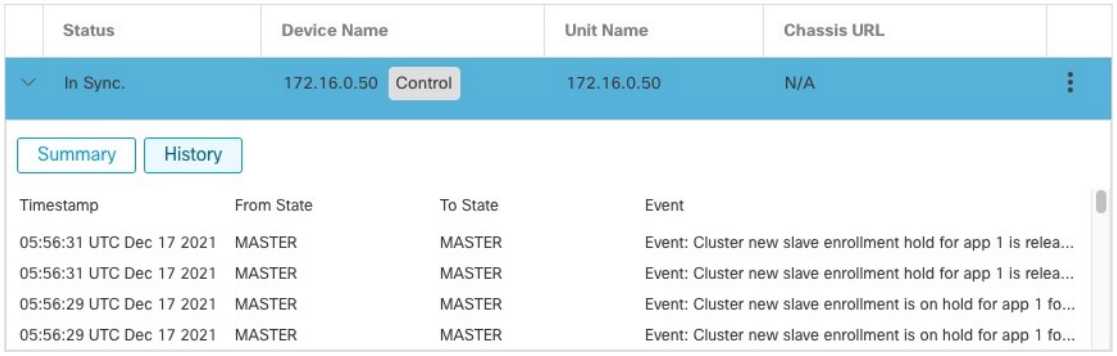


Figure 193: Node history

- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** and then click **Add** > **Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster health monitor

When a Firewall Threat Defense is the control node of a cluster, the Cloud-Delivered Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Cloud-Delivered Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

View the cluster health monitor

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.
- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.

- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 60: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Upgrade the cluster

This task upgrades a Firewall Threat Defense Virtual cluster to a new software version by updating the cloud instance template and performing a managed upgrade.

The cluster upgrade process involves updating both the cloud infrastructure template and the software package through the management center. The upgrade is performed one node at a time to maintain cluster availability.

Before you begin

- Before you upgrade a cluster in the public cloud, copy the target version image to your cloud image repository and update the image ID in the cluster deployment template (we actually recommend replacing the existing template with a modified copy). This ensures that after the upgrade, new instances — for example, instances launched during cluster scaling — will use the correct version. If the marketplace does not have the image you need, such as when the cluster has been patched, create a custom image from a snapshot of a standalone Firewall Threat Defense Virtual instance running the correct version, with no instance-specific (day 0) configurations.

Follow these steps to upgrade a Firewall Threat Defense Virtual cluster:

Procedure

Step 1 Upload the target image version to the cloud image storage.

Step 2 Update the cloud instance template of the cluster with the updated target image version.

a) Create a copy of the instance template with the target image version.

b) Attach the newly created template to cluster instance group.

Step 3 Upload the target image version upgrade package to the Cloud-Delivered Firewall Management Center.

Step 4 Perform a readiness check on the cluster that you want to upgrade.

Step 5 After a successful readiness check, initiate the installation of the upgrade package.

Step 6 The Cloud-Delivered Firewall Management Center upgrades the cluster nodes one at a time.

Step 7 The Cloud-Delivered Firewall Management Center displays a notification after successful upgrade of the cluster.

There is no change to the serial number and UUID of the instance after the upgrade.

Reference for clustering

This section includes more information about how clustering operates.

Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features and clustering

Centralized features for clustering

These features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Cloud-Delivered Firewall Management Center GUI. For more information, refer to FlexConfig policies, on page 1309.

- These application inspections are supported:
  - DCERPC and ESMTP
  - NetBIOS and PPTP
  - RSH
  - SQLNET and SUNRPC
  - TFTP
  - XDMCP
- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

Cisco Trustsec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

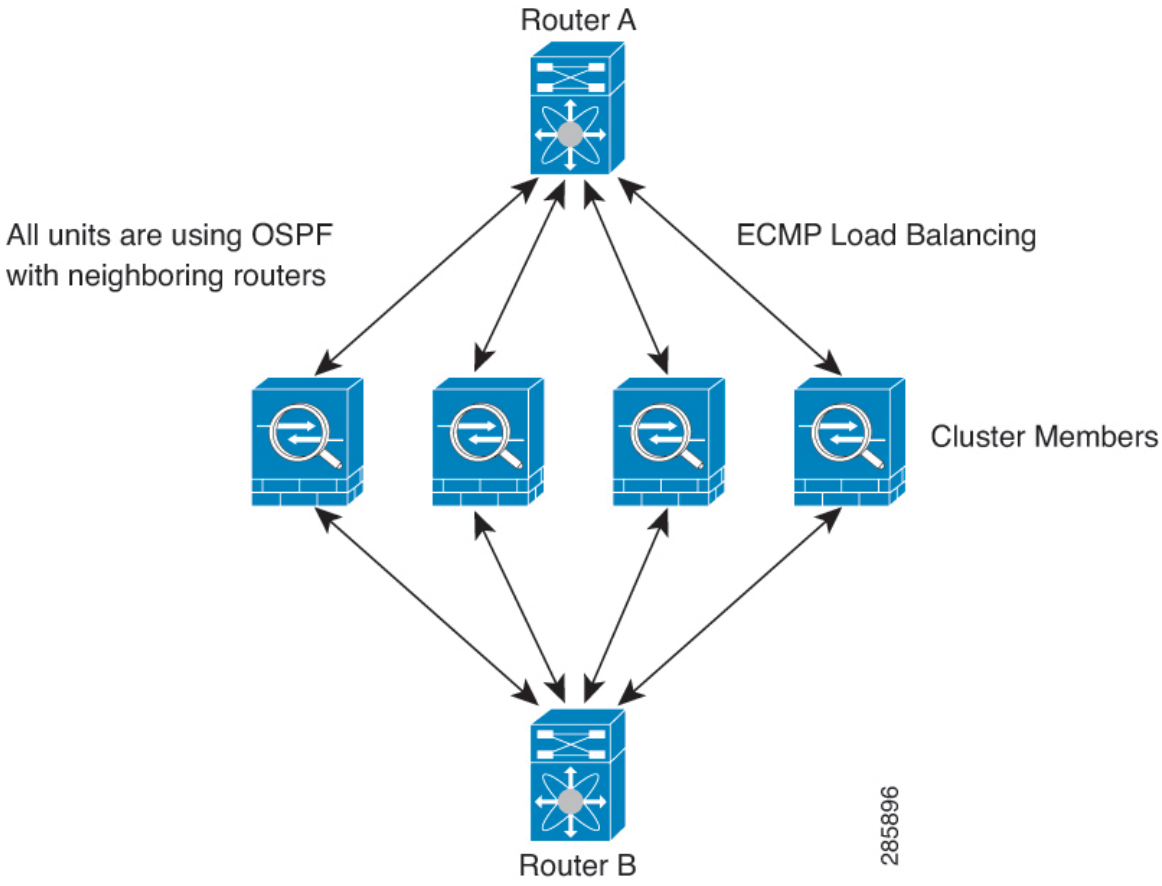
Connection settings and clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic routing and clustering

Dynamic routing and clustering are network configuration approaches that

- enable each node to run the routing protocol as a standalone router in Individual interface mode,
- allow routes to be learned by each node independently, and
- require separate router IDs for each node when communicating with external routers.



Routing behavior and load balancing

In Individual interface mode, ECMP is used to load balance traffic between multiple equal-cost paths. External routers can discover multiple paths to destinations through different cluster nodes.

Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when communicating with external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

Figure 194: Dynamic routing in individual interface mode

FTP and clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and clustering

Provides information about NAT behavior and limitations in clustering deployments.

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router requires a static route or policy-based routing (PBR) with Object Tracking for the mapped addresses, which must point to the main cluster IP address.
- No interface PAT on an individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP

- RSH
- SQLNET
- TFTP
- XDMCP
- SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

Throughput calculation

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control node election

Summary

The key components involved in the control node election process are:

- Cluster nodes: Communicate over the cluster control link and participate in the election process
- Election requests: Broadcast every 3 seconds by nodes when clustering is enabled
- Priority values: Set between 1 and 100 where 1 is the highest priority
- Control node: The elected node that coordinates cluster operations

Workflow

These stages describe how cluster nodes elect a control node:

1. When clustering is enabled for a node (or when it first starts up with clustering already enabled), the node broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request. The priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node. The existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High availability within the cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node health monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

Split brain scenario

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 milliseconds.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Cloud-Delivered Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 61: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—

Traffic	State Support	Notes
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

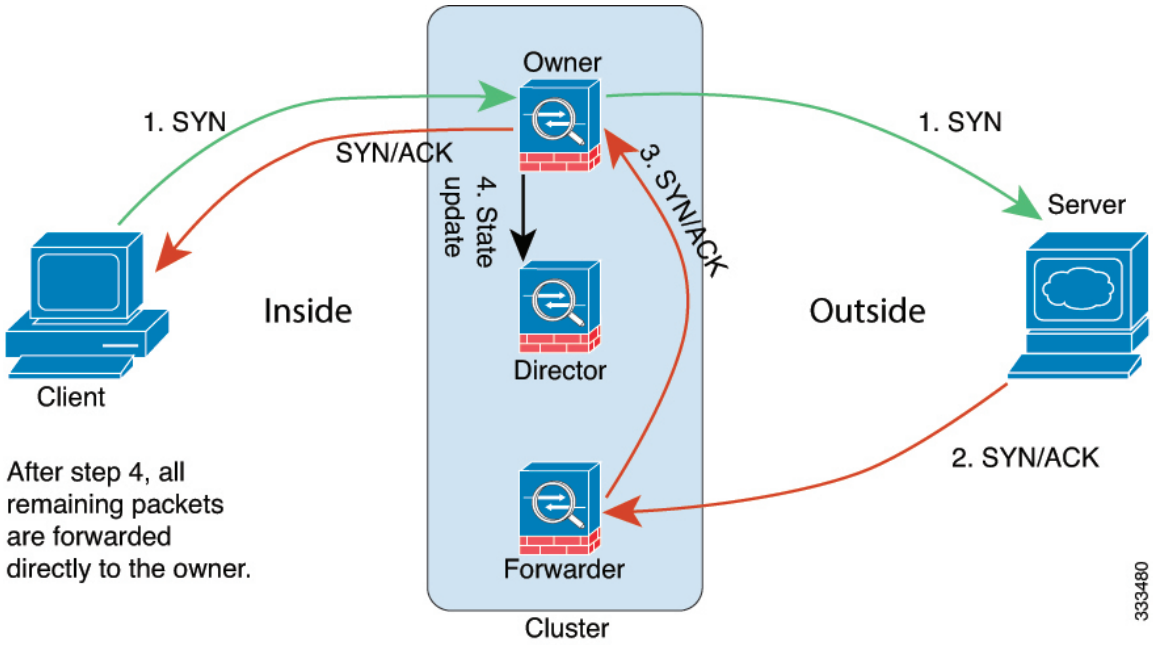
  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not

used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

Port Address Translation Connections



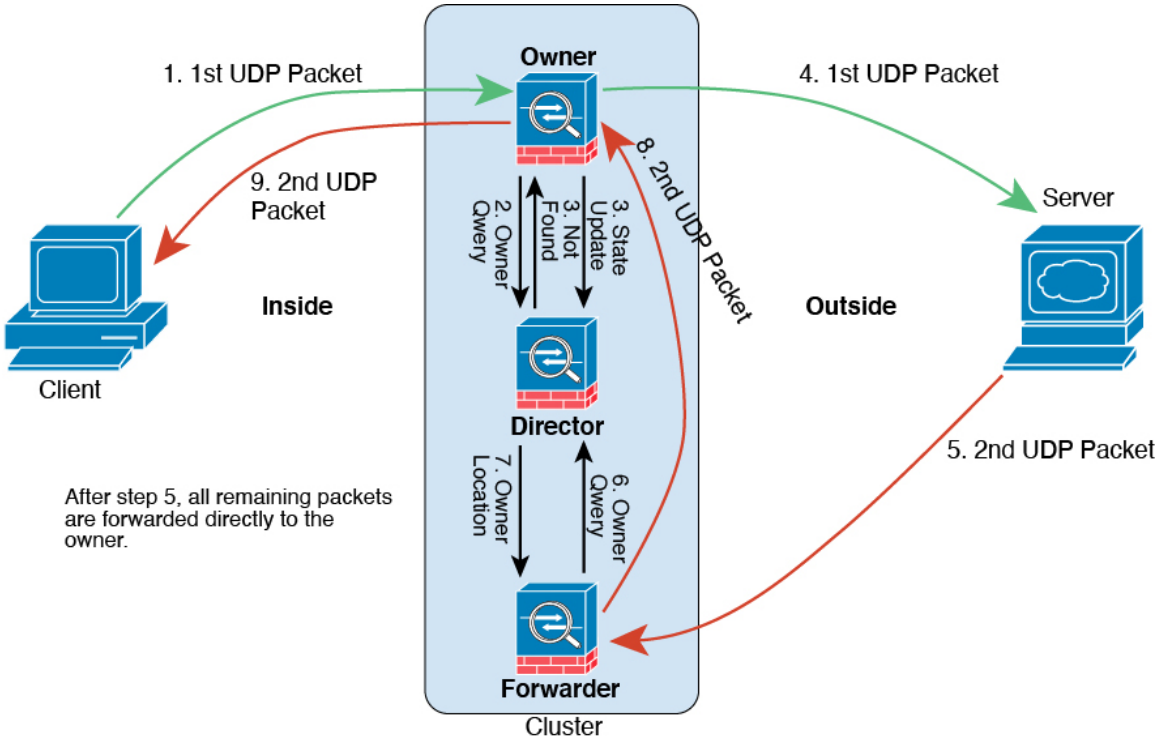
New connection ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

Sample data flow for TCP

The following example shows the establishment of a new connection.



1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

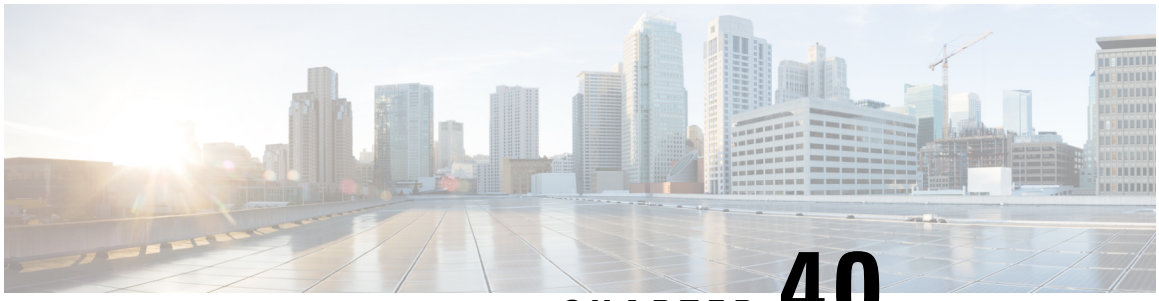
Sample data flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 195: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.



History for Threat Defense Virtual clustering in the public cloud

This reference provides the historical timeline and version information for Threat Defense Virtual clustering features introduced across different software releases and deployment platforms in public cloud environments.

Table 62: Feature history

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
MTU ping test from data node on node join	20241030	7.6.0	When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size twice the cluster control link MTU. Previously, only the control node sent a ping. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again. Added/modified commands: **show cluster history**. CHAPTER 40

Clustering: Firepower 4100/9300

Clustering lets you group multiple Firewall Threat Defense nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported features with clustering, on page 977.

About clustering on the Firepower 4100/9300 chassis

When you deploy a cluster on the Firepower 4100/9300 chassis, it does the following:

- For native instance clustering: Creates a *cluster-control link* (by default, port-channel 48) for node-to-node communication.

  For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

  For a cluster isolated to security modules within one Firepower 9300 chassis, this link utilizes the Firepower 9300 backplane for cluster communications.

  For clustering with multiple chassis, you need to manually assign physical interface(s) to this EtherChannel for communications between chassis.

- Creates the cluster bootstrap configuration within the application.

  When you deploy the cluster, the chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

- Assigns data interfaces to the cluster as *Spanned* interfaces.

  For a cluster isolated to security modules within one Firepower 9300 chassis, spanned interfaces are not limited to EtherChannels, like it is for clustering with multiple chassis. The Firepower 9300 supervisor uses EtherChannel technology internally to load-balance traffic to multiple modules on a shared interface, so any data interface type works for Spanned mode. For clustering with multiple chassis, you must use Spanned EtherChannels for all data interfaces.

Note Individual interfaces are not supported, with the exception of a management interface.

- Assigns a management interface to all units in the cluster.

Bootstrap configuration

A bootstrap configuration is a minimal cluster configuration that includes cluster name, cluster control link interface, and other cluster settings.

When you deploy the cluster, the Firepower 4100/9300 chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

Cluster members

Cluster members are security devices that work together to accomplish the sharing of the security policy and traffic flows.

Cluster member roles and management

One member of the cluster is the **control** unit. The control unit is determined automatically. All other members are **data** units.

You must perform all configuration on the control unit only; the configuration is then replicated to the data units.

Some features do not scale in a cluster, and the control unit handles all traffic for those features. .

Cluster control link

Cluster control link traffic includes both control and data traffic.

For native instance clustering: The cluster control link is automatically created using the Port-channel 48 interface.

For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

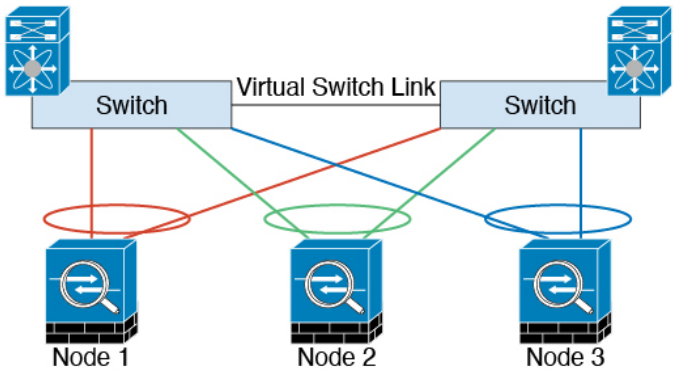
For a cluster isolated to security modules within one Firepower 9300 chassis, this interface has no member interfaces. This Cluster type EtherChannel utilizes the Firepower 9300 backplane for cluster communications. For clustering with multiple chassis, you must add one or more interfaces to the EtherChannel.

For a cluster with two chassis, do not directly connect the cluster control link from one chassis to the other chassis. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

Size the cluster control link

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features.

For example:



- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster control link redundancy

The diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster control link reliability for inter-chassis clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Cluster control link network

The Firepower 4100/9300 chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2.*chassis_id*.*slot_id*. For multi-instance clusters, which typically use different VLAN subinterfaces of the same EtherChannel, the same IP address can be used for different clusters because of VLAN separation. The cluster control link network cannot include any routers between units; only Layer 2 switching is allowed.

Management network

We recommend connecting all units to a single management network. This network is separate from the cluster control link.

Management interface

You must assign a Management type interface to the cluster. This interface is a special individual interface as opposed to a Spanned interface. The management interface lets you connect directly to each unit. This Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the Cloud-Delivered Firewall Management Center. It uses its own local authentication, IP address, and static routing.

Management interface configuration

Each cluster member uses a separate IP address on the management network that you set as part of the bootstrap configuration.

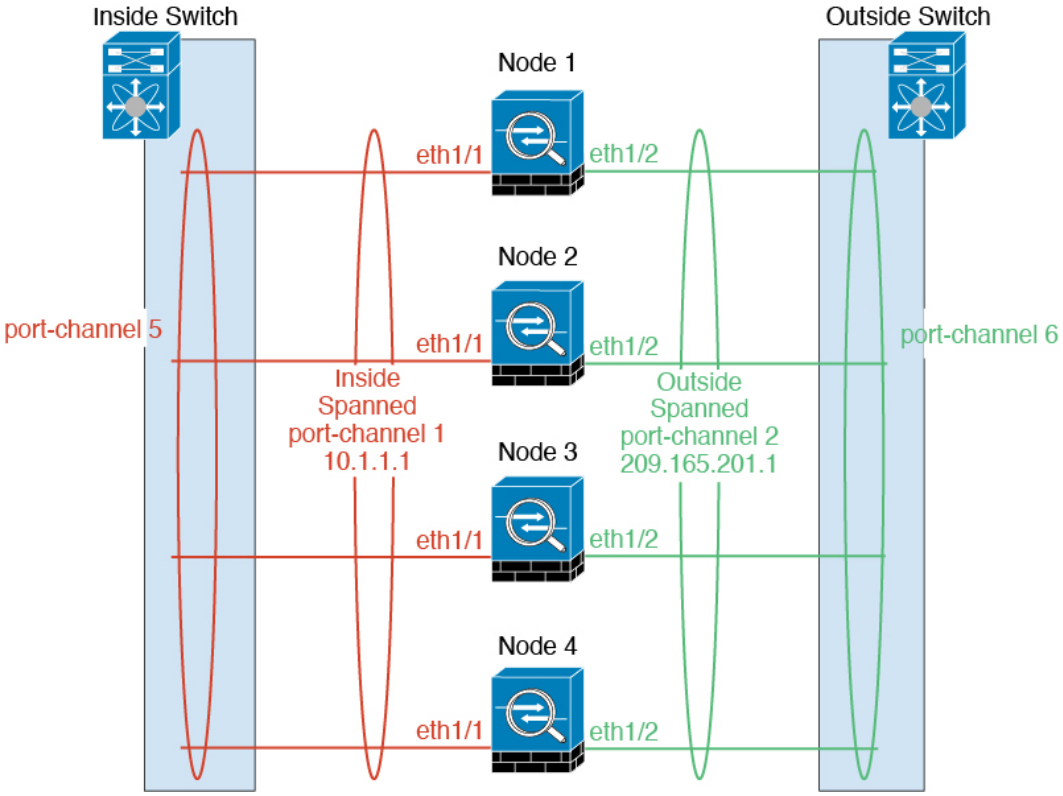
Cluster interfaces

For a cluster isolated to security modules within one Firepower 9300 chassis, you can assign either physical interfaces or EtherChannels (also known as port channels) to the cluster. The assigned interfaces are Spanned interfaces that load-balance traffic across all cluster members.

For clustering with multiple chassis, you can only assign data EtherChannels to the cluster. These Spanned EtherChannels include the same member interfaces on each chassis. On the upstream switch, all these interfaces are part of a single EtherChannel, so the switch does not recognize that it is connected to multiple devices.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Individual interfaces are not supported except for a management interface.



Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

For multi-instance clusters, each cluster requires dedicated data EtherChannels; you cannot use shared interfaces or VLAN subinterfaces.

Configuration replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Licenses for clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

Note APEX, PLUS, and VPN-Only licenses are not supported for clustering. Before you create a cluster, remove unsupported license assignments from the devices that will become cluster nodes.

When you add a cluster node to the Cloud-Delivered Firewall Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management** and the choose the **Add**, **Cluster** and then **License** area.

Note If you add the cluster before the Cloud-Delivered Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Cloud-Delivered Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and prerequisites for clustering

This topic provides the necessary prerequisites and hardware support details for configuring clustering on supported security appliances.

Cluster model support

The Firewall Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

User roles

The following user roles are required to manage clustering configurations:

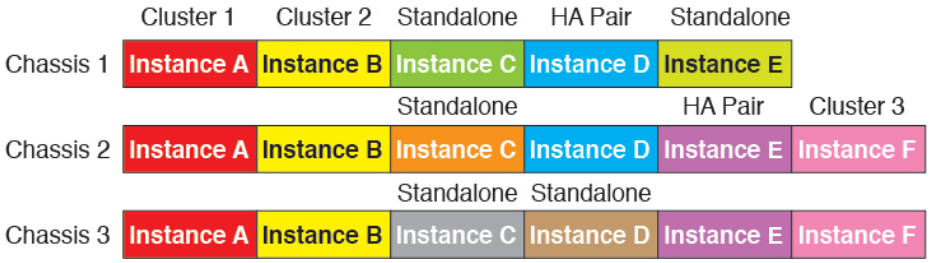
- Admin
- Access Admin
- Network Admin

Clustering hardware and software requirements

All chassis in a cluster:

- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.

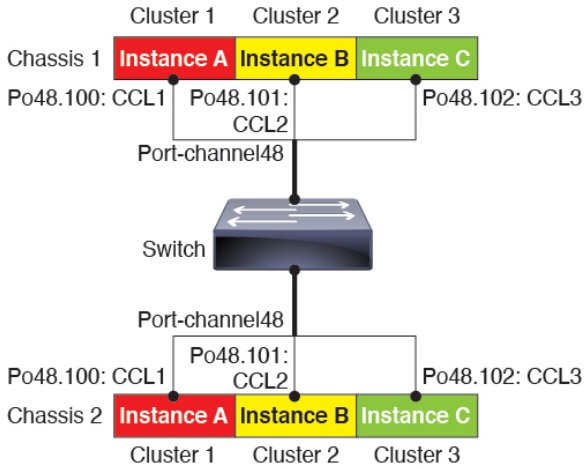
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



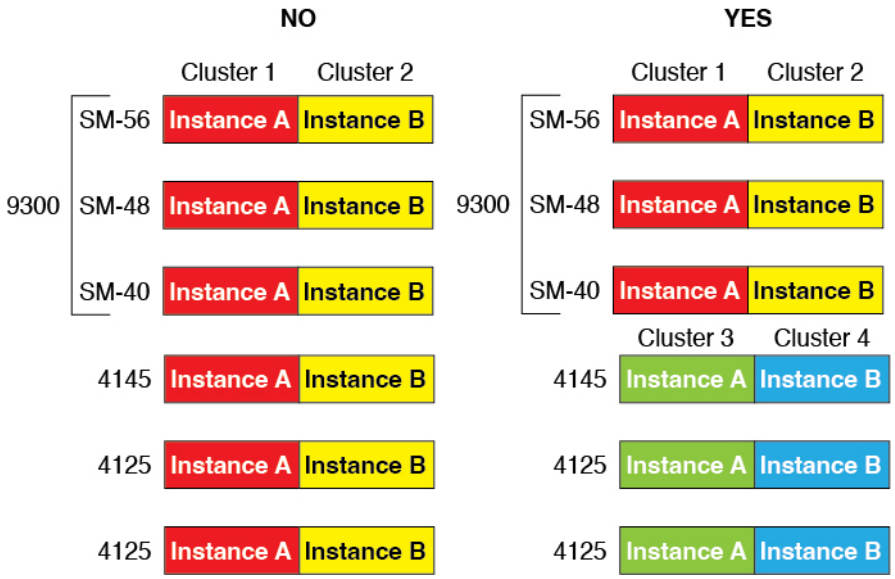
- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firewall Threat Defense, the Cloud-Delivered Firewall Management Center must also use the same NTP server. Do not set the time manually.

Multi-instance clustering requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.



- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.



- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.

- For supported switch characteristics, see Cisco FXOS Compatibility.

Clustering guidelines and limitations

Clustering is a deployment method that groups multiple security devices into a single logical unit to provide high availability and increased throughput.

Switches for Clustering

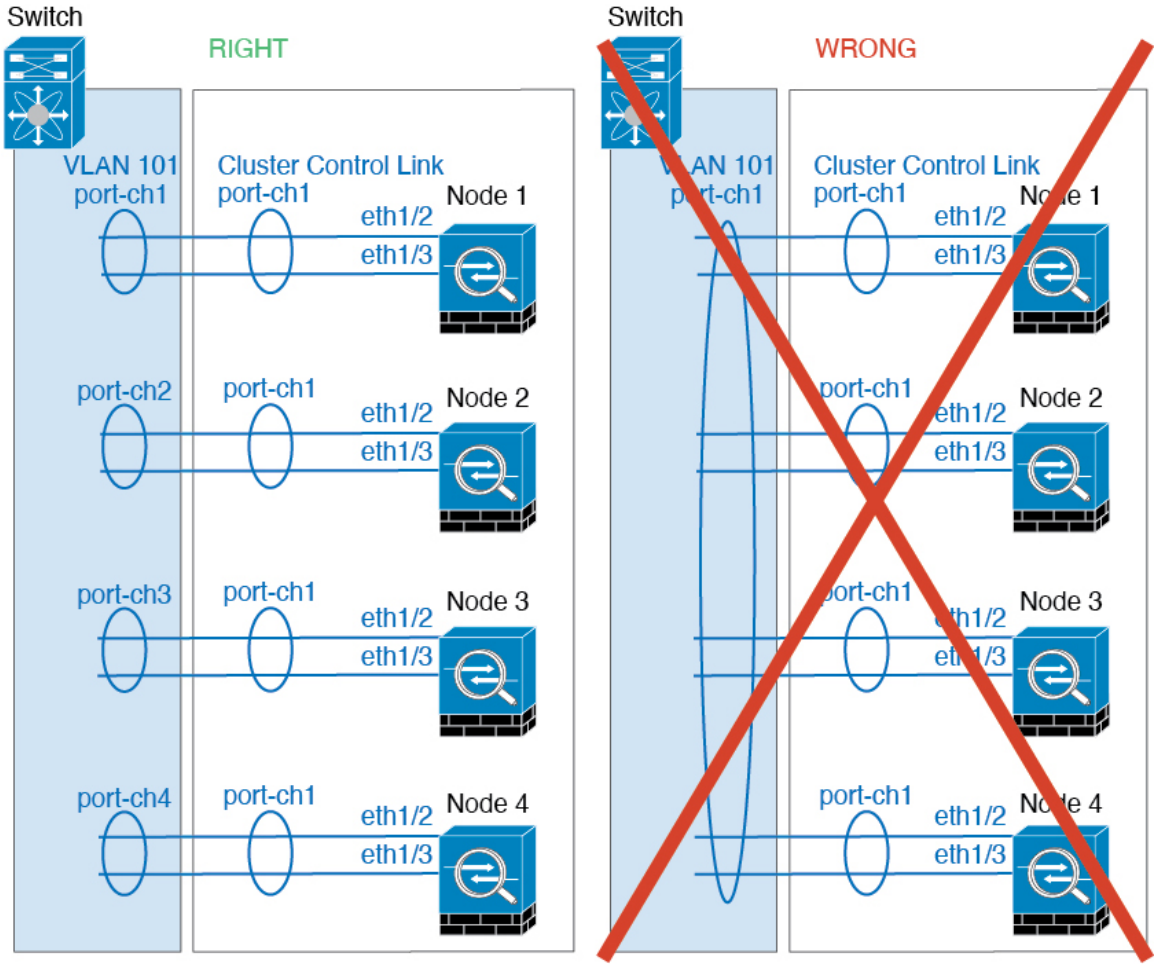
- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.

- Firepower 4100/9300 clusters support LACP graceful convergence. So you can leave LACP graceful convergence enabled on connected Cisco Nexus switches.
- When you see slow bundling of a Spanned EtherChannel on the switch, you can enable LACP rate fast for an individual interface on the switch. FXOS EtherChannels have the LACP rate set to fast by default.

Note that some switches, such as the Nexus series, do not support LACP rate fast when performing in-service software upgrades (ISSUs), so we do not recommend using ISSUs with clustering.



EtherChannels for Clustering

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

  - Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels

on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firepower 4100/9300 chassis or the switch, adding an additional switch to form a VSS, vPC, StackWise, or StackWise Virtual) you should disable the health check feature, and also disable interface monitoring for the disabled interfaces . When the topology change is complete, and the configuration change is synced to all units, you can re-enable the health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang connections; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel interface, when the syslog server port is down, and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the cluster. These messages can result in some units of the cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.

- We recommend connecting EtherChannels to a VSS, vPC, StackWise, or StackWise Virtual for redundancy.
- Within a chassis, you cannot cluster some security modules and run other security modules in standalone mode; you must include all security modules in the cluster.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults

- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is set to unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is set to 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure clustering

You can easily deploy the cluster from the Firepower 4100/9300 supervisor. All initial configuration is automatically generated for each unit. You can then add the units to the Cloud-Delivered Firewall Management Center and group them into a cluster.

FXOS: Add a Firewall Threat Defense cluster

A cluster is a deployment configuration that allows you to group security modules to increase capacity and redundancy.

Cluster Deployment Modes

In native mode: You can add a cluster to a single Firepower 9300 chassis that is isolated to security modules within the chassis, or you can use multiple chassis.

In multi-instance mode: You can add one or more clusters to a single Firepower 9300 chassis that are isolated to security modules within the chassis (you must include an instance on each module), or add one or more clusters on multiple chassis.

For clusters on multiple chassis, you must configure each chassis separately. Add the cluster on one chassis; you can then

Create a Firewall Threat Defense cluster

You can easily deploy the cluster from the Firepower 4100/9300 chassis supervisor. All initial configuration is automatically generated for each unit.

For clustering on multiple chassis, you must configure each chassis separately. Deploy the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment.

In a Firepower 9300 chassis, you must enable clustering for all 3 module slots, or for container instances, a container instance in each slot, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.
- For container instances, if you do not want to use the default profile, add a resource profile according to Add a resource profile for container instances.
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Management interface ID, IP addresses, and network mask
  - Gateway IP address
  - Firewall Management Center IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Firewall Threat Defense hostname and domain name

Procedure

Step 1 Configure interfaces.

a) Add at least one Data type interface or EtherChannel (also known as a port-channel) before you deploy the cluster. See Add an EtherChannel (port channel) or Configure a physical interface.

For clustering on multiple chassis, all data interfaces must be Spanned EtherChannels with at least one member interface. Add the same EtherChannels on each chassis. Combine the member interfaces from all cluster units into a single EtherChannel on the switch. See Clustering guidelines and limitations, on page 944 for more information about EtherChannels.

For multi-instance clustering, you cannot use FXOS-defined VLAN subinterfaces or data-sharing interfaces in the cluster. Only application-defined subinterfaces are supported. See FXOS interfaces and application interfaces for more information.

b) Add a Management type interface or EtherChannel. See Add an EtherChannel (port channel) or Configure a physical interface.

The management interface is required. Note that this management interface is not the same as the chassis management interface that is used only for chassis management (in FXOS, you might see the chassis management interface displayed as MGMT, management0, or other similar names).

For clustering on multiple chassis, add the same Management interface on each chassis.

For multi-instance clustering, you can share the same management interface across multiple clusters on the same chassis, or with standalone instances.

c) For clustering on multiple chassis, add a member interface to the cluster control link EtherChannel (by default, port-channel 48). See Add an EtherChannel (port channel).

Do not add a member interface for a cluster isolated to security modules within one Firepower 9300 chassis. If you add a member, the chassis assumes this cluster will be using multiple chassis, and will only allow you to use Spanned EtherChannels, for example.

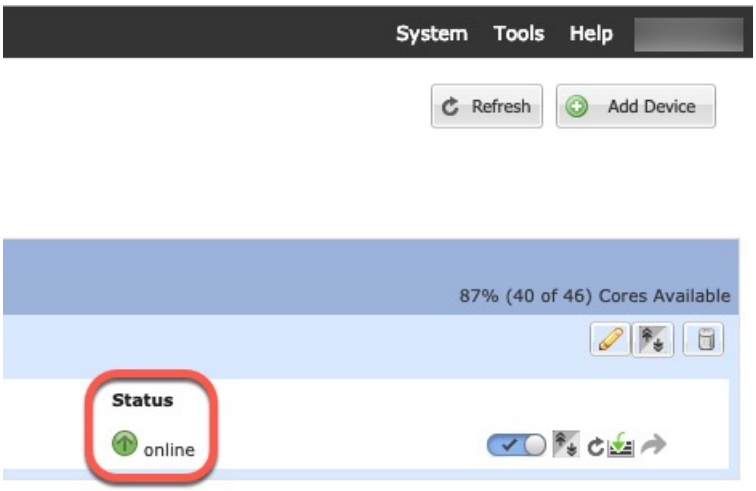
Add the same member interfaces on each chassis. The cluster control link is a device-local EtherChannel on each chassis. Use separate EtherChannels on the switch per device. See Clustering guidelines and limitations, on page 944 for more information about EtherChannels.

For multi-instance clustering, you can create additional Cluster type EtherChannels. Unlike the Management interface, the cluster control link is not sharable across multiple devices, so you will need a Cluster interface for each cluster. However, we recommend using VLAN subinterfaces instead of multiple EtherChannels; see the next step to add a VLAN subinterface to the Cluster interface.

d) For multi-instance clustering, add VLAN subinterfaces to the cluster EtherChannel so you have a subinterface for each cluster. See Add a VLAN subinterface for container instances.

If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

e) (Optional) Add an eventing interface. See Add an EtherChannel (port channel) or Configure a physical interface.



This interface is a secondary management interface for the Firewall Threat Defense devices. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI. For example, you can separate management traffic from events (such as web events). See the **configure network** commands in the Firewall Threat Defense command reference.

For clustering on multiple chassis, add the same eventing interface on each chassis.

Step 2 Choose **Logical Devices**.

Step 3 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can add the remaining cluster chassis, or for a cluster isolated to security modules within one Firepower 9300 chassis, start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

Add more cluster nodes

Add or replace the Firewall Threat Defense cluster node in an existing cluster. When you add a new cluster node in FXOS, the Cloud-Delivered Firewall Management Center adds the node automatically.

Note The FXOS steps in this procedure only apply to adding a new chassis ; if you are adding a new module to a Firepower 9300 where clustering is already enabled, the module will be added automatically.

Before you begin

- In the case of a replacement, you must delete the old cluster node from the Cloud-Delivered Firewall Management Center . When you replace it with a new node, it is considered to be a new device on the Cloud-Delivered Firewall Management Center .
- The interface configuration must be the same on the new chassis. You can export and import FXOS chassis configuration to make this process easier.

What to do next

1. To add another chassis to the cluster, repeat the procedure in Create a Firewall Threat Defense cluster , on page 947 except you must configure the following settings to be unique; otherwise, use the same configuration for both chassis.
   - Chassis ID
   - Management IP addresses

   Also be sure to set the startup version to the currently running version on the cluster nodes.
2. In the Cloud-Delivered Firewall Management Center , choose **Devices** > **Device Management** , and select the **Add** > **Device** to add the new logical device.
3. Choose **Add** > **Cluster** .

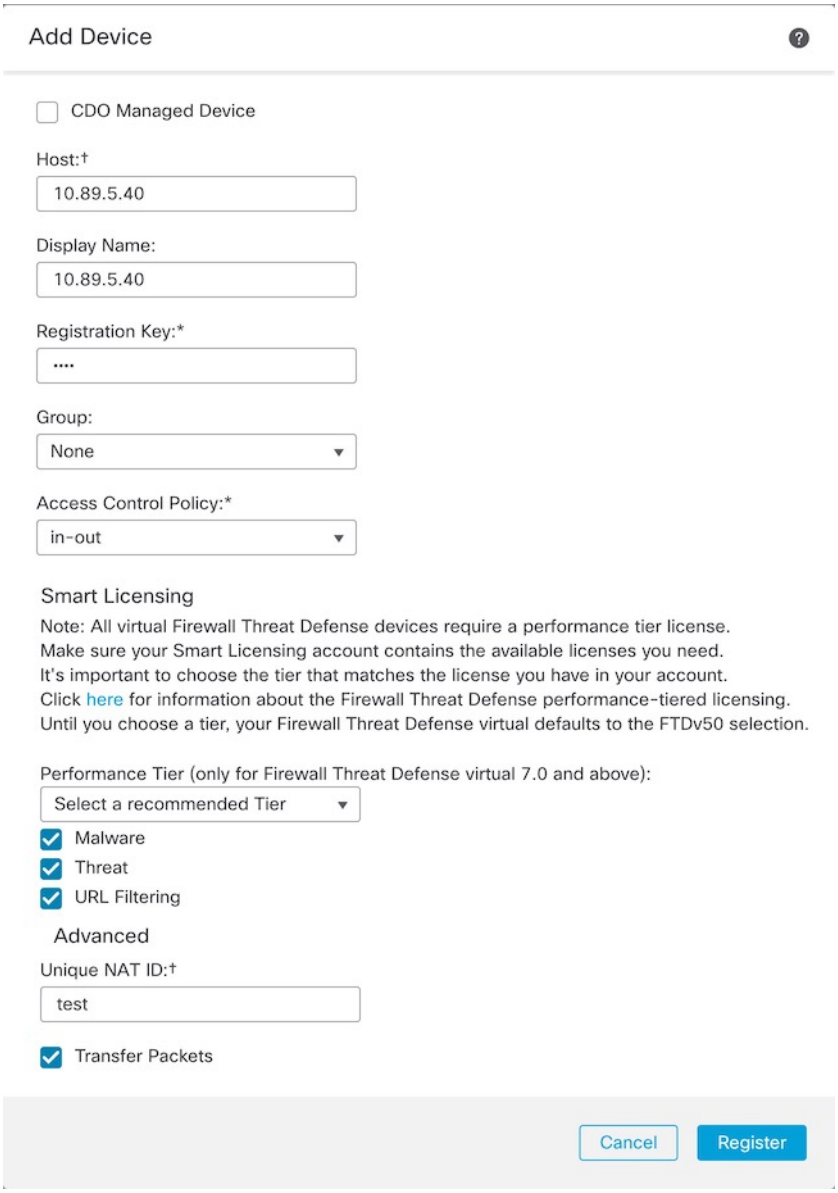
4. Choose the current control unit from the drop-down list.

   When you choose a control unit that is already in a cluster, then the existing cluster name is auto-filled, and all eligible data units are added to the box, including the new unit you just added to the Cloud-Delivered Firewall Management Center .

5. Click **Add** , and then **Deploy** . The cluster is updated to include the new member.

Cloud-Delivered Firewall Management Center: Add a cluster

Add one of the cluster units as a new device to the Cloud-Delivered Firewall Management Center; the Cloud-Delivered Firewall Management Center auto-detects all other cluster members.



Before you begin

- All cluster units must be in a successfully-formed cluster on FXOS prior to adding the cluster to the Cloud-Delivered Firewall Management Center. You should also check which unit is the control unit. Refer to the Firewall Chassis Manager **Logical Devices** screen or use the Firewall Threat Defense **show cluster info** command.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address you assigned when you deployed the cluster.

Figure 196: Add Device

a) In the **Host** field, enter the IP address or hostname of the control unit.

   We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

   If you used a NAT ID during device setup, you may not need to enter this field.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the Cloud-Delivered Firewall Management Center.

   This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used when you deployed the cluster in FXOS. The registration key is a one-time-use shared secret.

d) (Optional) Add the device to a device **Group**.

e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

f) Choose licenses to apply to the device.

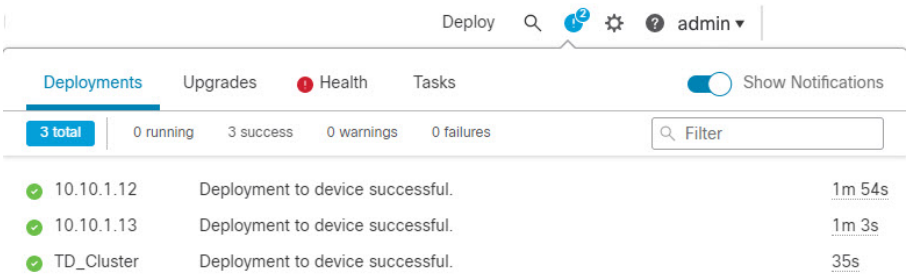
g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.

h) Check the **Transfer Packets** check box to allow the device to transfer packets to the Cloud-Delivered Firewall Management Center.

This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the Cloud-Delivered Firewall Management Center for inspection. If you disable it, only event information will be sent to the Cloud-Delivered Firewall Management Center but packet data is not sent.

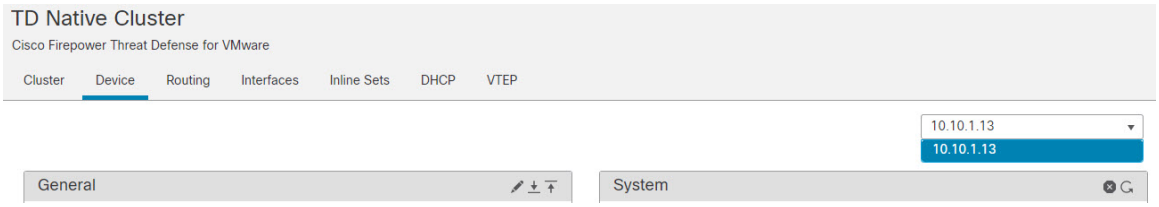
i) Click **Register**.

The Cloud-Delivered Firewall Management Center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up on the chassis, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.



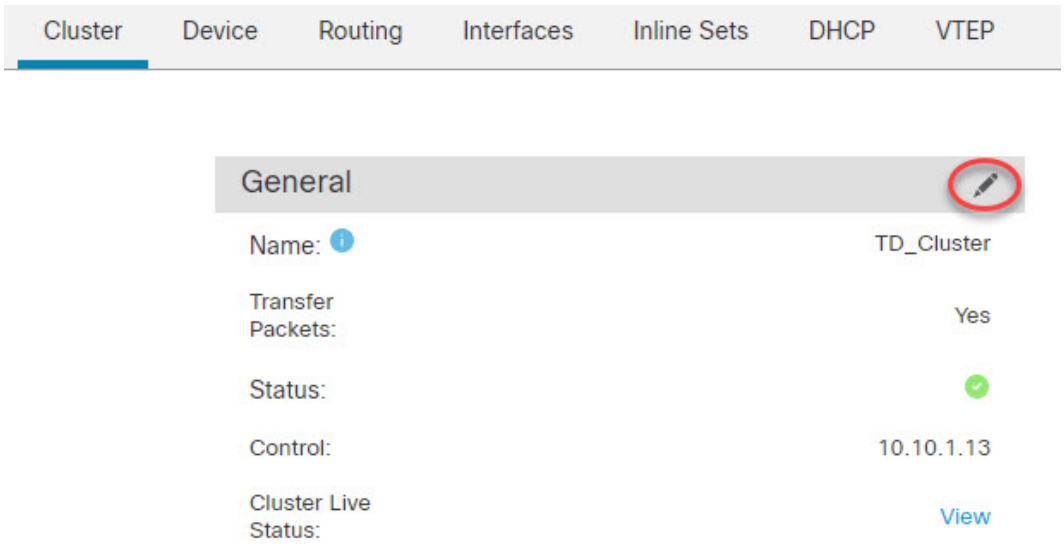
The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

A unit that is currently registering shows the loading icon.



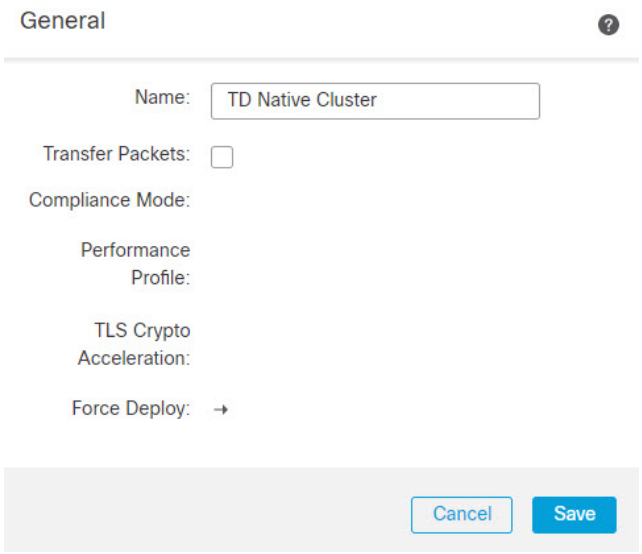
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The Cloud-Delivered Firewall Management Center updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile cluster members, on page 969.

Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

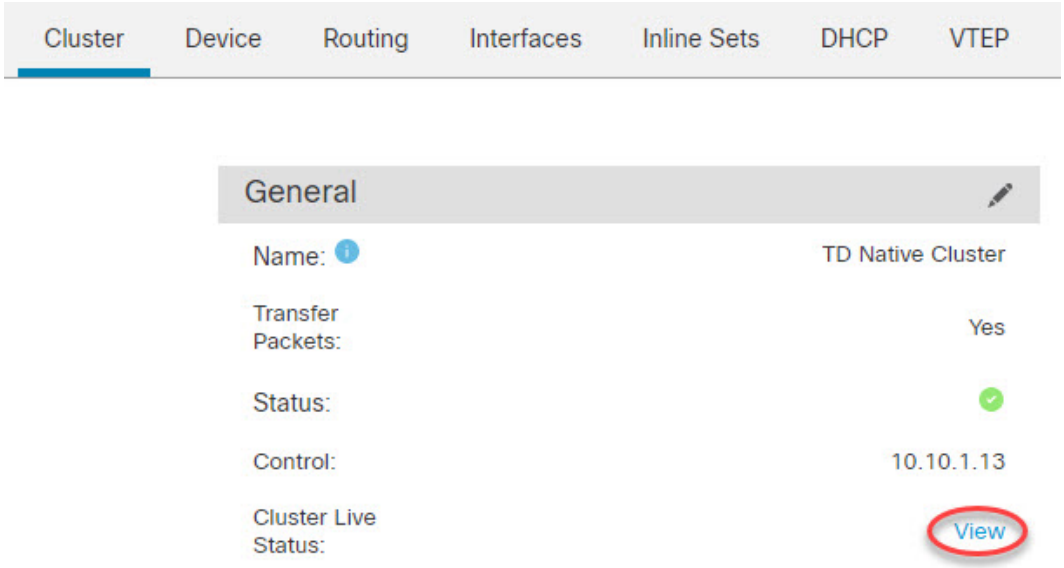


Most configuration can be applied to the cluster as a whole, and not member units in the cluster. For example, you can change the display name per unit, but you can only configure interfaces for the whole cluster.

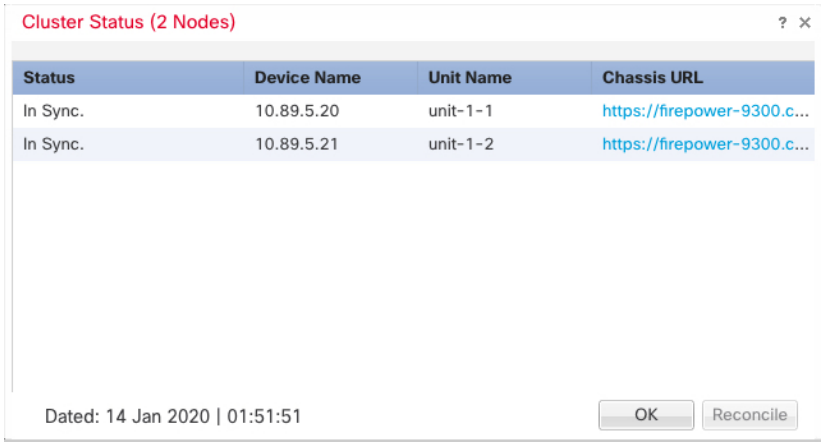
Step 3 On the **Devices** > **Device Management**and choose the **Add**, **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.



See the following cluster-specific items:

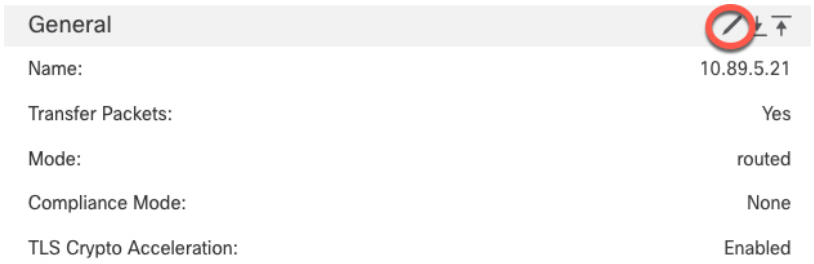


- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).

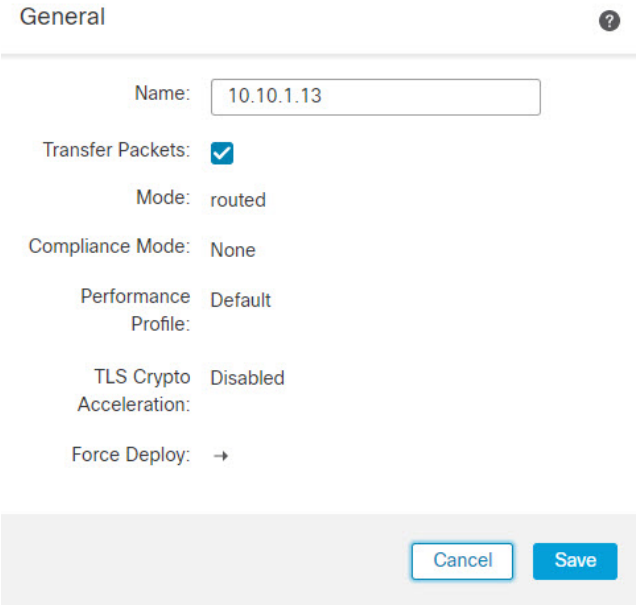


Then set the **Name** field.

- **General > View cluster status**—Click the **View cluster status** link to open the **Cluster Status** dialog box.

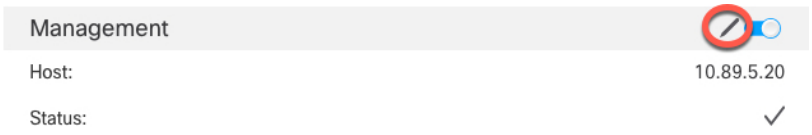


The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.



- **License**—Click **Edit** (✎) to set license entitlements.

Step 4 On the **Devices** > **Device Management** and then choose **Add Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.



- **General > Name**—Change the cluster member display name by clicking the **Edit** (✎).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Cloud-Delivered Firewall Management Center so that it can reach the device on the network; edit the **Host** address in the **Management** area.

Cloud-Delivered Firewall Management Center: Configure cluster, data interfaces

This procedure configures basic parameters for each data interface that you assigned to the cluster when you deployed it in FXOS. For clustering on multiple chassis, data interfaces are always Spanned EtherChannel interfaces. For the cluster control link interface for a cluster isolated to security modules within one Firepower 9300 chassis, you must increase the MTU from the default.

Note When using Spanned EtherChannels for clustering on multiple chassis, the port-channel interface will not come up until clustering is fully enabled. This requirement prevents traffic from being forwarded to a unit that is not an active unit in the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure the cluster control link.

For clustering on multiple chassis, set the cluster control link MTU to be at least 100 bytes higher than the highest MTU of the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. We suggest setting the MTU to the maximum of 9184; the minimum value is 1400 bytes. For example, because the maximum MTU is 9184, then the highest data interface MTU can be 9084, while the cluster control link can be set to 9184.

When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the initial ping fails, the node tries a ping using a smaller packet size (the MTU divided by 2, then by 4, then by 8) until a ping succeeds. A notification is generated so you can fix the MTU mismatch on connecting switches and try again.

For native clusters: The cluster control link interface is Port-Channel48 by default. If you don't know which interface is the cluster control link, check the FXOS configuration for chassis for the Cluster-type interface assigned to the cluster.

a) Click **Edit** (✎) for the cluster control link interface.
b) On the **General** page, in the **MTU** field, enter a value between 1400 and 9184but not between 2561 and 8362. Due to block pool handling, this MTU size is not optimal for system operation. We suggest using the maximum, 9184.
c) Click **OK**.

Step 4 Configure data interfaces.

a) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the data interface. The rest of this procedure applies to the subinterfaces. See Add a subinterface, on page 1060.
b) Click **Edit** (✎) for the data interface.
c) Configure the name and other parameters. For regular firewall interfaces, see Configure routed mode interfaces, on page 1080 or, for transparent mode, Bridge group interfaces, on page 1086. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 1119..

Note
If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. See, Step 3, on page 958 to increase the cluster control link MTU, after which you can continue configuring the data interfaces.

d) For clustering on multiple chassis, set a unique. manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

e) Click **OK**. Repeat the above steps for other data interfaces.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Cloud-Delivered Firewall Management Center: Configure Cluster Health Monitor Settings

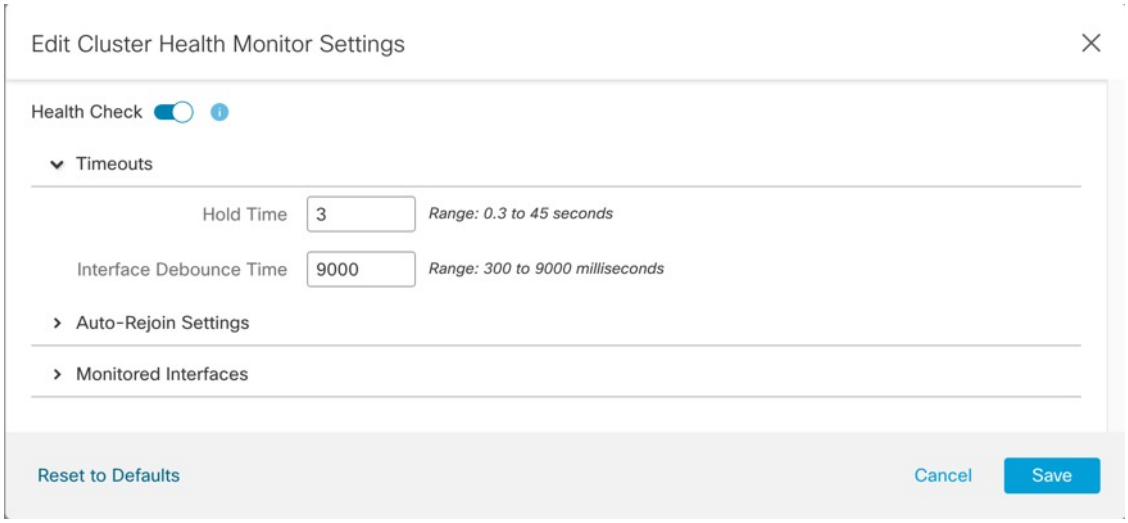
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



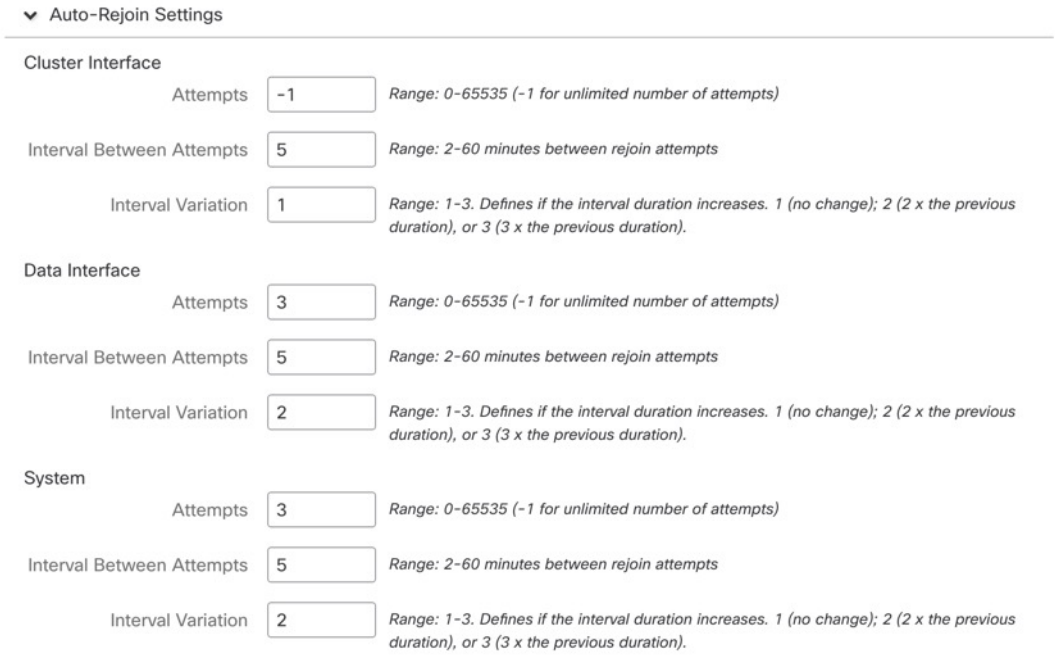
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 197: Disable the system health check



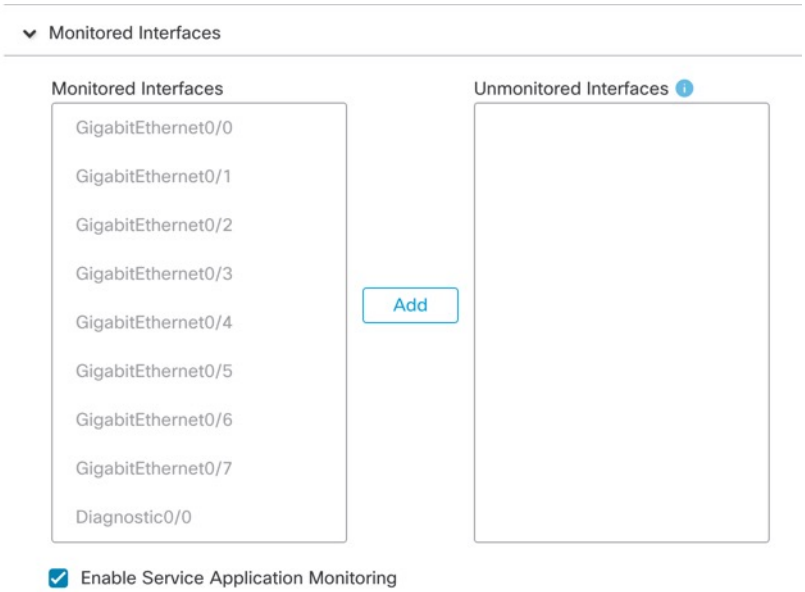
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 198: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 199: Configure monitored interfaces

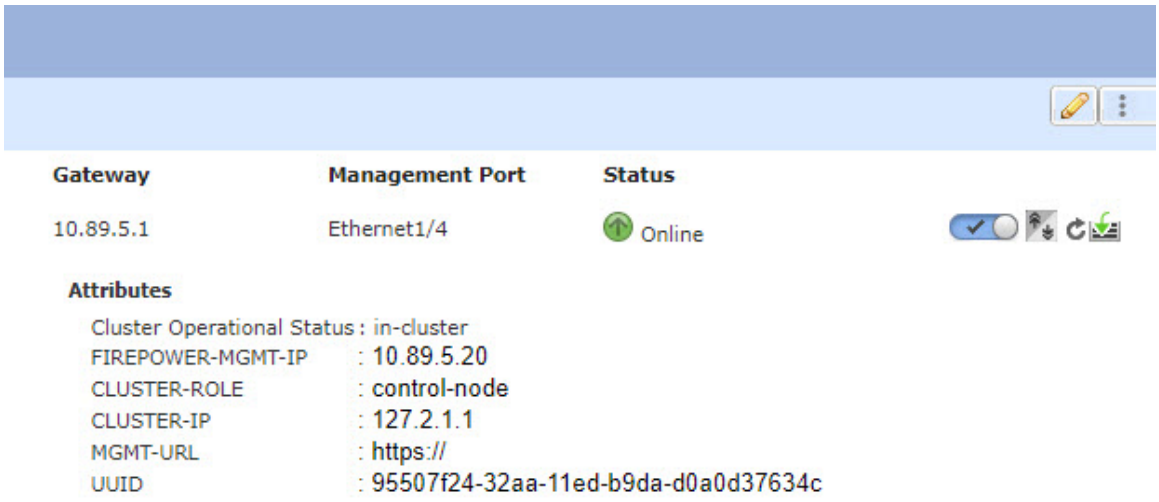
The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Deploy configuration changes.



FXOS: Remove a cluster node

The following sections describe how to remove nodes temporarily or permanently from the cluster.

Temporary removal

A cluster node will be automatically removed from the cluster due to a hardware or network failure, for example. This removal is temporary until the conditions are rectified, and it can rejoin the cluster. You can also manually disable clustering.

To check whether a device is currently in the cluster, check the cluster status

For Firewall Threat Defense using the Cloud-Delivered Firewall Management Center, you should leave the device in the Cloud-Delivered Firewall Management Center device list so that it can resume full functionality after you reenable clustering.

- Disable clustering in the application—You can disable clustering using the application CLI. Enter the **cluster remove unit** *name* command to remove any node other than the one you are logged into. The bootstrap configuration remains intact, as well as the last configuration synced from the control node, so you can later re-add the node without losing your configuration. If you enter this command on a data node to remove the control node, a new control node is elected.

  When a device becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, re-enable clustering. The Management interface remains up using the IP address the node received from the bootstrap configuration. However if you reload, and the node is still inactive in the cluster , the Management interface is disabled.

  To reenable clustering, on the Firewall Threat Defense enter **cluster enable**.

- Disable the application instance—
- Shut down the security module/engine—
- Shut down the chassis—

Permanent removal

You can permanently remove a cluster node using the following methods.

For Firewall Threat Defense using the Cloud-Delivered Firewall Management Center, be sure to remove the node from the Cloud-Delivered Firewall Management Center device list after you disable clustering on the chassis.

- Delete the logical device—
- Remove the chassis or security module from service—If you remove a device from service, you can add replacement hardware as a new node of the cluster.

Cloud-Delivered Firewall Management Center: Manage cluster members

After you deploy the cluster, you can change the configuration and manage cluster members.

Add a new cluster member

When you add a new cluster member in FXOS, the Cloud-Delivered Firewall Management Center adds the member automatically.

Before you begin

- Make sure the interface configuration is the same on the replacement unit as for the other chassis.

Follow these steps to add a new cluster member:

Procedure

Step 1 Add the new unit to the cluster in FXOS. Refer to the FXOS configuration guide.

Wait for the new unit to be added to the cluster. Refer to the Firewall Chassis Manager **Logical Devices** screen or use the Firewall Threat Defense **show cluster info** command to view cluster status.

Step 2 The new cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management** and choose the **Add**, **Cluster** tab **General** area **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the Cloud-Delivered Firewall Management Center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile**.
- System status **Tasks** —The Cloud-Delivered Firewall Management Center shows all registration events and failures.
- **Devices** > **Device Management** and then choose **Add Device**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

Replace a cluster member

You can replace a cluster member in an existing cluster. The Cloud-Delivered Firewall Management Center auto-detects the replacement unit. However, you must manually delete the old cluster member in the Cloud-Delivered Firewall Management Center. This procedure also applies to a unit that was reinitialized; in this case, although the hardware remains the same, it appears to be a new member.

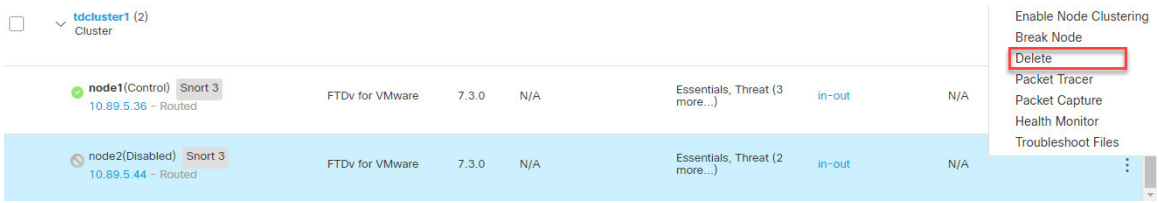
Before you begin

- Make sure the interface configuration is the same on the replacement unit as for other chassis.

Follow these steps to replace a cluster member:

Procedure

Step 1 For a new chassis, if possible, backup and restore the configuration from the old chassis in FXOS.



If you are replacing a module in a Firepower 9300, you do not need to perform these steps.

If you do not have a backup FXOS configuration from the old chassis, first perform the steps in Add a new cluster member, on page 964.

For information about all of the below steps, refer to the FXOS configuration guide.

a) Use the configuration export feature to export an XML file containing logical device and platform configuration settings for your Firepower 4100/9300 chassis.
b) Import the configuration file to the replacement chassis.
c) Accept the license agreement.
d) If necessary, upgrade the logical device application instance version to match the rest of the cluster.

Step 2 In the Cloud-Delivered Firewall Management Center for the old unit, choose **Devices** > **Device Management**, **More** (⋮) > **Delete** .

Step 3 Confirm that you want to delete the unit.

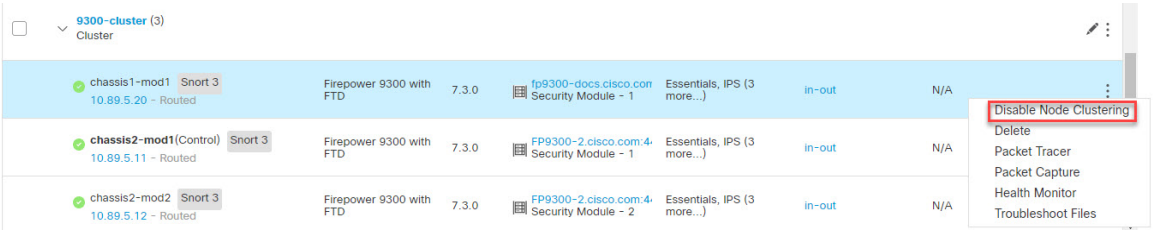
The unit is removed from the cluster and from the Cloud-Delivered Firewall Management Center devices list.

Step 4 The new or reinitialized cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮) icon or **Devices** > **Device Management** and then choose **Add**, **Cluster** page, **General** area, **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the Cloud-Delivered Firewall Management Center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile All**.

- Click **System** (⚙), and then click **Tasks**—The Cloud-Delivered Firewall Management Center shows all registration events and failures.

- **Devices** > **Device Management**, and then click **Add** > **Device**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

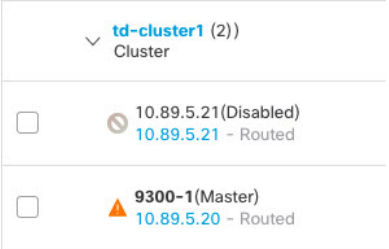


Deactivate a member

You may want to deactivate a member in preparation for deleting the unit, or temporarily for maintenance. This procedure is meant to temporarily deactivate a member; the unit will still appear in the Cloud-Delivered Firewall Management Center device list.

Note When a unit becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, reenable clustering. The Management interface remains up using the IP address the unit received from the bootstrap configuration. However if you reload, and the unit is still inactive in the cluster, the management interface is disabled. You must use the console for any further configuration.

Procedure



Step 1 For the unit you want to deactivate, choose **Devices** > **Device Management**, **More** (⋮), and then **Disable Clustering**.

You can also deactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮), and **Cluster Live Status**).

Step 2 Confirm that you want to disable clustering on the unit.

The unit will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To re-enable clustering, refer to Rejoin the cluster, on page 967.

Rejoin the cluster

If a unit was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster.

Procedure

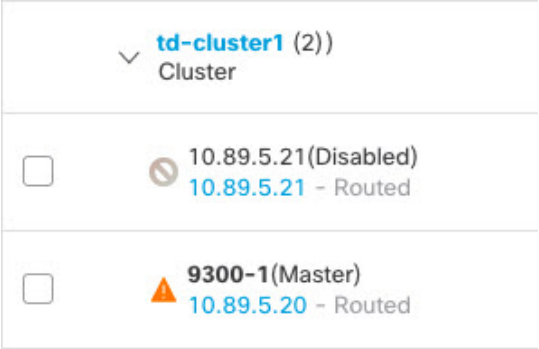
Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, **More** (⋮) > **Enable Clustering**.

You can also reactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**).

Step 2 Confirm that you want to enable clustering on the unit.

Unregister a data node

If you need to permanently remove a cluster node (for example, if you remove a module on the Firepower 9300, or remove a chassis), then you should unregister it from the Cloud-Delivered Firewall Management Center.



Do not unregister the node if it is still a healthy part of the cluster, or if you only want to disable the node temporarily. To remove it permanently from the cluster in FXOS, see FXOS: Remove a cluster node, on page 962. If you unregister it from the Cloud-Delivered Firewall Management Center, and it is still part of the cluster, it will continue to pass traffic, and could even become the control node—a control node that the Cloud-Delivered Firewall Management Center can no longer manage.

Before you begin

To manually deactivate the node, see Deactivate a member, on page 966. Before you unregister a node, the node must be inactive, either manually or because of a health failure.

Procedure

Step 1 Make sure the node is ready to be unregistered from the Cloud-Delivered Firewall Management Center. On **Devices** > **Device Management**, make sure the node shows **(Disabled)**.

You can also view each node's status on the **Cluster Status** dialog box available from **More** (⋮). If the status is stale, click **Reconcile All** on the **Cluster Status** dialog box to force an update.

Step 2 In the Cloud-Delivered Firewall Management Center for the data node you want to delete, choose **Devices** > **Device Management** and then click **Add** > **DeviceMore** (⋮) > **Unregister**.

Step 3 Confirm that you want to unregister the node.

The node is removed from the cluster and from the Cloud-Delivered Firewall Management Center devices list.

Change the control unit

The best method to change the control unit is to disable clustering on the control unit, wait for a new control election, and then re-enable clustering.

Caution If you must specify the *exact* unit you want to become the control unit, use the procedure in this section. Note that for centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**.

You can also access the **Cluster Status** dialog box from **Devices** > **Device Management** and choose the **Add**, **Cluster** page, **General** area, and **Cluster Live Status** link.

Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the check box, and click **OK**.

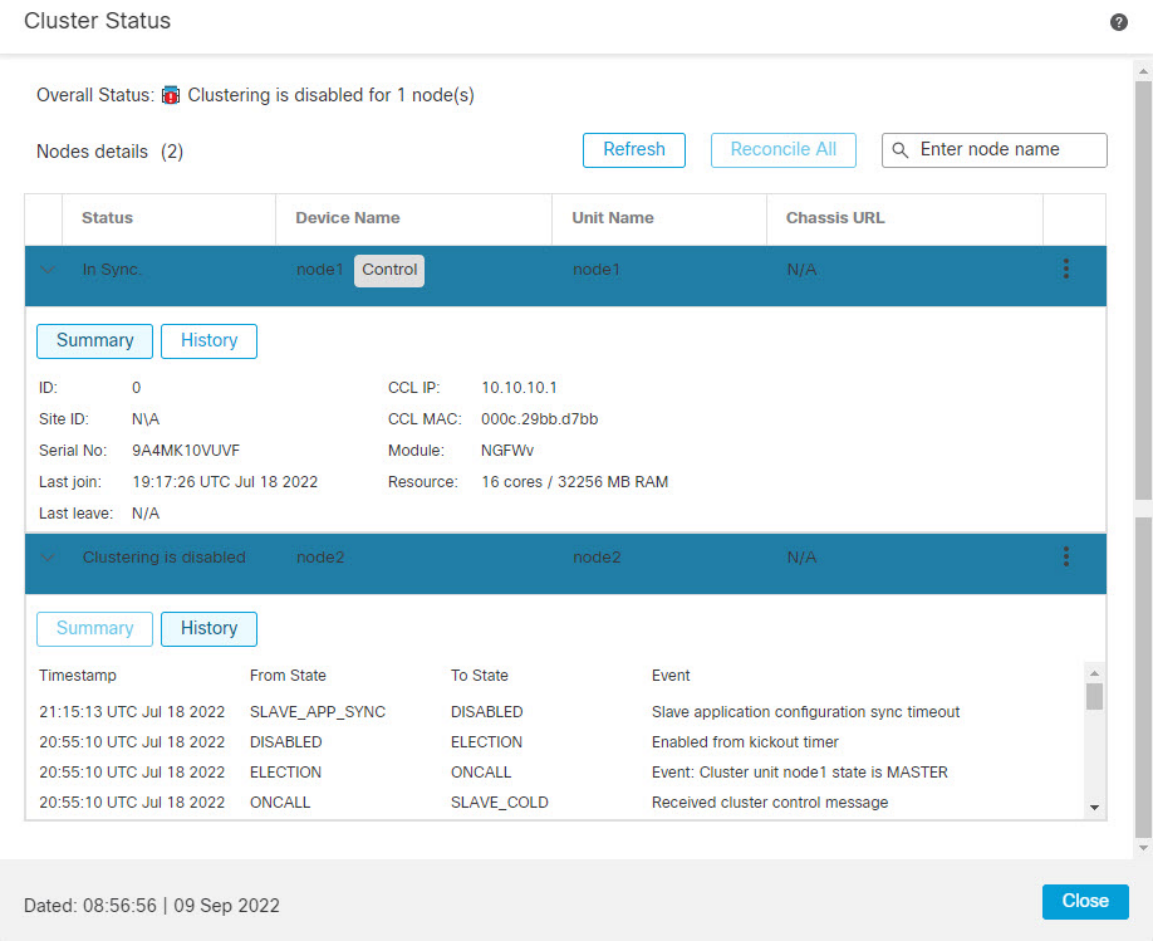
Reconcile cluster members

If a cluster member fails to register, you can reconcile the cluster membership from the chassis to the Cloud-Delivered Firewall Management Center. For example, a data unit might fail to register if the Cloud-Delivered Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management**, **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

You can also open the **Cluster Status** dialog box from the **Devices** > **Device Management** page **General** area, **Cluster Live Status** link.



Step 2 Click **Reconcile All**.

For more information about the cluster status, refer to Cloud-Delivered Firewall Management Center: Monitor the cluster, on page 969.

Cloud-Delivered Firewall Management Center: Monitor the cluster

You can monitor the cluster in Cloud-Delivered Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management** and then chose **Add**, **Cluster** page, **General** area, and **Cluster Live Status** link.

The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The unit is registered with the Cloud-Delivered Firewall Management Center.
- Pending Registration—The unit is part of the cluster, but has not yet registered with the Cloud-Delivered Firewall Management Center. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The unit is registered with the Cloud-Delivered Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- Joining cluster...—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Cloud-Delivered Firewall Management Center.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** (⋮) menu , you can perform the following status changes:

- **Disable Clustering**
- **Enable Clustering**

- **Change Role to Control**

- Click **System** (⚙), and then click **Tasks**.

  The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

- **Devices** > **Device Management** and then choose **Add Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes these states:

- In Sync.—The unit is registered with the Cloud-Delivered Firewall Management Center.
- Pending Registration—The unit is part of the cluster, but has not yet registered with the Cloud-Delivered Firewall Management Center. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The unit is registered with the Cloud-Delivered Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- Joining cluster...—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Cloud-Delivered Firewall Management Center.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** (⋮) menu, you can perform these status changes:

- **Disable Clustering**
- **Enable Clustering**
- **Change Role to Control**

Tasks page

Click **System** (⚙), and then click **Tasks**.

The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

Device management page

Devices > **Device Management** and then choose **Add Device** *cluster_name*.

When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

CLI commands for cluster monitoring

show cluster {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

To view aggregated data for the entire cluster or other information, use the **show cluster** command.

show cluster info [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

When a Firewall Threat Defense is the control node of a cluster, the Cloud-Delivered Firewall Management Center collects various metrics periodically from the device metric data collector.

The cluster health monitor is comprised of these components:

- Overview dashboard: Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Cloud-Delivered Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard: Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard: Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard: Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links: Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range: An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard: Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing cluster health

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

Ensure you have created a cluster from one or more devices in the Cloud-Delivered Firewall Management Center.

Follow these steps to view the cluster health monitor:

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 Click on the cluster name to view the cluster health statistics.

The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution: Traffic and packet distribution across the cluster nodes.
- Member Performance: Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL: Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, refer to Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 Configure the time range from the drop-down in the upper-right corner.

The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 View device monitor health and performance metrics in several predefined dashboards.

The metrics dashboards include:

- Overview: Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU: CPU utilization, including the CPU usage by process and by physical cores.

- Memory: Device memory utilization, including data plane and Snort memory usage.
- Interfaces: Interface status and aggregate traffic statistics.
- Connections: Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort: Statistics that are related to the Snort process.
- ASP drops: Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. Refer to Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

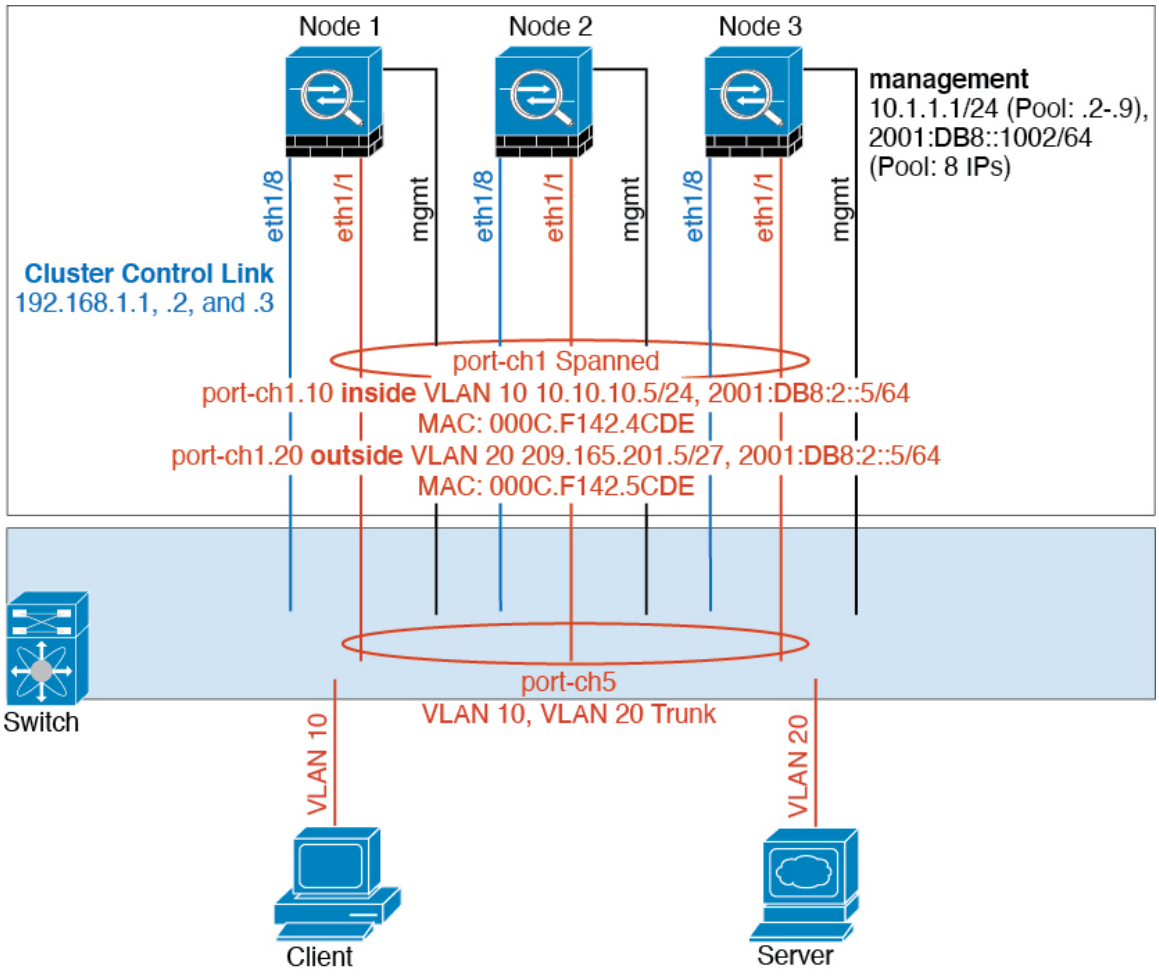
For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 63: Cluster Metrics

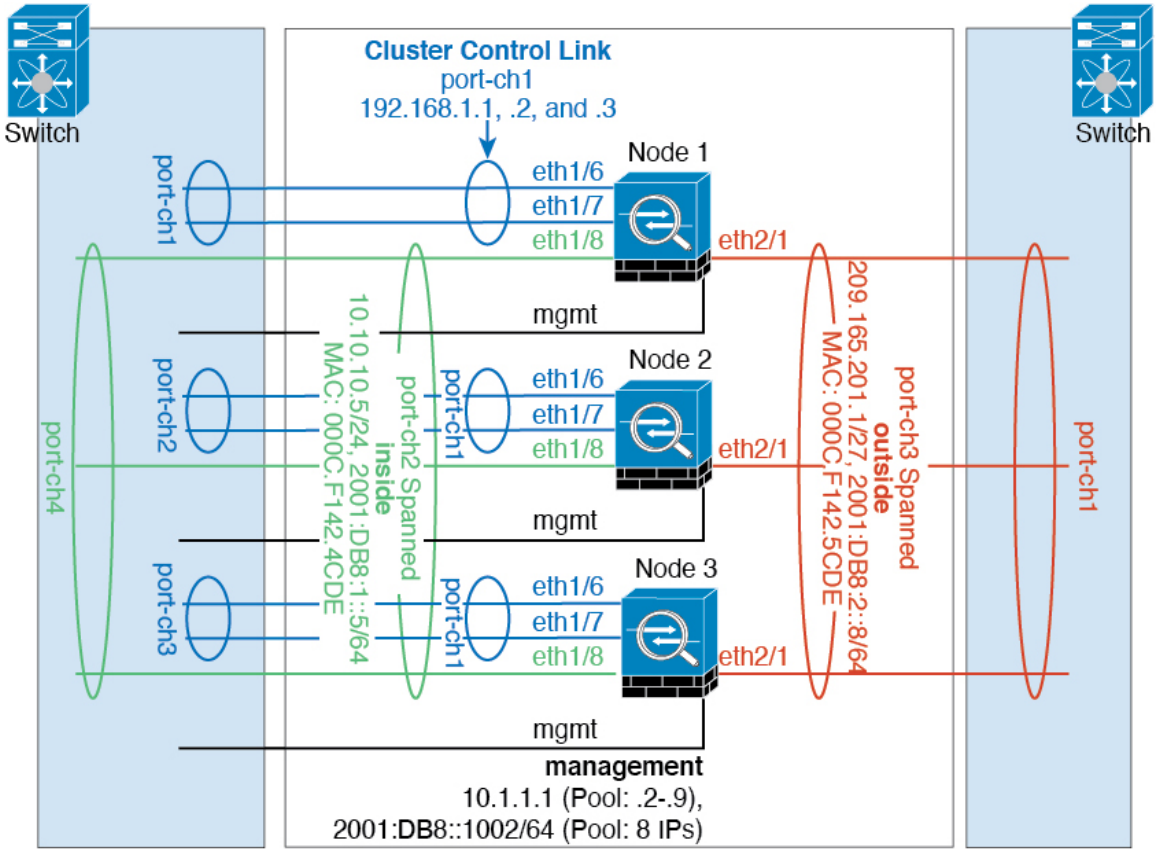
Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number



Examples for Clustering

These examples include typical deployments.

Firewall on a stick



Data traffic from different security domains are associated with different VLANs. For example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each Threat Defense has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The Threat Defense is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the Threat Defense becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic segregation

Provides the necessary bootstrap and interface configurations to implement traffic segregation using spanned EtherChannels in a cluster environment.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for clustering

This section includes more information about how clustering operates.

Firewall Threat Defense features and clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported features with clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Cloud-Delivered Firewall Management Center GUI. See FlexConfig policies, on page 1309.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Cloud-Delivered Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized features for clustering

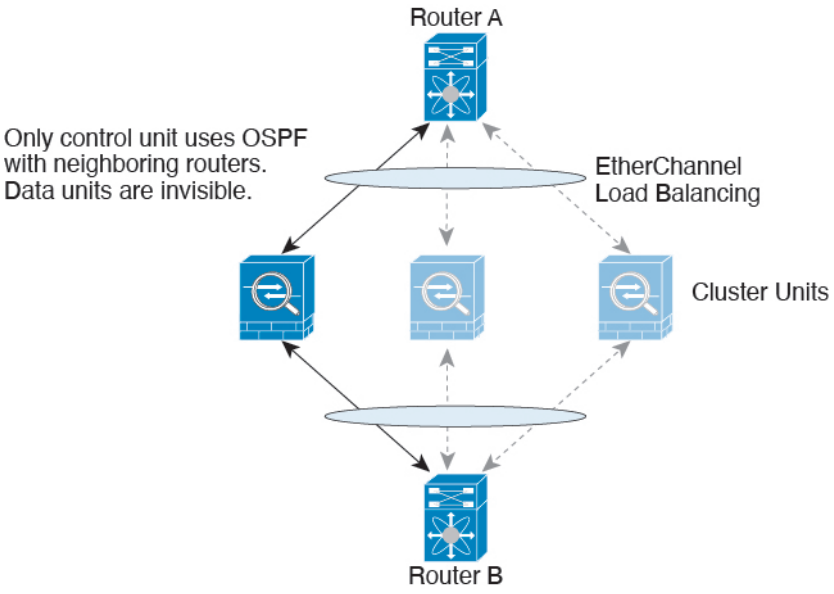
The following features are only supported on the control unit, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member units to the control unit over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control units before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control unit.

For centralized features, if the control unit fails, all connections are dropped, and you have to re-establish the connections on the new control unit.

- Site-to-site VPN
- The following application inspections:
  - DCERPC
  - NetBIOS
  - RSH
  - SUNRPC
  - TFTP
  - XDMCP
- Dynamic routing
- Static route monitoring



Connection settings

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic routing and clustering

The routing process only runs on the control unit, and routes are learned through the control unit and replicated to secondaries. If a routing packet arrives at a data unit, it is redirected to the control unit.

Figure 200: Dynamic Routing

After the data units learn the routes from the control unit, each unit makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control unit to data units. If there is a control unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

FTP and clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast routing and clustering

The control unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each data unit can forward multicast data packets.

NAT and clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When

a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP

- RSH
- SQLNET
- TFTP
- XDMCP
- SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP inspection and clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

TLS/SSL connections and clustering

The decryption states of TLS/SSL connections are not synchronized, and if the connection owner fails, then the decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Cisco TrustSec and clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and clustering

Site-to-site VPN is a centralized feature; only the control unit supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control unit and does not take advantage of the cluster high availability capabilities. If the control unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control unit is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the control unit.

VPN-related keys and certificates are replicated to all units.

Performance scaling factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, for TCP throughput, the Firepower 9300 with 3 SM-40 modules can handle approximately 135 Gbps of real world firewall traffic when running alone. For 2 chassis, the maximum combined throughput will be approximately 80% of 270 Gbps (2 chassis x 135 Gbps): 216 Gbps.

Control unit election

The control unit election is a automated process where cluster members determine which unit manages centralized features.

Election process and rules

Members of the cluster communicate over the cluster control link to elect a control unit as follows:

1. When you deploy the cluster, each unit broadcasts an election request every 3 seconds.
2. Any other units with a higher priority respond to the election request; the priority is set when you deploy the cluster and is not configurable.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes the control unit.
4. If a unit later joins the cluster with a higher priority, it does not automatically become the control unit; the existing control unit always remains as the control unit unless it stops responding, at which point a new control unit is elected.
5. In a *split brain* scenario when there are temporarily multiple control units, then the unit with highest priority retains the role while the other units return to data unit roles.

Note You can manually force a unit to become the control unit. For centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

High availability within the cluster

Clustering provides high availability by monitoring chassis, unit, and interface health and by replicating connection states between units.

Chassis-application monitoring

Chassis-application health monitoring is always enabled. The Firepower 4100/9300 chassis supervisor checks the Firewall Threat Defense application periodically (every second). If the Firewall Threat Defense device is up and cannot communicate with the Firepower 4100/9300 chassis supervisor for 3 seconds, the Firewall Threat Defense device generates a syslog message and leaves the cluster.

If the Firepower 4100/9300 chassis supervisor cannot communicate with the application after 45 seconds, it reloads the Firewall Threat Defense device. If the Firewall Threat Defense device cannot communicate with the supervisor, it removes itself from the cluster.

Unit health monitoring

Each unit periodically sends a broadcast keepaliveheartbeat packet over the cluster control link. If the control node does not receive any keepaliveheartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining node.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role. See Control unit election, on page 982 for more information.

Interface monitoring

Each node monitors the link status of all hardware interfaces in use, and reports status changes to the control node. For clustering on multiple chassis, Spanned EtherChannels use the cluster Link Aggregation Control Protocol (cLACP). Each chassis monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel, and informs the Firewall Threat Defense application if the interface is down. When you enable health monitoring, all physical interfaces are monitored by default (including the main EtherChannel for EtherChannel interfaces). Only named interfaces that are in an Up state can be monitored. For example, all member ports of an EtherChannel must fail before a *named* EtherChannel is removed from the cluster. You can optionally disable monitoring per interface.

If a monitored interface fails on a particular node, but it is active on other nodes, then the node is removed from the cluster. The amount of time before the Firewall Threat Defense device removes a node from the cluster depends on whether the node is an established member or is joining the cluster. The Firewall Threat Defense device does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the Firewall Threat Defense device to be removed from the cluster. For an established member, the node is removed after 500 ms.

For clustering on multiple chassis, if you add or delete an EtherChannel from the cluster, interface health-monitoring is suspended for 95 seconds to ensure that you have time to make the changes on each chassis.

Decorator application monitoring

When you install a decorator application on an interface, such as the Radware DefensePro application, then both the Firewall Threat Defense device and the decorator application must be operational to remain in the cluster. The unit does not join the cluster until both applications are operational. Once in the cluster, the unit monitors the decorator application health every 3 seconds. If the decorator application is down, the unit is removed from the cluster.

Status after failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

Rejoining scenarios and automatic retry behavior

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Cloud-Delivered Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members

are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

- Failed Chassis-Application Communication—When the Firewall Threat Defense application detects that the chassis-application health has recovered, it tries to rejoin the cluster automatically.

Data path connection state replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 64: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the cluster manages connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

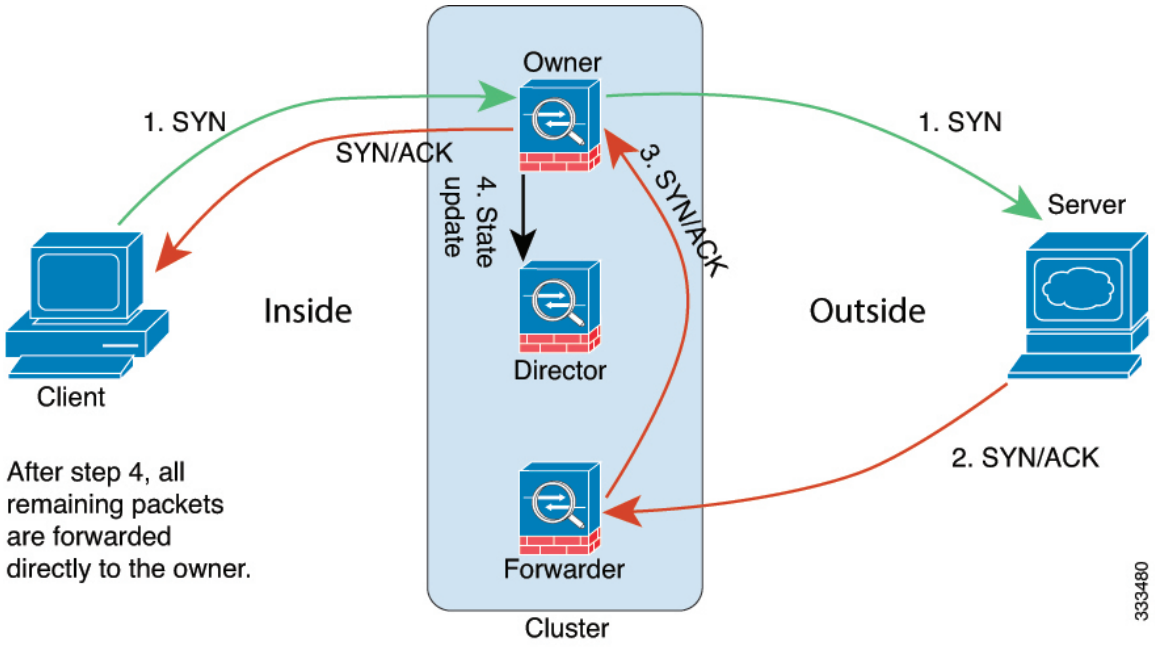
  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.

- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.



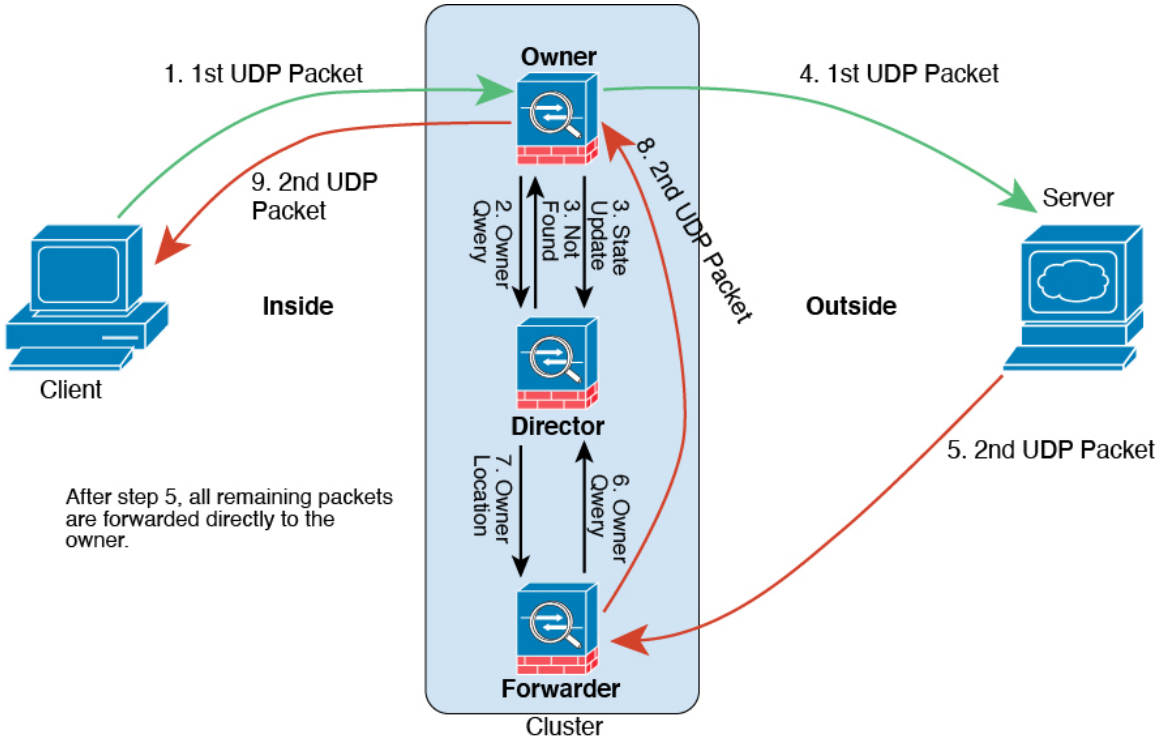
Port Address Translation Connections

New connection ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample data flow for TCP

The following example shows the establishment of a new connection.



1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample data flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. ***Figure 201: ICMP and UDP Data Flow***

   The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for clustering

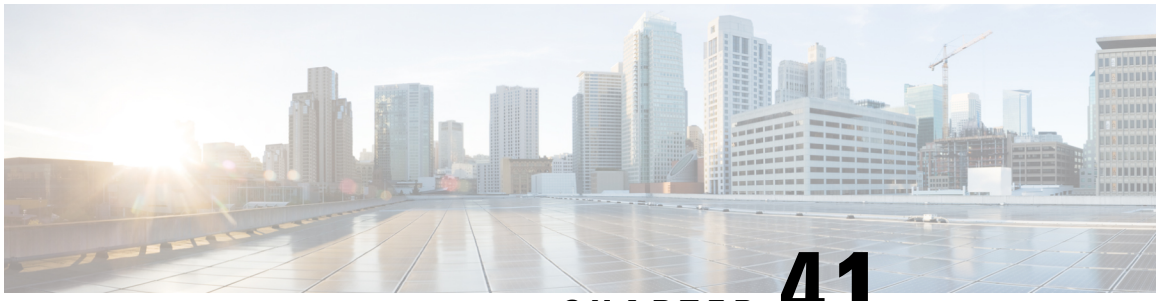
Table 65:

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
MTU ping test from data node on node join	20241030	7.6.0	When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size twice the cluster control link MTU. Previously, only the control node sent a ping. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again. Added/modified commands: **show cluster history**. See: Clustering for the Secure Firewall 3100/4200, Clustering for Threat Defense Virtual in a Private Cloud, Clustering for Threat Defense Virtual in a Public Cloud, Clustering for the Firepower 4100/9300
Cluster health monitor settings.	20221213	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard.	20221213	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**
Support for 16-node clusters.	20220609	7.2.0	You can now configure 16 node clusters for the Firepower 4100/9300. Previously, the maximum was 6 units. New/Modified screens: none. Supported platforms: Firepower 4100/9300
Cluster deployment for firewall changes completes faster.	20220609	7.2.0	Cluster deployment for firewall changes now completes faster. New/Modified screens: none.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Improved PAT port block allocation for clustering.	20220609	7.0.3	The improved PAT port block allocation ensures that the control unit keeps ports in reserve for joining nodes, and proactively reclaims unused ports. To best optimize the allocation, you can set the maximum nodes you plan to have in the cluster using the **cluster-member-limit** command using FlexConfig. The control unit can then allocate port blocks to the planned number of nodes, and it will not have to reserve ports for extra nodes you don't plan to use. The default is 16 nodes. You can also monitor syslog 747046 to ensure that there are enough ports available for a new node. New/Modified commands: **cluster-member-limit** (FlexConfig), **show nat pool cluster** [**summary**], **show nat pool ip detail**
Cluster deployment for Snort changes completes faster, and fails faster when there is an event.	20220609	7.0.3	Cluster deployment for Snort changes now completes faster. Also, when a cluster has an event that causes a Cloud-Delivered Firewall Management Center deployment to fail, the failure now occurs more quickly. New/Modified screens: none.
Improved cluster management.	20220609	7.0.3	Cloud-Delivered Firewall Management Center has improved cluster management functionality that formerly you could only accomplish using the CLI, including: • Enable and disable cluster units • Show cluster status from the Device Management page, including History and Summary per unit • Change the role to the control unit New/Modified screens: • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** > **General** area **> Cluster Live Status** link **Cluster Status** Supported platforms: Firepower 4100/9300

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Multi-instance clustering.	20220609	7.0.3	You can now create a cluster using container instances. On the Firepower 9300, you must include one container instance on each module in the cluster. You cannot add more than one container instance to the cluster per security engine/module. We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. New/Modified FXOS commands: **set port-type cluster** New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Add Cluster** • **Interfaces** > **All Interfaces** > **Add New** drop-down menu**Subinterface Type field** Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Configuration sync to data units in parallel.	20220609	7.0.3	The control unit now syncs configuration changes with data units in parallel by default. Formerly, synching occurred sequentially. New/Modified screens: none.
Messages for cluster join failure or eviction added to **show cluster history**.	20220609	7.0.3	New messages were added to the **show cluster history** command for when a cluster unit either fails to join the cluster or leaves the cluster. New/Modified commands: **show cluster history** New/Modified screens: none.
Initiator and responder information for Dead Connection Detection (DCD), and DCD support in a cluster.	20220609	7.0.3	If you enable Dead Connection Detection (DCD), you can use the **show conn detail** command to get information about the initiator and responder. Dead Connection Detection allows you to maintain an inactive connection, and the **show conn** output tells you how often the endpoints have been probed. In addition, DCD is now supported in a cluster. New/Modified commands: **show conn** (output only). Supported platforms: Firewall Threat Defense on the Firepower 4100/9300

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Adding clusters is easier.	20220609	7.0.3	You can now add any unit of a cluster to the Cloud-Delivered Firewall Management Center, and the other cluster units are detected automatically. Formerly, you had to add each cluster unit as a separate device, and then group them into a cluster. Adding a cluster unit is also now automatic. Note that you must delete a unit manually. New/Modified screens: **Devices** > **Device Management** > **Add** drop-down menu **Device** > **Add Device** dialog box **Devices** > **Device Management** > **Cluster** tab**General** area**Cluster Registration Status** **Current Cluster Summary** link **Cluster Status** dialog box Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Support for site-to-site VPN with clustering as a centralized feature.	20220609	7.0.3	You can now configure site-to-site VPN with clustering. Site-to-site VPN is a centralized feature; only the control unit supports VPN connections. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Automatically rejoin the cluster after an internal failure.	20220609	7.0.3	Formerly, many internal error conditions caused a cluster unit to be removed from the cluster, and you were required to manually rejoin the cluster after resolving the issue. Now, a unit will attempt to rejoin the cluster automatically at the following intervals: 5 minutes, 10 minutes, and then 20 minutes. Internal failures include: application sync timeout; inconsistent application statuses; and so on. New/Modified command: **show cluster info auto-join** No modified screens. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Clustering on multiple chassis for 6 modules; Firepower 4100 support.	20220609	7.0.3	With FXOS 2.1.1, you can now enable clustering on multiple chassis of the Firepower 9300 and 4100. For the Firepower 9300, you can include up to 6 modules. For example, you can use 1 module in 6 chassis, or 2 modules in 3 chassis, or any combination that provides a maximum of 6 modules. For the Firepower 4100, you can include up to 6 chassis. **Note** Inter-site clustering is also supported. However, customizations to enhance redundancy and stability, such as site-specific MAC and IP addresses, director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature. No modified screens. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300



Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Clustering on multiple modules with one Firepower 9300 chassis.	20220609	7.0.3	You can cluster up to 3 security modules within the Firepower 9300 chassis. All modules in the chassis must belong to the cluster. New/Modified screens: **Devices** > **Device Management** > **Add** > **Add Cluster** **Devices** > **Device Management** > **Cluster** Supported platforms: Firewall Threat Defense on the Firepower 9300

CHAPTER 41

Interface Overview

The Firewall Threat Defense device includes data interfaces that you can configure in different modes, as well as a management interface.

- Management interface, on page 997
- Interface Mode and Types, on page 999
- Security zones and interface groups, on page 999
- Auto-MDI/MDIX feature, on page 1001
- Redundant interfaces (deprecated), on page 1001
- Default settings for interfaces, on page 1001
- Create security zone and interface group objects, on page 1002
- Enable the physical interface and configure Ethernet settings, on page 1003
- Configure EtherChannel interfaces, on page 1006
- Sync Interface Changes with the Cloud-Delivered Firewall Management Center, on page 1014
- Network module management for Secure Firewall 3100/4200, on page 1015
- Merge the management and diagnostic interfaces, on page 1030
- History for interfaces, on page 1035

Management interface

A management interface is a shared physical interface that enables communication between the diagnostic logical interface and the management logical interface on security appliances.

Interface configuration details

In Version 7.3 and earlier, the physical management interface is shared between the Diagnostic logical interface and the Management logical interface. In Version 7.4 and later, the diagnostic interface is merged with management for a simplified user experience.

Management interface

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Cloud-Delivered Firewall Management Center. It uses its own IP address and static routing.

Management interface configuration and monitoring

You can configure its settings at the CLI using the **configure network** command. You can also view its status on the **Devices** > **Device Management** page. If you change the IP address at the CLI after you add it to the Cloud-Delivered Firewall Management Center, you can match the IP address in the Cloud-Delivered Firewall Management Center in the **Devices** > **Device Management** area.

You can alternatively manage the Firewall Threat Defense using a data interface instead of the management interface.

Diagnostic interface

Diagnostic interface shares a physical port with the Management interface but requires different IP addresses on the same network. A diagnostic interface allows only management traffic.

Legacy diagnostic interface support

For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available.

If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically.

If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. To manually merge the Management and Diagnostic interfaces, see Merge the management and diagnostic interfaces, on page 1030. Configurations that prevent an automatic merge include these:

- A data interface named "management"—This name is reserved for use with the merged Management interface.
- IP Address on Diagnostic
- DNS enabled on Diagnostic
- Syslog, SNMP, RADIUS or AD (for remote access VPN) source interface is Diagnostic
- RADIUS or AD (for remote access VPN) with no source interface specified, and there is at least one interface configured as management-only (including Diagnostic)—The default route lookup for these services has changed from the management-only routing table to the data routing table, with no fallback to management. Therefore, you cannot use a management-only interface other than Management.
- Static routes on Diagnostic
- Dynamic routing on Diagnostic
- HTTP server on Diagnostic
- ICMP on Diagnostic
- DDNS for Diagnostic
- FlexConfig using Diagnostic

For more information about how the legacy Diagnostic interface operates, see the 7.3 version of this guide.

Interface Mode and Types

You can deploy Firewall Threat Defense interfaces in two modes: Regular firewall mode and IPS-only mode. You can include both firewall and IPS-only interfaces on the same device.

Regular Firewall Mode

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 153 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the Firewall Threat Defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

IPS-Only Mode

You can configure your device in either a passive or inline IPS deployment. In a passive deployment, you deploy the system out-of-band from the flow of network traffic. In an inline deployment, you configure the system transparently on a network segment by binding two interfaces together.

Security zones and interface groups

You can assign each interface to a security zone, an interface group, or both. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface on one or more devices to the "inside" zone, and the "outside" interfaces to the "outside" zone. You can then configure your access control policy to enable traffic to go from the inside zone to the outside zone for every device using the same zones.

Security zones and interface groups functionality

To view the interfaces that belong to each object, choose **Objects** > **Object Management** and click **Interface**. This page lists the security zones and interface groups configured on your managed devices. You can expand each interface object to view the type of interfaces in each interface object.

Note Policies that apply to **any** zone (a global policy) apply to interfaces in zones as well as any interfaces that are not assigned to a zone.

Note The Management interface does not belong to a zone or interface group.

Security zones and interface groups have different membership and usage characteristics:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

  You can use interface groups in NAT policies, prefilter policies, and QoS policies, as well as features that let you specify the interface name directly, such as Syslog servers or DNS servers.

Some policies only support security zones, while other policies support zones and groups. Unless you need the functionality an interface group provides, you should default to using security zones because security zones are supported for all features.

You cannot change an existing security zone to an interface group or vice-versa. Instead, you must create a new interface object.

Note Although tunnel zones are not interface objects, you can use them in place of security zones in certain configurations; see Using tunnel zones to apply access control at the tunnel level, on page 2534.

Interface objects are categorized by these types:

- Passive—For IPS-only passive or ERSPAN interfaces.
- Inline—For IPS-only inline set interfaces.
- Switched—For regular firewall bridge group interfaces.
- Routed—For regular firewall routed interfaces.
- ASA—(Security zones only) For legacy ASA FirePOWER device interfaces.
- Management—(Interface groups only) For management-only interfaces.
- Loopback—(Interface groups only) For loopback interfaces.

All interfaces in an interface object must be of the same type. After you create an interface object, you cannot change the type of interfaces it contains.

The interface (or zone name) itself does not provide any default behavior in regarding the security policy. We recommend using names that are self-describing to avoid mistakes in future configuration. A good name signifies a logical segment or traffic specification, for example:
