- Names of internal interfaces—InsideV110, InsideV160, InsideV195
- Names of DMZ interfaces—DMZV11, DMZV12, DMZV-TEST
- Names of external interfaces—Outside-ASN78, Outside-ASN91

Auto-MDI/MDIX feature

Auto-MDI/MDIX is a feature that eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. The feature is enabled by default with auto-negotiation on RJ-45 interfaces and requires either speed or duplex to be set to auto-negotiate. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Redundant interfaces (deprecated)

Redundant interfaces were supported for the ASA 5500-X platforms only. We don't recommend configuring them for other platforms.

Default settings for interfaces

This section lists default settings for interfaces.

Default state of interfaces

The default state of an interface depends on the type.

- Physical interfaces—Disabled. The exception is the Management interface that is enabled for initial setup. Physical interfaces includes switch ports.
- VLAN subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces (ISA 3000)—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.
- EtherChannel port-channel interfaces (Firepower and Secure Firewall models)—Disabled.

Note For the Firepower 4100/9300, you can administratively enable and disable interfaces in both the chassis and in the Cloud-Delivered Firewall Management Center. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and Cloud-Delivered Firewall Management Center.

Default speed and duplex

By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.

By default, the speed and duplex for fiber (SFP) interfaces are set to the maximum speed, with auto-negotiation enabled. If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example,

N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

For the Secure Firewall 3100/4200 the speed is set to detect the installed SFP speed.

Create security zone and interface group objects

Create empty interface objects that can be populated with interfaces later, or create security zones while configuring interfaces to provide logical grouping and management of device interfaces.

Add security zones and interface groups to which you can assign device interfaces.

Tip You can create empty interface objects and add interfaces to them later. To add an interface, the interface must have a name. You can also create security zones (but not interface groups) while configuring interfaces.

Before you begin

Understand the usage requirements and restrictions for each type of interface object. See Security zones and interface groups, on page 999.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Interface**.

You can alternatively choose **Objects** > **Other FTD Objects** to create objects.

Step 2 Click **Add > Security Zone** or **Add > Interface Group**.

Step 3 Enter a **Name**.

Do not use the same name as a network or port object. These object names are deployed to the device, and duplicate names result in a failed deployment.

Step 4 Choose an **Interface Type**.

Step 5 (Optional) From the **Device** > **Interfaces** drop-down list, choose a device that contains interfaces you want to add.

You do not need to assign interfaces on this screen; you can instead assign interfaces to the zone or group when you configure the interface.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Enable the physical interface and configure Ethernet settings

Before you begin

If you changed the physical interfaces on the device after you added it to the Cloud-Delivered Firewall Management Center , you need to refresh the interface listing by clicking **Sync Interfaces from device** on the top left of **Interfaces** . For the 3100 /4200 , which supports hot swapping, see Network module management for Secure Firewall 3100/4200, on page 1015 before you change interfaces on a device.

This section describes how to:

- Enable the physical interface. By default, physical interfaces are disabled (with the exception of the Management interface).
- Set a specific speed and duplex. By default, speed and duplex are set to Auto.

This procedure only covers a small subset of interface settings. Refrain from setting other parameters at this point. For example, you cannot name an interface that you want to use as part of an EtherChannel interface. The exact interface options vary depending on your model and interface type.

Note For the Firepower 4100/9300 , you configure basic interface settings in FXOS. See Configure a physical interface for more information.

Note For switch ports, see Configure switch ports, on page 1040 .

You can also click the **Virtual Tunnels** tab to view details of dynamic and static VTIs of route-based VPNs on the device. For more information, see View virtual tunnel interface details, on page 1769 .

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Enable the interface by checking the **Enabled** check box.

a) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 4 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed** .

- **Duplex** —Choose **Full** or **Half** . SFP interfaces only support **Full** duplex. However, the SFP interface (Ethernet 1/5) of Secure Firewall 220 supports **Full** and **Half** duplex.
- **Speed** —Choose a speed (varies depending on the model). For SFPs, choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always full, autonegotiation

is enabled, and FEC is set to auto. For dual-speed transceivers, the lower speed is used. This option is useful if you later change the network module to a different model, and want the speed to update automatically. Some switches and transceivers don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

Note
You cannot modify the speed of a high availability or a cluster control link interface.

- **Auto-negotiation** —Set the interface to negotiate the link status and flow control.

  Except for the 1100 and 2100 , autonegotiation is set separately from the speed. Some switches don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

- **Forward Error Correction Mode** —For 25Gbps and higher interfaces, enable Forward Error Correction (FEC).

  For an EtherChannel member interface, configure FEC before adding it to the EtherChannel. If you remove the interface from EtherChannel and then reboot, reconfigure the FEC for the interface.

  Some switches don't support auto mode for FEC, especially for larger interfaces. Be sure to manually configure the setting, depending on the switch support. We don't recommend disabling FEC because the EtherChannel may not function correctly.

  The setting chosen when you use **auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 66: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC *x* M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate
25/50/100G	Clause 91 RS-FEC	Clause 91 RS-FEC

Note
From Version 7.4.2, Firewall Threat Defense supports the SFP 10G_25G_CSR_S module. To avoid link-down issues after a reboot, Forward Error Correction (FEC) must be enabled on these interfaces.

Step 5 (Optional) Enable Link Layer Discovery Protocol (LLDP) by clicking **Hardware Configuration** > **Network Connectivity** .

- **Enable LLDP Receive** —Enables the firewall to receive LLDP packets from its peers.

- **Enable LLDP Transmit** —Enables the firewall to send LLDP packets to its peers.

Step 6 (Optional) Enable pause (XOFF) frames for flow control by clicking **Hardware Configuration** > **Network Connectivity** , and checking **Flow Control Send** .

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note
The Firewall Threat Defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flowcontrol enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Step 7 In the **Mode** drop-down list, choose one of the following:

- **None** —Choose this setting for regular firewall interfaces and inline sets. The mode will automatically be changed to Routed, Switched, or Inline based on further configuration.
- **Passive** —Choose this setting for passive IPS-only interfaces.
- **Erspan** —Choose this setting for ERSPAN passive IPS-only interfaces.

Step 8 In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to distribute the traffic across multiple egress interfaces.

Step 9 Click **OK** .

Click **Save**.

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Continue configuring interfaces.

- Regular Firewall Interfaces, on page 1039
- Inline Sets and Passive Interfaces, on page 1119

Configure EtherChannel interfaces

This section tells how to configure EtherChannel interfaces.

About EtherChannels

This section describes EtherChannels.

EtherChannels

An 802.3ad EtherChannel is a logical interface, called a port-channel interface) that consists of a bundle of individual Ethernet links, known as a channel group. This approach increases the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels, depending on how many interfaces your model supports.

Channel group interfaces

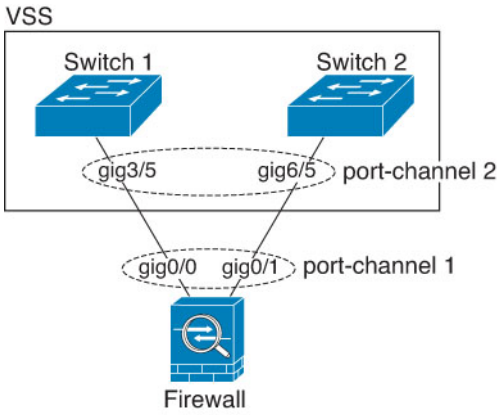
Channel group interfaces enable EtherChannel aggregation with specific capacity and configuration requirements. Understanding these interface specifications ensures proper EtherChannel deployment and performance.

Each channel group can have up to 8 active interfaces, except for the ISA 3000, which support 16 active interfaces. On switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group. Only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

The EtherChannel aggregates traffic across all the available active interfaces in the channel. A proprietary hash algorithm selects the interface, using criteria such as source or destination MAC addresses, IP addresses, TCP and UDP port numbers, and VLAN numbers.

EtherChannel connection to other devices



An EtherChannel connection to other devices requires the connected device to support 802.3ad EtherChannels for compatibility.

EtherChannel connection requirements and configurations

The device to which you connect the Firewall Threat Defense EtherChannel must also support 802.3ad EtherChannels. For example, you can connect to the Catalyst 6500 switch or the Cisco Nexus 7000.

When the switch is part of a Virtual Switching System (VSS) or Virtual Port Channel (vPC), you can connect Firewall Threat Defense interfaces within the same EtherChannel to separate switches in the VSS/vPC. The switch interfaces are members of the same EtherChannel port-channel interface because the separate switches act like a single switch.

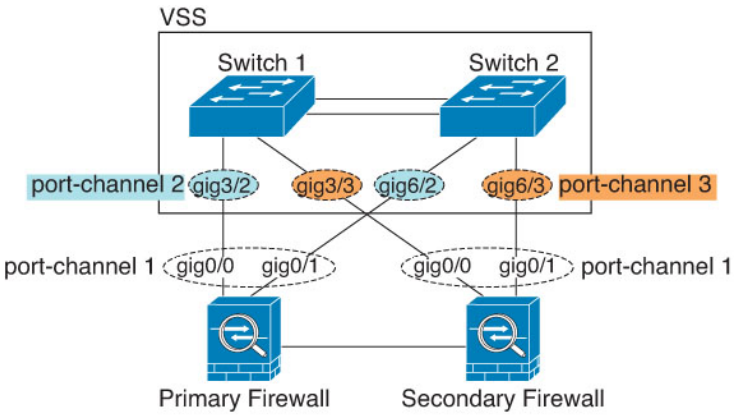


Figure 202: Connecting to a VSS/vPC

Note If the Firewall Threat Defense device is in transparent firewall mode, and you place the Firewall Threat Defense device between two sets of VSS/vPC switches, then be sure to disable Unidirectional Link Detection (UDLD) on any switch ports connected to the Firewall Threat Defense device with an EtherChannel. If you enable UDLD, then a switch port may receive UDLD packets sourced from both switches in the other VSS/vPC pair. The receiving switch will place the receiving interface in a down state with the reason "UDLD Neighbor mismatch".

If you use the Firewall Threat Defense device in an Active/Standby failover deployment, you need to create separate EtherChannels on the switches in the VSS/vPC, one for each Firewall Threat Defense device. On each Firewall Threat Defense device, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both Firewall Threat Defense devices,the EtherChannel would not be established because of the separate Firewall Threat Defense system IDs. Also, using a single EtherChannel would not be desirable because you do not want traffic sent to the standby Firewall Threat Defense device.

Figure 203: Active/Standby failover and VSS/vPC

Link aggregation control protocol

The Link Aggregation Control Protocol (LACP) is a network protocol that aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

LACP interface configuration modes

You can configure each physical interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- Passive—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. Not supported on hardware models.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

Load balancing

Load balancing is a distribution mechanism that distributes packets to interfaces in the EtherChannel and ensures transparent failover when active interfaces go down by rebalancing traffic between remaining links.

Load balancing operation details

The Firewall Threat Defense device distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable). The resulting hash is divided by the number of active links in a modulo operation where the resulting remainder determines which interface owns the flow. All packets with a *hash_value* **mod** *active_links* result of 0 go to the first interface in the EtherChannel, packets with a result of 1 go to the second interface, packets with a result of 2 go to the third interface, and so on. For example, if you have 15 active links, then the modulo operation provides values from 0 to 14. For 6 active links, the values are 0 to 5, and so on.

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

EtherChannel MAC address

An EtherChannel MAC address is a network identifier that is shared by all interfaces in the EtherChannel group. This makes the EtherChannel transparent to network applications and users by presenting one logical connection.

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

Platform-specific MAC address behavior

MAC address assignment for EtherChannel interface varies by hardware platform.

Firepower and Secure Firewall Hardware

The port-channel interface uses the MAC address of the internal interface Internal-Data 0/1. You can manually configure a MAC address for the port-channel interface if needed. All EtherChannel interfaces on a chassis use the same MAC address, so be aware that if you use SNMP polling, for example, multiple interfaces will have the same MAC address.

Note Member interfaces only use the Internal-Data 0/1 MAC address after a reboot. Prior to rebooting, the member interface uses its own MAC address. If you add a new member interface after a reboot, you will have to perform another reboot to update its MAC address.

Guidelines for EtherChannels and redundant interfaces

Provides essential configuration rules and limitations for implementing EtherChannels and redundant interfaces to maintain network stability and high availability.

Bridge Group

In routed mode, Cloud-Delivered Firewall Management Center -defined EtherChannels are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

High availability

- When you use an EtherChannel interface as a High availability link, it must be pre-configured on both units in the High availability pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because the High availability link itself is required for replication .
- If you use an EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal. For the Firepower 4100/9300 chassis , all interfaces, including EtherChannels, need to be pre-configured on both units.
- You can monitor EtherChannel interfaces for High availability . When an active member interface fails over to a standby interface, this activity does not cause the EtherChannel interface to appear to be failed when being monitored for device-level High availability . Only when all physical interfaces fail does the EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable) .
- If you use an EtherChannel interface for a High availability or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a High availability link. To alter the configuration, you need to temporarily disable High availability , which prevents High availability from occurring for the duration.

Model Support

- You cannot add EtherChannels in the Cloud-Delivered Firewall Management Center for the Firepower 4100/9300 or the Firewall Threat Defense Virtual . The Firepower 4100/9300 supports EtherChannels, but you must perform all hardware configuration of EtherChannels in FXOS on the chassis.

- You cannot use Firepower 1010 or Secure Firewall 1210/1220 switch ports or VLAN interfaces in EtherChannels.

Clustering

- To configure a spanned EtherChannel or an individual cluster interface, see the clustering chapter.

General Redundant Interface Guidelines

- You can configure up to 8 redundant interface pairs.
- All the Firewall Threat Defense configuration refers to the logical redundant interface instead of the member physical interfaces.
- You cannot use a redundant interface as part of an EtherChannel, nor can you use an EtherChannel as part of a redundant interface. You cannot use the same physical interfaces in a redundant interface and an EtherChannel interface. You can, however, configure both types on the Firewall Threat Defense device if they do not use the same physical interfaces.
- If you shut down the active interface, then the standby interface becomes active.
- Redundant interfaces do not support the Management *slot* / *port* interfaces as members. You can, however, set a redundant interface comprised of non- Management interfaces as management-only.

General EtherChannel Guidelines

- You can configure up to 48 EtherChannels, depending on how many interfaces are available on your model.
- Each channel group can have up to 8 active interfaces, except for ASA models and the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- When you add the first member interface, it sets the required hardware properties of all member interfaces.
    - The media type of member interfaces can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix RJ-45 and SFP interfaces.
    - All interfaces must be set to the same speed and duplex.
    - The first interface sets the speed *capacity* , which cannot be changed later.
- The device to which you connect the Firewall Threat Defense EtherChannel must also support 802.3ad EtherChannels.
- The Firewall Threat Defense device does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the Firewall Threat Defense device will drop the tagged LACPDUs.
- The LACP rate depends on the model. When you set the rate (normal or fast), the device requests that rate from the connecting switch.

- In Cisco IOS software versions earlier than 15.1(1)S2, Firewall Threat Defense does not support connecting an EtherChannel to a switch stack. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time.
- Match the speed, duplex, and auto-negotiation settings on every EtherChannel member interface and its corresponding peer port. For a 10/100-Mbps member link, use auto-negotiation at both ends, or use the same fixed speed and duplex settings at both ends. If one end is fixed at full duplex while the other end uses auto-negotiation, the auto-negotiating side defaults to half duplex, resulting in a duplex mismatch.
- All the Firewall Threat Defense configuration refers to the logical EtherChannel interface instead of the member physical interfaces.

Configure an EtherChannel

Create an EtherChannel port-channel interface to aggregate multiple physical interfaces into a single logical interface for increased bandwidth and redundancy.

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. See Add an EtherChannel (port channel) for more information.

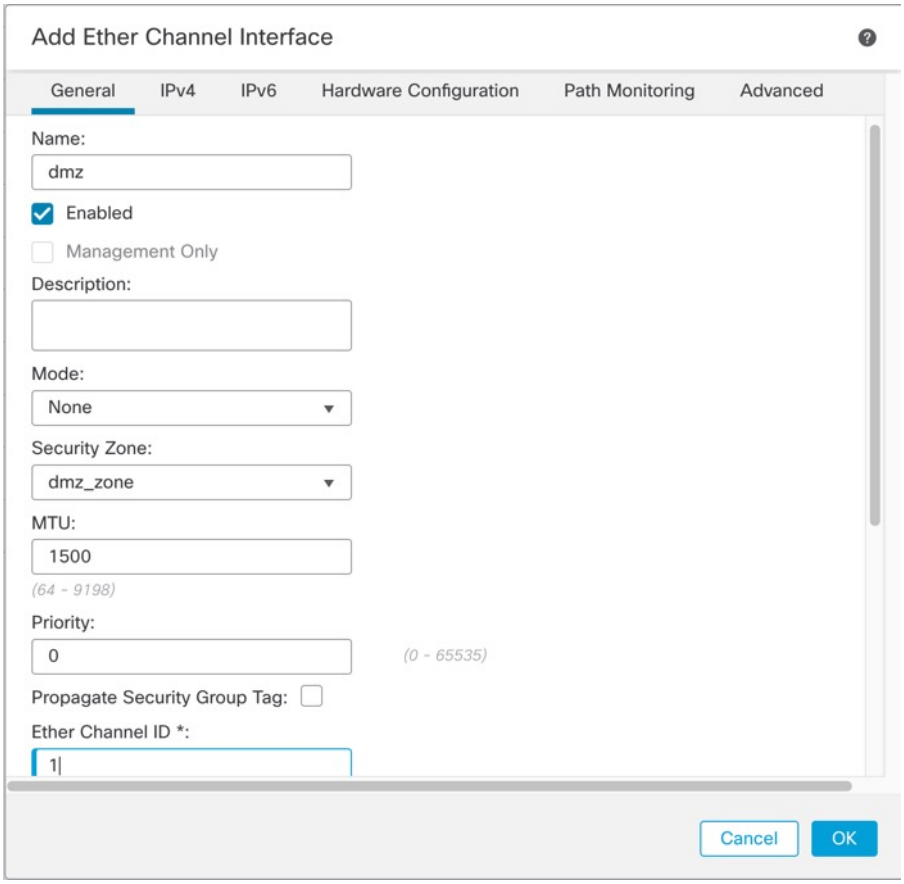
Before you begin

- When you add the first member interface, it sets the required hardware properties of all member interfaces. See Guidelines for EtherChannels and redundant interfaces, on page 1009 for more details about member interface requirements.
- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name.

Note If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

Follow these steps to configure an EtherChannel:

Procedure



Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Enable the member interfaces according to Enable the physical interface and configure Ethernet settings, on page 1003.

Step 3 Click **Add Interfaces** > **Ether Channel Interface**.

Step 4 On the **General** tab, set the **Ether Channel ID** to a number between 1 and 48 (1 and 8 for the Firepower 1010 and Secure Firewall 1210, 1 and 10 for the Secure Firewall 1220).

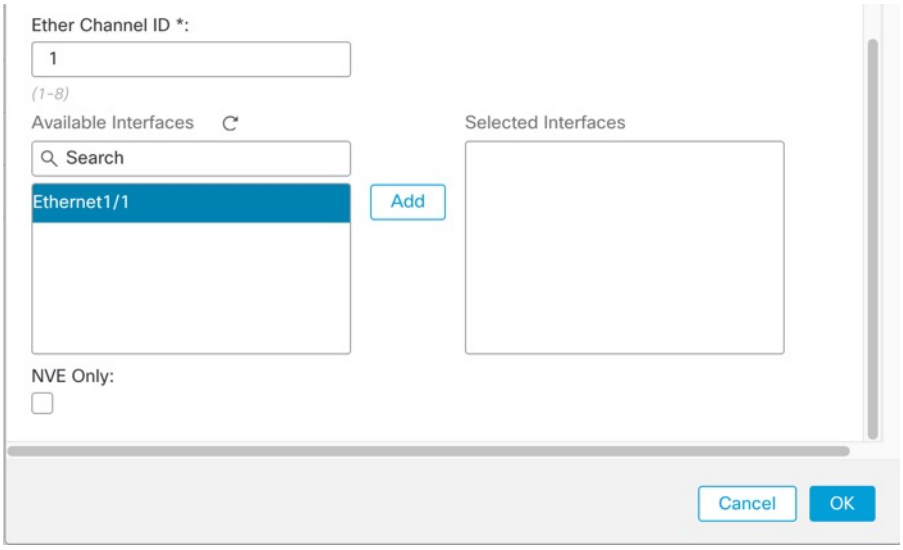


Figure 204: Add EtherChannel interface

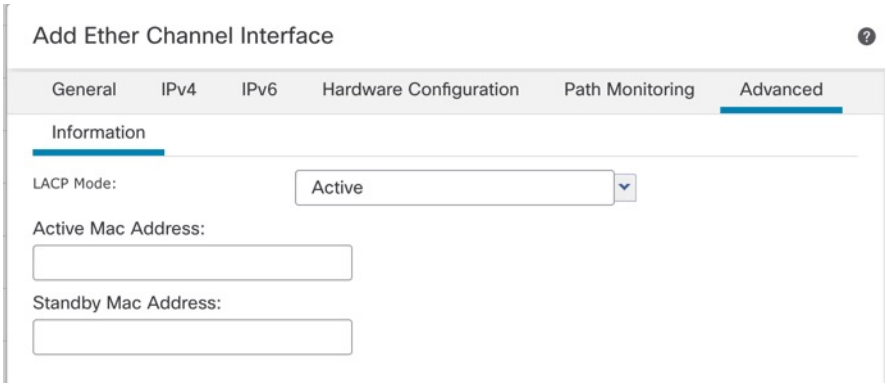
Step 5 In the **Available Interfaces** area, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members.



Make sure all interfaces are the same type and speed capability.

Figure 205: Available interfaces

Step 6 (Optional) Click the **Advanced** tab to customize the EtherChannel. Set the following parameters on the **Information** sub-tab:

Figure 206: Advanced

- (ISA 3000 only) **Load Balancing**—Select the criteria used to load balance the packets across the group channel interfaces. By default, the Firewall Threat Defense device balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see Load balancing, on page 1008.
- **LACP Mode**—Choose Active, Passive, or On. We recommend using Active mode (the default). Passive mode is only available for the ISA 3000 only.
- (Secure Firewall 3100/4200 only) **LACP Rate**—Choose Default, Normal, or Fast. The defualt is Normal (also known as slow). Sets the LACP data unit receive rate for a physical interface in the channel group. We recommend that you set the same rate on both sides.

- (ISA 3000 only) **Active Physical Interface: Range**—From the left drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 16. The default is 1. From the right drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 16. The default is 16. If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer.
- **Active MAC Address**—Set a manual MAC address if desired. The mac_address is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

Step 7 Click the **Hardware Configuration** tab and set the Duplex and Speed for all member interfaces.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

For regular firewall interfaces:

- Add a VLAN subinterface. See Add a subinterface, on page 1060.
- Configure the routed or transparent mode interface parameters: Configure routed mode interfaces, on page 1080 or Bridge group interfaces, on page 1086. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 1119.

Sync Interface Changes with the Cloud-Delivered Firewall Management Center

Synchronize interface changes to ensure the Cloud-Delivered Firewall Management Center and device configurations remain aligned when physical interfaces are added or removed.

Addition or deletion of physical interfaces on the device can cause the Cloud-Delivered Firewall Management Center and the device to get out of sync. The Cloud-Delivered Firewall Management Center can detect interface changes by one of these methods:

- Event sent from the device
- Synchronize when you deploy from the Cloud-Delivered Firewall Management Center

  If the Cloud-Delivered Firewall Management Center detects interface changes when it attempts to deploy, the deployment will fail. You must first accept the interface changes.
- Manual synchronization

Adding a new interface, or deleting an unused interface has minimal impact on the Firewall Threat Defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the Firewall Threat Defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any

configuration associated with that interface. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the Cloud-Delivered Firewall Management Center.

When the Cloud-Delivered Firewall Management Center detects changes, the **Interface** page shows status (removed, changed, or added) to the left of each interface.

This procedure describes how to manually sync interface changes if required. If interface changes are temporary, you should not save the changes in the Cloud-Delivered Firewall Management Center; you should wait until the device is stable, and then re-sync.

Before you begin

Follow these steps to sync interface changes with the Cloud-Delivered Firewall Management Center:

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 If required, click **Sync Interfaces** on the top left of **Interfaces**.

Step 3 After the changes are detected, see these steps.

a) You will see a red banner on **Interfaces** indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.

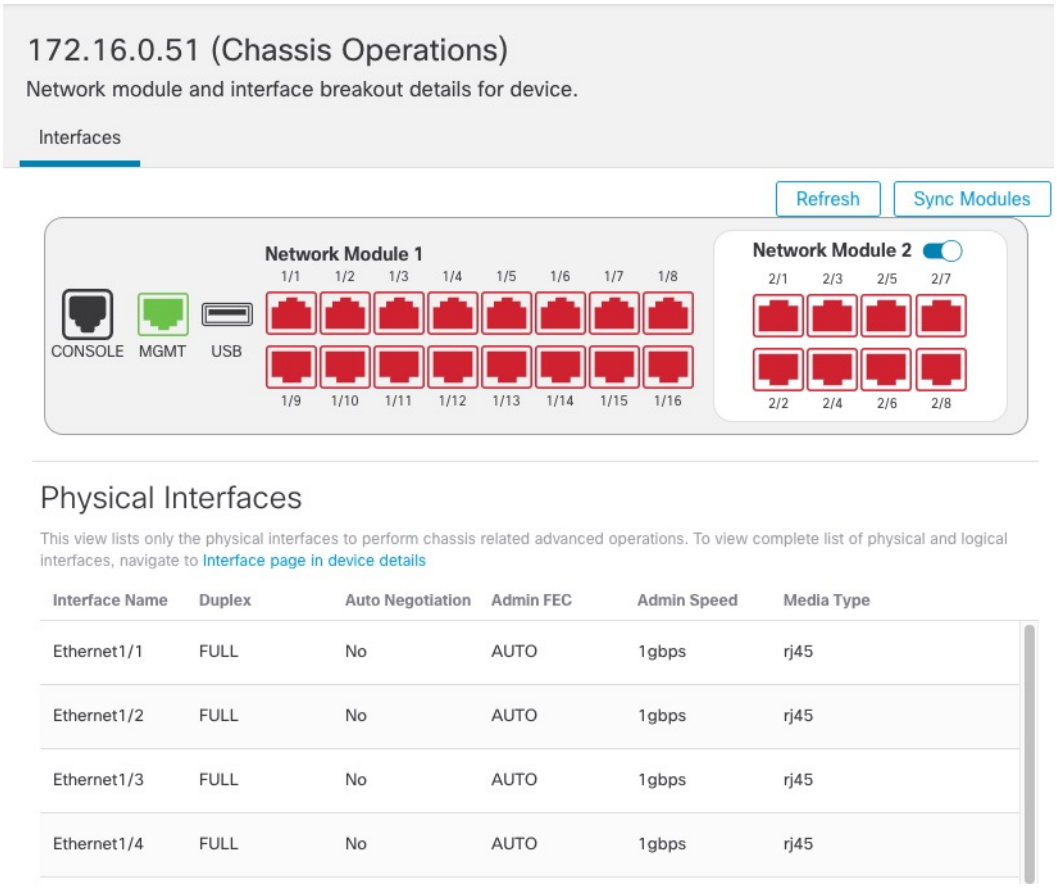
b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

c) Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.

Step 4



Network module management for Secure Firewall 3100/4200

If you install a network module before powering on the device, the network module becomes enabled and ready for use automatically.

Network module management operations

To view physical interface details for the device, and to manage the network module, open the **Chassis Operations** page. From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit. The **Chassis Operations** page opens for the device.

Figure 207: Chassis operations

Click **Refresh** to refresh interface status. Click **Sync Modules** if you made a hardware change on the device that you need to detect.

If you need to make changes to your network module installation after initial bootup, then see the following procedures.

Configure breakout ports

This task configures breakout ports to create smaller ports from 40GB or higher interfaces, allowing you to split a single high-capacity interface into multiple physical Ethernet ports that can be used like any other physical Ethernet port, including being added to EtherChannels.

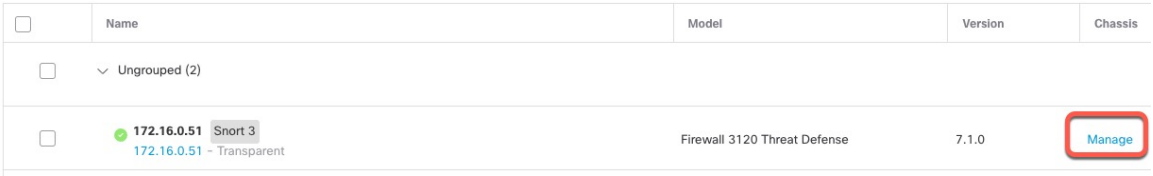
You can configure smaller breakout ports for each 40GB or higher interface. This procedure tells you how to break out and rejoin the ports. The breakout ports can be used just like any other physical Ethernet port, including being added to EtherChannels. For example, you can break out four 10GB ports from a 40GB interface. The exact size and number of ports depends on your model.

Changes are immediate; you do not need to deploy to the device. After you break or rejoin, you cannot roll back to the previous interface state.

Before you begin

- You must use a supported breakout cable. See the hardware installation guide for more information.

- The interface cannot be in use for the following before breaking or rejoining:
  - Failover link
  - Cluster control link
  - Have a subinterface
  - EtherChannel member
  - BVI member
  - Manager access interface
- Breaking or rejoining an interface that is used directly in your security policy can impact the configuration; however, the action is not blocked.



Follow these steps to configure breakout ports:

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 208: Manage chassis

The **Chassis Operations** page opens for the device (in multi-instance mode, this page is called **Chassis Manager**). This page shows physical interface details for the device.

Step 2 Break out ports from a 40GB or higher interface.

a) Click **Break** ( ) to the right of the interface.

Click **Yes** on the confirmation dialog box. If the interface is in use, you will see an error message. You must resolve any use cases before you can retry the breakout.

For example, to break out the Ethernet2/1 40GB interface, the resulting child interfaces will be identified as Ethernet2/1/1, Ethernet2/1/2, Ethernet2/1/3, and Ethernet2/1/4.

On the interfaces graphic, a port that is broken out has this appearance:

Figure 209: Breakout ports

b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 210: Go to interface page

c) At the top of the **Interfaces** page, click **Click to know more**.

The **Interface Changes** dialog box opens.

Figure 211: View interface changes

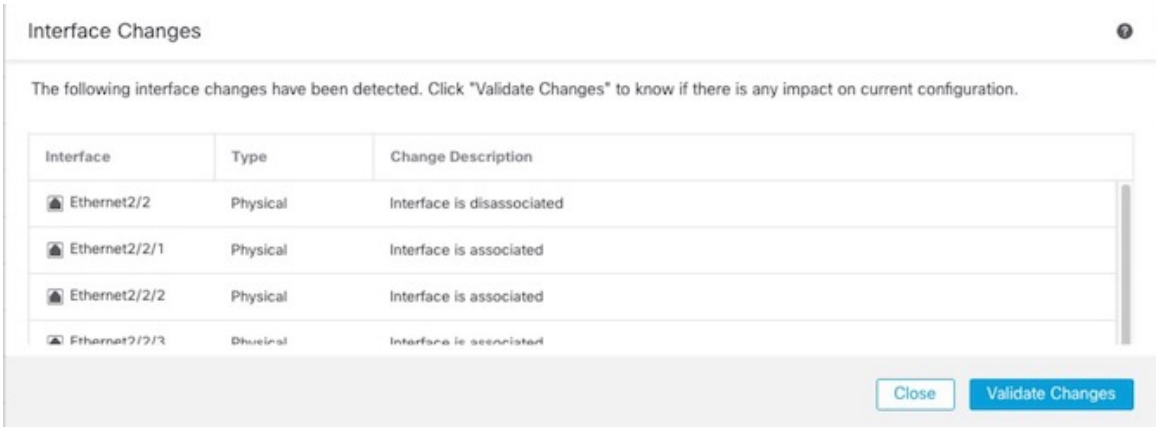


Figure 212: Interface changes

d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, change your policy and rerun the validation.

Replacing the parent interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

e) Click **Close** to return to the **Interfaces** page.

f) Click **Save** to save the interface changes to the firewall.

g) If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

Step 3 Rejoin breakout ports.

You must rejoin all child ports for the interface.

a) Click **Join** ( ) to the right of the interface.

Click **Yes** on the confirmation dialog box. If any child ports are in use, you will see an error message. You must resolve any use cases before you can retry the rejoin.

b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 213: Go to interface page

c) At the top of the **Interfaces** page, click **Click to know more**.

The **Interface Changes** dialog box opens.

Figure 214: View interface changes

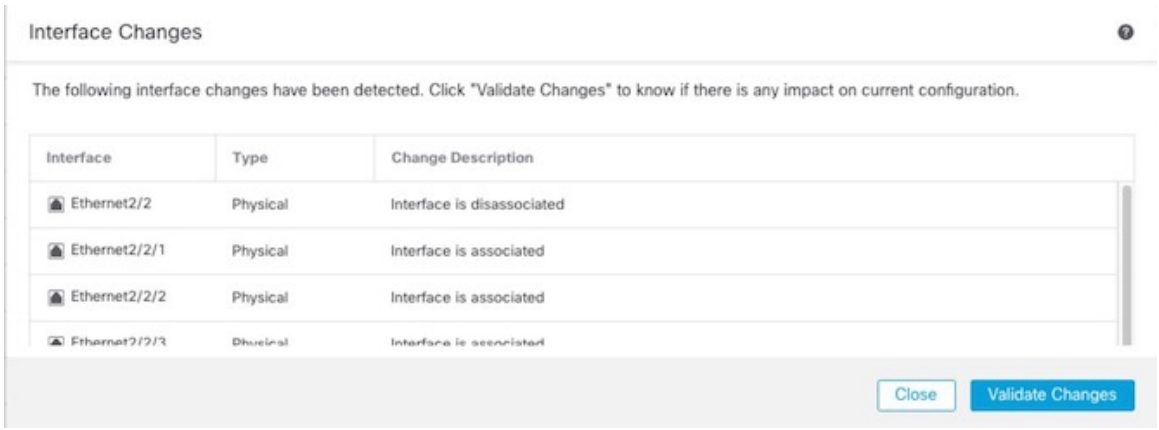

Figure 215: Interface changes

d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the child interfaces that are used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

e) Click **Close** to return to the **Interfaces** page.

f) Click **Save** to save the interface changes to the firewall.

g) If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

Add a network module

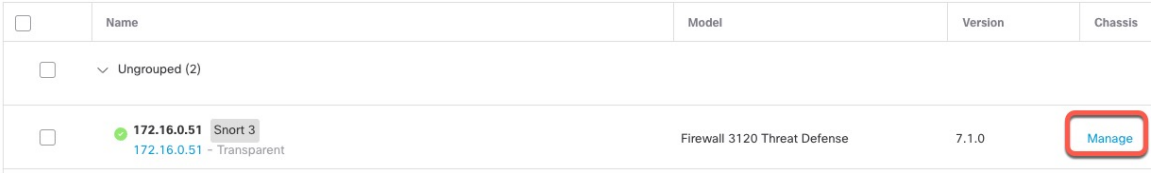
This task enables you to add network module functionality to a firewall that is already operational, expanding its interface capabilities.

Adding a new module requires a reboot of the firewall system.

Procedure

Step 1 Install the network module according to the hardware installation guide.

For clustering or High Availability, install the network module on all nodes.



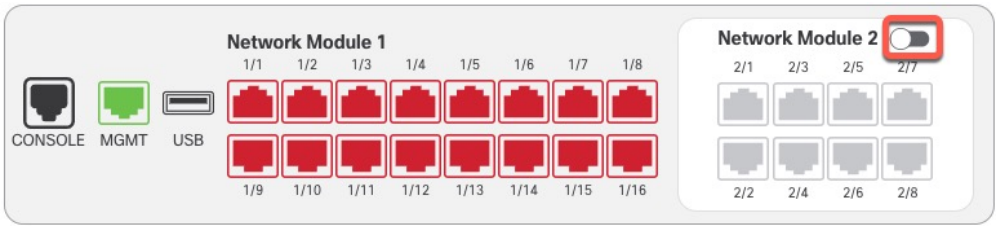
Step 2 Reboot the firewall; see Shut down or restart the device, on page 107.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 710), and reboot the former control node/active unit.

Step 3 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

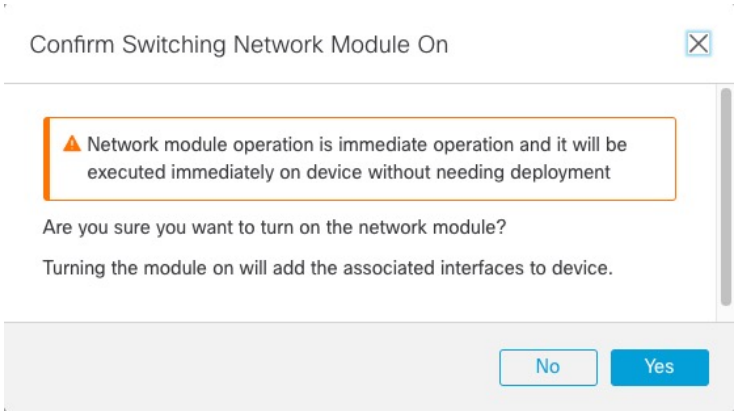
For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 216: Manage chassis



The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 4 Click **Sync Modules** to update the page with the new network module details.



Step 5 On the interfaces graphic, click the slider ( ) to enable the network module.

Figure 217: Enable the network module

Step 6 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 218: Confirm enable

Step 7 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 219: Go to interface page

Step 8 (Optional) At the top of the **Interfaces** page, you see a message that the interface configuration has changed. You can click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 220: View interface changes

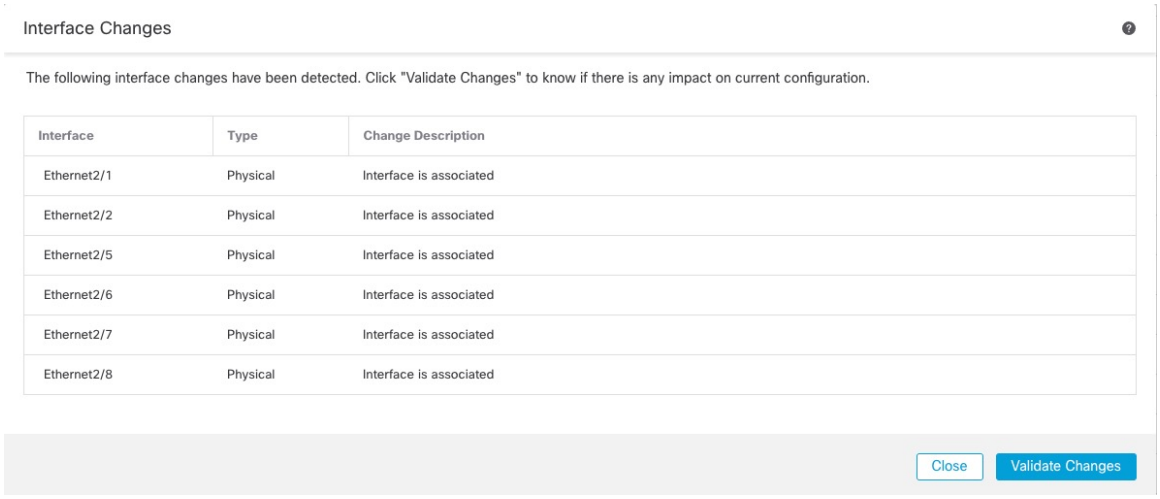


Figure 221: Interface changes

Click **Close** to return to the **Interfaces** page. (Because you are adding a new module, there shouldn't be any configuration impact, so you do not need to click **Validate Changes**.)

Step 9 Click **Save** to save the interface changes to the firewall.

Hot swap the network module

You can hot swap a network module for a new module of the same type without having to reboot.

You must shut down the current module to remove it safely. This procedure describes how to shut down the old module, install a new module, and enable it.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit. You cannot disable a network module if the cluster control link/failover link is on the module.

Procedure

Step 1 For clustering or High Availability, perform the following steps.

- **Clustering**—Ensure the unit you want to perform the hot swap on is a data node; then break the node so it is no longer in the cluster.

  You will add the node back to the cluster after you perform the hot swap. Alternatively, you can perform all operations on the control node, and the network module changes will sync to all data nodes. However, you will lose use of those interfaces on all nodes during the hot swap.

- **High Availability**—To avoid failing over when you disable the network module:
  - If the failover link is on the network module, you must break High Availability. See Break a high availability pair, on page 714. Disabling the network module with an active failover link is not allowed.
  - Disable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 708.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

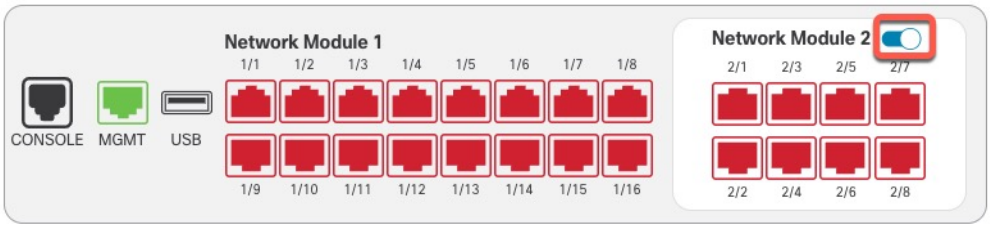

Figure 222: Manage chassis

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

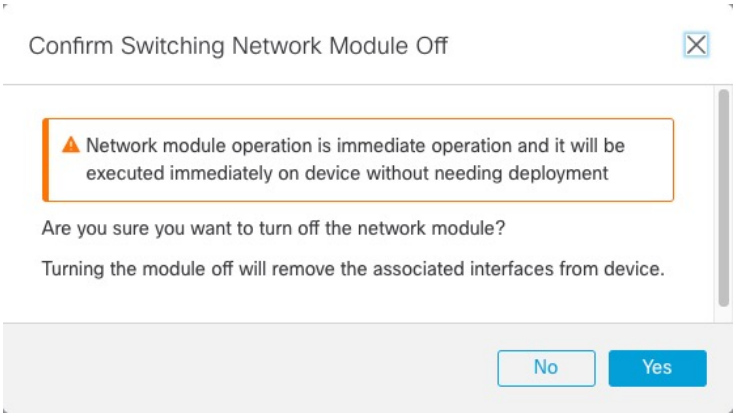

Figure 223: Disable the network module

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

Step 4 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

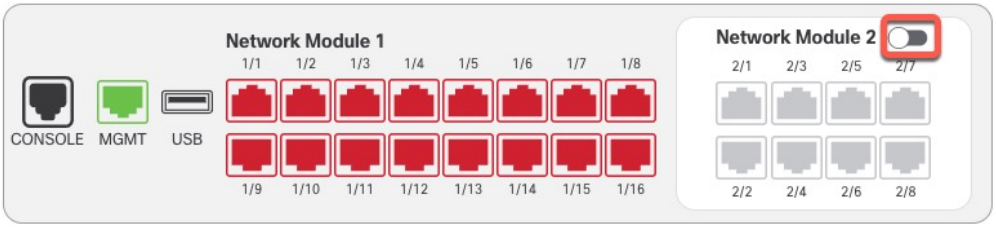

Figure 224: Confirm disable

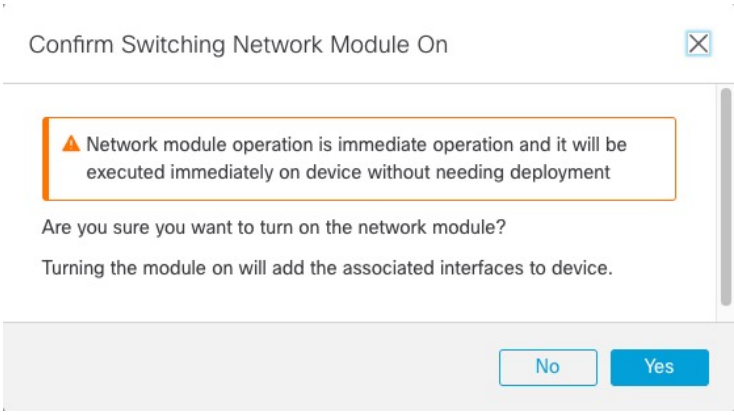
Step 5 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.



Step 6 In the Cloud-Delivered Firewall Management Center, enable the new module by clicking the slider ().

Figure 225: Enable the network module

Step 7 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 226: Confirm enable

Step 8 For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster.
- **High Availability**—
  - If you broke High Availability, then reform High Availability. See Add a high availability pair, on page 705.
  - Reenable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 708.

Replace the network module with a different type

Replace an existing network module with a different type to accommodate new interface requirements or hardware upgrades.

If you replace a network module with a different type, then a reboot is required. If the new module has fewer interfaces than the old module, you will have to manually remove any configuration related to interfaces that will no longer be present.

For clustering or High Availability, you can only perform chassis operations on the control node or active unit.

Before you begin

For High Availability, you cannot disable a network module if the failover link is on the module. You will have to break the high availability pair (see Break a high availability pair, on page 714), which means you will have downtime when you reboot the active unit. After the units finish rebooting, you can reform High Availability.

Follow these steps to replace the network module with a different type:

Procedure

Step 1 For clustering or High Availability, perform the following steps.

- **Clustering**—To avoid downtime, you can break each node one at a time so it is no longer in the cluster when you perform the network module replacement.

  Add the node back to the cluster after the replacement.

- **High Availability**—To avoid failing over when you replace the network module, disable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 708.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 227: Manage chassis

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

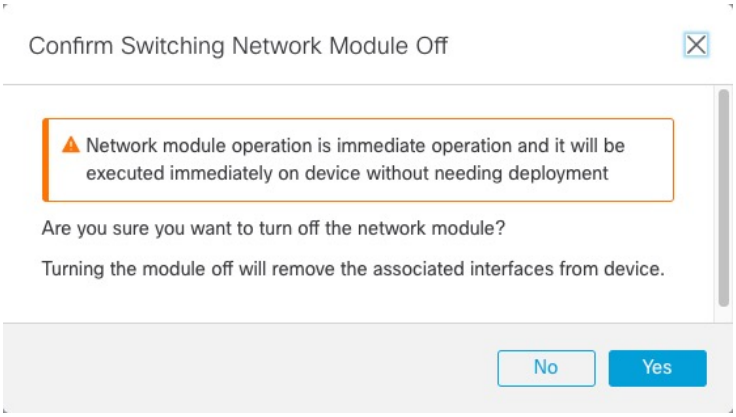


Figure 228: Disable the network module

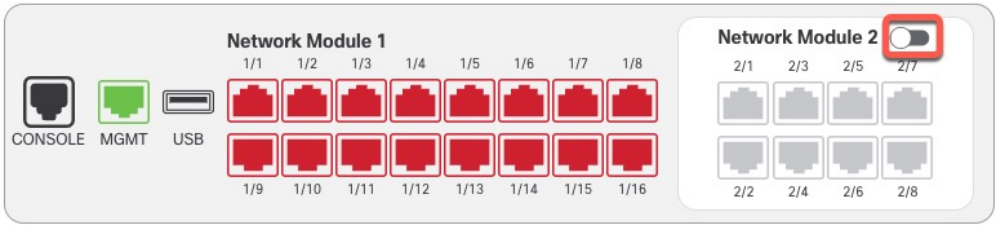
Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

a) You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 229: Confirm disable

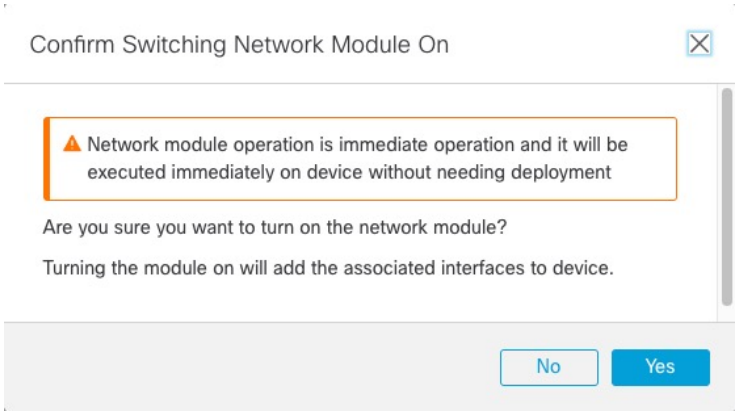
Step 4 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.



Reboot the firewall. Refer to Shut down or restart the device, on page 107 for guidance.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 710), and reboot the former control node/active unit.

Step 5 In the Cloud-Delivered Firewall Management Center, click **Sync Modules** to update the page with the new network module details.



Step 6 Enable the new module by clicking the slider ( ).

Figure 230: Enable the network module

a) Click **Yes** when prompted to confirm that you want to turn the network module on.

Figure 231: Confirm enable

Step 7 Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 232: Go to interface page

Step 8 If the network module has *fewer* interfaces:

a) At the top of the **Interfaces** page, click **Click to know more**.

The **Interface Changes** dialog box opens.

Figure 233: View interface changes

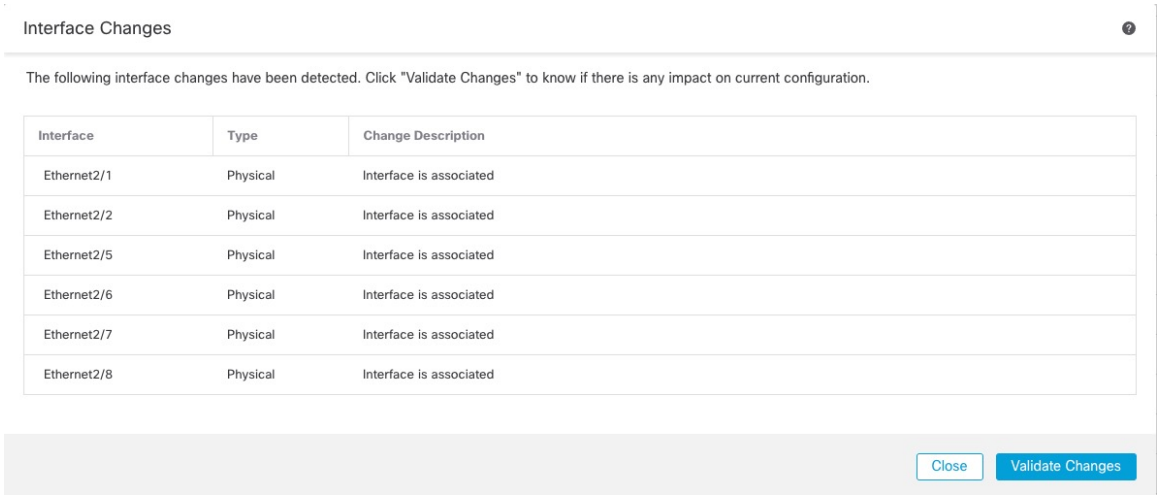


Figure 234: Interface changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 9 To change the interface speed, see Enable the physical interface and configure Ethernet settings, on page 1003.

The default speed is set to Detect SFP, which detects the correct speed from the SFP installed. You only need to fix the speed if you manually set the speed to a particular value and you now need a new speed.

Click **Save** to save the interface changes to the firewall.

What to do next

- If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.
- For clustering, add the node back to the cluster.
- For high availability, reenable interface monitoring for interfaces on the network module. See Configure standby IP addresses and interface monitoring, on page 708.

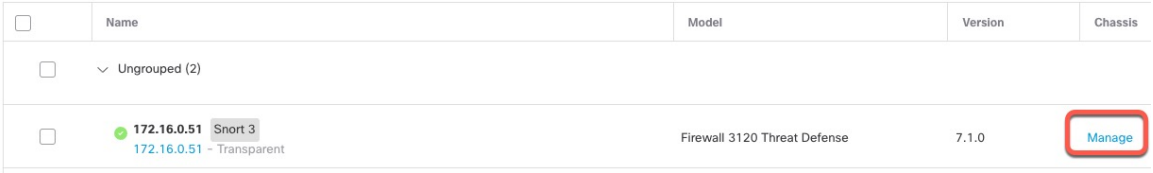
Remove the network module

Remove a network module permanently from the chassis when it is no longer needed or requires replacement.

If you want to permanently remove the network module, follow these steps. Removing a network module requires a reboot.

For clustering or High Availability, you can only perform chassis operations on the control node or active unit.

Before you begin



For clustering or High Availability, make sure the cluster or failover link is not on the network module.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column.

For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

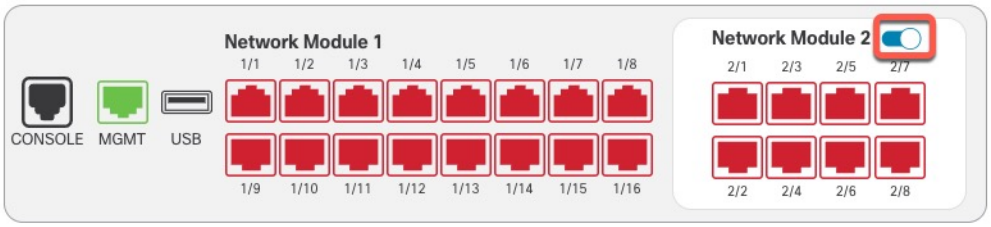


Figure 235: Manage chassis

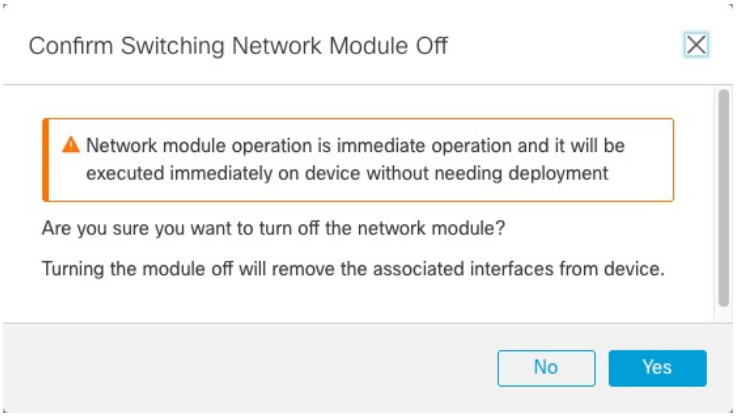
The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.



Step 2 On the interfaces graphic, click the slider ( ) to disable the network module.

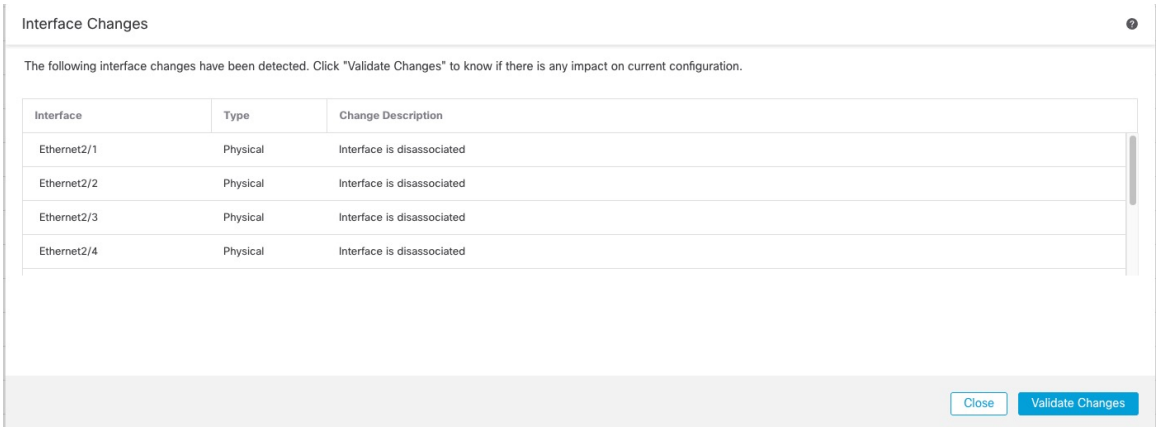
Figure 236: Disable the network module

Step 3 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 237: Confirm disable

Step 4 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 238: Go to interface page



Step 5 At the top of the **Interfaces** page, you see a message that the interface configuration has changed.

Figure 239: View interface changes

a) Click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 240: Interface changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 6 Click **Save** to save the interface changes to the firewall.

Step 7 If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

Step 8 Reboot the firewall; see Shut down or restart the device, on page 107.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 710), and reboot the former control node/active unit.

Merge the management and diagnostic interfaces

This task merges the Management and Diagnostic interfaces on devices that have existing Diagnostic interface configurations that prevent automatic merging.

Starting with version 7.4, Firewall Threat Defense supports a merged Management and Diagnostic interface. "If your configuration uses the Diagnostic interface, the interfaces are not merged automatically. You must perform this procedure to complete the merge. This procedure requires you to acknowledge configuration changes and, in some cases, manually fix the configuration.

The Backup/Restore and Cloud-Delivered Firewall Management Center configuration rollback functions save and restore the merged state, whether it is non-merged or merged. For example, if you merge the interfaces and then restore an old non-merged configuration, the restored configuration will be in a non-merged state.

This table shows the available configuration on the legacy Diagnostic interface, and how the merge is completed.

Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the Firewall Threat Defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

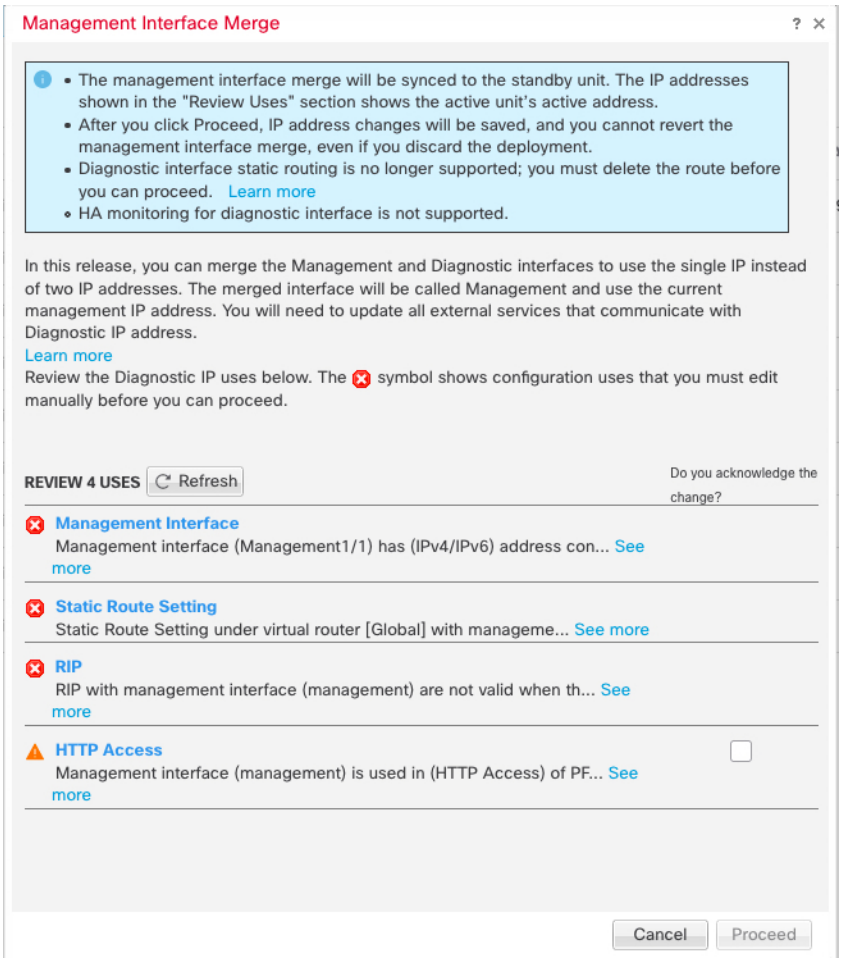
  The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

Follow these steps to merge the Management and Diagnostic interfaces:

Procedure



Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) for your Firewall Threat Defense. The **Interfaces** page is selected by default. .

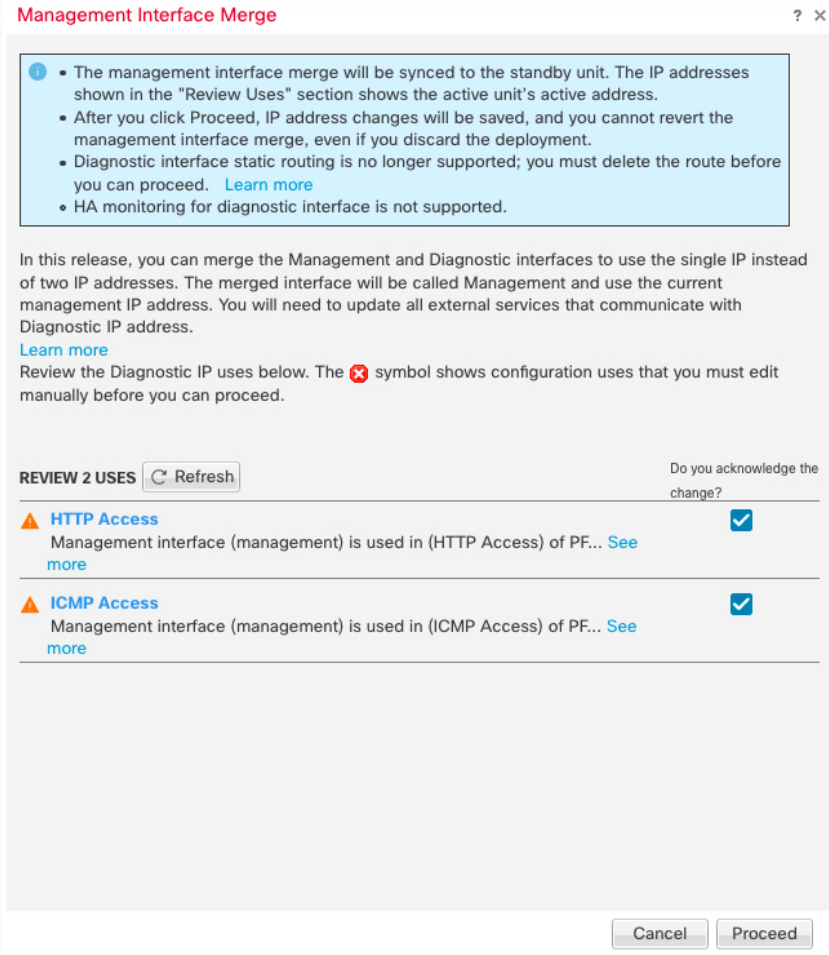
Step 2 Edit the Diagnostic interface, and remove the IP address.

You cannot complete the merge until after you have removed the Diagnostic IP address.

Step 3 Click **Management Interface Merge** in the **Management Interface action needed** area.

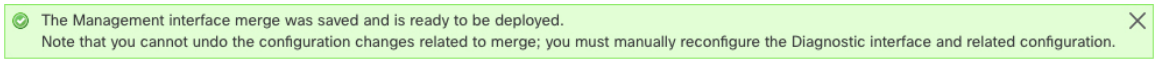
The **Management Interface Merge** dialog box shows all the occurrences of the Diagnostic interface in the configuration. For any occurrences that require you to manually remove or change the configuration, they will appear with a warning icon. Platform Settings that will no longer work on your device are marked with a caution icon and require your acknowledgement.

Step 4 If you need to manually remove or change any listed configurations, do the following.



a) Click **Cancel** to close the **Management Interface Merge** dialog box.

b) Navigate to the feature area. You can then delete the item, or choose a data interface instead.



c) Reopen the **Management Interface Merge** dialog box.

There should no longer be any warnings.

Step 5 For each configuration caution, click the box in **Do you acknowledge the change?** column, and then click **Proceed**.

After the configuration is merged, you see a success banner:

Step 6 Deploy the new merged configuration.

Caution
After you deploy the merged configuration, you can unmerge the interfaces from Cloud-Delivered Firewall Management Center; however the Diagnostic interface will have to be reconfigured manually. See Unmerge the management interface, on page 1034. Also, if you restore a configuration that is unmerged, or roll back to an unmerged configuration, then the device will revert to that unmerged configuration.

After the merge, the Management interface is shown on the **Interfaces** page, although it is read-only.

Step 7 After the merge, if you had any external services that communicated with the Diagnostic interface, you need to change their configuration to use the Management interface IP address.

For example:

- SNMP client

- RADIUS server—RADIUS servers often verify the IP address for incoming traffic, so you need to change that IP address to the Management address. Moreover, for a High Availability pair, you need to allow both the primary and secondary Management IP addresses; the Diagnostic interface used to support a single "floating" IP address that stayed with the active unit, but Management does not support that functionality.

Unmerge the management interface

This task separates the merged Management and Diagnostic interface into two distinct interfaces. This is useful when migrating network configurations or when separate interface management is required for specific network architectures.

The Firewall Threat Defense 7.4 and later supports a merged Management and Diagnostic interface. If you need to unmerge your interfaces, perform this procedure. We recommend using unmerged mode temporarily while you migrate your network to a merged mode deployment. Separate Management and Diagnostic interfaces may not be supported in all future releases.

Unmerging the interfaces does not restore your original Diagnostic configuration (if you upgraded and then merged your interfaces). You will need to reconfigure the Diagnostic interface manually. Also, the Management interface will now be named "management"; you cannot rename it "diagnostic."

Alternatively, if you used the Backup function to save an old unmerged configuration, you can restore that configuration or you can use the or Cloud-Delivered Firewall Management Center configuration rollback feature, and the device will be in an unmerged state with the Diagnostic configuration intact.

Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the Firewall Threat Defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

  The following output shows that the Management interfaces are not merged:

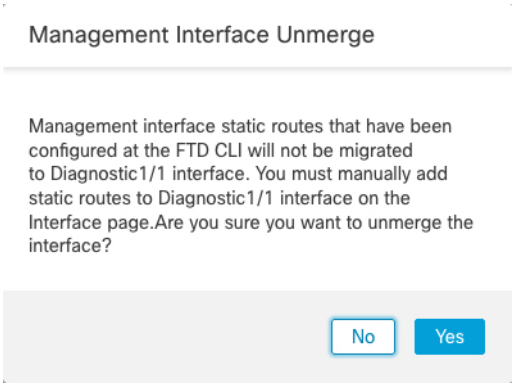
```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

Follow these steps to unmerge the Management Interface:

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) for your Firewall Threat Defense. The **Interfaces** page is selected by default.



Step 2 For the Management interface, click **Unmerge Management Interface** ( ).

Figure 241: Management interface selection

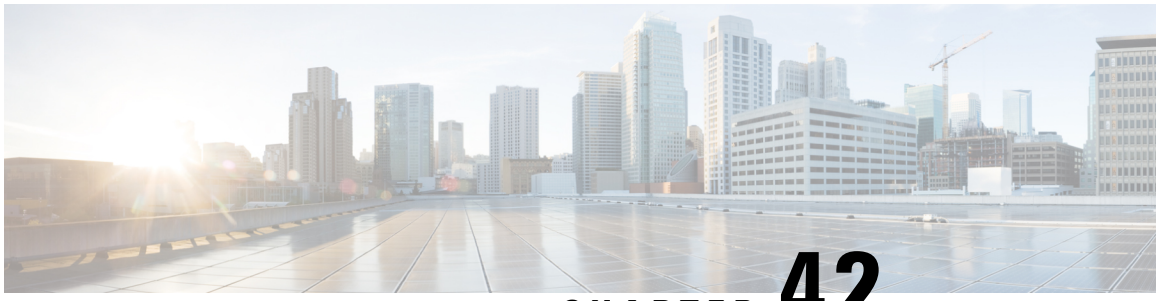
Step 3 Click **Yes** to confirm that you want to unmerge the interface.

Figure 242: Unmerge confirmation

Step 4 Deploy the new unmerged configuration.

Note
If you restore a configuration that is merged, or roll back to a merged configuration, then the device will revert to that merged configuration.

After the merge, the Management interface is no longer shown on the **Interfaces** page.



History for interfaces

This reference provides the complete version history for interface-related features, enhancements, and changes across different versions of the Secure Firewall system.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Sync Device is now called **Sync Interfaces**	20250219	7.7.0	**Sync Device** was changed to **Sync Interfaces** to indicate that this function is only for interface changes. This function no longer detects changes made to the manager access interface; see **Devices** > **Device Management** > **Device** > **Management** > **Manager Access Details: Configuration**. Other out-of-band configuration changes performed at the diagnostic CLI in recovery-config mode need to be discovered at **Devices** > **Device Management** > **Device** > **Health** > **Out of Band Status**. New/Modified screens: **Devices** > **Device Management** > **Interfaces**
Loopback and Management type interface group objects	7.4.0	7.4.0	You can now create interface group objects that include only management-only interfaces or only loopback interfaces. You can then use these groups for management features such as DNS servers, HTTP access, or SSH. Loopback groups are supported for any feature that supports loopback interfaces. Note that DNS does not support management interfaces. New/Modified screens: **Objects** > **Object Management** > **Interface** > **Add** > **Interface Group**
Merged Management and Diagnostic interfaces	7.4.0	7.4.0	For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available. If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically. If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration. New/Modified screens: **Devices** > **Device Management** > **Interfaces** New/Modified commands: **show management-interface convergence**
Default Forward Error Correction (FEC) on Secure Firewall 3100 fixed ports changed to Clause 108 RS-FEC from Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers	7.2.4	7.2.4	When you set the FEC to Auto on the Secure Firewall 3100 fixed ports, the default type is now set to Clause 108 RS-FEC instead of Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
LLDP support for the Firepower 2100, Secure Firewall 3100	7.2.0	7.2.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 2100 and Secure Firewall 3100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Network Connectivity** New/Modified commands: **show LLDP status**, **show LLDP neighbors**, **show LLDP statistics**
Pause Frames for Flow Control for the Secure Firewall 3100	7.2.0	7.2.0	If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Network Connectivity**
Support for hot swapping the network module for the Secure Firewall 3100	7.1.0	7.1.0	You can add or remove the network module on the Secure Firewall 3100 while the firewall is powered up. To replace a module with another module of the same type, you do not need to reboot. After initial bootup, adding a module, permanently removing a module, or replacing a module with a new type requires a reboot. New/Modified screens: **Devices** > **Device Management** > **Chassis Operations**
Support for Forward Error Correction for the Secure Firewall 3100	7.1.0	7.1.0	Secure Firewall 3100 25 Gbps interfaces support Forward Error Correction (FEC). FEC is enabled by default and set to Auto. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
Support for setting the speed based on the SFP for the Secure Firewall 3100	7.1.0	7.1.0	The Secure Firewall 3100 supports speed detection for interfaces based on the SFP installed. Detect SFP is enabled by default. This option is useful if you later change the network module to a different model, and want the speed to update automatically. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
LLDP support for the Firepower 1100.	7.1.0	7.1.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 1100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **LLDP** New/Modified commands: **show LLDP status**, **show LLDP neighbors**, **show LLDP statistics**

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Interface auto-negotiation is now set independently from speed and duplex, interface sync improved.	7.1.0	7.1.0	Interface auto-negotiation is now set independently from speed and duplex. Also, when you sync the interfaces in Cloud-Delivered Firewall Management Center, hardware changes are detected more effectively. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed** Supported platforms: Firepower 1000, 2100, Secure Firewall 3100
Firepower 1100/2100 series fiber interfaces now support disabling auto-negotiation.	6.7.0	6.7.0	You can now configure a Firepower 1100/2100 series fiber interface to disable flow control and link status negotiation. Previously, when you set the fiber interface speed (1000 or 10000 Mbps) on these devices, flow control and link status negotiation was automatically enabled. You could not disable it. Now, you can deselect **Auto-negotiation** and set the speed to 1000 to disable flow control and link status negotiation. You cannot disable negotiation at 10000 Mbps. New/modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed**

CHAPTER 42

Regular Firewall Interfaces

This chapter includes regular firewall Firewall Threat Defense interface configuration including EtherChannels, VLAN subinterfaces, IP addressing, and more.

- Requirements and prerequisites for regular firewall interfaces, on page 1039
- Configure switch ports, on page 1040
- Loopback interfaces, on page 1052
- Guidelines for Loopback Interfaces, on page 1053
- Configure a loopback interface, on page 1053
- Rate-Limit traffic to the loopback interface, on page 1054
- VLAN subinterfaces and 802.1Q trunking, on page 1058
- Configure VXLAN Interfaces, on page 1062
- Configure routed and transparent mode interfaces, on page 1077
- Advanced interface settings, on page 1103
- History for Regular Firewall Interfaces, on page 1115

Requirements and prerequisites for regular firewall interfaces

This reference provides the requirements and prerequisites for configuring regular firewall interfaces, including supported models and required user roles.

Model support

Firewall Threat Defense

User roles

- Admin

- Network Admin

Configure switch ports

For supported platforms, you can configure each interface to run as a regular firewall interface or as a Layer 2 hardware switch port. This section includes tasks for starting your switch port configuration, including enabling or disabling the switch mode and creating VLAN interfaces and assigning them to switch ports. This section also describes how to customize Power over Ethernet (PoE) on supported interfaces.

About switch ports

This section describes the switch ports for models with Layer 2 switches.

Switch ports and interfaces

Switch ports and firewall operate at different OSI layers to handle traffic forwarding.

Port and interface types

For each physical interface, you can set its operation as a firewall interface or as a switch port. This information describes physical interface and port types as well as logical VLAN interfaces to which you assign switch ports:

- Physical firewall interface—In routed mode, these interfaces forward traffic between networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces are bridge group members that forward traffic between the interfaces on the same network at Layer 2, using the configured security policy to apply firewall services. In routed mode, you can also use Integrated Routing and Bridging with some interfaces as bridge group members and others as Layer 3 interfaces. By default, the Ethernet 1/1 interface is configured as a firewall interface. You can also configure these interfaces to be IPS-only (passive interfaces).
- Physical switch port—Switch ports forward traffic at Layer 2, using the switching function in hardware. Switch ports on the same VLAN can communicate with each other using hardware switching, and traffic is not subject to the Firewall Threat Defense security policy. Access ports accept only untagged traffic, and you can assign them to a single VLAN. Trunk ports accept untagged and tagged traffic, and can belong to more than one VLAN. By default, Ethernet 1/2 and subsequent ports are configured as access switch ports on VLAN 1. You cannot configure the Management interface as a switch port.
- Logical VLAN interface—These interfaces operate the same as physical firewall interfaces, with the exception that you cannot create subinterfaces, IPS-only interfaces (inline sets and passive interfaces), or EtherChannel interfaces. When a switch port needs to communicate with another network, then the Firewall Threat Defense device applies the security policy to the VLAN interface and routes to another logical VLAN interface or firewall interface. You can even use Integrated Routing and Bridging with VLAN interfaces as bridge group members. Traffic between switch ports on the same VLAN are not subject to the Firewall Threat Defense security policy, but traffic between VLANs in a bridge group are subject to the security policy, so you may choose to layer bridge groups and switch ports to enforce the security policy between certain segments.

Power Over Ethernet

PoE is available on these ports:

- Secure Firewall 1210CP—Ethernet 1/5, 1/6, 1/7, and 1/8 using IEEE 802.3af (PoE), 802.3at (PoE+) up to 30 watts per port, up to a combined 120 watts.

PoE+ uses Link Layer Discovery Protocol (LLDP) to negotiate the power level. Power is only supplied when needed.

If you shut down the interface, then you disable power to the device.

Auto-MDI/MDIX feature

Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase.

Auto-MDI/MDIX configuration details

For all switch ports, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. The interface enables Auto-MDI/MDIX when either the speed or duplex is set to auto-negotiate. If you set both the speed and duplex to fixed values, auto-negotiation is disabled, and Auto-MDI/MDIX is also disabled. When the speed and duplex are set to 1000 and full, the interface always auto-negotiates. Auto-MDI/MDIX enabled in this state, and disabling it is not possible.

Prerequisites for switch ports

This reference provides model support and other prerequisites for switch ports.

Model support

- Secure Firewall 200
- Firepower 1010
- Secure Firewall 1210/1220

Guidelines for switch ports

Context mode restrictions

Multiple context mode is not supported on several firewall models, with specific exceptions for the Secure Firewall 1210/1220.

- The Secure Firewall 220 does not support multiple context mode.
- The Firepower 1010 does not support multiple context mode.
- The Secure Firewall 1210/1220 does not support multiple context mode.

High availability and clustering limitations

Do not use switch port functionality when using High availability because switch ports operate in hardware and continue to pass traffic on both active and standby units.

- No cluster support.

- Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High availability, but a simpler setup is to use physical firewall interfaces instead.
- You can only use a firewall interface as the failover link.

Logical VLAN interfaces (SVIs) configuration requirements

Ensure unique VLAN IDs between logical VLAN interfaces and VLAN subinterfaces on firewall interfaces to prevent conflicts.

- If you also use VLAN subinterfaces on a firewall interface, you cannot use the same VLAN ID as for a logical VLAN interface.
- MAC Addresses:
  - Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC address, on page 1110.
  - Transparent firewall mode—Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC address, on page 1110.

Bridge groups restrictions

You cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.

VLAN interface and switch port unsupported features

VLAN interfaces and switch ports do not support these features.

- Dynamic routing
- Multicast routing
- Equal-Cost Multi-Path routing (ECMP)
- Inline sets or Passive interfaces
- EtherChannels—Switch ports cannot be part of an EtherChannel. PoE is also not supported on a port in an EtherChannel.
- Failover and state link
- Security group tagging (SGT)

Other guidelines and limitations

Configure a maximum of 60 named interfaces and ensure the Management interface is not configured as a switch port.

Default settings

Know the default interface assignments for each firewall model to properly plan your configuration.

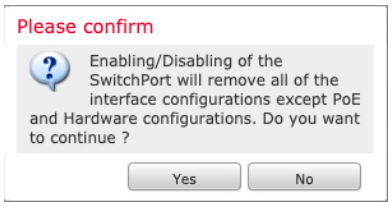
- Ethernet 1/1 is a firewall interface.
- On 1010, Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- On 1210, Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- On 1220, Ethernet 1/2 through Ethernet 1/10 are switch ports assigned to VLAN 1.
- On 220, Ethernet 1/2 through Ethernet 1/5 are switch ports assigned to VLAN 1.
- Default Speed and Duplex—By default, the speed and duplex are set to auto-negotiate.

Configure switch ports and power over ethernet

To configure switch ports and PoE, complete the following tasks.

Enable or disable switch port mode

Set each interface independently to be either a firewall interface or a switch port based on your network requirements.



You can set each interface independently to be either a firewall interface or a switch port. By default, Ethernet 1/1 is a firewall interface, and the remaining Ethernet interfaces are configured as switch ports.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

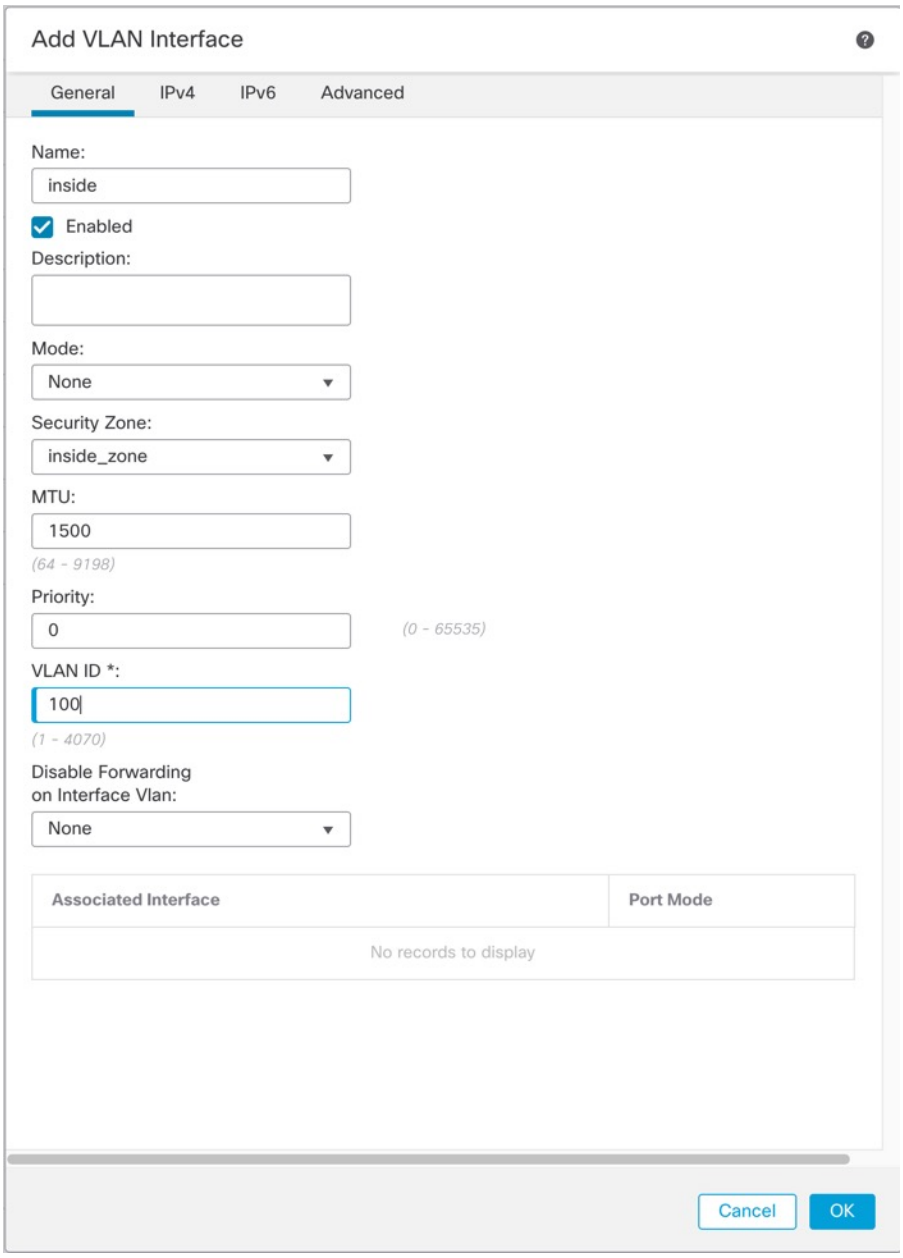
Step 2 Set the switch port mode by clicking the slider in the **SwitchPort** column so it shows as **Slider enabled** () or **Slider disabled** ().

By default, switch ports are set to access mode in VLAN 1. You must manually add a logical VLAN 1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the Firewall Threat Defense security policy (see Configure a VLAN interface, on page 1044). You cannot set the Management interface to switch port mode. When you change the switch port mode, all unsupported configuration is removed:

In addition, the interface is disabled if it was already enabled. Be sure to reenable the interface.

Configure a VLAN interface

Configure VLAN interfaces to enable traffic routing and participation in the Firewall Threat Defense security policy.



By default, switch ports are assigned to VLAN1; however, you must manually add the logical VLAN1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the Firewall Threat Defense security policy.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Add Interfaces** > **VLAN Interface**.

Step 3 On **General**, set the following VLAN-specific parameters:

If you are editing an existing VLAN interface, the **Associated Interface** table shows switch ports on this VLAN.

a) Set the **VLAN ID** between 1 and 4070, excluding IDs in the range 3968 to 4047, which are reserved for internal use.

   You cannot change the VLAN ID after you save the interface; the VLAN ID is both the VLAN tag used, and the interface ID in your configuration.

b) (Optional) Choose a VLAN ID for **Disable Forwarding on Interface VLAN** to disable forwarding to another VLAN.

For example, you have one VLAN assigned to the outside for internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can disable forwarding on the home VLAN. The business network can access the home network, but the home network cannot access the business network.

Step 4 To complete the interface configuration, see one of these procedures:

- Configure routed mode interfaces, on page 1080
- Configure general bridge group member interface parameters, on page 1086

Step 5 Click **OK**.

Step 6 Click **Save**.

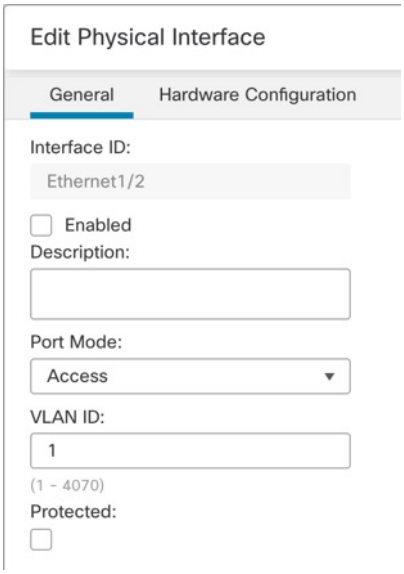
You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure switch ports as access ports

Configure switch ports as access ports to assign them to a single VLAN for network segmentation and traffic management.

To assign a switch port to a single VLAN, configure it as an access port. Access ports accept only untagged traffic. The interfaces that are enabled with switch ports and assigned to VLAN1 are as follows:

Device Models	Switch Port Interfaces
Secure Firewall 220	Ethernet 1/2 through Ethernet 1/5
Firepower 1010	Ethernet 1/2 through Ethernet 1/8
Secure Firewall 1210	Ethernet 1/2 through Ethernet 1/8
Secure Firewall 1220	Ethernet 1/2 through Ethernet 1/10



Note The device does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the Firewall Threat Defense does not end up in a network loop.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 243: Edit physical interface

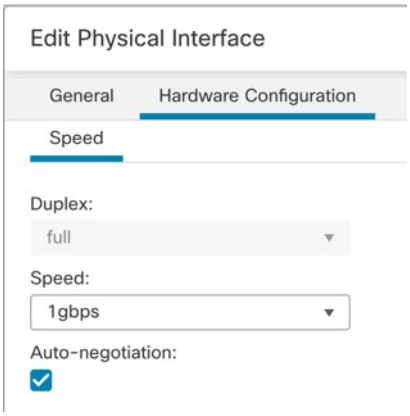
Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Access**.

Step 6 In the **VLAN ID** field, set the VLAN for this switch port, between 1 and 4070.



The default VLAN ID is 1.

Step 7 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Figure 244: Hardware configuration

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

Note
If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

Step 9 Click **OK**.

Click **Save**.

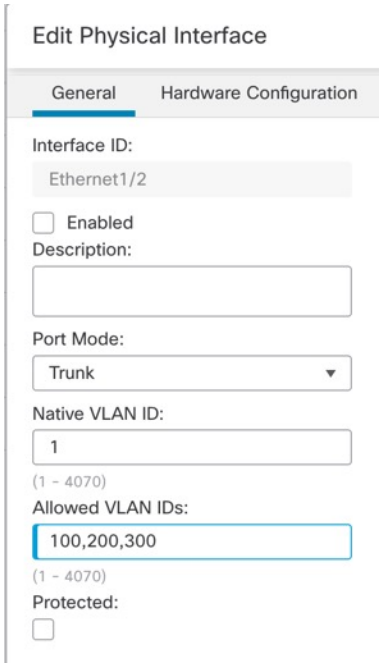
What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure switch ports as trunk ports

This task creates a trunk port that can carry multiple VLANs using 802.1Q tagging.

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk ports accept untagged and tagged traffic. Traffic on allowed VLANs pass through the trunk port unchanged.



When the trunk receives untagged traffic, it tags it to the native VLAN ID so that the Firewall Threat Defense device can forward the traffic to the correct switch ports or can route it to another firewall interface. When the Firewall Threat Defense device sends native VLAN ID traffic out of the trunk port, it removes the VLAN tag. Be sure to set the same native VLAN on the trunk port on the other switch so that the untagged traffic will be tagged to the same VLAN.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 245: Set trunk port mode

Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Trunk**.

Step 6 Set the VLAN IDs:

a) In the **Native VLAN ID** field, set the native VLAN for this switch port, between 1 and 4070.

The default native VLAN ID is 1.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

b) In the **Allowed VLAN IDs** field, enter the VLANs for this trunk port between 1 and 4070.

You can identify up to 20 IDs in one of these ways:

- A single number (n)
- A range (n-x)

- Numbers and ranges separated by commas, for example:

  5,7-10,13,45-100

  You can enter spaces instead of commas.

If you include the native VLAN in this field, it is ignored; the trunk port always removes the VLAN tagging when sending native VLAN traffic out of the port. Moreover, it will not receive traffic that still has native VLAN tagging.

Step 7 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

Step 9 Click **OK**.

Click **Save**.

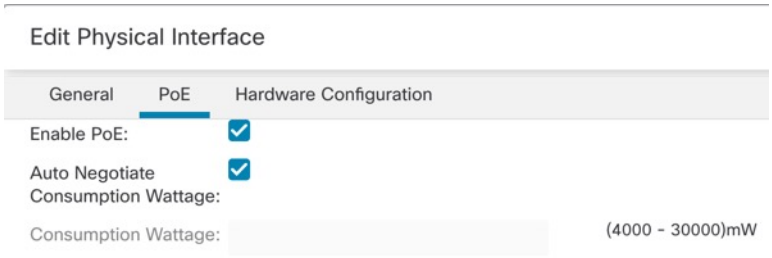
What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Power over Ethernet

Configure Power over Ethernet (PoE) settings to control power delivery to connected devices and optimize power allocation.

Power over Ethernet (PoE) ports provide power for devices such as IP phones or wireless access points. PoE is enabled by default. This procedure describes how to disable and enable PoE and how to set optional parameters.



Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for Ethernet1/7 or 1/8 on Firepower 1010 or for any interface from Ethernet 1/5-1/8 on Secure Firewall 1210CP .

Step 3 Click **PoE**.

Figure 246: PoE

Step 4 Check the **Enable PoE** check box.

PoE is enabled by default.

Step 5 Choose autonegotiation or manual power.

- **Auto Negotiate Consumption Wattage**—Delivers power automatically to the powered device using a wattage appropriate to the class of the powered device. The firewall uses LLDP to further negotiate the correct wattage. When you connect a device of a certain class, it will be provisioned up to the maximum for that class in case it ever needs to use more power. For example, if you add a class 4 device that requests 12.95W, it will be allocated 30W even if it doesn't currently use all that power. Some devices can renegotiate power needs. If you know your device needs less power than is allocated, you can instead set the **Consumption Wattage** manually to free up the power for other devices.

- **Consumption Wattage**—Uncheck the **Auto Negotiate Consumption Wattage** check box to set the manual wattage to manually specify the wattage in milliwatts, from 4000 to 30000. Use this option if you want to set the watts manually and disable LLDP negotiation. For manual allocation, the class will show in **show power inline** output as *n/a* because the class is not used to decide the power consumption.

  View the current PoE status using the **show power inline** command.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Loopback interfaces

A loopback interface is a software-only interface that emulates a physical interface. This interface is reachable on IPv4 and IPv6 through multiple physical interfaces. The loopback interface helps to overcome path failures. It is accessible from any physical interface. If one interface goes down, you can access the loopback interface from another.

Loopback interfaces can be used for:

- AAA
- BGP
- DNS
- HTTP
- ICMP
- IPsec flow offload—Secure Firewall 1200/3100/4200 only
- NetFlow
- SNMP
- SSH
- Static and dynamic VTI tunnels
- Syslog

The Firewall Threat Defense can distribute the loopback address using dynamic routing protocols, or you can configure a static route on the peer device to reach the loopback IP address through one of the Firewall Threat Defense's physical interfaces. You cannot configure a static route on the Firewall Threat Defense that specifies the loopback interface.

Related Topics

Guidelines for Loopback Interfaces, on page 1053
Configure a loopback interface, on page 1053

Guidelines for Loopback Interfaces

This topic outlines the specific constraints and supported configurations for loopback interfaces in various network environments.

Firewall Mode

- Supported in routed mode only.

High availability and Clustering

- No clustering support.

Additional Guidelines and Limitations

- TCP sequence randomization is always disabled for traffic from the physical interface to the loopback interface.

Configure a loopback interface

Configure a loopback interface to provide a virtual interface that remains active regardless of physical interface status, commonly used for routing protocols and management purposes.

Loopback interfaces are virtual interfaces that provide stable IP addresses for device management and routing protocols. They remain active as long as the device is operational, making them ideal for network management tasks.

Before you begin

Follow these steps to add a loopback interface for a device:

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 From the **Add Interfaces** drop-down list, choose **Loopback Interface**.

Step 3 In the **General** tab, configure the following parameters:

a) **Name**—Enter a name for the loopback interface.
b) **Enabled**—Check the check box to enable the loopback interface.
c) **Loopback ID**—Enter the loopback ID between 1 to 1024.
d) **Description**—Enter a description for the loopback interface.

Step 4 Configure the routed mode interface parameters. See Configure routed mode interfaces, on page 1080.

Rate-Limit traffic to the loopback interface

You should rate-limit traffic going to the loopback interface IP address to prevent excessive load on the system. You can add a connection limit rule to the global service policy.

Rate-limiting protects the system from Denial of Service (DoS) attacks and ensures stable performance by controlling the number of connections to critical interface addresses.

Before you begin

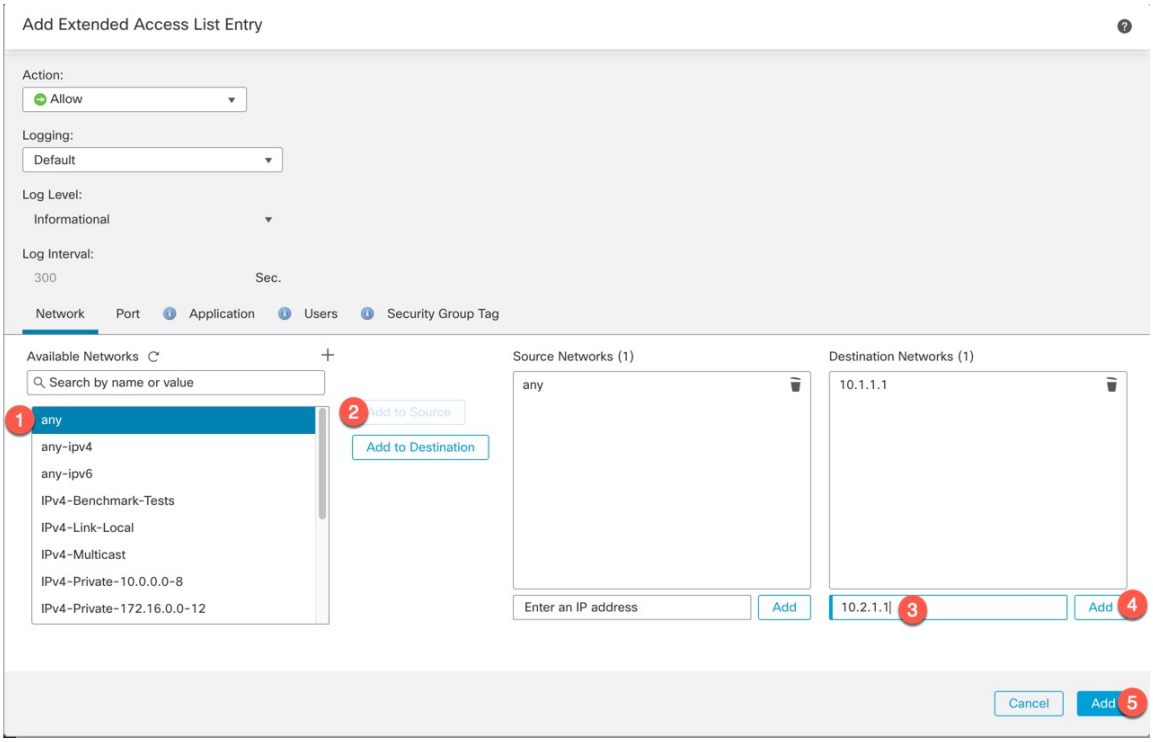
Follow these steps to rate-limit traffic to the loopback interface:

Procedure

Step 1 Create an extended access list identifying traffic to the loopback interface IP address(es).

a. Choose **Objects** > **Object Management** > **Access List** > **Extended**.

b. Click **Add Extended Access List** to create a new ACL.

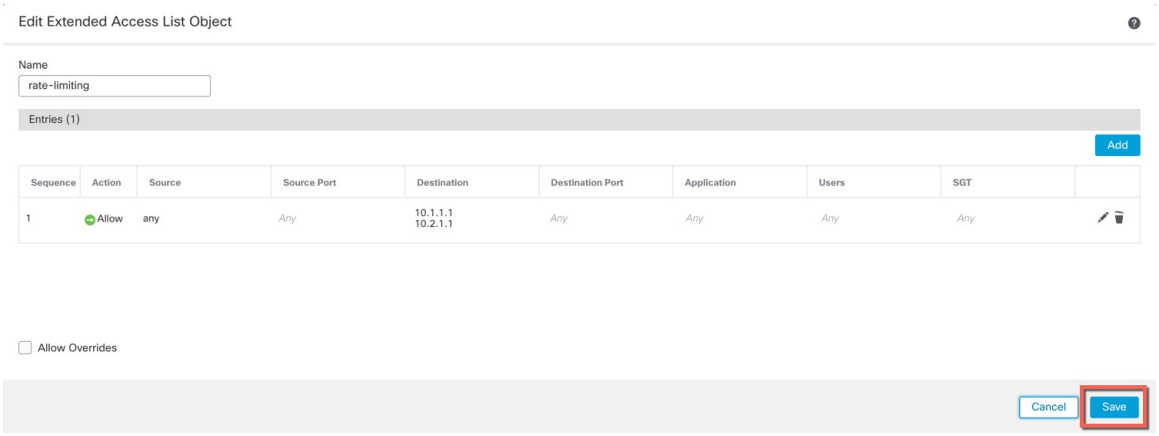


c. In the **New Extended Access List Object** dialog box, enter a name for the ACL (no spaces allowed), and click **Add** to create a new entry.

Figure 247: Name ACL and add entry

d. Configure the source (any) and destination addresses (loopback IP addresses) on the **Network** tab.

Figure 248: Source and destination networks



Note
Keep the default **Action** as **Allow** (match) and other settings as-is.

- Source—Select **any** from the **Available Networks** list, and click **Add to Source**. You can also narrow this access list by specifying the source IP addresses instead of **any**.
- Destination—Type an address in the edit box below the **Destination Networks** list and click **Add**. Repeat for each loopback interface.

e. Click **Add** to add the entry to the ACL.

f. Click **Save** to save the ACL.

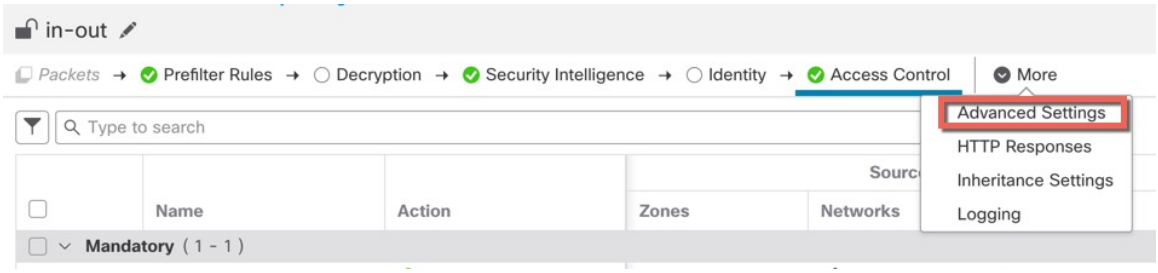


Figure 249: Save ACL

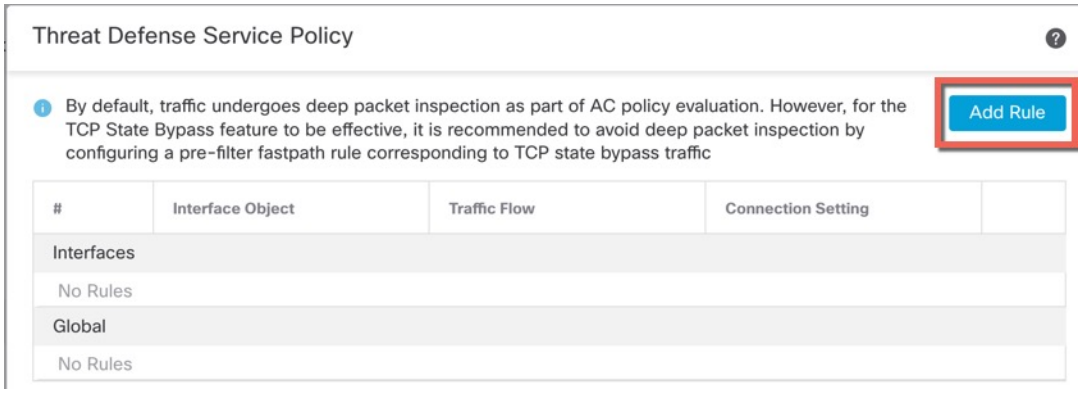
Step 2 Choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** (✎) for the access control policy assigned to your device.

Step 3 Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Figure 250: Advanced settings



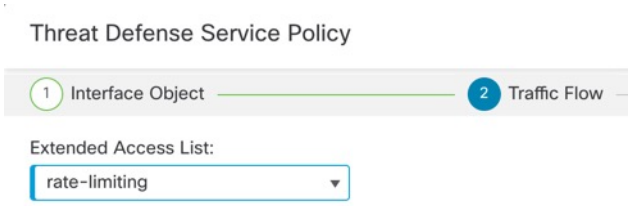
Step 4 Click **Edit** (✎) in the **Threat Defense Service Policy** group.

Figure 251: Threat defense service policy

Step 5 Click **Add Rule** to create a new rule.

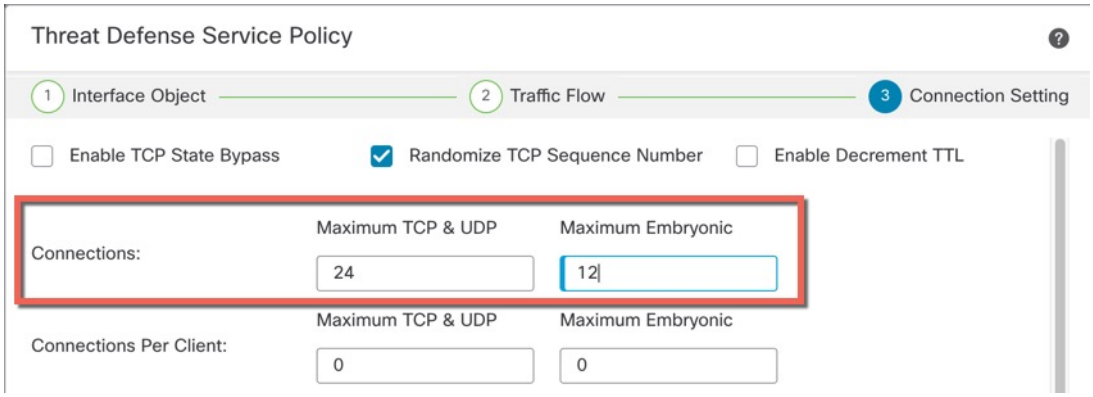
Figure 252: Add rule

The service policy rule wizard opens to step you through the process of configuring the rule.



Step 6 In the **Interface Object** step, click **Global** to create a global rule, which applies to all interfaces, then click **Next**.

Figure 253: Global policy



Step 7 In the **Traffic Flow** step, select the extended access list object you created in Step 1, on page 1054, and then click **Next**.

Figure 254: Choose extended access list

Step 8 In the **Connection Setting** step, set the **Connections** limits.

Figure 255: Set connection limits

Set the **Maximum TCP & UDP** connections to the expected number of connections for the loopback interface, and the **Maximum Embryonic** connections to a lower number. For example, you can set it to 5/2, or 10/5, or 1024/512, depending on the expected loopback interface sessions you need.

Setting the embryonic connection limit enables TCP Intercept, which protects the system from a DoS attack perpetrated by flooding an interface with TCP SYN packets.

Step 9 Click **Finish** to save your changes.

Click **OK**.

Click **Save** on the **Advanced Settings** window.

What to do next

Deploy the changes to the affected devices.

VLAN subinterfaces and 802.1Q trunking

VLAN subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs let you keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

Guidelines for VLAN subinterfaces

Model support

- 1010/200/1210/1220—VLAN subinterfaces are not supported on switch ports or VLAN interfaces.

High availability and clustering

Do not use a subinterface for the failover or state link or for the cluster control link. The exception is for multi-instance mode: you can use a *chassis*-defined subinterface for these links.

Additional guidelines

- Preventing untagged packets on the physical interface—If you use subinterfaces, disable the physical interface from passing traffic. The physical interface transmits untagged packets. This behavior also applies to the active physical interface in a redundant interface pair and also to EtherChannel links. For the subinterface to pass traffic, the physical, redundant, or EtherChannel interface must be enabled. If you want to let the physical, redundant, or EtherChannel interface pass untagged packets, you can configure the name as usual.
- Configure subinterfaces only on non-Management interfaces. Avoid using the dedicated Management interface configured at the CLI or a data interface used for manager access.
- All subinterfaces on the same parent interface must be either members of bridge groups or routed interfaces; you cannot mix and match.
- The Firewall Threat Defense does not support the Dynamic Trunking Protocol (DTP), so configure the connected switch port to trunk unconditionally.
- Assign unique MAC addresses to the subinterfaces that are defined on the Firewall Threat Defense. Subinterfaces use the same burned-in MAC address of the parent interface by default. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense.

Note If you manually assign a MAC address, be sure to assign MAC addresses to all subinterfaces on the same physical interface to avoid unexpected behavior and outages.

Maximum number of VLAN subinterfaces by device model

Your device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface.

This table explains the limits for each device model.

Model	Maximum VLAN Subinterfaces
Secure Firewall 200	1024
Firepower 1010	60
Firepower 1120	512
Firepower 1140, 1150	1024
Secure Firewall 1200	1024
Secure Firewall 3100	1024

Model	Maximum VLAN Subinterfaces
Secure Firewall 4200	1024
Firepower 4100	1024
Firepower 9300	1024
Firewall Threat Defense Virtual	50
ISA 3000	100

Add a subinterface

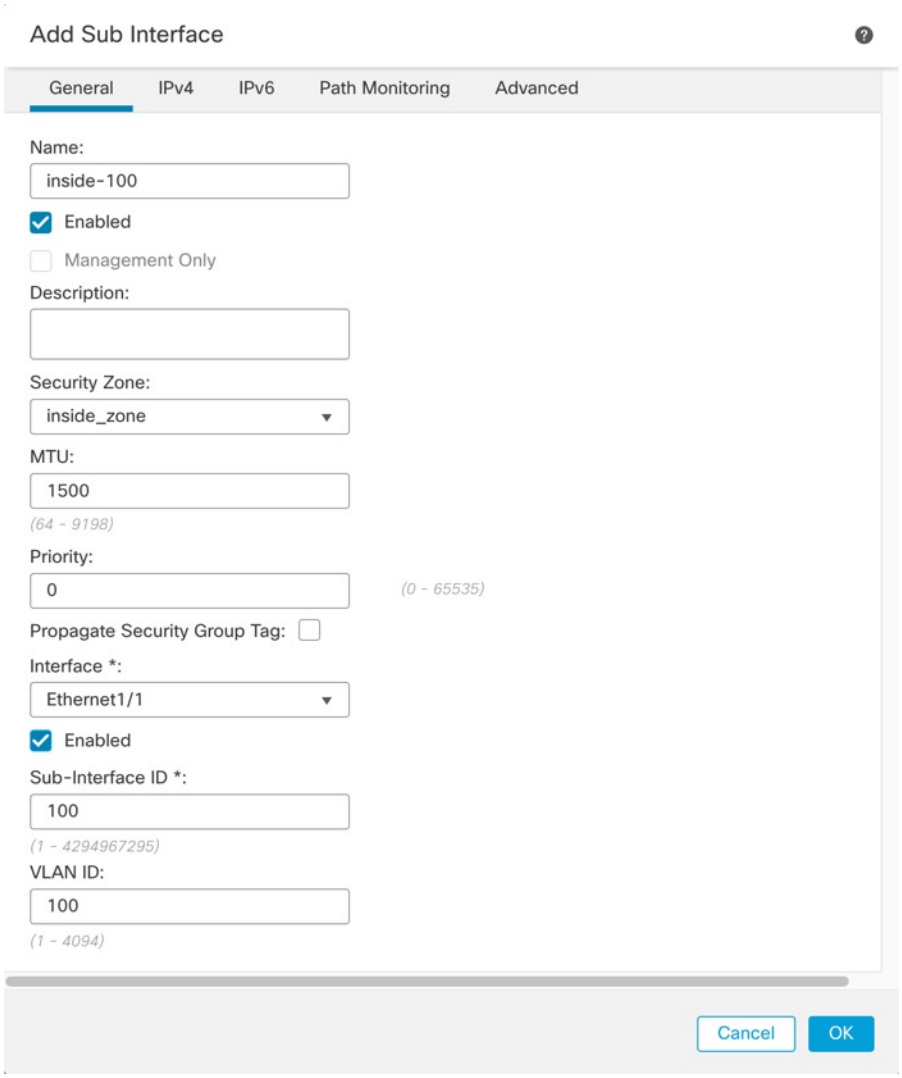
This task enables you to add subinterfaces to physical, redundant, or port-channel interfaces for network segmentation using VLAN tagging.

Add one or more subinterfaces to a physical, redundant, or port-channel interface.

For the Firepower 4100/9300, you can configure subinterfaces in FXOS for use with container instances; see Add a VLAN subinterface for container instances. These subinterfaces appear in the Cloud-Delivered Firewall Management Center interface list. You can also add subinterfaces in Cloud-Delivered Firewall Management Center, but only on parent interfaces that do not already have subinterfaces defined in FXOS.

Note The parent physical interface passes untagged packets. You may not want to pass untagged packets, so be sure not to include the parent interface in your security policy.

Procedure



Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** () for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Enable the parent interface according to Enable the physical interface and configure Ethernet settings, on page 1003.

Step 3 Click **Add Interfaces** > **Sub Interface**.

Step 4 On **General**, set these parameters:

Figure 256: Add subinterface

a) **Interface**—Choose the physical, redundant, or port-channel interface to which you want to add the subinterface.

b) **Sub-Interface ID**—Enter the subinterface ID as an integer between 1 and 4294967295. The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.

c) **VLAN ID**—Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

   This VLAN ID must be unique.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 7 Configure the routed or transparent mode interface parameters. See Configure routed mode interfaces, on page 1080 or Bridge group interfaces, on page 1086.

Configure VXLAN Interfaces

This chapter tells how to configure Virtual eXtensible LAN (VXLAN) interfaces. VXLAN interfaces act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks.

VXLAN interfaces

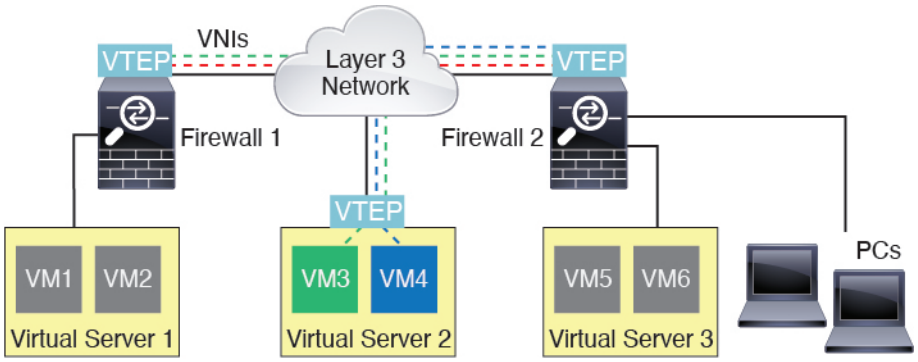
Virtual Extensible Local Area Network (VXLAN) is a network encapsulation protocol that provides flexible placement of multitenant segments throughout the data center. VXLAN offers higher scalability, supporting up to 16 million Layer 2 segments. VXLAN delivers Ethernet Layer 2 network services similar to VLAN and provides greater extensibility and flexibility.

Additional information

For detailed information about VXLAN, see RFC 7348.

encapsulation

The Firewall Threat Defense supports two types of VXLAN encapsulation:



- VXLAN (all models)—VXLAN uses MAC Address-in-User Datagram Protocol (MAC-in-UDP) encapsulation. The original Layer 2 frame has a VXLAN header added and is then placed in a UDP-IP packet.
- Geneve (Firewall Threat Defense Virtual only)—Geneve has a flexible inner header that is not limited to the MAC address. Geneve encapsulation is required for transparent routing of packets between an Amazon Web Services (AWS) Gateway Load Balancer and appliances, and for sending extra information.

VXLAN tunnel endpoints

A VXLAN tunnel endpoint (VTEP) devices performs VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces to which you apply your security policy, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP network communication

This figure shows two Firewall Threat Defenses and Virtual Server 2 acting as VTEPs across a Layer 3 network, extending the VNI 1, 2, and 3 networks between sites. The Firewall Threat Defenses act as bridges or gateways between VXLAN and non-VXLAN networks.

The underlying IP network between VTEPs is independent of the VXLAN overlay. Encapsulated packets are routed based on the outer IP address header, which has the initiating VTEP as the source IP address and the terminating VTEP as the destination IP address. For VXLAN encapsulation: The destination IP address can be a multicast group when the remote VTEP is not known. With Geneve, the Firewall Threat Defense only supports static peers. The destination port for VXLAN is UDP port 4789 by default (user configurable). The destination port for Geneve is 6081.

VTEP source interface

A VTEP source interface is a regular interface (physical, EtherChannel, or even VLAN) that you plan to associate with all VNI interfaces. You can configure one VTEP source interface per Firewall Threat Defense Virtual.

VTEP source interface characteristics

The VTEP source interface can be devoted wholly to VXLAN traffic, although it is not restricted to that use. You can use the interface to handle regular traffic and apply a security policy to it. However, for VXLAN traffic, you must apply all security policies to the VNI interfaces. The VTEP interface serves as a physical port only.

In transparent firewall mode, the VTEP source interface is not part of a BVI. You must configure an IP address for it, similar to how the management interface is configured.

Because you can only configure one VTEP source interface, you cannot configure both VXLAN and Geneve interfaces on the same device. There is an exception for Firewall Threat Defense Virtual clustering on AWS or Azure, where you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve (AWS) or VXLAN (Azure) interface can be used for the Gateway Load Balancer.

VNI interfaces

A VNI interface is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. VNI interfaces are similar to VLAN interfaces. You can apply your security policy directly to each interface.

VNI interface configuration details

You can add only one VTEP interface. All VNI interfaces are associated with the same VTEP interface. There is an exception for Firewall Threat Defense Virtual clustering on AWS or Azure. For AWS clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve interface can be used for the AWS Gateway Load Balancer. For Azure clustering, you can have two VTEP

source interfaces: a VXLAN interface is used for the cluster control link, and a second VXLAN interface can be used for the Azure Gateway Load Balancer.

How VXLAN and Geneve packets are processed

Summary

The key components involved in VXLAN and Geneve packet processing are:

- VTEP source interface: Performs encapsulation and decapsulation of VXLAN and Geneve traffic
- Inner MAC frame: The original packet payload that gets encapsulated
- Outer frame: The encapsulated packet with VXLAN or Geneve headers
- Remote VTEP: The destination endpoint for encapsulated traffic

Workflow

These stages describe how VXLAN and Geneve packet processing work:

1. Traffic entering and exiting the VTEP source interface is subject to VXLAN processing, specifically encapsulation or decapsulation.

   Encapsulation processing includes these tasks:

   - The VTEP source interface encapsulates the inner MAC frame with the VXLAN header.
   - The UDP checksum field is set to zero.
   - The Outer frame source IP is set to the VTEP interface IP.
   - The Outer frame destination IP is decided by a remote VTEP IP lookup.

   Decapsulation: the Firewall Threat Defense only decapsulates a VXLAN packet if:

   - It is a UDP packet with the destination port set to 4789 (this value is user configurable).
   - The ingress interface is the VTEP source interface.
   - The ingress interface IP address is the same as the destination IP address.
   - The VXLAN packet format is compliant with the standard.

2. Traffic entering and exiting the VTEP source interface is subject to Geneve processing, specifically encapsulation or decapsulation.

   Encapsulation processing includes these tasks:

   - The VTEP source interface encapsulates the inner MAC frame with the Geneve header.
   - The UDP checksum field is set to zero.
   - The Outer frame source IP is set to the VTEP interface IP.
   - The Outer frame destination IP is set the peer IP address that you configured.

   Decapsulation; the Firewall Threat Defense only decapsulates a Geneve packet if:

- It is a UDP packet with the destination port set to 6081 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The Geneve packet format is compliant with the standard.

Peer VTEPs

A peer VTEP is a VXLAN Tunnel Endpoint that enables the Firewall Threat Defense to send packets to devices behind remote VTEPs.

When the Firewall Threat Defense sends a packet to a device behind a peer VTEP, the Firewall Threat Defense needs two important pieces of information:

- The destination MAC address of the remote device
- The destination IP address of the peer VTEP

The Firewall Threat Defense maintains a mapping of destination MAC addresses to remote VTEP IP addresses for the VNI interfaces.

VXLAN peer configuration methods

There are two ways in which the Firewall Threat Defense can find this information:

- A single peer VTEP IP address can be statically configured on the Firewall Threat Defense.

  For IPv4: The Firewall Threat Defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC address.

  For IPv6: The Firewall Threat Defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A group of peer VTEP IP addresses can be statically configured on the Firewall Threat Defense.

  For IPv4: The Firewall Threat Defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC addresses.

  For IPv6: The Firewall Threat Defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A multicast group can be configured on each VNI interface (or on the VTEP as a whole).

  For IPv4: The Firewall Threat Defense sends a VXLAN-encapsulated ARP broadcast packet within an IP multicast packet through the VTEP source interface. The response to this ARP request enables the Firewall Threat Defense to learn both the remote VTEP IP address along with the destination MAC address of the remote end node.

  For IPv6: The Firewall Threat Defense sends a Multicast Listener Discovery (MLD) Report message through the VTEP source interface to indicate that the Firewall Threat Defense is listening on the VTEP interface for the multicast address traffic.

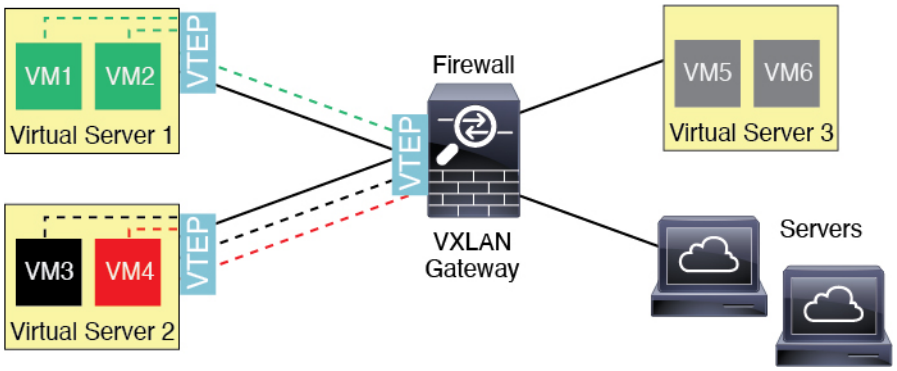
  This option is not supported with Geneve.

Geneve peer configuration

The Firewall Threat Defense Virtual only supports statically defined peers. You can define the Firewall Threat Defense Virtual peer IP address on the AWS Gateway Load Balancer. Because the Firewall Threat Defense Virtual never initiates traffic to the Gateway Load Balancer, you do not also have to specify the Gateway Load Balancer IP address on the Firewall Threat Defense Virtual. It learns the peer IP address when it receives Geneve traffic. Multicast groups are not supported with Geneve.

VXLAN use cases

This section describes the use cases for implementing VXLAN on the Firewall Threat Defense.

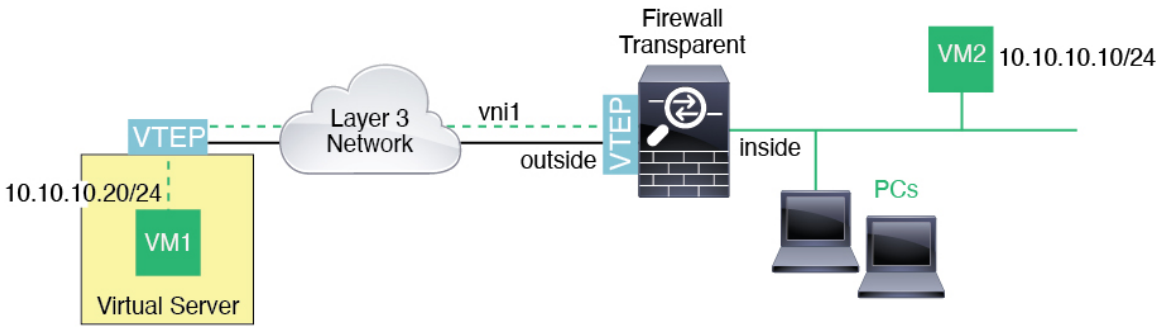


VXLAN bridge or gateway overview

A VTEP acts as a bridge or gateway between end nodes, such as VMs, servers, and PCs, and the VXLAN overlay network.

VXLAN Packet Processing

For incoming frames received with VXLAN encapsulation over the VTEP source interface, the Firewall Threat Defense strips out the VXLAN header and forwards it to a physical interface connected to a non-VXLAN network based on the destination MAC address of the inner Ethernet frame.

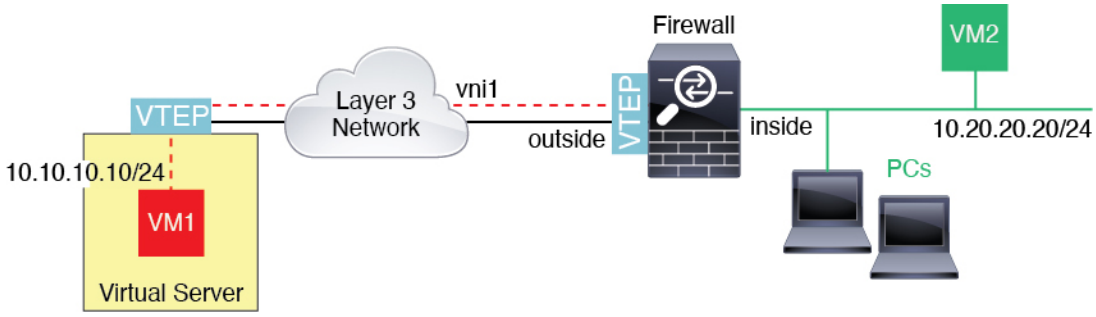


The Firewall Threat Defense always processes VXLAN packets rather than forwarding them untouched between two other VTEPs.

VXLAN bridge

A VXLAN bridge is a network configuration where the Firewall Threat Defense connects a remote VXLAN segment to a local segment.

When you use a bridge group (transparent firewall mode, or optionally routed mode), the Firewall Threat Defense can serve as a VXLAN bridge between a (remote) VXLAN segment and a local segment where both are in the same network. In this case, one member of the bridge group is a regular interface while the other member is a VNI interface.



VXLAN gateway (routed mode)

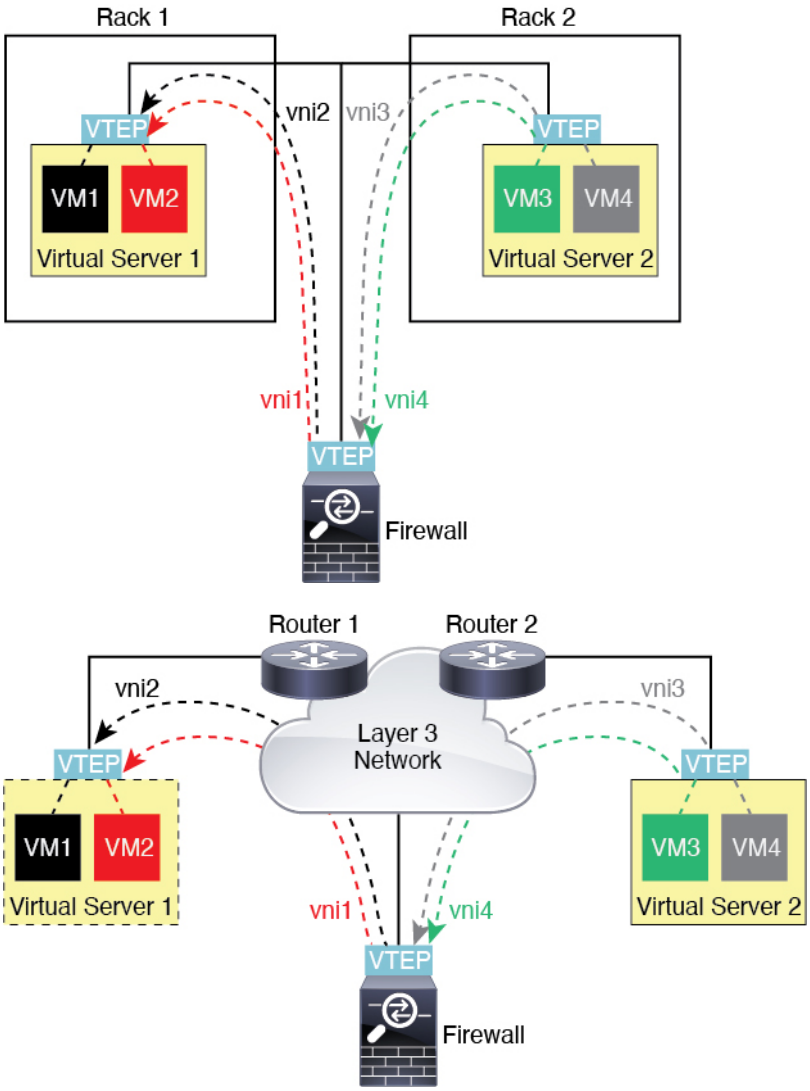
The Firewall Threat Defense functions as a router between VXLAN and non-VXLAN domains, connecting devices on different networks.

VXLAN Gateway Visual Representation

This figure illustrates the VXLAN gateway connectivity.

Router Between VXLAN Domains

A VXLAN-stretched Layer 2 domain enables a VM to utilize a Firewall Threat Defense as its default gateway regardless of physical proximity.



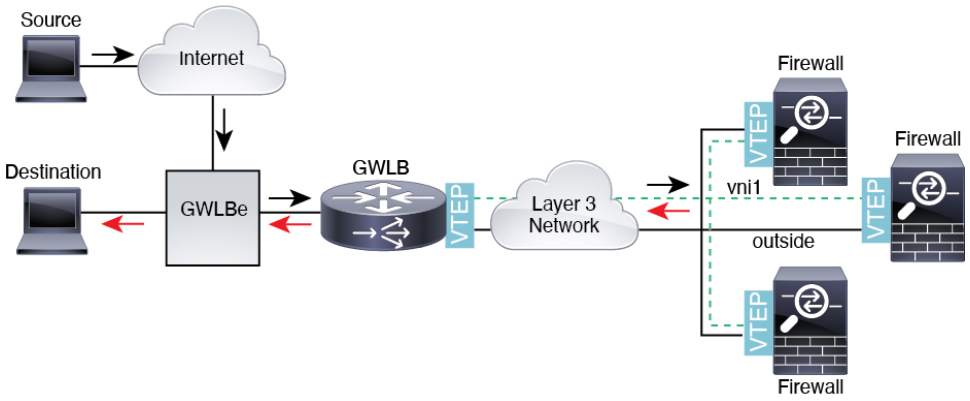
Routing Process and Packet Flow

The following steps outline the packet flow between VMs across VXLAN domains:

1. For packets from VM3 to VM1, the destination MAC address is the Firewall Threat Defense MAC address, because the Firewall Threat Defense is the default gateway.
2. The VTEP source interface on Virtual Server 2 receives packets from VM3, then encapsulates the packets with VNI 3's VXLAN tag and sends them to the Firewall Threat Defense .
3. When the Firewall Threat Defense receives the packets, it decapsulates the packets to get the inner frames.
4. The Firewall Threat Defense uses the inner frames for route lookup, then finds that the destination is on VNI 2. If it does not already have a mapping for VM1, the Firewall Threat Defense sends an encapsulated ARP broadcast on the multicast group IP on VNI 2.
5. The Firewall Threat Defense encapsulates the packets again with the VXLAN tag for VNI 2 and sends the packets to Virtual Server 1. Before encapsulation, the Firewall Threat Defense changes the inner frame destination MAC address to be the MAC of VM1.

6. When Virtual Server 1 receives the VXLAN packets, it decapsulates the packets and delivers the inner frames to VM1.

Note The Firewall Threat Defense must use dynamic VTEP peer discovery because it has multiple VTEP peers in this scenario.



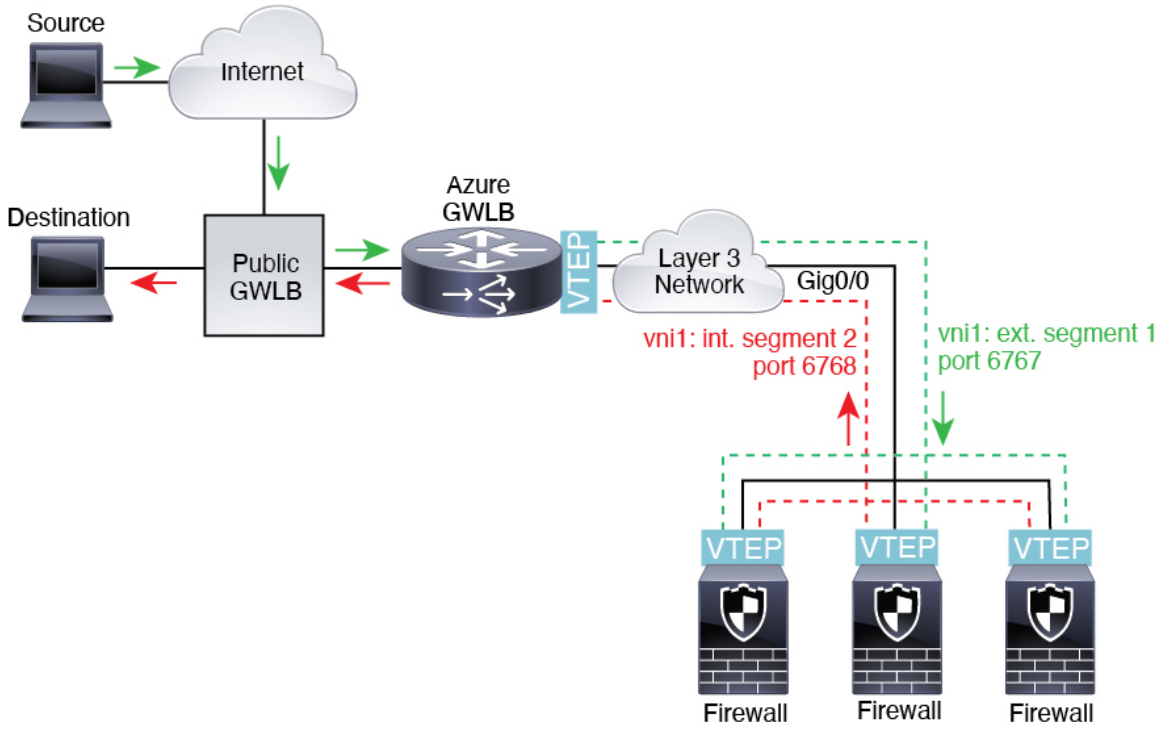
Geneve Single-Arm Proxy

In a Geneve single-arm proxy deployment, network traffic is routed through a centralized proxy device for inspection and policy enforcement.

Note This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Firewall Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Firewall Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Figure 257: Geneve Single-Arm Proxy



Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, Firewall Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Firewall Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 258: Azure Gateway Load Balancer with Paired Proxy

Requirements and prerequisites for VXLAN interfaces

This reference provides the model requirements and prerequisites for configuring VXLAN interfaces on supported platforms.

Model requirements

- VXLAN encapsulation is supported on all models.
- Geneve encapsulation is supported for these models:
  - Firewall Threat Defense Virtual in Amazon Web Services (AWS)
- VXLAN in *paired proxy mode* is supported for these models:
  - Firewall Threat Defense Virtual in Azure
- Firepower 1010 and Secure Firewall 1210/1220 switch ports and VLAN interfaces are not supported as VTEP interfaces.

Guidelines for VXLAN interfaces

Firewall mode restrictions

Geneve interfaces are only supported in routed firewall mode.

- Paired proxy VXLAN interfaces are only supported in routed firewall mode.

IPv6 support restrictions

The VNI interface supports both IPv4 and IPv6 traffic.

- For VXLAN encapsulation, the VTEP source interface supports both IPv4 and IPv6. The Firewall Threat Defense Virtual cluster control link VTEP source interface only supports IPv4.

  For Geneve, the VTEP source interface only supports IPv4.

Clustering restrictions

Clustering does not support VXLAN in Individual Interface mode except for the cluster control link (Firewall Threat Defense Virtual only) Only Spanned EtherChannel mode supports VXLAN.

An exception is made for AWS, which can use an additional Geneve interface for use with the GWLB and for Azure, which can use an additional paired proxy VXLAN interface for use with the GWLB.

Routing restrictions

Only static routing or Policy Based Routing is supported on the VNI interface; dynamic routing protocols are not supported.

VPN restrictions

You cannot configure the VTEP source interface for VPN or use it as a VTI.

MTU requirements

If the source interface MTU is less than the required minimum, the Firewall Threat Defense automatically raises the MTU to meet encapsulation requirements.

- VXLAN encapsulation—If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the Firewall Threat Defense automatically raises the MTU to 1554 bytes or 1574 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 54 bytes for IPv4 or +64 bytes for IPv6. For the Firewall Threat Defense Virtual, this MTU requires a restart to enable jumbo frame reservation.
- Geneve encapsulation—If the source interface MTU is less than 1806 bytes, then the Firewall Threat Defense automatically raises the MTU to 1806 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 306 bytes. This MTU requires a restart to enable jumbo frame reservation.

Configure VXLAN or Geneve interfaces

You can configure either VXLAN or Geneve interfaces.

Configure VXLAN interfaces

Configure VXLAN interfaces to enable virtualized network overlay functionality and network segmentation.

VXLAN provides Layer 2 overlay network capabilities over existing Layer 3 infrastructure. You can configure either VXLAN or Geneve interfaces, but not both simultaneously.

Note You can configure either VXLAN or Geneve (Firewall Threat Defense Virtual only). For Geneve interfaces, see Configure geneve interfaces, on page 1074.

Note For Azure GWLB, the VXLAN interface is configured when you deploy the VM using the ARM template. You can use this section to change your configuration.

Follow these steps to configure VXLAN interfaces.

Procedure

Step 1 Configure the VTEP source interface, on page 1072.

Step 2 Configure the VNI interface, on page 1073.

Step 3 (Azure GWLB) Allow gateway load balancer health checks, on page 1076.

Configure the VTEP source interface

This task enables you to set up VXLAN network virtualization by configuring a Network Virtualization Endpoint (NVE) on your firewall device.

You can configure one VTEP source interface per Firewall Threat Defense device. The VTEP is defined as a Network Virtualization Endpoint (NVE). VXLAN is the default encapsulation type. An exception is made for clustering on the Firewall Threat Defense Virtual in Azure, where you can use one VTEP source interface for the cluster control link and a second one for the data interface connected to the Azure GWLB.

Procedure

Step 1 If you want to specify a group of peer VTEPs, add a network object with the peer IP addresses. See Create a network object, on page 2985.

Step 2 Choose **Devices** > **Device Management**.

Step 3 Click **Edit** (✎) next to the device on which you want to configure VXLAN.

Step 4 (Optional) Specify that the source interface is NVE-only.

This setting is optional for routed mode where this setting restricts traffic to VXLAN and common management traffic only on this interface. This setting is automatically enabled for transparent firewall mode.

a) Click **Interfaces**.

b) Click **Edit** (✎) for the VTEP source interface.

c) On the **General** page, check the check box of **NVE Only**.

Step 5 Click **VTEP** if it is not already displaying.

Step 6 Check **Enable NVE**.

Step 7 Click **Add VTEP**.

a) For the **Encapsulation Type**, choose **VXLAN**.

For AWS, you can choose between **VXLAN** and **Geneve**. Other platforms have **VXLAN** chosen automatically.

b) Enter the value for the **Encapsulation port** within the specified range.

The default value is 4789.

c) Select the **VTEP Source Interface**.

Select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the Cloud-Delivered Firewall Management Center automatically raises the MTU to 1554 bytes or 1574 bytes.

d) Select the **Neighbor Address**. The available options are:

- **None**—No neighbor address is specified.
- **Peer VTEP**—Specify a peer VTP address.
- **Peer Group**—Specify a network object with the peer IP addresses.
- **Default Multicast**—Specify a default multicast group for all associated VNI interfaces. If you do not configure the multicast group per VNI interface, then this group is used. If you configure a group at the VNI interface level, then that group overrides this setting.

Step 8 Click **OK**.

Step 9 Click **Save**.

What to do next

Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI interface

Add a VNI interface, associate it with the VTEP source interface, and configure basic interface parameters.

For the Firewall Threat Defense Virtual in Azure, you can configure either a regular VXLAN interface, or you can configure a paired proxy mode VXLAN interface for use with the Azure GWLB. Paired proxy mode is the only supported mode with clustering.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure VXLAN.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

a) Enter the interface **Name** and **Description**.
b) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.
c) Enter a value for the **Priority** field within the specified range. By default, 0 is selected.
d) Enter a value for the **Priority** field within the specified range. By default, 0 is selected.
e) Enter a value for the **VNI ID** between 1 and 10000.

This ID is only an internal interface identifier.

Step 5 (Paired Proxy VXLAN for Azure gateway load balancer) Enable proxy paired mode and set the required parameters.

a) Check **Proxy Paired**.
b) Set the **Internal Port** between 1024 and 65535.
c) Set the **Internal Segment ID** between 1 and 16777215.
d) Set the **External Port** between 1024 and 65535.
e) Set the **External Segment ID** between 1 and 16777215.

Step 6 (Regular VXLAN) Enter a value for the **VNI Segment ID** between 1 and 16777215.

The segment ID is used for VXLAN tagging.

Step 7 Enter the **Multicast Group IP Address**.

If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface.

Step 8 Check **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 9 Click **OK**.

Click **Save** to save the interface configuration.

What to do next

Configure the routed or transparent interface parameters. See Configure routed and transparent mode interfaces, on page 1077.

Configure geneve interfaces

To configure Geneve interfaces for Firewall Threat Defense Virtual, perform the following steps.

Note You can configure either VXLAN or Geneve. For information about VXLAN interfaces, see Configure VXLAN interfaces, on page 1071.

1. Configure the VTEP source interface, on page 1075.
2. Configure the VNI, on page 1075.
3. Allow gateway load balancer health checks, on page 1076.

Configure the VTEP source interface

Configure the VTEP source interface to enable network virtualization functionality on the device.

You can configure one VTEP source interface per Firewall Threat Defense Virtual device. The VTEP is defined as a Network Virtualization Endpoint (NVE).

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **VTEP**.

Step 4 Check **Enable NVE**.

Step 5 Click **Add VTEP**.

a) For the **Encapsulation Type**, choose **Geneve**.

b) Enter the value for the **Encapsulation port** within the specified range.

We do not recommend changing the Geneve port; AWS requires a port of 6081.

c) Select the **VTEP Source Interface**.

You can select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1806 bytes, then the Cloud-Delivered Firewall Management Center automatically raises the MTU to 1806 bytes.

d) Click **OK**.

Step 6 Click **Save**.

Step 7 Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI

This task enables you to add a VNI interface and configure its basic parameters for Geneve functionality on your device.

Add a VNI, associate it with (VTEP) source interface, and configure basic interface parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

a) In the **Name** and **Description** fields, provide relevant information.

b) In the **VNI ID** field, enter a value between 1 and 10000.

Note
This ID is only an internal interface identifier.

Step 5 Check the **Enable Proxy** check box.

Note
When the AWS proxy is enabled on the VNI interface of your device, configuring NAT is not allowed.

This option enables single-arm proxy, and allows traffic to exit the same interface it entered (U-turn traffic). If you edit the interface later , you cannot disable single-arm proxy. To disable single-arm proxy, delete the existing interface and create a new VNI interface.

This option is only available for a Geneve VTEP.

Step 6 Select **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 7 Click **OK**.

Step 8 Click **Save**.

What to do next

Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Allow gateway load balancer health checks

The AWS or Azure gateway load balancer (GWLB) requires appliances to answer a health check properly. The GWLB will only send traffic to appliances that are considered healthy.

Configure one of these methods to enable proper health check responses.

Procedure

Step 1 Configure SSH. See Configure Secure Shell

Allow SSH from the GWLB IP address. The GWLB will attempt to establish a connection to the Firewall Threat Defense Virtual, and the Firewall Threat Defense Virtual's prompt to log in is taken as proof of health. An SSH login attempt will time out after 1 minute. You will need to configure a longer health check interval on the GWLB to accommodate this timeout.

Step 2 Configure HTTP(S) Redirection Using Static Interface NAT with Port Translation.

You can configure the Firewall Threat Defense Virtual to redirect health checks to a metadata HTTP(S) server. For HTTP(S) health checks, the HTTP(S) server must reply to the GWLB with a status code in the range 200 to 399. Because the Firewall Threat Defense Virtual has limits on the number of simultaneous management connections, you may choose to offload the health check to an external server.

Static interface NAT with port translation lets you redirect a connection to a port (such as port 80) to a different IP address. For example, translate an HTTP packet from the GWLB with a destination of the Firewall Threat Defense Virtual outside interface so that it appears to be from the Firewall Threat Defense Virtual outside interface with a destination of the HTTP server. The Firewall Threat Defense Virtual then forwards the packet to the mapped destination address. The HTTP server responds to the Firewall Threat Defense Virtual outside interface, and then the Firewall Threat Defense Virtual forwards the response back to the GWLB. You need an access rule that allows traffic from the GWLB to the HTTP server.

a) Permit HTTP(S) traffic on the outside interface from the GWLB network in an access rule. See Access Control Rules, on page 2041.
b) For HTTP(S), translate the source GWLB IP address to the Firewall Threat Defense Virtual outside interface IP address; then translate the destination of the outside interface IP address to the HTTP(S) server IP address. See Configure static manual NAT, on page 1614.

Configure routed and transparent mode interfaces

This section includes tasks to complete the regular interface configuration for all models in routed or transparent firewall mode.

Routed and transparent mode interfaces

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

Interface types by firewall mode

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 153 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the Firewall Threat Defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

Dual IP stack (IPv4 and IPv6)

A dual IP stack is a network configuration that enables both IPv6 and IPv4 addresses on the same interface on Firewall Threat Defense device. Make sure you configure a default route for both IPv4 and IPv6.

31-bit subnet masks

A 31-bit subnet mask includes only two addresses for point-to-point connections.

31-bit subnet mask implementation

For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. Normally, the first and last address in a 2-address subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4.

31-bit subnet mask use cases

The failover link between two Firewall Threat Defenses only requires two addresses. Any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog.

Note: 31-bit subnet and clustering compatibility

You can use a 31-bit subnet mask for cluster interfaces, excluding the management interface and the cluster control link.

31-bit subnet and failover

A Firewall Threat Defense using a 31-bit subnet for its interface IP address can't configure a standby IP address due to insufficient addresses.

Interface monitoring limitations

When using a 31-bit subnet for the Firewall Threat Defense interface IP address, you cannot configure a standby IP address for the interface because there are not enough addresses. Normally, an interface for failover should have a standby IP address so the active unit can perform interface tests to ensure standby interface health. Without a standby IP address, the Firewall Threat Defense cannot perform any network tests; only the link state can be tracked.

For the failover and optional separate state link, which are point-to-point connections, you can also use a 31-bit subnet.

31-bit subnet and management

If you have a directly-connected management station, you can use a point-to-point connection for SSH or HTTP on the Firewall Threat Defense, or for SNMP or Syslog on the management station.

Recommendation: 31-bit subnet unsupported features

The 31-bit subnet does not support certain network features that require multiple host addresses.

- BVI interfaces for bridge groups—The bridge group requires at least 3 host addresses: the BVI, and two hosts connected to two bridge group member interfaces. you must use a /29 subnet or smaller.
- Multicast Routing

Guidelines and limitations for routed and transparent mode interfaces

Context mode

- PPPoE is not supported in multiple context mode.
- For multiple context mode in transparent mode, each context must use different interfaces; you cannot share an interface across contexts.
- For multiple context mode in transparent mode, each context typically uses a different subnet. You can use overlapping subnets, but your network topology requires router and NAT configuration to make it possible from a routing standpoint.

High availability, Clustering, and Multi-Instance

Do not configure failover links with the procedures in this chapter. See the High availability chapter for more information.

- For cluster interfaces, see the clustering chapter for requirements.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- When you use High availability, you must set the IP address and standby address for data interfaces manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. See the High availability chapter for more information.

IPv6

IPv6 is supported on all interfaces.

- You can only configure IPv6 addresses manually in transparent mode.
- The Firewall Threat Defense device does not support IPv6 anycast addresses.
- DHCPv6 and prefix delegation options are not supported with transparent mode, clustering, or High availability.

Model guidelines

For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, bridge groups are not supported.

- For the Firepower 2100 series, bridge groups are not supported in routed mode.

VLAN IDs for the ASASM

- If you add an interface for a VLAN that is not yet assigned to the ASA by the switch, the interface will be in the down state. When you assign the VLAN to the ASA, the interface changes to an up state. See the **show interface** command for more information about interface states.

Transparent mode and bridge group guidelines

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The Firewall Threat Defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the Firewall Threat Defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).

- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
-
- For the 200/ 1010/ 1210// 1220, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the Firewall Threat Defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, Firewall Threat Defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using bridge group members. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Additional guidelines and requirements

The Firewall Threat Defense supports only one 802.1Q header in a packet and does not support multiple headers (known as Q-in-Q support) for firewall interfaces.**Note:** For inline sets and passive interfaces, the FTD supports Q-in-Q up to two 802.1Q headers in a packet, with the exception of the Firepower 4100/9300, which only supports one 802.1Q header.

- Interface problems, such as frequent up/down status changes, can prevent the floating connection timer from applying correctly to the connections going through the interface. If you have problems with an interface's status, consider clearing all connections after the status becomes stable to clear invalid connections.

Configure routed mode interfaces

Before you begin

- Firepower 4100/9300
  1. Configure a physical interface
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (port channel)
     - Add a VLAN subinterface for container instances in FXOS
     - Configure a loopback interface, on page 1053
     - Add a subinterface, on page 1060 in Cloud-Delivered Firewall Management Center
     - Configure VXLAN interfaces, on page 1071

- (Optional) **All other models:**
  - Configure an EtherChannel, on page 1011
  - Configure a loopback interface, on page 1053
  - Add a subinterface, on page 1060
  - Configure VXLAN interfaces, on page 1071
  - Firewall Threat Defense Virtual on AWS: Configure geneve interfaces, on page 1074
  - Firepower 1010 and Secure Firewall 1210/1220 : Configure a VLAN interface, on page 1044

This procedure describes how to set the name, security zone, and IPv4 address.

Note Not all fields are supported for all interface types.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

Step 4 Enable the interface by checking the **Enabled** check box.

a) (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

b) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

c) In the **Mode** drop-down list, choose **None** .

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types.

d) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New** .

The routed interface is a Routed-type interface, and can only belong to Routed-type zones.

e) See Configure the MTU, on page 1109 for information about the **MTU** .

f) In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to route the traffic across multiple egress interfaces. For more information, see Configure policy-based routing policy, on page 1548.

Step 5 Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability, clustering , and loopback interfaces only support static IP address configuration; DHCP and PPPoE are not supported.

- **Use Static IP** —Enter the IP address and subnet mask. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254 or /31). In this case, no IP addresses are reserved for the network or broadcast addresses. You cannot set the standby IP address in this case. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management** page, click **High Availability** in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP** —Configure the following optional parameters:
  - **Obtain default route using DHCP** —Obtains the default route from the DHCP server.
  - **DHCP route metric** —Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.
- **Use PPPoE** —If the interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, configure the following parameters:
  - **VPDN Group Name** —Specify a group name of your choice to represent this connection.
  - **PPPoE User Name** —Specify the username provided by your ISP.
  - **PPPoE Password/Confirm Password** —Specify and confirm the password provided by your ISP.
  - **PPP Authentication** —Choose **PAP** , **CHAP** , or **MSCHAP** .

    PAP passes a cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.
  - **PPPoE route metric** —Assign an administrative distance to the learned route. Valid values are from 1 to 255. By default, the administrative distance for the learned routes is 1.
  - **Enable Route Settings** —To manually configure the PPPoE IP address, check this box and then enter the **IP Address** .

    If you select the **Enable Route Settings** check box and leave the **IP Address** blank, the **ip address pppoe setroute** command is applied as shown in this example:

```
interface GigabitEthernet0/2
nameif inside2_pppoe
cts manual
  propagate sgt preserve-untag
  policy static sgt disabled trusted
security-level 0
pppoe client vpdn group test
pppoe client route distance 10
ip address pppoe setroute
```

- **Store Username and Password in Flash** —Stores the username and password in flash memory.

  The Firewall Threat Defense device stores the username and password in a special location of NVRAM.

Step 6 (Optional) Configure these fields, if you require them.

a) (Optional) See Configure IPv6 addressing, on page 1090 to configure IPv6 addressing on the **IPv6** tab.

b) (Optional) See Configure the MAC address, on page 1110 to manually configure the MAC address on the **Advanced** tab.

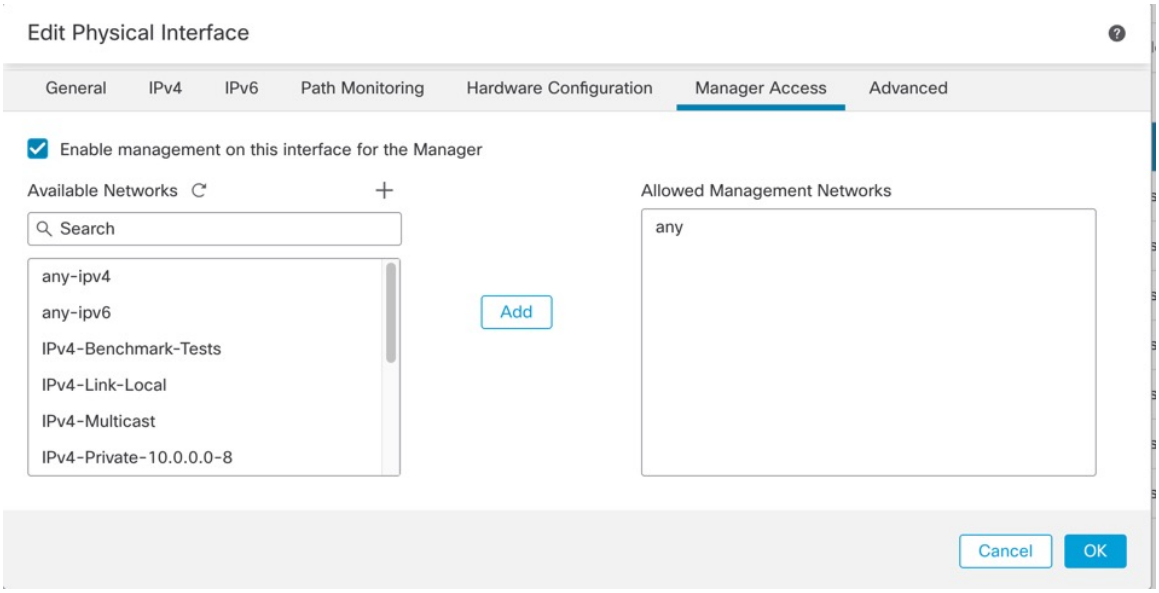
c) Enable Cloud-Delivered Firewall Management Center manager access on a data interface on the **Manager Access** page.

You can enable manager access from a data interface when you first setup the Firewall Threat Defense . If you want to enable or disable manager access after you added the Firewall Threat Defense to the Cloud-Delivered Firewall Management Center , see:

- Enable manager access: Change the manager access interface from management to data, on page 1174

  Note
  You cannot enable manager access unless you first initiate the manager interface migration from Management to a data interface. After you initiate the migration, you can enable manager access on the **Manager Access** page and save the configuration successfully.

- Disable manager access: Change the manager access interface from data to management, on page 1178



If you want to change the manager access interface from one data interface to another data interface, you must disable manager access on the original data interface, but do not disable the interface itself yet; the original data interface must be used to perform the deployment. If you want to use the same IP address on the new manager access interface, you can delete or change the IP configuration on the original interface; this change should not affect the deployment. If you use a different IP address for the new interface, then also change the device IP address shown in the Cloud-Delivered Firewall Management Center ; see Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center, on page 1167 . Be sure to also update related configuration to use the new interface such as static routes, DDNS, and DNS settings.

Manager access from a data interface has the following limitations:

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the Cloud-Delivered Firewall Management Center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.

- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the Firewall Threat Defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the Cloud-Delivered Firewall Management Center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For Firewall Threat Defense Virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- Clustering is not supported. You must use the Management interface in this case.

Figure 259: Manager Access

- Check **Enable management on this interface for the manager** to use this data interface for management instead of the dedicated Management interface.
- (Optional) In the **Allowed Management Networks** box, add the networks from which you want to allow manager access. By default, any networks are allowed.

Step 7 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex. However, the SFP interface (Ethernet 1/5) of Secure Firewall 220 supports **Full** and **Half** duplex.
- **Speed**—Choose a speed (varies depending on the model).For SFPs, choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always full, autonegotiation is enabled, and FEC is set to auto. For dual-speed transceivers, the lower speed is used. This option is useful if you later change the network module to a different model, and want the speed to update

automatically. Some switches and transceivers don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

Note
You cannot modify the speed of a high availability or a cluster control link interface.

- **Auto-negotiation**—Set the interface to negotiate the link status and flow control.

  Except for the 1100 and 2100, autonegotiation is set separately from the speed. Some switches don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

- **Forward Error Correction Mode**—For 25Gbps and higher interfaces, enable Forward Error Correction (FEC).

  For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. If you remove the interface from the EtherChannel, after rebooting, you may need to reconfigure the FEC for the interface.

  Some switches don't support auto mode for FEC, especially for larger interfaces. Be sure to manually configure the setting, depending on the switch support. We don't recommend disabling FEC; if you do so, the EtherChannel may not come up properly.

  The setting chosen when you use **auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 67: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate
25/50/100G	Clause 91 RS-FEC	Clause 91 RS-FEC

Note
From Version 7.4.2, Firewall Threat Defense supports the SFP 10G_25G_CSR_S module. To avoid link-down issues after a reboot, Forward Error Correction (FEC) must be enabled on these interfaces.

Step 8 Click **OK** .

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Bridge group interfaces

A bridge group is a group of interfaces that the Secure Firewall Threat Defense device bridges instead of routes.

Bridge group support

Bridge groups are supported in both transparent and routed firewall mode.

For more information about bridge groups, see Bridge groups, on page 155.

To configure bridge groups and associated interfaces, perform these steps.

Configure general bridge group member interface parameters

This task configures the name and security zone for each bridge group member interface to enable bridge group functionality.

The same bridge group can include different types of interfaces: physical interfaces, VLAN subinterfaces, Firepower 1010 and Secure Firewall 1210/1220 VLAN interfaces, EtherChannels, and redundant interfaces. The Management interface is not supported. In routed mode, EtherChannels are not supported. For the Firepower 4100/9300, data-sharing type interfaces are not supported.

Before you begin

- Firepower 4100/9300
  1. Configure a physical interface
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (port channel)
     - Add a VLAN subinterface for container instances in FXOS
     - Add a subinterface, on page 1060 in Cloud-Delivered Firewall Management Center
- (Optional) **All other models:**
  - Configure an EtherChannel, on page 1011
  - Add a subinterface, on page 1060
  - Firepower 1010 and Secure Firewall 1210/1220: Configure a VLAN interface, on page 1044

Follow these steps to configure general bridge group member interface parameters:

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Configure these fields:

a) In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

b) Enable the interface by checking the **Enabled** check box.

c) (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

d) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

e) In the **Mode** drop-down list, choose **None**.

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types. After you assign this interface to a bridge group, the mode will show as **Switched**.

f) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

The bridge group member interface is a Switched-type interface, and can only belong to Switched-type zones. Do not configure any IP address settings for this interface. You will set the IP address for the Bridge Virtual Interface (BVI) only. Note that the BVI does not belong to a zone, and you cannot apply access control policies to the BVI.

Step 4 Refer to Configure the MTU, on page 1109 for information about **MTU**.

Step 5 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed** .

- **Duplex** —Choose **Full** or **Half** . SFP interfaces only support **Full** duplex. However, the SFP interface (Ethernet 1/5) of Secure Firewall 220 supports **Full** and **Half** duplex.
- **Speed** —Choose a speed (varies depending on the model). For SFPs, choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always full, autonegotiation is enabled, and FEC is set to auto. For dual-speed transceivers, the lower speed is used. This option is useful if you later change the network module to a different model, and want the speed to update automatically. Some switches and transceivers don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

  Note
  You cannot modify the speed of a high availability or a cluster control link interface.

- **Auto-negotiation** —Set the interface to negotiate the link status and flow control.

  Except for the 1100 and 2100 , autonegotiation is set separately from the speed. Some switches don't support autonegotiation, especially for higher speed interfaces. In this case, set the interface on the Firewall Threat Defense to a manual speed and also disable **Auto-negotiation** so the link can come up.

- **Forward Error Correction Mode** —For 25Gbps and higher interfaces, enable Forward Error Correction (FEC).

  For an EtherChannel member interface, configure FEC before adding it to the EtherChannel. If you remove the interface from EtherChannel and then reboot, reconfigure the FEC for the interface.

  Some switches don't support auto mode for FEC, especially for larger interfaces. Be sure to manually configure the setting, depending on the switch support. We don't recommend disabling FEC because the EtherChannel may not function correctly.

  The setting chosen when you use **auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

  Table 68: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC *x* M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate
25/50/100G	Clause 91 RS-FEC	Clause 91 RS-FEC

Note
From Version 7.4.2, Firewall Threat Defense supports the SFP 10G_25G_CSR_S module. To avoid link-down issues after a reboot, Forward Error Correction (FEC) must be enabled on these interfaces.

Step 6 (Optional) Refer to Configure IPv6 addressing, on page 1090 to configure IPv6 addressing on the **IPv6** tab.

Step 7 (Optional) Refer to Configure the MAC address, on page 1110 to manually configure the MAC address on the **Advanced** tab.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure the bridge virtual interface (BVI)

Configure a Bridge Virtual Interface (BVI) to provide IP addressing for each bridge group, which enables traffic routing and management functionality for the bridge group members.

Each bridge group requires a BVI for which you configure an IP address. The Firewall Threat Defense uses this IP address as the source address for packets originating from the bridge group. The BVI IP address must

be on the same subnet as the connected network. For IPv4 traffic, the BVI IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

For routed mode, if you provide a name for the BVI, then the BVI participates in routing. Without a name, the bridge group remains isolated as in transparent firewall mode.

Before you begin

You cannot add the BVI to a security zone; therefore, you cannot apply Access Control policies to the BVI. You must apply your policy to the bridge group member interfaces based on their zones.

Follow these steps to configure the Bridge Virtual Interface (BVI):

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** () for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Choose **Add Interfaces** > **Bridge Group Interface**.

a) (Routed Mode) In the **Name** field, enter a name up to 48 characters in length.

You must name the BVI if you want to route traffic outside the bridge group members, for example, to the outside interface or to members of other bridge groups. The name is not case-sensitive.

Step 3 In the **Bridge Group ID** field, enter the bridge group ID between 1 and 250.

Step 4 In the **Description** field, enter a description for this bridge group.

Step 5 On the **Interfaces** tab, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members of the bridge group.

Step 6 Click the **IPv4** tab.

a) (Routed Mode) To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability and clustering interfaces only support static IP address configuration; DHCP is not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management**, click the **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.

b) (Transparent Mode) In the **IP Address** field, enter the IPv4 address and subnet mask.

Do not assign a host address (/32 or 255.255.255.255) to the BVI. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The Firewall Threat Defense device drops all ARP

packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the Firewall Threat Defense device drops the ARP request from the downstream router to the upstream router.

For High Availability, set the standby IP address on the **Devices** > **Device Management** page, click the **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

Step 7 (Optional) Refer to Configure IPv6 addressing, on page 1090 to configure IPv6 addressing.

Step 8 (Optional) Refer to Add a static ARP entry, on page 1111 and Add a static MAC address and disable MAC learning for a bridge group, on page 1112 (for transparent mode only) to configure the **ARP** and **MAC** settings.

Step 9 Click **OK**.

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 addressing

This section describes how to configure IPv6 addressing in routed and transparent mode.

About IPv6

This section includes information about IPv6.

IPv6 addressing

IPv6 addressing provides 128 bits of network addressing, which provides more than enough globally unique IP addresses. It supports both public global addresses and private link-local addresses, and

IPv6 address types

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. For a bridge group, this address needs to be configured for the BVI, and not per member interface. You can also configure a global IPv6 address for the management interface in transparent mode.
- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Neighbor Discovery functions such as address resolution. In a bridge group, only member interfaces have link-local addresses; the BVI does not have a link-local address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. For bridge group member interfaces, when you configure the global address on the BVI, the Firewall Threat Defense device automatically generates link-local addresses for member

interfaces. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Modified EUI-64 interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The Firewall Threat Defense device can enforce this requirement for hosts attached to the local link.

Address verification process

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and this system log message is generated:

```
325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link.

IPv6 prefix delegation client configuration

The Firewall Threat Defense can act as a DHPCv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the Firewall Threat Defense can then subnet and assign to its inside interfaces.

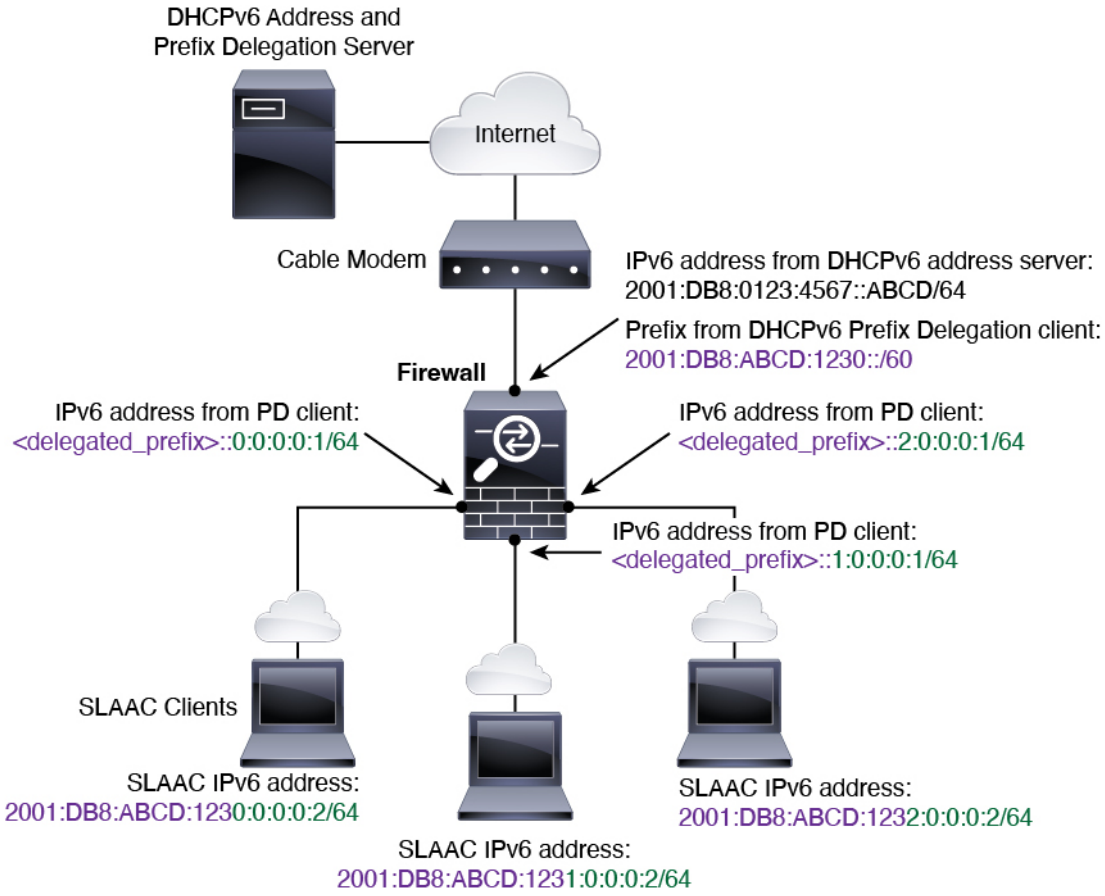
IPv6 prefix delegation

IPv6 prefix delegation enables the Firewall Threat Defense to function as a Dynamic Host Control Protocol for IPv6 (DHCPv6) prefix delegation client and receive one or more IPv6 prefixes. This feature allows the Firewall Threat Defense to subnet and assign these prefixes to its inside interfaces. It enable the hosts connected to inside interfaces to use Stateless Address Auto Configuration (SLAAC) to obtain global IPv6 addresses.

Client and server behavior

The client interface, such as the outside interface connected to a cable modem, receives IPv6 prefixes that the Firewall Threat Defense can then subnet and assign to its inside interfaces. The inside Firewall Threat Defense interfaces do not in turn act as Prefix Delegation servers; the Firewall Threat Defense can only provide global IP addresses to SLAAC clients.

If a router is connected to the Firewall Threat Defense, it can act as a SLAAC client to obtain its IP address. However, if you want to use a subnet of the delegated prefix for the networks behind the router, you must manually configure those addresses on the router's inside interfaces.



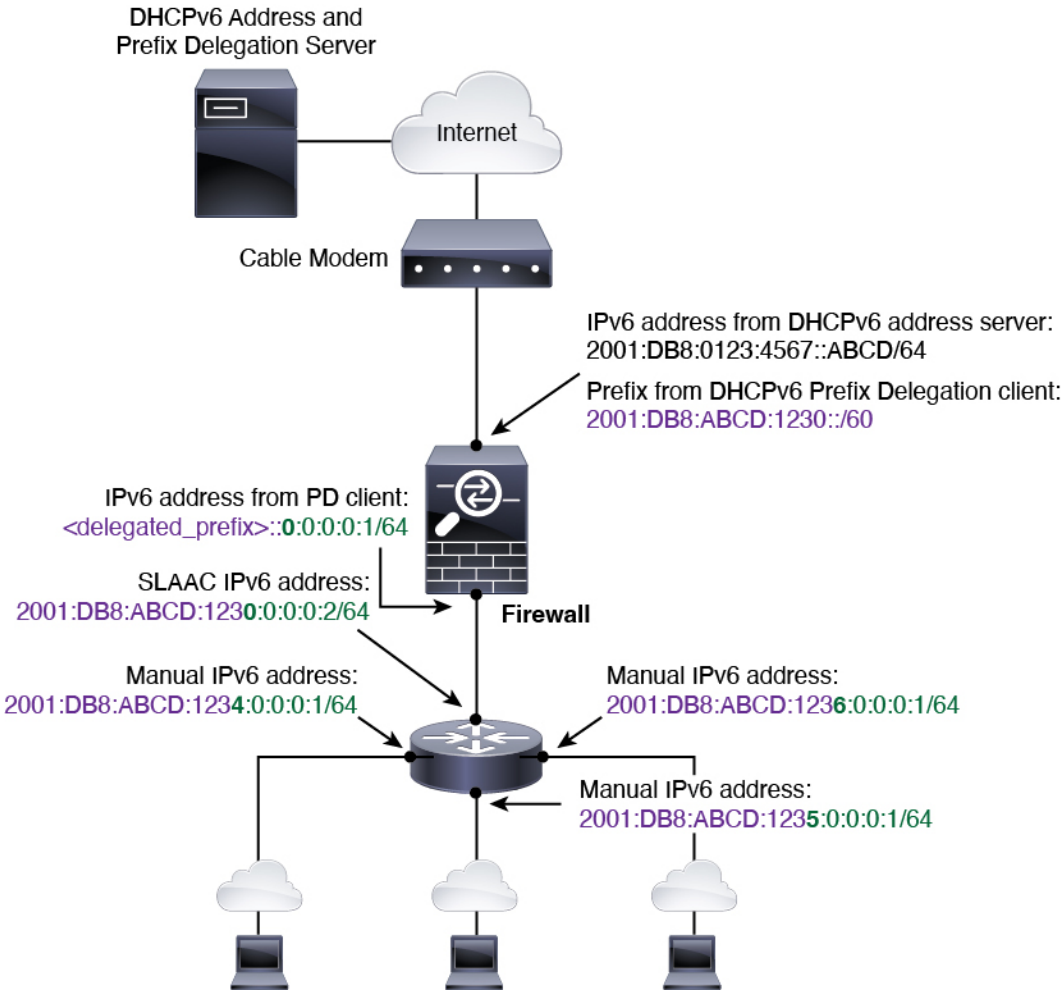
The Firewall Threat Defense includes a light DHCPv6 server. This server provides information, such as the DNS server and domain name, to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets, and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages. In other words, the addresses are based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

IPv6 prefix delegation /64 subnet example

Here is an IPv6 prefix delegation /64 subnet example that demonstrates how a device subnets delegated prefixes into /64 networks and assigns global IPv6 addresses to interfaces.

IPv6 prefix delegation /64 subnet configuration

This example shows the Firewall Threat Defense receiving an IP address on the outside interface using the DHCPv6 address client. It also gets a delegated prefix using the DHCPv6 Prefix Delegation client. The Firewall Threat Defense subnets the delegated prefix into /64 networks and assigns global IPv6 addresses to its inside interfaces dynamically using the delegated prefix plus a manually configured subnet (::0, ::1, or ::2) and IPv6 address (0:0:0:1) per interface. SLAAC clients connected to those inside interfaces obtain IPv6 addresses on each /64 subnet.



IPv6 prefix delegation /62 subnet examples

IPv6 prefix delegation /62 subnet enables subnetting of prefixes into 4 /62 subnets for downstream router delegation. It allows manual configuration of /64 subnets on router interfaces when dynamic prefix assignment is not available.

IPv6 /62 subnet delegation configuration

This example shows the Firewall Threat Defense subnetting the prefix into 4 /62 subnets: 2001:DB8:ABCD:123**0**::/62, 2001:DB8:ABCD:123**4**::/62, 2001:DB8:ABCD:123**8**::/62, and 2001:DB8:ABCD:123**C**::/62. The Firewall Threat Defense uses one of 4 available /64 subnets on 2001:DB8:ABCD:1230::/62 for its inside network (::0). You can then manually use additional /62 subnets for downstream routers. The router shown uses 3 of 4 available /64 subnets on 2001:DB8:ABCD:1234::/62 for its inside interfaces (::4, ::5, and ::6). In this case, the inside router interfaces cannot dynamically obtain the delegated prefix, so you need to view the delegated prefix on the Firewall Threat Defense, and then use that prefix for your router configuration. Usually, ISPs delegate the same prefix to a given client when the lease expires, but if the Firewall Threat Defense receives a new prefix, you will have to modify the router configuration to use the new prefix. The DHCP unique identifier (DUID) is persistent across reboots.

Enable the IPv6 prefix delegation client

Enable the DHCPv6 Prefix Delegation client to obtain one or more IPv6 prefixes that can be subnetted and assigned to inside networks.

Enable the DHCPv6 Prefix Delegation client on one or more interfaces. The Firewall Threat Defense obtains one or more IPv6 prefixes that it can subnet and assign to inside networks. Typically, the interface on which you enable the prefix delegation client obtains its IP address using the DHCPv6 address client; only other Firewall Threat Defense interfaces use addresses derived from the delegated prefix.

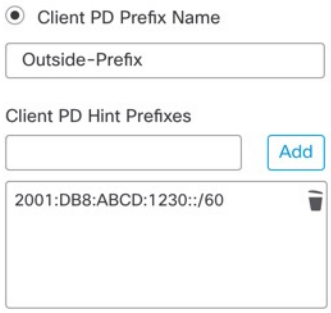
This feature is supported only in routed mode.

This feature is not supported in clustering or High Availability.

Before you begin

When you use Prefix Delegation, you must set the Firewall Threat Defense IPv6 neighbor discovery router advertisement interval to be much lower than the preferred lifetime of the prefix assigned by the DHCPv6 Server to prevent IPv6 traffic interruption. For example, if the DHCPv6 server sets the preferred Prefix Delegation lifetime to 300 seconds, you should set the Firewall Threat Defense RA interval to be 150 seconds. To set the preferred lifetime, use the **show ipv6 general-prefix** command. To set the Firewall Threat Defense RA interval, see Configure IPv6 neighbor discovery, on page 1099. The default is 200 seconds.

Procedure



Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **IPv6** page, and then click **DHCP**.

Step 4 Click **Client PD Prefix Name** and enter a name for this prefix.

Figure 260: Enable the prefix delegation client

The name can be up to 200 characters.

Step 5 (Optional) Enter the prefix and prefix length in the **Client PD Hint Prefixes** field to provide one or more hints to the DHCP server about the delegated prefix you want to receive, then click **Add**.

Typically you want to request a particular prefix length, such as ::/60, or if you have received a particular prefix before and want to ensure you get it again when the lease expires, you can enter the whole prefix as the hint. If you enter multiple hints (different prefixes or lengths), then it is up to the DHCP server which hint to honor, or whether to honor the hint at all.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure a global IPv6 address

Before you begin

For IPv6 neighbor discovery for bridge groups, you must explicitly allow Neighbor Solicitation (ICMPv6 type 135) and Neighbor Advertisement (ICMPv6 type 136) packets through the Firewall Threat Defense bridge group member interfaces using a bidirectional access rule.

To configure a global IPv6 address for any routed mode interface and for the transparent or routed mode BVI, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately. For bridge groups, configuring the global address on the BVI automatically configures link-local addresses on all member interfaces.

For subinterfaces defined on the Firewall Threat Defense , we recommend that you also set the MAC address manually, because they use the same burned-in MAC address of the parent interface. IPv6 link-local addresses are generated based on the MAC address, so assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense . See Configure the MAC address, on page 1110 .

Firewall Threat Defense Feature History:

- 7.3—DHCPv6 Address client
- 7.3—DHCPv6 Prefix Delegation client
- 7.3—DHCPv6 stateless server

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **IPv6** page.

For routed mode, the **Basic** page is selected by default. For transparent mode, the **Address** page is selected by default.

Step 4 On the **Basic** page, check **Enable IPv6** .

Use this option if you want to only configure the link-local addresses. Otherwise, configuring an IPv6 address enables IPv6 processing automatically.

Step 5 Configure the global IPv6 address using one of the following methods.

For failover and clustering, and for loopback interfaces, you must set the IP address manually. For clustering, manually configuring the link-local address is also not supported.

- (Routed interface) Stateless autoconfiguration—Check the **Autoconfiguration** check box.

  Enabling stateless autoconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.

  Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the Firewall Threat Defense device does send Router Advertisement messages in this case. Click the **Settings** tab and click the **IPv6** tab and then uncheck the **Enable RA** check box to suppress messages.

- Manual configuration—To manually configure a global IPv6 address:

  a. Click the **Address** page, and click (+) **Add Address** .

  The **Add Address** dialog box appears.

  b. In the **Address** field, enter either a full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. (Routed Mode) If you only enter the prefix, then be sure to check the **Enforce EUI 64** check box to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked).

  For High Availability (if you did not set **Enforce EUI 64**), set the standby IP address on the **Devices** > **Device Management** page, click **High Availability** in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

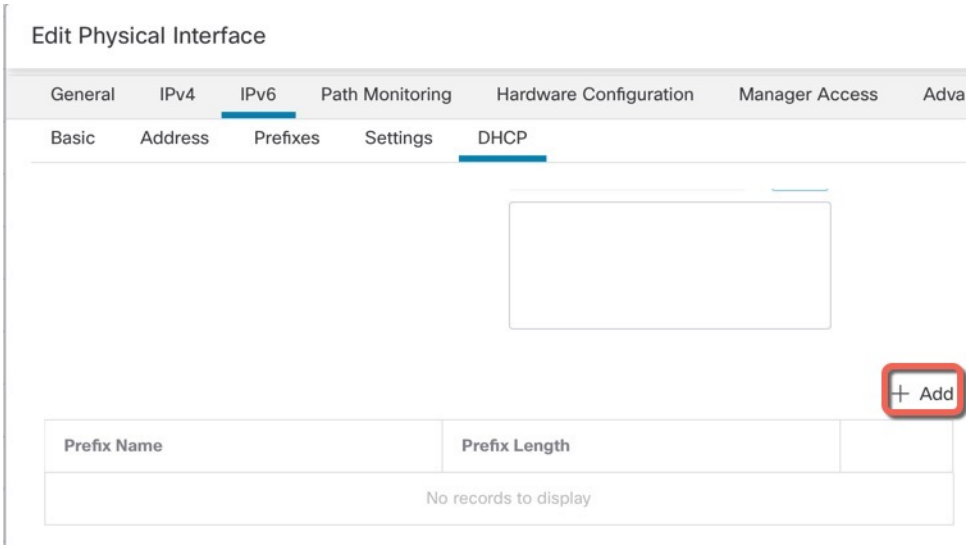
- (Routed interface) Obtain an address using DHCPv6—To use DHCPv6:

  Figure 261: Enable the DHCPv6 Client

  a. Click the **DHCP** page.

  b. Check the check box of **Enable DHCP Client** .

  c. (Optional) Check the check box of **Enable default route using DHCP** to obtain a default route from Router Advertisements.



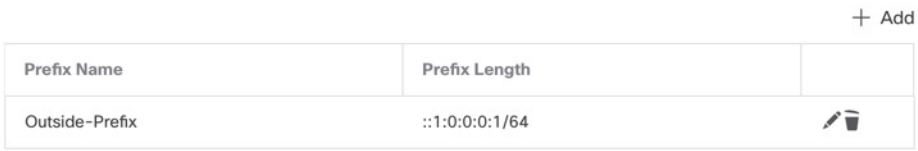
- (Routed interface) Use a delegated prefix—To assign an IPv6 address using the delegated prefix:

  This feature requires the Firewall Threat Defense to have the DHCPv6 Prefix Delegation client enabled *on a different interface* . See Enable the IPv6 prefix delegation client, on page 1093 .

a. Click the **DHCP** page.

b. Click (+) .

Figure 262: Use a Delegated Prefix



c. Enter the IPv6 address and **Prefix Length** .

Typically, the delegated prefix will be /60 or smaller so you can subnet to multiple /64 networks. /64 is the supported subnet length if you want to support SLAAC for connected clients. You should specify an address that completes the /60 subnet, for example ::1:0:0:0:1. Enter :: before the address in case the prefix is smaller than /60. For example, if the delegated prefix is 2001:DB8:1234:5670::/60, then the global IP address assigned to this interface is 2001:DB8:1234:5671::1/64. The prefix that is advertised in router advertisements is 2001:DB8:1234:5671::/64. In this example, if the prefix is smaller than /60, the remaining bits of the prefix will be 0's as indicated by the leading ::. For example, if the prefix is 2001:DB8:1234::/48, then the IPv6 address will be 2001:DB8:1234::1:0:0:0:1/64.

d. Click **OK** .

Figure 263: Prefix Delegation Table

e. Optionally enable the DHCPv6 stateless server on this interface (see Enable the DHCPv6 stateless server, on page 1232). If you do so, we recommend that you also check the **Enable DHCP for non-address config** option.

Step 6 For Routed interfaces, you can optionally set these values on the **Basic** page:

- To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.

- To manually set the link-local address, enter an address in the **Link-Local address** field.

  A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

  Clustering does not support manual link-local addresses.

Step 7 For Routed interfaces, you can optionally set the following values on the **DHCP** page:

- Check the **Enable DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- Check the **Enable DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address. Use this option when using the DHCPv6 stateless server with DHCPv6 prefix delegation.

Step 8 For Routed interfaces, see Configure IPv6 neighbor discovery, on page 1099 to configure settings on the **Prefixes** and **Settings** pages. For BVI interfaces, see the following parameters on the **Settings** page:

- **DAD attempts** —The maximum number of DAD attempts , between 1 and 600. Set the value to 0 to disable duplicate address detection (DAD) processing. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses . 1 attempt is the default.
- **NS Interval** —The interval between IPv6 neighbor solicitation retransmissions on an interface , between 1000 and 3600000 ms . The default value is 1000 ms.
- **Reachable Time** —The amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred , between 0 and 3600000 ms . The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 9 Click **OK** .

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 neighbor discovery

Before you begin

Supported in Routed mode only. For IPv6 neighbor settings supported in transparent mode, see Configure a global IPv6 address, on page 1095 .

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cached values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

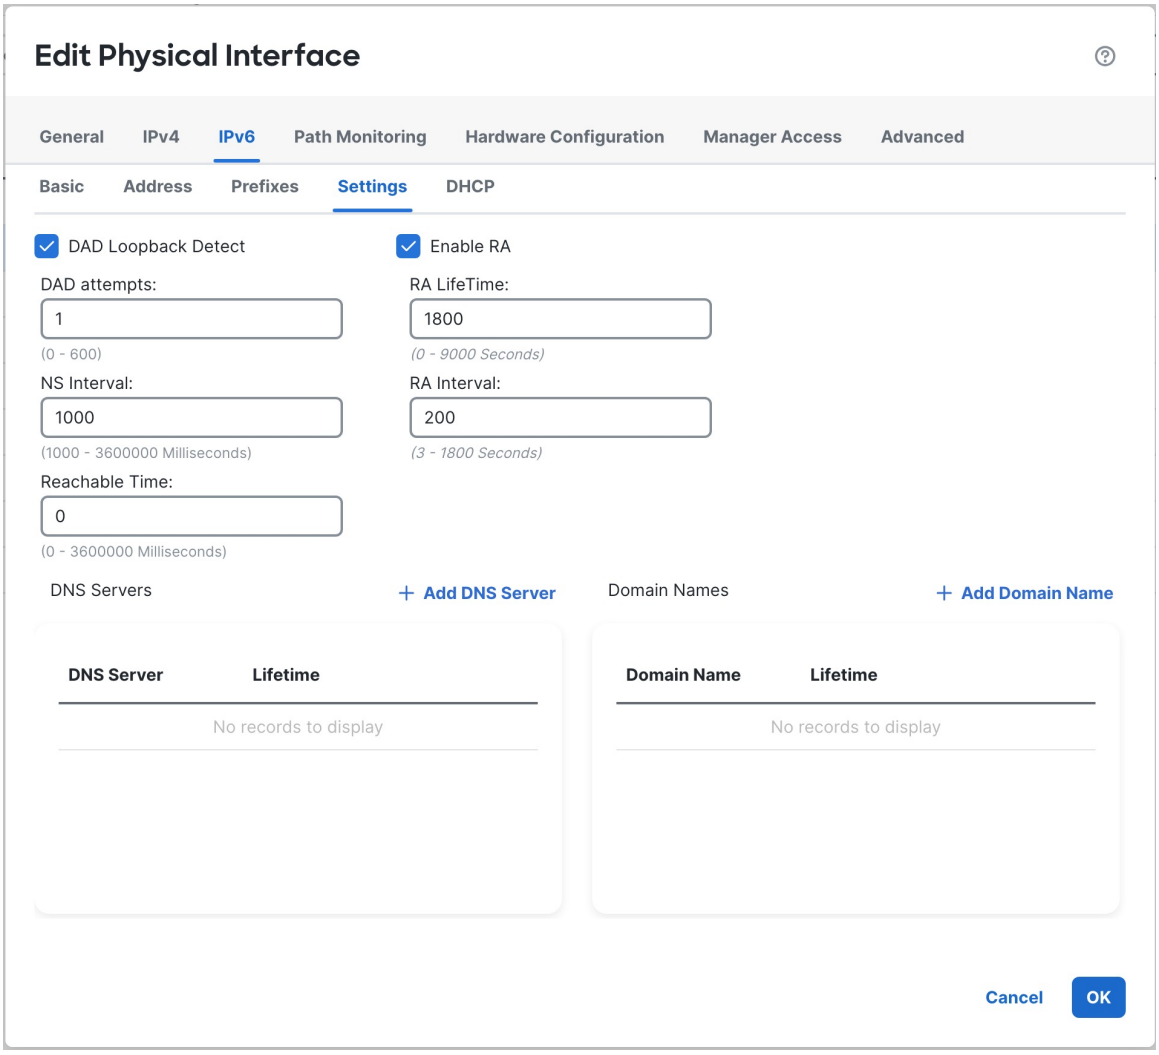
Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click **IPv6** , and then **Prefixes**.

To configure the IPv6 router advertisements with IPv6 prefixes, perform these steps:



a) Click (+) **Add Prefix** .
b) In the **Address** field, enter the IPv6 address with the prefix length or check the **Default** check box to use the default prefix.
c) (Optional) Uncheck the **Advertisement** check box to indicate that the IPv6 prefix is not advertised. For the **Default** prefix, this setting only applies to on-link prefixes. Off-link prefixes will still be advertised unless you uncheck **Advertisement** for a specific off-link prefix.
d) Check the **Off Link** check box to indicate that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.
e) To use the specified prefix for autoconfiguration, check the **Autoconfiguration** check box.
f) For the **Prefix Lifetime** , click **Duration** or **Expiration Date** .

- **Duration** —Enter a **Preferred Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days). Enter a **Valid Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days). Alternatively, check the **Infinite** check box to set an unlimited duration.
- **Expiration Date** —Choose a **Valid** and **Preferred** date and time.

g) Click **OK** .

Step 4 Click **Settings**.

Figure 264: IPv6 Settings

a) (Optional) Set the maximum number of **DAD attempts** , between 1 and 600. 1 attempt is the default. Set the value to 0 to disable duplicate address detection (DAD) processing.

   This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses.

   During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces.

   When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

   ```
   325002: Duplicate address ipv6_address/MAC_address on interface
   ```

   If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used.

b) (Optional) Configure the interval between IPv6 neighbor solicitation retransmissions in the **NS Interval** field, between 1000 and 3600000 ms.

The default value is 1000 ms.

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICPMv6 Type 136) on the local link.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link.

Step 5 (Optional) Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred in the **Reachable Time** field, between 0 and 3600000 ms.

The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 6 (Optional) To suppress the router advertisement transmissions, uncheck the **Enable RA** check box. If you enable router advertisement transmissions, you can set the RA lifetime and interval.

Router advertisement messages (ICMPv6 Type 134) are automatically sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You may want to disable these messages on any interface for which you do not want the Firewall Threat Defense to supply the IPv6 prefix (for example, the outside interface).

- **RA Lifetime** —Configure the router lifetime value in IPv6 router advertisements, between 0 and 9000 seconds.

  The default is 1800 seconds.

- **RA Interval** —Configure the interval between IPv6 router advertisement transmissions, between 3 and 1800 seconds.

  The default is 200 seconds.

  To prevent synchronization with other IPv6 nodes, the firewall randomly adjusts the value that you set (jitter).

Step 7 (Optional) Configure the Recursive DNS Server (RDNSS) option to advertise a list of DNS servers to IPv6 clients.

This option is useful for clients that use SLAAC instead of DHCPv6 for their addressing. Note that if you enabled the prefix delegation client on the Firewall Threat Defense , you can alternatively pass along the DNS server information that the Firewall Threat Defense received using the Firewall Threat Defense 's DHCPv6 stateless server. If you configure both methods, the client will receive both sets of servers.

a) In the **DNS Servers** area, click **Add DNS Server** .

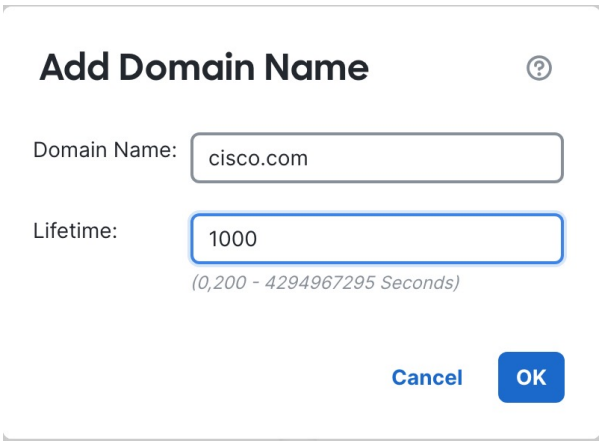
Figure 265: Add a DNS Server

b) Enter the **DNS Server** IPv6 Address.

c) Enter the maximum **Lifetime** , in seconds, that the DNS server will be used for name resolution, between 200 and 4294967295. If you set the value to 0, the entry will not be used. If you set the value to 4294967295, the entry will never expire. The default is 3 x the maximum RA interval. The value must be greater than or equal to the **RA Interval** .

d) Click **OK** .

e) Repeat for up to 8 servers.



The servers are advertised in the order you add them.

Step 8 (Optional) Configure the DNS Search List (DNSSL) option to advertise a list of search domains to IPv6 clients.

This option is useful for clients that use SLAAC instead of DHCPv6 for their addressing. Note that if you enabled the prefix delegation client on the Firewall Threat Defense , you can alternatively pass along the DNS domain that the Firewall Threat Defense received using the Firewall Threat Defense 's DHCPv6 stateless server. If you configure both methods, the client will receive both sets of domains.

a) In the **Router Advertisement DNS-SEARCH-LIST** area, click **Add** .

Figure 266: Add a Domain for Search

b) Enter the **Domain Name** .

c) Enter the maximum **Lifetime** , in seconds, that the domain will be used, between 200 and 4294967295. If you set the value to 0, the entry will not be used. If you set the value to 4294967295, the entry will never expire. The default is 3 x the maximum RA interval. The value must be greater than or equal to the **RA Interval** .
d) Click **OK** .
e) Repeat for up to 5 domains.

The domains are advertised in the order you add them.

Step 9 Click **OK**.

Click **Save**.

What to do next

Go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Advanced interface settings

This section describes how to configure MAC addresses for regular firewall mode interfaces, how to set the maximum transmission unit (MTU), and how to set other advanced parameters.

About advanced interface configuration

This section describes advanced interface settings.

MAC addresses

Media Access Control (MAC) address is a unique physical address of a network device.

You can manually assign MAC addresses to override the default. For container instances, the FXOS chassis automatically generates unique MAC addresses for all interfaces.

Note You might want to assign unique MAC addresses to subinterfaces defined on the Firewall Threat Defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense device.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Default MAC addresses

This reference provides information about default MAC addresses used in network devices and their configurations.

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- VLAN interfaces (Firepower 1010 and Secure Firewall 1210/1220)—Routed firewall mode: All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC address, on page 1110.

  Transparent firewall mode: Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC address, on page 1110.
- EtherChannels—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.
- EtherChannels (ASA Models)—The port-channel interface uses the lowest-numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can configure a MAC address for the port-channel interface. We recommend configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.
- Subinterfaces (Firewall Threat Defense-defined)—All subinterfaces of a physical interface use the same burned-in MAC address. You might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces.

MTU

Maximum Transmission Unit (MTU) specifies the maximum frame *payload* size that the Firewall Threat Defense can transmit on a given Ethernet interface. The MTU value *excludes* Ethernet headers, VLAN tags, or other overhead. For example, if you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when VLAN tagging is used. Do not set the MTU value higher to accommodate these headers.

VXLAN and geneve encapsulation requirements

For Geneve, the entire Ethernet datagram is being encapsulated, so the new IP packet is larger and requires a larger MTU. Set the Firewall Threat Defense VTEP source interface MTU to the network MTU plus 306 bytes.

Path MTU discovery

Path MTU Discovery enables all devices in a network path between two hosts to coordinate the MTU so they can standardize on the lowest MTU in the path.

Path MTU discovery support

The Firewall Threat Defense supports Path MTU Discovery (as defined in RFC 1191).

Default MTU

The default MTU on the Firewall Threat Defense device is 1500 bytes. This value does not include the 18-22 bytes for the Ethernet header, VLAN tagging, or other overhead.

MTU and fragmentation

IPv4 packets that are larger than the specified MTU are fragmented into multiple frames.

Packet handling details

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For TCP packets, the endpoints typically use their MTU to determine the TCP maximum segment size (MTU - 40, for example). If additional TCP headers are added along the way, for example for site-to-site VPN tunnels, then the TCP MSS might need to be adjusted down by the tunneling entity. See TCP MSS, on page 1106.

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

Note The Firewall Threat Defense can receive frames larger than the configured MTU as long as there is room in memory.

Full reassembly for inspected fragmented packets

The FTD performs virtual reassembly by default. However, when features such as DNS or voice media inspection are active, the firewall performs full reassembly before forwarding. This ensures packets are processed correctly by inspection engines.

For example, SIP packets subject to inspection require full reassembly. If SIP inspection is disabled, the system maintains virtual reassembly. To avoid issues, we recommend reducing SIP message size or using TCP or TLS for large messages rather than sending large SIP INVITE packets over UDP.

The firewall merges fragments in memory. If the egress interface MTU is smaller than the reassembled packet, the device will refragment the data to fit. To verify behavior, use packet captures on the egress interface and adjust MTU settings as needed.

MTU and jumbo frames configuration

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network.

- Matching MTUs on the traffic path—We recommend that you set the MTU on all Firewall Threat Defense interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.
- Accommodating jumbo frames—You can set the MTU 9000 bytes or higher when you enable jumbo frames. The maximum depends on the model.

TCP MSS

The TCP maximum segment size (MSS) is the size of the TCP payload *before* any TCP and IP headers are added. TCP MSS values are exchanged between client and server during the three-way handshake when establishing connections. UDP packets are not affected.

TCP MSS configuration and behavior

You can set the TCP MSS on the Firewall Threat Defense device for through traffic using the Sysopt_Basic object in FlexConfig. By default, the maximum TCP MSS is set to 1380 bytes. This setting is useful if the Firewall Threat Defense device must increase the packet size for IPsec VPN encapsulation. However, for non-IPsec endpoints, you should disable the maximum TCP MSS on the Firewall Threat Defense device.

If you set a maximum TCP MSS and either endpoint of a connection requests a TCP MSS larger than this value, the Firewall Threat Defense device overwrites the TCP MSS in the request packet with the Firewall Threat Defense device maximum. If the host or server does not request a TCP MSS, the Firewall Threat Defense device assumes the RFC 793-default value of 536 bytes for IPv4 or 1220 bytes for IPv6, but does not modify the packet.

You can also configure the minimum TCP MSS. If a host or server requests a very small TCP MSS, the Firewall Threat Defense device can increase the value. By default, the minimum TCP MSS is not enabled.

For to-the-box traffic, including for SSL VPN connections, this setting does not apply. The Firewall Threat Defense device derives the TCP MSS from MTU: MTU minus 40 for IPv4 or MTU minus 60 for IPv6.

TCP MSS adjustment scenario

For example, you leave the default MTU as 1500 bytes. A host requests an MSS of 1500 minus the TCP and IP header length, which sets the MSS to 1460. If the Firewall Threat Defense device maximum TCP MSS is 1380 (the default), then the Firewall Threat Defense device changes the MSS value in the TCP request packet to 1380. The server then sends packets with 1380-byte payloads. The Firewall Threat Defense device can add up to 120 bytes of headers to the packet, and the resulting packet fits within the MTU size of 1500 bytes.

Default TCP MSS

A default TCP MSS is a network configuration setting that sets the maximum TCP MSS on the Firewall Threat Defense device to 1380 bytes by default, accommodates IPv4 IPsec VPN connections where the headers can equal up to 120 bytes, and fits within the default MTU of 1500 bytes.

Suggested maximum TCP MSS setting

The default TCP MSS assumes the Firewall Threat Defense device acts as an IPv4 IPsec VPN endpoint and has an MTU of 1500. When the Firewall Threat Defense device acts as an IPv4 IPsec VPN endpoint, it needs to accommodate up to 120 bytes for TCP and IP headers.

If you change the MTU value, use IPv6, or do not use the Firewall Threat Defense device as an IPsec VPN endpoint, then you should change the TCP MSS setting using the Sysopt_Basic object in FlexConfig.

Note If you explicitly set an MSS, a component such as TLS/SSL decryption or server discovery might require a particular MSS.In that case, the component sets the MSS based on the interface MTU and ignores your MSS setting.

- Normal traffic—Disable the TCP MSS limit and accept the value established between connection endpoints. Because connection endpoints typically derive the TCP MSS from the MTU, non-IPsec packets usually fit this TCP MSS.
- IPv4 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 120. For example, if you use jumbo frames and set the MTU to 9000, then you need to set the TCP MSS to 8880 to take advantage of the new MTU.
- IPv6 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 140.

ARP inspection for bridge group traffic

This reference describes ARP inspection functionality for bridge group traffic in transparent firewall configurations.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the Firewall Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the Firewall Threat Defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the Firewall Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Management interface never floods packets even if this parameter is set to flood.

MAC address tables

A MAC address table associates each MAC address with its source interface for accurate packet routing.

MAC address table behavior

When you use bridge groups, the Firewall Threat Defense learns and builds a MAC address table in a way similar to a normal bridge or switch. When a device sends a packet through the bridge group, the Firewall Threat Defense adds the MAC address to its table. The table associates the MAC address with the source interface so that the Firewall Threat Defense knows to send any packets addressed to the device out the correct interface. Because traffic between bridge group members is subject to the Firewall Threat Defense security policy, if the destination MAC address of a packet is not in the table, the Firewall Threat Defense does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the packets for directly-connected devices or for remote devices.

- Packets for directly-connected devices—The Firewall Threat Defense generates an ARP request for the destination IP address so that it can learn which interface receives the ARP response.
- Packets for remote devices—The Firewall Threat Defense generates a ping to the destination IP address so that it can learn which interface receives the ping reply.

The original packet is dropped.

Default settings

This reference provides default configuration settings for ARP inspection, MAC address table entries, and interface behavior for MAC address learning.

- If you enable ARP inspection, the default setting is to flood non-matching packets.
- The default timeout value for dynamic MAC address table entries is five minutes.
- By default, each interface automatically learns the MAC addresses of entering traffic, and the Firewall Threat Defense device adds corresponding entries to the MAC address table.

Note Secure Firewall Threat Defense device generates a reset packet to reset a connection that is denied by a stateful inspection engine. Here, the destination MAC address of the packet is not determined based on the ARP table lookup but instead it is taken directly from the packets (connections) that are being denied.

Guidelines for ARP inspection and the MAC address table

Consider these configuration support limitations for ARP inspection and MAC address table management:

- ARP inspection is only supported for bridge groups.
- MAC address table configuration is only supported for bridge groups.

Configure the MTU

Customize the MTU on the interface, for example, to allow jumbo frames.

For the ISA 3000 and the Firewall Threat Defense Virtual: Changing the MTU above 1500 bytes automatically enables jumbo-frame reservation. You must restart the system before you can use jumbo frames. For the Firewall Threat Defense Virtual that supports clustering, you can enable jumbo-frame reservation in the Day0 configuration, so in that case, you do not need to restart. After you restart, you cannot disable jumbo-frame reservation. An exception is for the Firewall Threat Defense Virtual, where you can disable jumbo-frame reservation in the Day0 configuration, if supported. If you use an interface in an inline set, the MTU setting is not used. However, the jumbo-frame reservation setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo-frame reservation, you must set the MTU of *any* interface above 1500 bytes.

Jumbo frames are enabled by default on other platforms.

Caution Changing the highest MTU value on the device for a data interface restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Inspection is interrupted on all data interfaces, not just the interface you modified. Whether this interruption drops traffic or passes it without further inspection depends on the model of the managed device and the interface type. This caution does not apply to management-only interfaces. See Snort restart traffic behavior, on page 196 for more information.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 On the **General** tab, set the **MTU**. The minimum and maximum depends on your platform.

The default is 1500 bytes.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 6 For the ISA 3000 and the Firewall Threat Defense Virtual, if you set the MTU above 1500 bytes, restart the system to enable jumbo-frame reservation. See Shut down or restart the device, on page 107.

Configure the MAC address

This task allows you to manually assign MAC addresses to interfaces, including active and standby MAC addresses for high availability configurations.

You might need to manually assign a MAC address. You can also set the Active and Standby MAC addresses on the **Devices** > **Device Management** window by choosing **High Availability** from the **Add** drop-down list. If you set the MAC address for an interface on both screens, the addresses on the **Interfaces** > **Advanced** tab take precedence.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab.

The **Information** tab is selected.

Step 4 (For clustering in individual interface mode) Choose a MAC address pool from the drop-down list.

You can add MAC address pools according to Configure address pools, on page 2954.

Step 5 (For other modes) Set the active and standby MAC addresses.

a) In the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

b) In the **Standby MAC Address** field, enter a MAC address for use with High Availability.

If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a static ARP entry

Add static ARP entries to control ARP packet flow and support ARP inspection for bridge group members or routed interfaces.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection (see Configure ARP inspection, on page 1244). ARP inspection compares ARP packets with *static* ARP entries in the ARP table.

For routed interfaces, you can enter static ARP entries, but dynamic entries are usually sufficient. For routed interfaces, the ARP table is used to deliver packets to directly-connected hosts. Although senders identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry must time out before it can be updated with the new information.

For transparent mode, the Firewall Threat Defense only uses dynamic ARP entries in the ARP table for traffic to and from the Firewall Threat Defense device, such as management traffic.

Before you begin

This screen is only available for named interfaces.

Follow these steps to add a static ARP entry:

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP** tab (called **ARP and MAC** for transparent mode).

Step 4 Click (+)**Add ARP Config**.
The **Add ARP Config** dialog box appears.

Step 5 In the **IP Address** field, enter the IP address of the host.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.

Step 7 To perform proxy ARP for this address, check the **Enable Alias** check box.

If the Firewall Threat Defense device receives an ARP request for the specified IP address, then it responds with the specified MAC address.

Step 8 Click **OK**, and then click **OK** again to exit the Advanced settings.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a static MAC address and disable MAC learning for a bridge group

Add static MAC addresses to the MAC address table and optionally disable MAC address learning to guard against MAC spoofing and control traffic flow through the Firewall Threat Defense device.

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can disable MAC address learning. If you do not statically add MAC addresses to the table, no traffic can pass through the Firewall Threat Defense device. You can also add static MAC addresses to the MAC address table. One benefit to adding static entries is to guard against MAC spoofing. If a client uses the same MAC address as a static entry and sends traffic to an interface that does not match the static entry, the Firewall Threat Defense device drops the traffic and generates a system message. When you add a static ARP entry (see Add a static ARP entry, on page 1111), a static MAC address entry is automatically added to the MAC address table.

Before you begin

This screen is only available for named BVIs in transparent mode.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP and MAC** tab.

Step 4 (Optional) Disable MAC learning by unchecking the **Enable MAC Learning** check box.

Step 5 To add a static MAC address, click **Add MAC Config**.
The **Add MAC Config** dialog box appears.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b. Click **OK**.

Step 7 Click **OK** to exit the Advanced settings.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Set security configuration parameters

This task configures security parameters on named interfaces to prevent IP spoofing attacks and control packet fragmentation behavior. You can enable anti-spoofing protection, configure full fragment reassembly, and customize fragment handling settings.

This section describes how to prevent IP spoofing, allow full fragment reassembly, and override the default fragment setting at the device level in **Platform Settings**.

Anti-spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the Firewall Threat Defense device only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the device to also look at the source address. This is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the Firewall Threat Defense device, the device routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the Firewall Threat Defense device can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the device uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the Firewall Threat Defense device drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the device drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Fragment per packet

By default, the Firewall Threat Defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the Firewall Threat Defense device. Fragmented packets are often used as DoS attacks.

Fragment reassembly

The Firewall Threat Defense device performs the following fragment reassembly processes:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed.
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow.
- IP fragments that terminate at the Firewall Threat Defense device are always fully reassembled.
- If **Full Fragment Reassembly** is disabled (the default), the fragment set is forwarded to the transport layer for further processing.
- If **Full Fragment Reassembly** is enabled, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

Full reassembly for inspected fragmented packets

The Firewall Threat Defense performs virtual reassembly by default. However, when features such as DNS or voice media inspection are active, the firewall performs full reassembly before forwarding. This ensures packets are processed correctly by inspection engines.

For example, SIP packets subject to inspection require full reassembly. If SIP inspection is disabled, the system maintains virtual reassembly. To avoid issues, we recommend reducing SIP message size or using TCP or TLS for large messages rather than sending large SIP INVITE packets over UDP.

The firewall merges fragments in memory. If the egress interface MTU is smaller than the reassembled packet, the device will refragment the data to fit. To verify behavior, use packet captures on the egress interface and adjust MTU settings as needed.

Before you begin

This screen is only available for named interfaces.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **Security Configuration** tab.

Step 4 To enable Unicast Reverse Path Forwarding, check the **Enable Anti Spoofing** check box.

Step 5 To enable full fragment reassembly, check the **Allow Full Fragment Reassembly** check box.

Step 6 To change the number of fragments allowed per packet, check the **Override Default Fragment Setting** check box, and set the following values:

- **Size**—Set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200. Set this value to 1 to disable fragments.
- **Chain**—Set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.
- **Timeout**—Set the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.

Step 7 Click **OK**.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

History for Regular Firewall Interfaces

Provides a comprehensive history of interface-related features, including hardware support, protocol enhancements, and configuration changes for Secure Firewall devices.

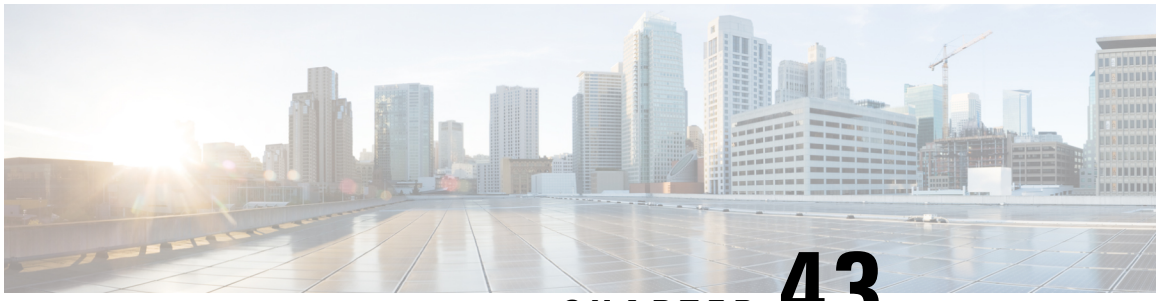


Table 69: History for Regular Firewall Interfaces

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Recursive DNS Server (RDNSS) and DNS Search List (DNSSL) options to advertise a list of DNS servers and domains to IPv6 clients	10.0.0 20251121	10.0.0	You can now configure Recursive DNS Server (RDNSS) and DNS Search List (DNSSL) options to provide DNS servers and domains to SLAAC clients using router advertisements. New/modified screens: **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **Settings** New/modified commands: **show ipv6 nd detail** , **show ipv6 nd ra dns-search-list** , **show ipv6 nd ra dns server** , **show ipv6 nd summary**
Secure Firewall 200 hardware switch support	10.0.0 20251121	10.0.0	The Secure Firewall 200 supports setting each Ethernet interface to be a switch port or a firewall interface.
Secure Firewall 1210CP IEEE 802.3bt support (PoE++ and Hi-PoE)	7.7.0	7.7.0	See the following improvements related to support for IEEE 802.3bt: • PoE++ and Hi-PoE—Up to 90W per port. • Single- and dual-signature powered devices (PDs). • Power budgeting is done on a first-come, first-served basis. • Power budget fields were added to **show power inline** . New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **PoE** New/Modified commands: **show power inline**
For models with built-in-switches, subinterfaces can't use VLAN 1	7.6	7.6	For models with built-in switches, you cannot create a subinterface using VLAN 1. VLAN 1 is reserved for the logical VLAN interface for switch ports. If you upgrade a 1010 to 7.6 or later, and you have assigned VLAN 1 to a subinterface, you must change the VLAN ID for your subinterface to a new VLAN. You will not be able to deploy the configuration using VLAN 1.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Secure Firewall supports Dual-Arm Deployment Mode on AWS with GWLB	7.6	7.6	The Secure Firewall supports the dual-arm deployment mode on AWS with GWLB. This mode enables the firewall to directly forward internet-bound traffic to the internet through the internet gateway after traffic inspection, while also performing network address translation (NAT).
Secure Firewall 1210/1220 hardware switch support	7.6	7.6	The Secure Firewall 1210/1220 supports setting each Ethernet interface to be a switch port or a firewall interface
Secure Firewall 1210CP PoE+ support on Ethernet ports 1/5-1/8	7.6	7.6	The Secure Firewall 1210CP supports Power over Ethernet+ (PoE+) on Ethernet ports 1/5-1/8.
VXLAN VTEP IPv6 support	7.4	Any	You can now specify an IPv6 address for the VXLAN VTEP interface. IPv6 is not supported for the threat defense virtual cluster control link or for Geneve encapsulation. New/Modified screens: • **Devices** > **Device Management** > **Edit** > **VTEP** > **Add VTEP** **Devices** > **Device Management** > **Edit** > **Interfaces** > **Add Interfaces** > **VNI Interface** Requires Firewall Threat Defense version 7.4. You can specify an IPv6 address for the VXLAN VTEP interface for Secure Firewall 4200 Series devices only.
Loopback interface support for BGP and management traffic	7.4	Any	You can use a loopback interface for: AAA, BGP, DNS, HTTP, ICMP, IPsec Flow Offload, NetFlow, SNMP, SSH, and Syslog. Requires Firewall Threat Defense version 7.4.
Loopback interface support for VTI	7.3	Any	You can now add a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface. For VTI, in addition to setting a loopback interface as the source interface, support has also been added to inherit the IP address from a loopback interface instead of a statically configured IP address. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Add Interfaces** > **Add Loopback Interface**

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
IPv6 DHCP	7.3	Any	The Firewall Threat Defense now supports the following features for IPv6 addressing: DHCPv6 Address client, DHCPv6 Prefix Delegation client, BGP router advertisement for delegated prefixes, and DHCPv6 stateless server. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **DHCP** • **Objects** > **Object Management** > **DHCP IPv6 Pool** New/Modified commands: **show bgp ipv6 unicast** , **show ipv6 dhcp** , **show ipv6 general-prefix**
Paired proxy VXLAN for the Firewall Threat Defense Virtual for the Azure Gateway Load Balancer	7.3	Any	You can configure a paired proxy mode VXLAN interface for the Firewall Threat Defense Virtual in Azure for use with the Azure Gateway Load Balancer (GWLB). New/Modified screens: **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** Supported platforms: Firewall Threat Defense Virtual in Azure
VXLAN support	7.2	Any	VXLAN encapsulation support was added. New/Modified screens: **Devices** > **Device Management** > **Device** > **VTEP** , **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** , and **Devices** > **Device Management** > **Device** > **Interfaces** edit physical interface **> General** Supported platforms: All.
Geneve support for the Firewall Threat Defense Virtual	7.1	Any	Geneve encapsulation support was added for the Firewall Threat Defense Virtual to support single-arm proxy for the Amazon Web Services (AWS) Gateway Load Balancer. This feature requires Snort 3.
31-bit Subnet Mask	7.0	Any	For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. This feature is not supported for BVIs for bridge groups or with multicast routing. New/Modified screens: **Devices** > **Device Management** > **Interfaces**

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Synchronization between the Firewall Threat Defense operational link state and the physical link state for the Firepower 4100/9300	6.7	Any	The Firepower 4100/9300 chassis can now synchronize the Firewall Threat Defense operational link state with the physical link state for data interfaces. **Note** This feature is not supported for clustering, container instances, or Firewall Threat Defense with a Radware vDP decorator. It is also not supported for ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices** > **Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled** , **show interface expand detail**
Firepower 1010 hardware switch support	6.5	Any	The Firepower 1010 supports setting each Ethernet interface to be a switch port or a firewall interface.
Firepower 1010 PoE+ support on Ethernet 1/7 and Ethernet 1/8	6.5	Any	The Firepower 1010 supports Power over Ethernet+ (PoE+) on Ethernet 1/7 and Ethernet 1/8 when they are configured as switch ports.
VLAN subinterfaces for use with container instances	6.3.0	Any	To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances.
Data-sharing interfaces for container instances	6.3.0	Any	To provide flexible physical interface use, you can share interfaces between multiple instances.
Integrated Routing and Bridging	6.2.0	Any	Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group.

CHAPTER 43

Inline Sets and Passive Interfaces

You can configure IPS-only passive interfaces, passive ERSPAN interfaces, and inline sets.

- IPS interfaces, on page 1119
- Requirements and prerequisites for inline sets, on page 1123
- Guidelines for configuring inline sets and passive interfaces, on page 1125
- Configure a passive interface, on page 1127
- Configure Inline Sets, on page 1128

IPS interfaces

Intrusion Prevention System (IPS) interfaces include passive interfaces, passive Enhanced Remote Switch Port Analyzer (ERSPAN) interfaces, and inline sets. Interfaces in IPS-only mode bypass many firewall checks and support only IPS security policy (Snort). Implement IPS-only interfaces if you have a separate firewall protecting these interfaces and want to avoid firewall function overhead.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

Inline sets

An inline set acts like a bump on the wire and binds one or more interface pairs together to slot into an existing network. This function allows the Firewall Threat Defense to be installed in any network environment without requiring configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally and retransmit all traffic out of the other interface in the inline pair unless traffic is explicitly dropped. When you have multiple inline pairs in an inline set, traffic can only pass between the interfaces in the pair; it can't pass between interfaces in different pairs.

Tap mode functionality

With tap mode, the Firewall Threat Defense is deployed inline, but the network traffic flow is undisturbed. Instead, the Firewall Threat Defense makes a copy of each packet so that it can analyze the packets. Note that rules of these types do generate intrusion events when they are triggered, and the table view of intrusion events indicates that the triggering packets would have dropped in an inline deployment.

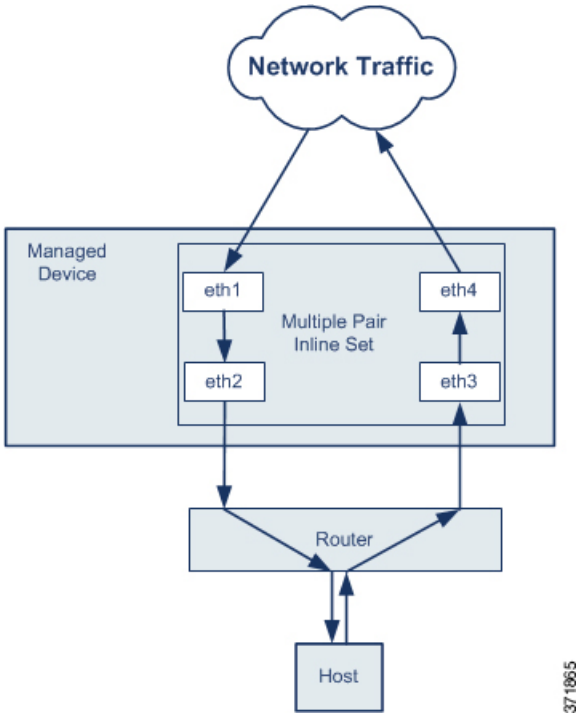
There are benefits to using tap mode with Firewall Threat Defense that are deployed inline:

- You can set up the cabling between the Firewall Threat Defense and the network as if the Firewall Threat Defense were inline and analyze the kinds of intrusion events the Firewall Threat Defense generates.
- Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency.
- When you are ready to deploy the Firewall Threat Defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the Firewall Threat Defense and the network.

Note Tap mode *significantly* impacts Firewall Threat Defense performance, depending on the traffic.

Note Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

Multiple inline pairs and asynchronous routing



Asynchronous routing is a network configuration that routes traffic between a host on your network and external hosts through different inline pairs, depending on whether the traffic is inbound or outbound. It requires multiple inline pairs in an inline set to correctly analyze network traffic.

If you deploy asynchronous routing, but you include only one inline pair in an inline set, the device might not correctly analyze your network traffic because it might see only half of the traffic.

Multiple inline pairs configuration

Adding multiple inline pairs to the same inline set lets the system identify the inbound and outbound traffic as part of the same traffic flow. For passive interfaces only, you can also achieve this by including the interface pairs in the same security zone.

Figure 267: Asynchronous routing

Note If you assign multiple inline pairs to a single inline set, but you experience issues with duplicate traffic, you might need to reassign your inline pairs to separate inline sets or modify your security zones.

If fragments of a packet are received on different interface pairs, they are not reassembled and get dropped. Make sure all the fragments of the packet are received and sent on the same interface pair.

Passive interfaces

Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the switch. This function allows the system to view network traffic without participating in the flow of data.

Passive interface functionality

The SPAN or mirror port allows for traffic to be copied from other ports on the switch. When you configure the Firewall Threat Defense in a passive deployment, the Firewall Threat Defense cannot take certain actions such as blocking or shaping traffic.

Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches and use GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the Firewall Threat Defense is in routed firewall mode.

Note Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See Intel Ethernet Products for more information on Intel network adapters.

Hardware Bypass for inline sets

Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. It maintains network connectivity when software or hardware failures occur and is available for certain interface modules on supported models.

Supported interface modules

For information about which interface modules support this feature, see Requirements and prerequisites for inline sets, on page 1123.

Hardware Bypass triggers

Hardware Bypass can be triggered in these scenarios.

- Firewall Threat Defense crash
- Firewall Threat Defense reboot
- Security Module reboot
- Chassis crash
- Chassis reboot
- Manual trigger
- Chassis power loss
- Security Module power loss

Note Hardware bypass is intended for unplanned/unexpected failure scenarios, and is not automatically triggered during planned software upgrades. Hardware bypass activates only at the end of a planned upgrade process, when the Firewall Threat Defense application reboots.

Hardware bypass switchover

When you switch from normal operation to hardware bypass, or back to normal operation, you may experience several seconds of interrupted traffic. During this time, connections may drop.

Connection interruption factors

Several factors can affect the length of the traffic interruption during hardware bypass switchover.

- Copper port auto-negotiation
- Behavior of the optical link partner such as how it handles link faults and de-bounce timing
- Spanning tree protocol convergence
- Dynamic routing protocol convergence

You may also experience dropped connections due to application identification errors when analyzing connections midstream after the returning to normal operations.

Snort Fail Open vs. Hardware Bypass

Snort Fail Open and Hardware Bypass allow traffic to flow during system failures.

Functionality differences

You can configure the Snort Fail Open option for inline sets other than those in tap mode. This option either drops traffic or allows traffic to pass without inspection when the Snort process is busy or down. Snort Fail Open is supported on all inline sets except those in tap mode, not just on interfaces that support Hardware Bypass.

The Hardware Bypass functionality allows traffic to flow during a hardware failure, including a complete power outage, and certain limited software failures. A software failure that triggers Snort Fail Open does not trigger a Hardware Bypass.

Hardware Bypass status

When the system has power, the Bypass LED indicates the Hardware Bypass status. See the Firepower chassis hardware installation guide for LED descriptions.

Requirements and prerequisites for inline sets

This reference provides the requirements and prerequisites that must be met before configuring inline sets, including user role permissions and hardware bypass support information.

User roles

- Admin
- Access Admin
- Network Admin

Hardware Bypass Support

The Firewall Threat Defense supports Hardware Bypass for interface pairs on specific network modules on the following models:

- Firepower 2130 and 2140
- Secure Firewall 3100
- Firepower 4100

- Secure Firewall 4200
- Firepower 9300

Note The ISA 3000 has a separate implementation for Hardware Bypass, which you can enable using FlexConfig only (see FlexConfig policies, on page 1309). Do not use this chapter to configure ISA 3000 Hardware Bypass.

Note You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

The supported Hardware Bypass network modules for these models include:

- Firepower 2130 and 2140:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR2K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR2K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR2K-NM-6X10LR-F)
- Secure Firewall 3100:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR3K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR3K-XNM-8X1GF)
- Secure Firewall 4200:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR4K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR4K-XNM-8X1GF)
- Firepower 4100:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR4K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR4K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR4K-NM-6X10LR-F)

- Firepower 2-port 40G SR FTW Network Module single-wide (FPR4K-NM-2X40G-F)
- Firepower 8-port 1G Copper FTW Network Module single-wide (FPR-NM-8X1G-F)

- Firepower 9300:
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR9K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR9K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR9K-NM-2X40G-F)

Hardware Bypass can only use the following port pairs:

- 1 & 2
- 3 & 4
- 5 & 6
- 7 & 8

Guidelines for configuring inline sets and passive interfaces

Firewall mode restrictions

Use ERSPAN interfaces only when the device is in routed firewall mode.

Clustering restrictions

Consider clustering limitations when configuring inline sets and passive interfaces.

- Link State Propagation for an inline set is not supported with clustering.

Multi-Instance mode restrictions

Use unshared physical interfaces or EtherChannels when configuring multi-instance mode.

- Multi-instance shared interfaces are not supported. You must use an unshared interface.
- Multi-instance chassis-defined subinterfaces are not supported. You must use a physical interface or EtherChannel.

General configuration guidelines

Consider these interface and traffic inspection requirements when configuring inline sets and passive interfaces.

- Inline sets and passive interfaces support only physical interfaces and EtherChannels. You cannot use VLANs or other virtual interfaces, including multi-instance chassis-defined subinterfaces.
- Because IPS interfaces do not support regular firewall protections, traffic must pass through the same Firewall Threat Defense to ensure all traffic is inspected according to the IPS security policy (Snort).
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using inline sets. If there are two neighbors on either side of the Firewall Threat Defense

running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

- For inline sets and passive interfaces, the Firewall Threat Defense supports up to two 802.1Q headers in a packet (also known as Q-in-Q support), with the exception of the Firepower 4100/9300, which only supports one 802.1Q header. **Note:** Firewall-type interfaces do not support Q-in-Q, and only support one 802.1Q header.
- Firewall Threat Defense does not support frames with Ethertype 0x8988. If a source in the Application Centric Infrastructure (ACI) fabric has Precision Time Protocol (PTP) enabled, ACI inserts Ethertype 0x8988 into data-plane frames before mirroring. Firewall Threat Defense drops frames with Ethertype 0x8988 and does not inspect them.

Hardware Bypass Guidelines

Consider Hardware Bypass limitations and clustering requirements when configuring inline sets.

- Hardware Bypass ports are supported only for inline sets.
- Hardware Bypass ports cannot be part of an EtherChannel.
- Hardware Bypass is not supported in high availability mode.
- Hardware Bypass ports are supported with intra-chassis clustering on the Firepower 9300. Ports are placed in Hardware Bypass mode when the last unit in the chassis fails. Inter-chassis clustering is not supported, because inter-chassis clustering only supports Spanned EtherChannels; Hardware Bypass ports cannot be part of an EtherChannel.
- If all modules in an intra-chassis cluster on the Firepower 9300 fail, then Hardware Bypass is triggered on the final unit, and traffic continues to pass. When units come back up, Hardware Bypass returns to standby mode. If rules matching application traffic are used, connections might be dropped and require reestablishment. Connections are dropped because state information is not retained on the cluster unit, and the unit cannot identify the traffic as belonging to an allowed application. To prevent a traffic drop, use a port-based rule instead of an application-based rule, if appropriate for your deployment.
- You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

Unsupported firewall features on IPS interfaces

These firewall features are not supported on IPS interfaces.

- DHCP server
- DHCP relay
- DHCP client
- TCP Intercept
- Routing
- NAT
- VPN
- Application inspection

- QoS
- NetFlow
- VXLAN

Configure a passive interface

Configure a passive or ERSPAN interface to enable network monitoring and traffic analysis capabilities on your security device.

This section describes how to:

- Enable the interface. By default, interfaces are disabled.
- Set the interface mode to Passive or ERSPAN. For ERSPAN interfaces, you will set the ERSPAN parameters and the IP address.
- Change the MTU. By default, the MTU is set to 1500 bytes. For more information about the MTU, see MTU, on page 1104.
- Set a specific speed and duplex (if available). By default, speed and duplex are set to Auto.

Note For the Secure Firewall Threat Defense on the FXOS chassis, you configure basic interface settings on the Firepower 4100/9300. See Configure a physical interface for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 1011.

Follow these steps to configure a passive interface:

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Mode** drop-down list, choose **Passive** or **ERSPAN**.

Step 4 Enable the interface by checking the **Enabled** check box.

Set these values:

a. In the **Name** field, enter a name up to 48 characters in length.

b. From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

c. Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 (Optional) On **General**, set the **MTU** between 64 and 9198 bytes; for the Secure Firewall Threat Defense Virtual and Secure Firewall Threat Defense on the FXOS chassis, the maximum is 9000 bytes.

The default is 1500 bytes.

Step 6 For ERSPAN interfaces, set the following parameters:

- **Flow ID**—Configure the ID used by the source and destination sessions to identify the ERSPAN traffic, between 1 and 1023. This ID must also be entered in the ERSPAN destination session configuration.
- **Source IP**—Configure the IP address used as the source of the ERSPAN traffic.
- **IPv4**—Set the IPv4 address and mask

Step 7 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Inline Sets

Enable traffic inspection by configuring multiple inline sets using physical interfaces or EtherChannels, including optional Hardware Bypass.

Inline sets allow you to designate pairs of interfaces or EtherChannels for traffic inspection, with optional Hardware Bypass. You can configure multiple inline pairs per set.

Note For the Firepower 4100/9300 , you configure basic interface settings in FXOS on the chassis. See Configure a physical interface for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 1011 .
- We recommend that you set STP PortFast for STP-enabled switches that connect to the Firewall Threat Defense inline pair interfaces. This setting is especially useful for Hardware Bypass configurations and can reduce bypass times.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 For each interface in the inline pair, name the interface and enable it. Also configure necessary hardware settings, ensuring they match between interfaces in the inline pair. You can configure multiple pairs of interfaces.

a) Click **Edit** (✎) for the interface you want to edit.
b) In the **Name** field, enter a name up to 48 characters in length.
c) Enable the interface by checking the **Enabled** check box.
d) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

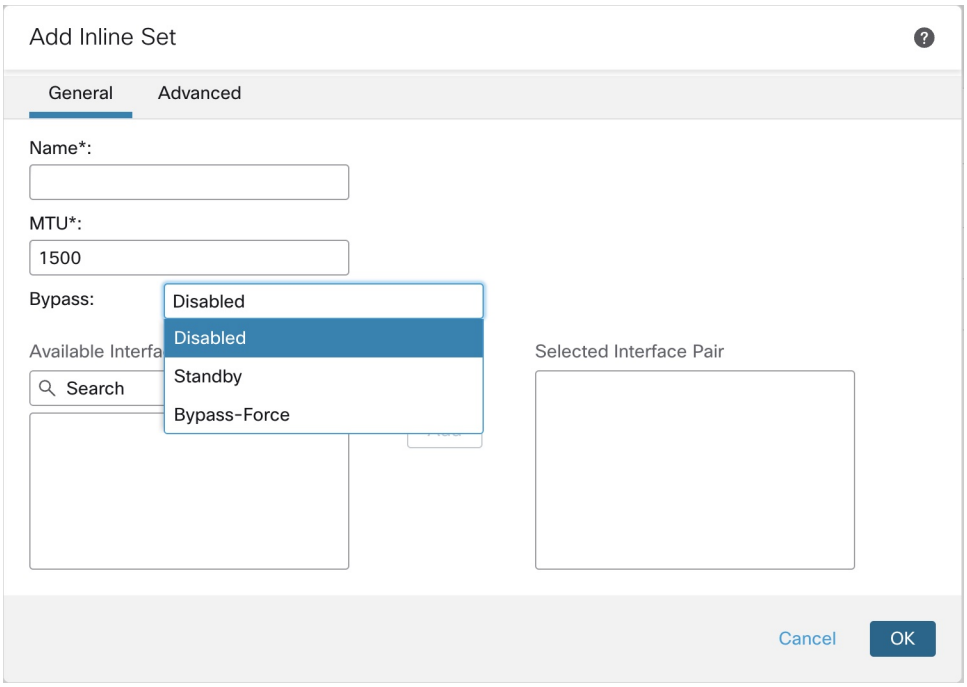
e) Leave the **Mode** as **None** .

After you add this interface to an inline set, this field will show Inline for the mode.

f) Do not set the security zone yet; you must set it after you create the inline set later in this procedure.
g) (Optional) Set the duplex and speed by clicking **Hardware Configuration** .

The exact speed and duplex options depend on your hardware.

- **Duplex** —Choose **Full** , **Half** , or **Auto** . Auto is the default.
- **Speed** —Choose **10** , **100** , **1000** , or **Auto** . Auto is the default.



h) Click **OK** .

Do not set any other settings for this interface.

Step 3 Click **Inline Sets**.

Step 4 Click **Add Inline Set**.

Figure 268: Add Inline Set

The **Add Inline Set** dialog box appears with **General** selected.

Step 5 In the **Name** field, enter a name for the set.

Step 6 (Optional) Change the **MTU** to enable jumbo frames.

For inline sets, the MTU setting is not used. However, the jumbo frame setting is relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo frames, you must set the MTU of *any* interface on the device above 1500 bytes.

Step 7 Configure Hardware Bypass.

a) For the **Bypass** mode, choose one of the following options:

- **Disabled** —Set Hardware Bypass to disabled for interfaces where Hardware Bypass is supported, or use interfaces where Hardware Bypass is not supported.
- **Standby** —Set Hardware Bypass to the standby state on supported interfaces. Only pairs of Hardware Bypass interfaces are shown. In the standby state, the interfaces remain in normal operation until there is a trigger event.
- **Bypass-Force** —Manually forces the interface pair to go into a bypass state. **Inline Sets** shows **Yes** for any interface pairs that are in Bypass-Force mode.

b) In the **Available Interfaces Pairs** area, click a pair and then click **Add** to move it to the **Selected Interface Pair** area.

All possible pairings between named and enabled interfaces with the mode set to None show in this area.

Step 8 (Optional) Click **Advanced** to set the following optional parameters:

- **Tap Mode** —Set to inline tap mode.

Note that you cannot enable this option and strict TCP enforcement on the same inline set.

Note
Perform Tap mode changes during a maintenance window. Changing the mode while the device is passing traffic can cause traffic disruption.

Note
Tap mode significantly impacts the Firewall Threat Defense performance, depending on the traffic.

- **Propagate Link State** —Configure link state propagation.

  Link state propagation automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the device senses the change and updates the link state of the other interface to match it. Note that devices require up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

  Note
  Do not enable **Propagate Link State** when using clustering.

- **Snort Fail Open** —Enable or disable either or both of the **Busy** and **Down** options if you want new and existing traffic to pass without inspection (enabled) or drop (disabled) when the Snort process is busy or down.

  By default, traffic passes without inspection when the Snort process is down, and drops when it is busy.

  When the Snort process is:

  - Busy—It cannot process traffic fast enough because traffic buffers are full, indicating that there is more traffic than the device can handle, or because of other software resource issues.
  - Down—It is restarting because you deployed a configuration that requires it to restart. See Configurations that restart the snort process when deployed or activated, on page 198 .

  When the Snort process is down and comes back up, it inspects *new* connections. To prevent false positives and false negatives, it does not inspect existing connections on inline, routed, or transparent interfaces because initial session information might have been lost while it was down.

  Note
  When Snort fails open, features that rely on the Snort process do not function. These include application control and deep inspection. The system performs only basic access control using simple, easily determined transport and network layer characteristics.

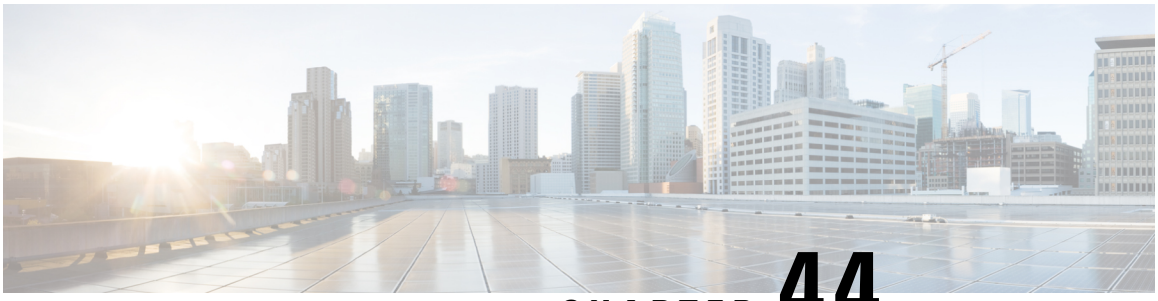
  Note
  The **Strict TCP Enforcement** option is not supported.

Step 9 Set the security zone for each interface.

a) Click **Interfaces** .

b) Click **Edit** ( ) for the member interface.

c) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New** .



You can only set the zone after you add the interface to the inline set; adding it to an inline set configures the mode to Inline and lets you choose inline-type security zones.

d) Click **OK** .

Click **Save**.

What to do next

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

CHAPTER 44

Device Settings

After you add a device, you can edit device-related settings on the **Device** page.

1. Choose **Devices** > **Device Management**.
2. Next to the device you want to modify, click **Edit** ( ).
3. Click **Device**.

- Edit general settings, on page 1133
- Edit license settings, on page 1140
- View system information, on page 1141
- View the inspection engine, on page 1142
- Edit health settings, on page 1143
- Edit management settings, on page 1153
- View inventory details, on page 1186
- Edit applied policies, on page 1186
- Edit advanced settings, on page 1188
- Edit deployment settings, on page 1192
- Edit cluster health monitor settings, on page 1195
- Hot swap an SSD, on page 1198
- Disable the USB port, on page 1201
- Configure SNMP for FXOS, on page 1204
- Configure alarms for the ISA 3000, on page 1207
- History for Device Settings, on page 1219

Edit general settings

Edit general device settings to customize the device name, packet transfer options, and force deployment settings for managed devices.

The **General** section of the **Device** page displays the settings described in this table.

Figure 269: General

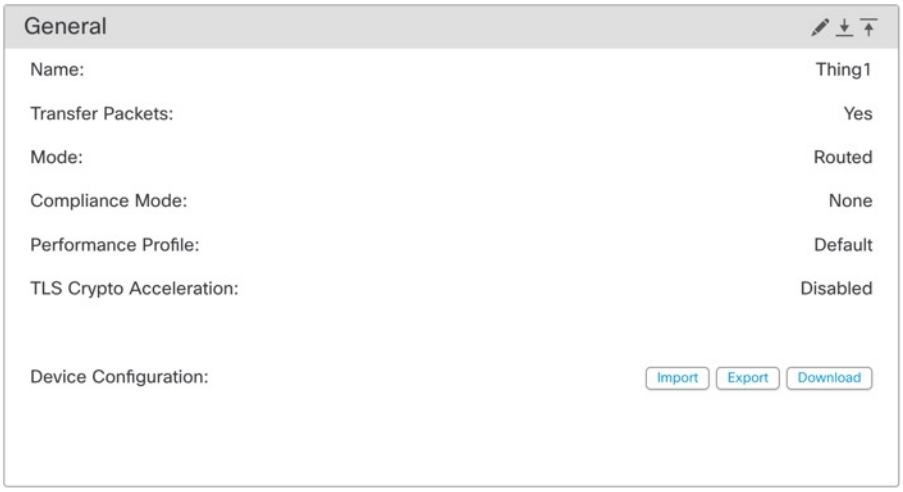


Table 70: General section table fields

Field	Description
Name	The display name of the device on the Cloud-Delivered Firewall Management Center.
Transfer Packets	This displays whether or not the managed device sends packet data with the events to the Cloud-Delivered Firewall Management Center.
Mode	The displays the mode of the management interface for the device: **routed** or **transparent**.
Compliance Mode	This displays the security certifications compliance for a device. Valid values are CC, UCAPL and None.
Performance Profile	This displays the core allocation performance profile for the device, as configured in the platform settings policy.
TLS Crypto Acceleration:	Shows whether TLS crypto acceleration is enabled or disabled.
Device Configuration	Lets you copy, export, or import a configuration. See Copy a configuration to another device, on page 1135 and Export and import the device configuration, on page 1136.
OnBoarding Method	Shows whether the device was registered using a registration key or using the serial number (zero-touch provisioning).

You can edit some of these settings from this section.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, click **Edit** ( ).

a) Enter a **Name** for the managed device.

b) Check **Transfer Packets** to allow packet data to be stored with events on the Cloud-Delivered Firewall Management Center.

c) Click **Force Deploy** to force deployment of current policies and device configuration to the device.

Note
Force-deploy consumes more time than the regular deployment since it involves the complete generation of the policy rules to be deployed on the Firewall Threat Defense.

Step 5 For **Device Configuration** actions, see Copy a configuration to another device, on page 1135 and Export and import the device configuration, on page 1136.

Step 6 Click **Deploy**.

What to do next

- Deploy configuration changes.

Copy a configuration to another device

Copy configurations and policies from a pre-configured device to a new device, instead of manually reconfiguring the new device.

When a new device is deployed in the network, you can copy configurations and policies from a pre-configured device, instead of manually reconfiguring the new device.

Before you begin

Confirm that:

- The source and destination devices are the same model and are running the same version of the software.
- The source is either a standalone device or a high availability pair.
- The destination device is a standalone device.
- The source and destination devices have the same number of physical interfaces.
- The source and destination devices are in the same firewall mode: routed or transparent.
- The source and destination devices are in the same security-certifications-compliance mode.
- The source and destination devices are in the same domain.
- No configuration deployment is in progress on the source or the destination devices.

Follow these steps to copy a configuration to another device:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, do one of the following:

- Click **Get Device Configuration** ( ) to copy device configuration from another device to the new device. On the **Get Device Configuration** page, select the source device in the **Select Device** drop-down list.
- Click **Push Device Configuration** ( ) to copy device configuration from the current device to the new device. On the **Push Device Configuration** page, select the destination to which configuration is to be copied in the **Target Device** drop-down list.

Step 5 (Optional) Check **Include shared policies configuration** check box to copy policies.

Shared policies such as AC policy, NAT, Platform Settings and FlexConfig policies can be shared across multiple devices.

Step 6 Click **OK**.

You can monitor the status of the copy device configuration task on **Tasks** in the Message Center.

When the copy device configuration task is initiated, it erases the configuration on the target device and copies the configuration of the source device to the destination device.

Warning When you have completed the copy device configuration task, you cannot revert the target device to its original configuration.

Export and import the device configuration

Export device-specific configuration to create a backup that can be imported for the same device in various scenarios including moving the device to a different Cloud-Delivered Firewall Management Center, restoring old configurations, or reregistering a device.

You can export all device-specific configurations available on the Device pages, including:

- Interfaces
- Inline Sets
- Routing
- DHCP
- VTEP

- Associated objects

You can then import the saved configuration for the same device in these use cases:

- Moving the device to a different Cloud-Delivered Firewall Management Center—First unregister the device from the original Cloud-Delivered Firewall Management Center, then add the device to the new Cloud-Delivered Firewall Management Center. Then you can import the saved configuration.
- Restore an old configuration—If you deployed changes that negatively impacted the operation of the device, you can import a backup copy of a known working configuration to restore a previous operational state.
- Reregistering a device—If you unregister a device from the Cloud-Delivered Firewall Management Center, but then want to add it back, you can import the saved configuration.

Before you begin

Review these guidelines:

- You can only import the configuration to the same device (the UUID must match). You cannot import a configuration to a different device, even if it is the same model.
- Do not change the version running on the device between exporting and importing; the version must match.
- If you make inventory changes after your export (such as adding or deleting network modules or configuring or joining breakout ports), the device inventory will not match the Cloud-Delivered Firewall Management Center. In this case, the device inventory will be maintained, and you will be prompted to sync the interfaces (see Sync Interface Changes with the Cloud-Delivered Firewall Management Center, on page 1014) and discard incompatible configuration in the Cloud-Delivered Firewall Management Center when you try to deploy. You will have to repeat the inventory changes and related configuration in the Cloud-Delivered Firewall Management Center.
- If you export a standalone configuration, you cannot import it to a high availability pair or vice versa.
- If an object doesn't exist, it will be created. If an object exists, but the value is different, refer to this table:

Table 71: Object import action

Scenario	Import Action
Object exists with the same name and value.	Reuse existing objects.
Object exists with the same name but different value.	Network and Port objects: Create object overrides for this device. See Object overrides, on page 2939. Interface objects: Create new objects. For example, if both the type (security zone or interface group) and the interface type (routed or switched, for example) do not match, then a new object is created. All other objects: Reuse existing objects even though the values are different.
Object doesn't exist.	Create new objects.

Follow these steps to export and import the device configuration:

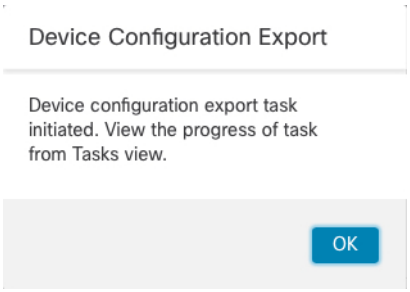
Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to edit, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 Export the configuration.



a) In the **General** area, click **Export**.

Figure 270: Export device configuration

You are prompted to acknowledge the export; click **OK**.

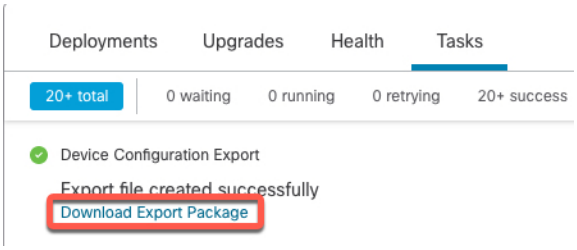


Figure 271: Acknowledge export

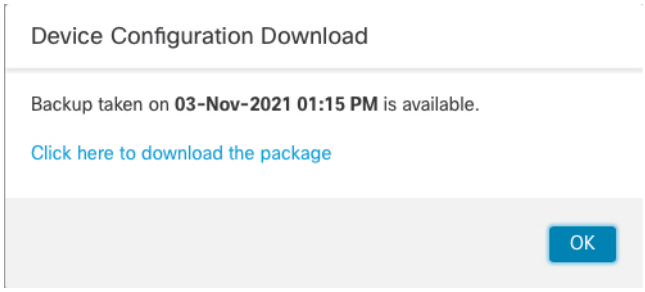
You can view the export progress in the **Tasks** page.



b) Click **Notifications**, and then click the **Tasks** tab. Verify if the export has completed, and then click **Download Export Package**. Alternatively, you can click the **Download** button in the **General** area.

Figure 272: Export task

You are prompted to download the package; click **Click here to download the package** to save the file locally, and then click **OK** to exit the dialog box.

Figure 273: Download package

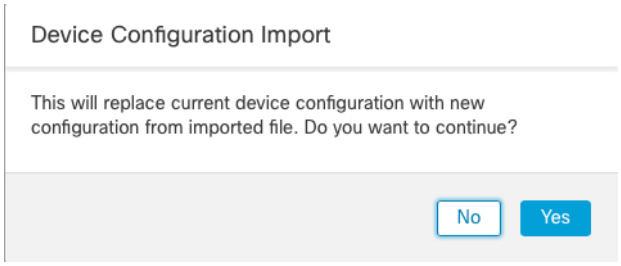
Step 5 Import the configuration.

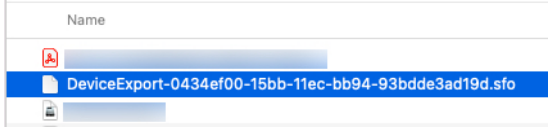
a) In the **General** area, click **Import**.

Figure 274: Import device configuration

You are prompted to acknowledge that the current configuration will be replaced. Click **Yes** and then navigate to the configuration package (with the suffix .sfo; note that this file is different from the Backup/Restore files).

Figure 275: Import package





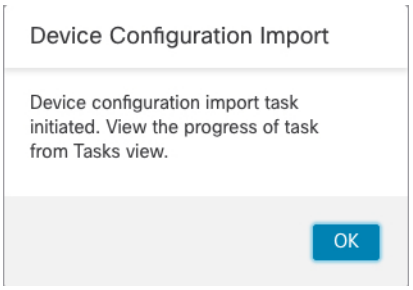


Figure 276: Navigate to package

You are prompted to acknowledge the import; click **OK**.

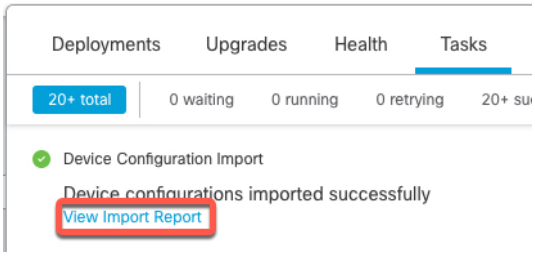

Figure 277: Acknowledge import

You can view the import progress in the **Tasks** page.

b) To view the import reports, click **Notifications**, and then click the **Tasks** tab. Click **View Import Report**.

Figure 278: View import report

The **Device Configuration Import Reports** page provides links to available reports.

Cisco Firepower Management Center

Device Configuration Import Reports

Device	Shared Policies	Device Configurations
0434ef00-15bb-11ec-bb94-93bdde3ad19d	Report does not exist	Device configurations import report

c) Deploy configuration changes.

Edit license settings

Enable or disable specific licenses on your managed device to control which features are available for use.

The **License** section of the **Device** page displays the licenses enabled for the device.

You can enable licenses on your device if you have available licenses on your Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to enable or disable licenses, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **License** section, click **Edit** ( ).

Step 5 Check or clear the check box next to the license you want to enable or disable for the managed device.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

View system information

The **System** section of the **Device** page displays a read-only table containing system information. You can also shut down or restart the device from this pane, using the icons at the top-right corner.

Figure 279: System

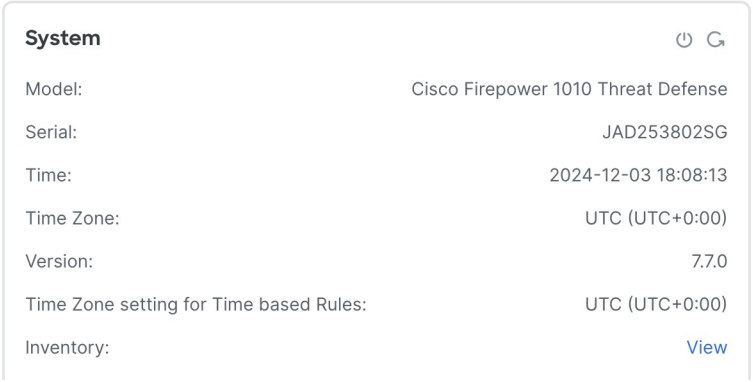

Table 72: System section table fields

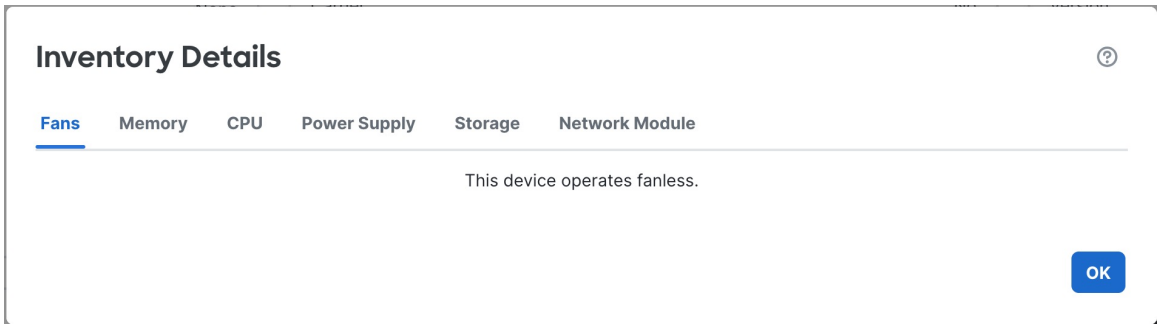
Field	Description
Shut Down Device ( )	Shuts down the device. See Shut down or restart the device, on page 107.
Restart Device ( )	Restarts the device. See Shut down or restart the device, on page 107.
Model	Model name and number.



Field	Description
Serial	PCB (circuit board) serial number. The firewall includes two serial numbers: the chassis serial number and the PCB serial number. The chassis serial number is shown in the Inventory section.
Time	Current system time of the device.
Time Zone	Time zone.
Version	Version of the software currently installed on the managed device.
Time Zone setting for Time based rules	Current system time of the device in the time zone specified in device platform settings.
Inventory	Inventory details. See View Device Inventory.

View device inventory

Click **View** next to **Inventory** in the **System** section to view a table of device inventory information including Fans, Memory, CPU, Power Supply, Storage, and Network Modules.

The **Inventory Details** table displays information about all the Cisco products installed in the Firewall Threat Defense devices assigned with a product identifier (PID). The PID is the product name using which the product can be ordered.

Figure 280: Inventory details

View the inspection engine

The Inspection Engine section of the **Device** page shows whether your device uses Snort 2 or Snort 3. To switch the inspection engine, see *Enable Snort 3 on an Individual Device* in the *Custom Snort 3 Intrusion Policies for Access Control* .

Note Snort3 is default for Secure Firewall 1200. It does not support Snort2.

Edit health settings

The **Health** section of the **Device** page displays the information described in this table.

Figure 281: Health

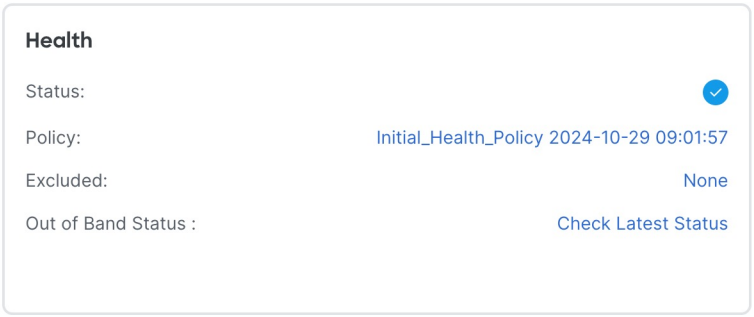


Table 73: Health section table fields

Field	Description
Status	An icon that represents the current health status of the device. Clicking the icon displays the Health Monitor for the appliance.
Policy	A link to a read-only version of the health policy currently deployed at the device.
Excluded	A link to the **Health Exclude** page, where you can enable and disable health exclusion modules.
Out of Band Status	A link to the **Out-of-Band configuration details** dialog box where you can view out-of-band configuration changes made at the device CLI. You must acknowledge the configuration differences and manually match any changes you want to keep in the Cloud-Delivered Firewall Management Center before the next deployment. See Out-of-band configuration detection, on page 1143.

Out-of-band configuration detection

Out-of-band configuration detection

- enables select configuration changes directly at the device CLI when you lose the management connection to your device
- allows restoration of the management connection if you are using a data interface for manager access
- detects configuration changes on the device after the management connection is restored, requiring manual acknowledgment and synchronization with the Cloud-Delivered Firewall Management Center.

Configuration change purposes

If you lose the management connection to your device, you can make select configuration changes directly at the device CLI to:

- Restore the management connection if you are using a data interface for manager access
- Make select configuration changes that can't wait until the connection is restored

Caution You are expected to know the commands that are required for recovery or emergency use. Do not use this feature to experiment with configuration changes. If you do not know which commands are required or are unsure about the effect of a command, we recommend that you contact Cisco TAC for guidance.

After the management connection is restored, the Cloud-Delivered Firewall Management Center will detect the configuration changes on the device. It does not automatically update the device configuration in the Cloud-Delivered Firewall Management Center.You must view the configuration differences, acknowledge that the device configuration differs, and manually apply the same changes in the Cloud-Delivered Firewall Management Center before deploying.

Caution When you deploy after acknowledgment, any configurations not present in the Cloud-Delivered Firewall Management Center configuration will be overwritten on the device.

Guidelines for out-of-band configuration

Supported feature areas in recovery-config mode

You can configure the following feature areas at the diagnostic CLI in recovery-config mode:

- Interfaces
- Static Routes
- Dynamic Routing: BGP and OSPF
- Prefilters
- Site-to-site VPN

Like other diagnostic CLI commands, refer to the ASA command reference for more information about each command.

Unsupported features

Be aware of these feature limitations in recovery-config mode:

- Not supported in multi-instance mode.
- You cannot add or delete EtherChannels.
- Some platform-dependent interface commands such as speed, duplex, and fec are not supported.

High availability and clustering restrictions

Consider these restrictions when using recovery-config mode in high availability or clustering environments:

- Recovery-config mode is only available on the active/control node.
- If a failover or cluster switchover occurs before you exit the recovery-config-mode session, the Cloud-Delivered Firewall Management Center will not detect the change on the new active/control node. We recommend re-entering recovery-config mode on the new active/control node and making a small change to trigger discovery of all of your previous changes. Otherwise, if you do not manually match the changes in the Cloud-Delivered Firewall Management Center, they will be overwritten at deployment without any notification.
- If you make out-of-band configuration changes on the active/control node and the high availability or cluster enters 'split brain' mode before a configuration sync (for example, due to a failover or cluster-control-link failure), the changes will be lost if a different node becomes active/control after the cluster returns to a healthy state.
- If you have an active recovery-config-mode session, then new nodes cannot join or rejoin the high availability/cluster until you exit the session.

Additional configuration guidelines

Follow these guidelines when making configuration changes in recovery-config mode:

- To modify an existing rule or route, delete the existing command using the **no** form of the command and then re-add the modified rule. This method avoids conflicts and errors. For example:

  Incorrect:

```
firepower# show running-config route
route outside 10.0.0.0 255.0.0.0 20.1.1.1 1
firepower# configure recovery-config

 CAUTION: The config CLI is for emergency use only. Use the config CLI if the management
 center is
unreachable, and use it only under exceptional circumstances, such as loss of connectivity
 or
to restore manager access. Do not change management center's auto-generated
configurations.

 After your management center is reachable, manually make the same configuration changes
 in the
management center. The management center cannot implement them automatically. When you
 deploy
from the management center, out-of-band configuration changes will be overwritten. Also,
 node join
will be blocked till config CLI session is active, so make sure to exit from the config
 CLI after
changes are made.

Would you like to proceed ? [Y]es/[N]o: y
firepower(recovery-config)# route outside 10.0.0.0 255.0.0.0 30.1.1.1
firepower(recovery-config)# exit
Unsaved changes are not kept if you reboot.Save changes to memory ? [Y]es/[N]o: y
Cryptochecksum: ccfc11a8 4e46d55e 0c99b5ae 3b18a8f1

3939 bytes copied in 0.70 secs
firepower# show running-config route
route outside 10.0.0.0 255.0.0.0 20.1.1.1 1
```

```
route outside 10.0.0.0 255.0.0.0 30.1.1.1 1
firepower#
```

In this case, a second route is added instead of replacing the first route.

Correct:

```
firepower# show running-config route
route outside 10.0.0.0 255.0.0.0 20.1.1.1 1
firepower# configure recovery-config

 CAUTION: The config CLI is for emergency use only. Use the config CLI if the management
 center is
unreachable, and use it only under exceptional circumstances, such as loss of connectivity
 or
to restore manager access. Do not change management center's auto-generated
configurations.

 After your management center is reachable, manually make the same configuration changes
 in the
management center. The management center cannot implement them automatically. When you
 deploy
from the management center, out-of-band configuration changes will be overwritten. Also,
 node join
will be blocked till config CLI session is active, so make sure to exit from the config
 CLI after
changes are made.

Would you like to proceed ? [Y]es/[N]o: y
firepower(recovery-config)# no route outside 10.0.0.0 255.0.0.0 20.1.1.1
firepower(recovery-config)# route outside 10.0.0.0 255.0.0.0 30.1.1.1
firepower(recovery-config)# exit
Unsaved changes are not kept if you reboot.Save changes to memory ? [Y]es/[N]o: y
Cryptochecksum: 81bcc51d 43771bbd 15b6dde6 afeb3442

3945 bytes copied in 0.70 secs
firepower# show running-config route
route outside 10.0.0.0 255.0.0.0 30.1.1.1 1
firepower#
```

- If you have auto rollback enabled (refer to Edit deployment settings, on page 1192), and you lose management connectivity because of a deployment, you should not start an out-of-band configuration. Instead, either wait 20 minutes for auto rollback to the previous deployment to occur or manually roll back at the CLI using the **configure policy rollback** command (refer to Manually Roll Back the configuration if the Cloud-Delivered Firewall Management Center loses Connectivity, on page 1181). Auto rollback will overwrite out-of-band configuration changes if the management connection is still down.
- For prefilter rules, we don't recommend adding completely new rules (the **access-control advanced** command). Integration of prefilter rules with the intrusion policy and logging requires the Cloud-Delivered Firewall Management Center, which generates the rule ID and integrates it with other policies.
- All recovery-config-mode sessions will be logged in syslog with the username "enable_15".

Access recovery-config mode in the diagnostic CLI

This task allows you to make out-of-band configuration changes when the management connection is down using the diagnostic CLI recovery-config mode.

You can use the diagnostic CLI recovery-config mode to make out-of-band configuration changes when the management connection is down. Be sure to make the same changes in the Cloud-Delivered Firewall Management Center. Local changes will always be overwritten by the Cloud-Delivered Firewall Management Center deployment.

For high availability and clustering, make your changes on the active/control node. This mode is not supported in multi-instance mode.

Procedure

Step 1 Connect to the device CLI using either the console port or SSH.

See Log into the Command-Line Interface on the device, on page 99.

Step 2 Access the diagnostic CLI.

system support diagnostic-CLI

enable (Press enter without entering a password when prompted.)

Example:

```
> system support diagnostic-cli
firepower> enable
Password:
```

Step 3 Show the current running configuration for reference.

show running-config

Note
You cannot enter **show** commands in recovery-config mode.

Step 4 Enter recovery-config mode.

configure recovery-config

Example:

```
firepower# configure recovery-config

 CAUTION: The config CLI is for emergency use only. Use the config CLI if the management
center is
unreachable, and use it only under exceptional circumstances, such as loss of connectivity
 or
to restore manager access. Do not change management center's auto-generated configurations.

 After your management center is reachable, manually make the same configuration changes
in the
management center. The management center cannot implement them automatically. When you
deploy
from the management center, out-of-band configuration changes will be overwritten. Also,
node join
will be blocked till config CLI session is active, so make sure to exit from the config CLI
 after
changes are made.

Would you like to proceed ? [Y]es/[N]o: y
```

```
firepower(recovery-config)#
```

Step 5 You can now enter select configuration commands.

Enter **?** to view available commands.

See Guidelines for out-of-band configuration, on page 1144 for supported feature areas.

See the ASA configuration guides or command reference for details about the commands.

Tip
Keep track of all of the commands you changed. Although the Cloud-Delivered Firewall Management Center shows you the differential later, it's good practice to keep a record of your command changes in case you need to make iterative changes for restoring the management connection.

Example:

```
firepower(recovery-config)# ?

  access-list           Configure an access control element
  as-path               BGP autonomous system path filter
  bfd                   BFD configuration commands
  bfd-template          BFD template configuration
  cluster               Cluster configuration
  community-list        Add a community list entry
  crypto                Configure IPSec, ISAKMP, Certification authority, key
  end                   Exit from configure mode
  exit                  Exit from config mode
  extcommunity-list     Add a extended community list entry
  group-policy          Configure or remove a group policy
  interface             Select an interface to configure
  ip                    Configure IP address pools
  ipsec                 Configure transform-set, IPSec SA lifetime and PMTU
                        Aging reset timer
  ipv6                  Configure IPv6 address pools
  ipv6                  Global IPv6 configuration commands
  isakmp                Configure ISAKMP options
  jumbo-frame           Configure jumbo-frame support
  mac-address           MAC address options
  management-interface  Management interface
  mtu                   Specify MTU(Maximum Transmission Unit) for an interface

  no                    Negate a command or set its defaults

  policy-list           Define IP Policy list
  prefix-list           Build a prefix list
  route                 Configure a static route for an interface
  route-map             Create route-map or enter route-map configuration mode
  router                Enable a routing process
  sla                   IP Service Level Agreement
  sysopt                Set system functional options
  time-range            Define time range entries
  tunnel-group          Create and manage the database of connection specific
                        records for IPSec connections
  vpdn                  Configure VPDN feature
  vrf                   Configure a VRF
  zone                  Create or show a Zone
firepower(recovery-config)#
```

Step 6 Exit recovery-config mode to be prompted to save your changes. Enter **exit** to exit each submode until you return to enable mode.

You can choose to save your changes to the startup configuration or keep changes only in the running configuration by not saving. Running configuration changes won't be retained after a reboot. If you make additional changes later and decide to save the configuration, all of your previous changes are also saved, since the entire running configuration is saved.

Deployment is be blocked when the recovery-config-mode session is open.

Example:

```
firepower(recovery-config)# interface Ethernet0/1
firepower(config-if)# ip address 10.0.0.2 255.0.0.0
firepower(config-if)# exit
firepower(recovery-config)# exit
Unsaved changes are not kept if you reboot. Save changes to memory ? [Y]es/[N]o: y

Cryptochecksum: 81a9073e f9535916 9c333d7e 9a3e5e76

3756 bytes copied in 0.70 secs
firepower#

Unsaved changes are not kept if you reboot. Save changes to memory ? [Y]es/[N]o:

Cryptochecksum: 81a9073e f9535916 9c333d7e 9a3e5e76

3756 bytes copied in 0.70 secs
firepower#
```

Step 7 Return to the Firewall Threat Defense CLI by typing Ctrl+a, then d, or you can enter **exit** to exit each mode.

Note
If you type Ctrl+a, then d to return to the Firewall Threat Defense CLI without first exiting recovery-config mode, the recovery-config-mode session will remain open, and deployment will be blocked.

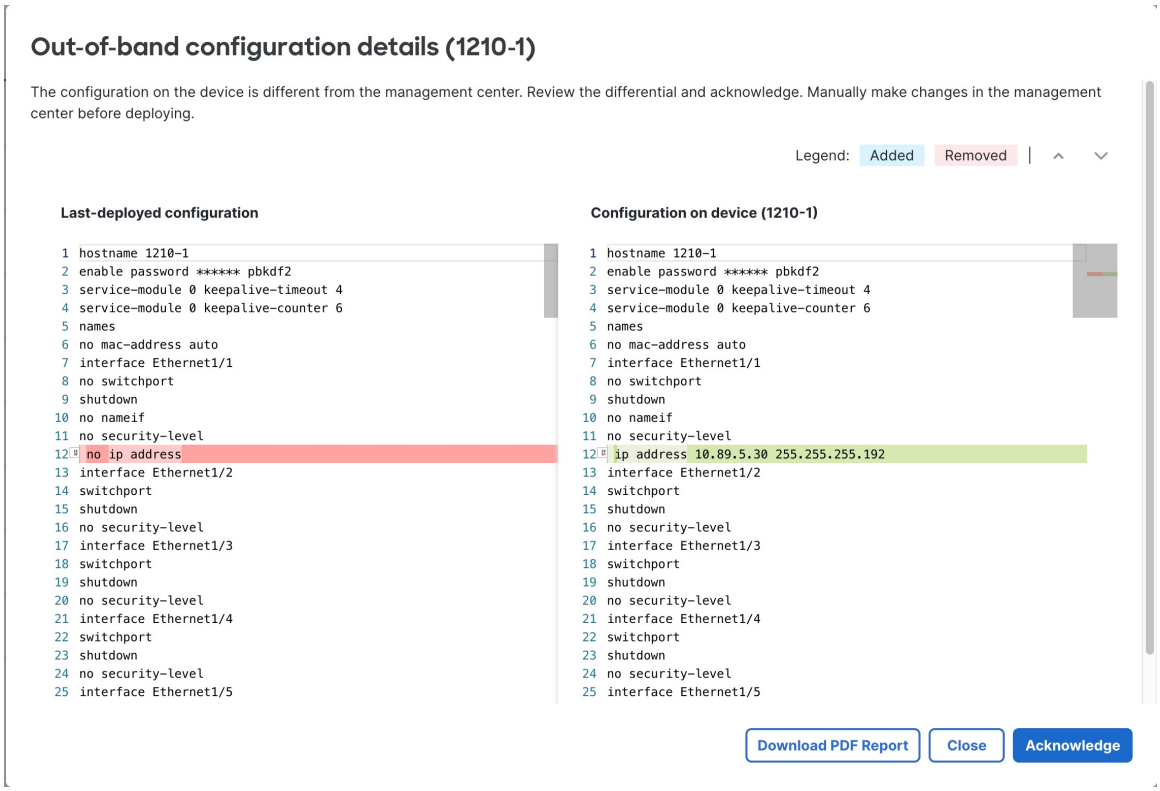
Example:

```
firepower# exit

Logoff

User enable_1 logged in to firepower
Logins over the last 1 days: 4.  Last login: 20:42:51 UTC Dec 4 2024 from console
Failed logins since the last login: 0.
Type help or '?' for a list of available commands.
firepower> exit
Console connection detached.
>
```

Acknowledge the out-of-band configuration



This task acknowledges out-of-band configuration changes detected by the Cloud-Delivered Firewall Management Center and enables deployment by matching configurations within the system.

When the Cloud-Delivered Firewall Management Center detects an out-of-band configuration change on a device, you must acknowledge the changes and match the configuration within the Cloud-Delivered Firewall Management Center that you want to keep. Until you acknowledge the changes, deployment will be blocked.

Procedure

Step 1 Open the **Out-of-Band configuration details** dialog box.

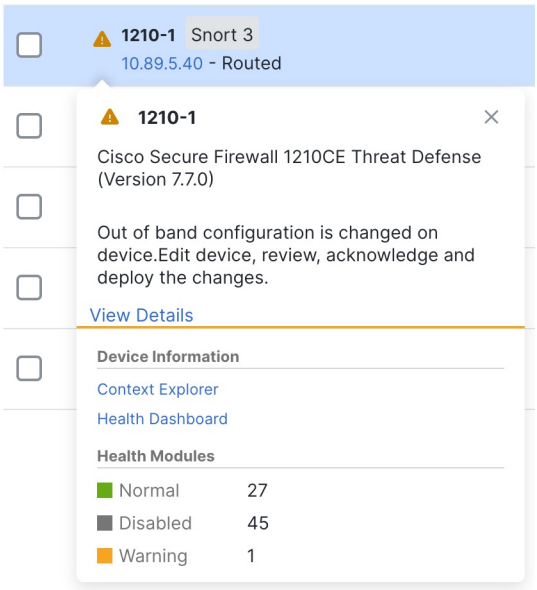


Figure 282: Out-of-Band configuration details

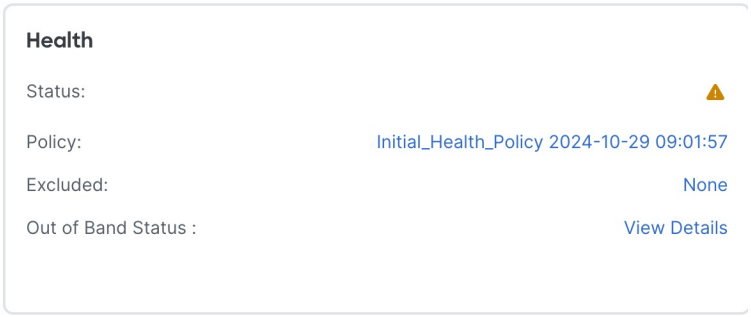
Note
Some commands, when set to a default setting, don't appear in the command output. However, the non-default command will show on either side as green (added) or red (removed). For example, if you add **no shutdown** to an interface in recovery-config mode, the **shutdown** command will show in red on the left **Last-deployed configuration** pane while **no shutdown** will *not* appear in the right **Configuration on device** pane. In this case, although the default setting for an interface is **shutdown**, the parser considers **no shutdown** to be the default and doesn't show it.

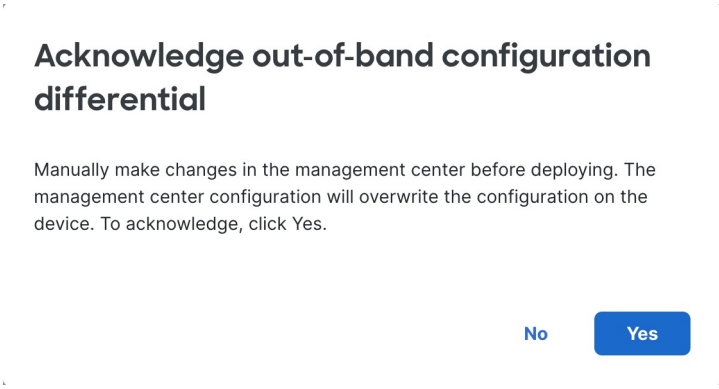


You can open the dialog box from multiple locations. For example, on the **Devices** > **Device Management** page, your device will have a warning. Click **View Details**.

Figure 283: Device management warning

Or, from the **Devices** > **Device Management**, and then navigate to **Health** tile under **Device** tab, you can click **View Details**.

Figure 284: Health Out-of-Band status



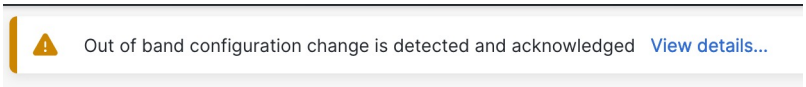
Note
If the out-of-band notification hasn't yet reached the Cloud-Delivered Firewall Management Center, you can check for changes using the **Check Latest Status** link in the Health tile.

Step 2 Click **Download PDF Report** so you can refer to the configuration changes you need to make after you close the dialog box.

Or you can bring up the dialog box at any time to review the changes.

Step 3 Click **Acknowledge**, and then **Yes**.

Figure 285: Acknowledge

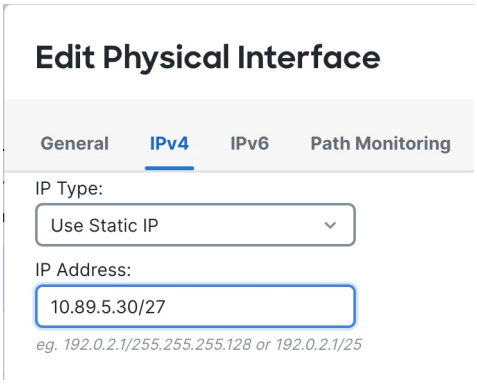


If you want to prevent an accidental deployment until after you've made your configuration changes, you can instead make the changes and then come back and click **Acknowledge**.

Step 4 Click **Close** on the **Out-of-Band configuration details** dialog box.

You can still revisit the dialog box to review the changes you need to make until you deploy. The status on the Device page changes to show you have acknowledged the out-of-band configuration:

Figure 286: Acknowledgement status



Step 5 Make the configuration changes that you made at the CLI.

You'll need to match the configuration CLI to Cloud-Delivered Firewall Management Center screens; there aren't links from the CLI changes directly to screens.

If you don't want to keep your changes, you can simply deploy and overwrite the device configuration. You should make all necessary changes to maintain the management connection as well as any other changes you want to keep. For example, if you changed the IP address at the CLI, you need to go to the **Interfaces** page, edit the interface, and set that IP address to match:

Figure 287: Match the IP address change

There is no checking mechanism that you made the same change; you could set the IP address differently if you want.

Step 6 Deploy configuration changes.

After you deploy, you can view the configuration differential—whether you made the changes or not—on the **System** (⚙) > **Monitoring** > **Audit** page. Check for the subsystem called *Device* > *Device Management* > *Out of band changes*.

Edit management settings

These settings control how the Cloud-Delivered Firewall Management Center establishes the management connection with the device.

Configure a redundant manager access data interface

This task configures a redundant manager access data interface to ensure continuous management connectivity. The secondary interface provides automatic failover capabilities when the primary management interface becomes unavailable, maintaining device management functionality.

When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. You can configure only one secondary interface. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces.

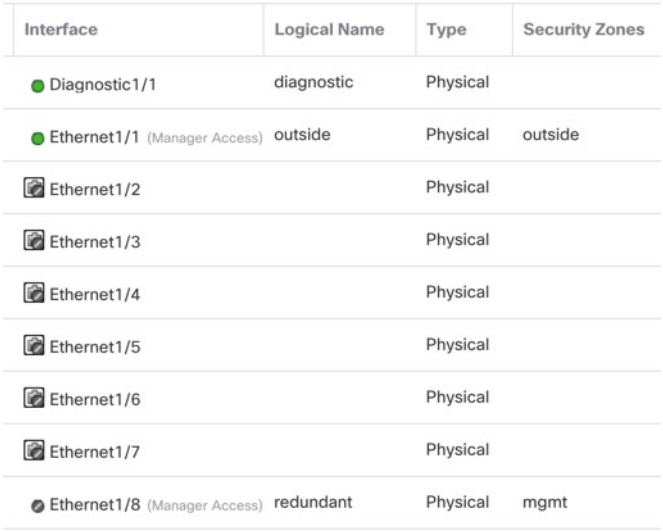
Before you begin

- The secondary interface needs to be in a separate security zone from the primary interface.
- All of requirements apply to the primary interface also apply to the secondary interface.

Follow these steps to configure a redundant manager access data interface:

Procedure

Step 1 On the **Devices** > **Device Management** page, click **Edit** (✎) for the device.



Step 2 Enable manager access for the secondary interface.

This setting is in addition to standard interface settings such as enabling the interface, setting the name, setting the security zone, and setting a static IPv4 address.

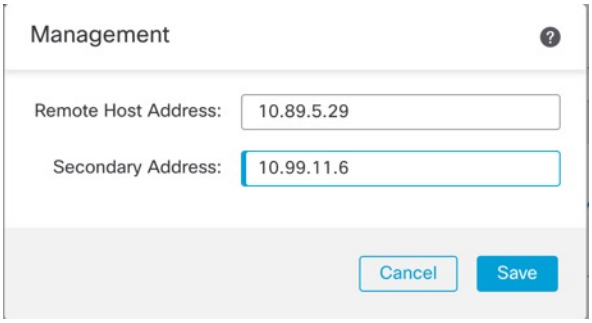
a) Choose **Interfaces** > **Edit Physical Interface** > **Manager Access**.
b) Check **Enable management on this interface for the Manager**.
c) Click **OK**.

Both interfaces show **(Manager Access)** in the interface listing.

Figure 288: Interface listing

Step 3 Add the secondary address to the **Management** settings.

a) Click **Device**, and view the **Management** area.

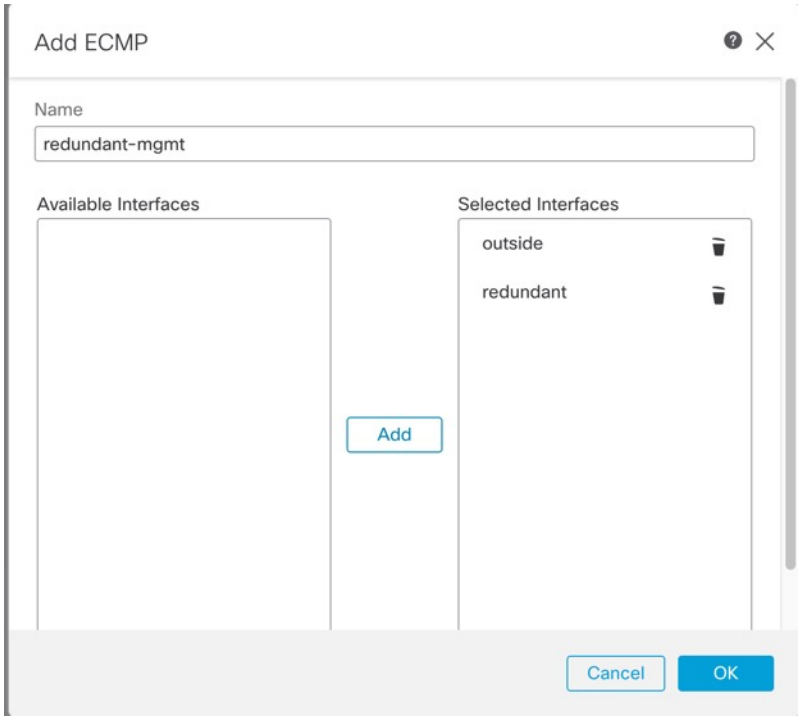


b) Click **Edit** ( ).

Figure 289: Edit management address

c) In the **Management** dialog box, modify the name or IP address in the **Secondary Address** field

Figure 290: Management IP address

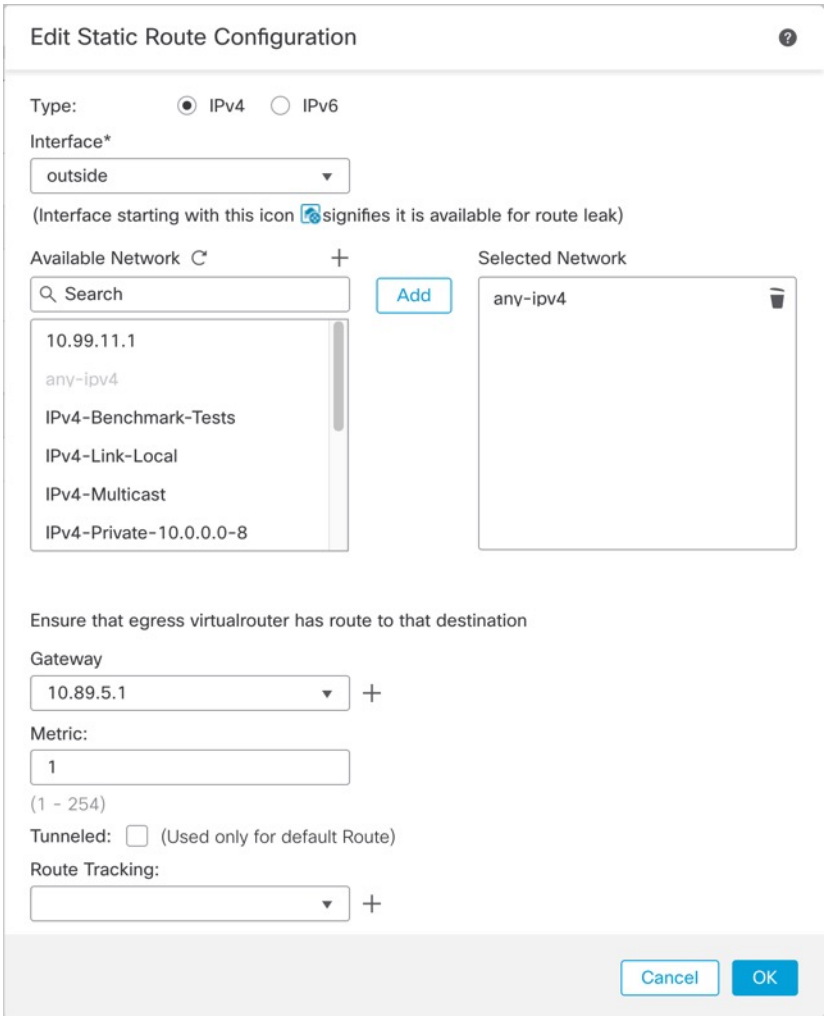


d) Click **Save**.

Step 4 Create an ECMP zone with both interfaces.

a) Click **Routing**.
b) From the virtual router drop-down, choose the virtual router in which the primary and secondary interfaces reside.
c) Click **ECMP**, and then click **Add**.
d) Enter a **Name** for the ECMP zone.
e) Select the primary and secondary interfaces under the **Available Interfaces** box, and then click **Add**.

Figure 291: Add an ECMP zone



f) Click **OK**, and then **Save**.

Step 5 Add equal-cost default static routes for both interfaces and enable SLA tracking on both.

The routes should be identical except for the gateway and should both have metric 1. The primary interface should already have a default route that you can edit.

Figure 292: Add/Edit static route

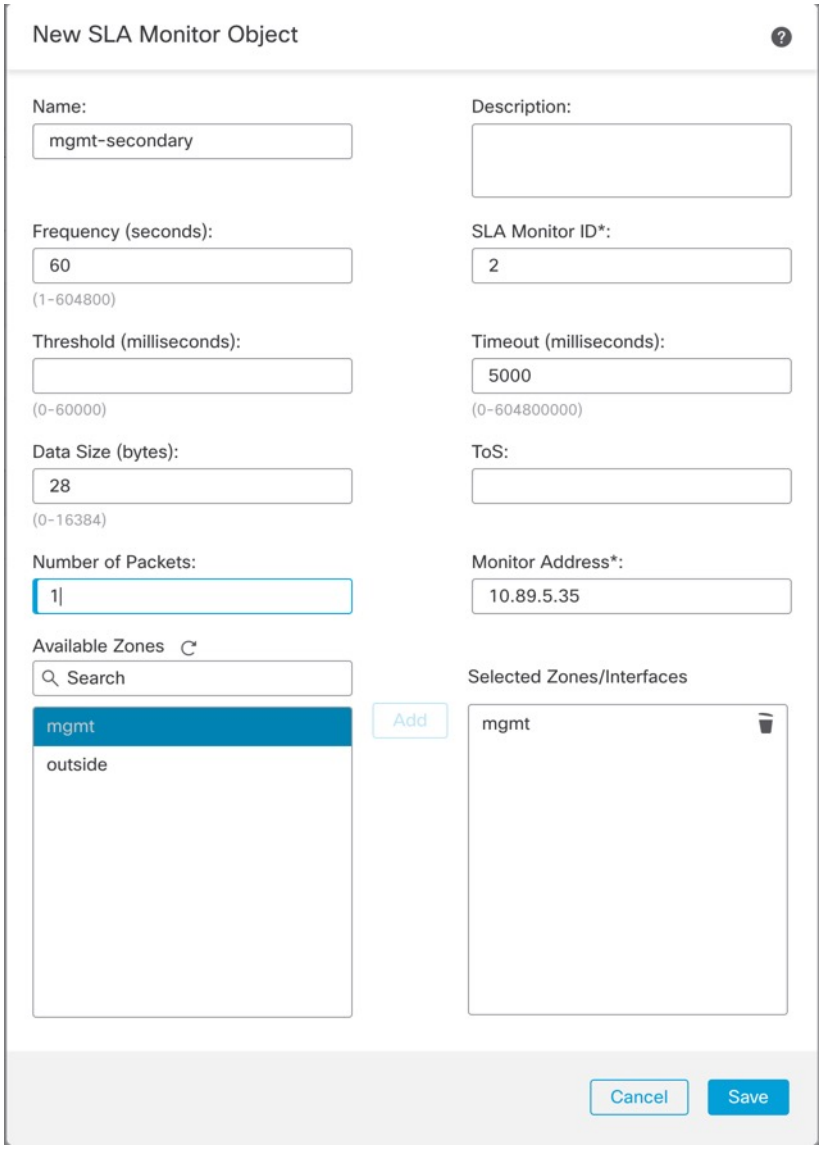
a) Click **Static Route**.

b) Either click **Add Route** to add a new route, or click **Edit** (✎) for an existing route.

c) From the **Interface** drop-down, choose the interface.

d) For the destination network, select **any-ipv4** from the **Available Networks** box and click **Add**.

e) Enter the default **Gateway**.



f) For **Route Tracking**, click **Add** (+) to add a new SLA monitor object.

g) Enter the required parameters including the following:

- The **Monitor Address** as the Cloud-Delivered Firewall Management Center IP address.
- The zone for the primary or secondary management interface in **Available Zones**; for example, choose the outside zone for the primary interface object, and the mgmt zone for the secondary interface object.

See Configure an SLA monitor, on page 3034 for more information.

Figure 293: Add SLA monitor

h) Click **Save**, then choose the SLA object you just created in the **Route Tracking** drop-down list.

i) Click **OK**, and then **Save**.

Repeat for the default route for the other management interface.

Step 6 Deploy configuration changes.

To deploy this feature, the Cloud-Delivered Firewall Management Center enables the secondary interface for management traffic, including auto-generated policy-based routing configuration for management traffic to get to the right data interface. The Cloud-Delivered Firewall Management Center also deploys a second instance of the **configure network management-data-interface** command. Note that if you edit the secondary

interface at the CLI, you cannot configure the gateway or otherwise alter the default route, because the static route for this interface can only be edited in the Cloud-Delivered Firewall Management Center.

Change manager access interface settings

Changing manager interface settings on the device or on the Cloud-Delivered Firewall Management Center can disrupt the management connection. Review these scenarios that change interface settings and reestablish the management connection.

Change the device IP address

Change the device IP address, and then update the address in the Cloud-Delivered Firewall Management Center.

Set the device IP address

Use one of these methods to set the manager access interface IP address.

Modify Firewall Threat Defense management interface settings at the CLI

Many management interface settings are set during device initial setup; this task allows you to update them, add event-only interfaces (if supported), or configure static routes, DNS domains, and other advanced settings. Use the CLI when you need direct device access or troubleshooting. If you wish to configure network settings for a data interface used for management, use the device management center interface instead.

Note This topic applies to the dedicated management interface. You can alternatively configure a data interface for management. If you want to change network settings for that interface, you should do so within Cloud-Delivered Firewall Management Center and not at the CLI. If you need to troubleshoot a disrupted management connection, and need to make changes directly on the Firewall Threat Defense , see Modify the Firewall Threat Defense data interface used for management at the CLI, on page 1163 .

For information about the Firewall Threat Defense CLI, see the *Cisco Secure Firewall Threat Defense Command Reference* .

Before you begin

- You can create user accounts that can log into the CLI using the **configure user add** command ; see Add an internal user at the CLI, on page 183 . You can also configure AAA users according to Configure external authentication, on page 1249 .
- Be cautious when making changes to the management interface using SSH. If you cannot re-connect because of a configuration error, access the device console port.
- In high-availability configurations, when you modify the management IP address of a registered device from the device CLI or from the Cloud-Delivered Firewall Management Center , the standby Cloud-Delivered Firewall Management Center does not reflect the changes even after a high-availability synchronization. To ensure that the standby Cloud-Delivered Firewall Management Center is also updated, switch roles between the two Cloud-Delivered Firewall Management Center s, making the secondary Cloud-Delivered Firewall Management Center as the active unit. Modify the management IP address of

the registered device on the **Device Management** page of the standby Cloud-Delivered Firewall Management Center .

Procedure

Step 1 Connect to the device CLI, either from the console port or using SSH.

Step 2 Log in with the Admin username and password.

Step 3 (Firepower 4100/9300 /Secure Firewall 4200 only) Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You always need a management interface for management traffic. If your device has a second management interface, you can enable it for event-only traffic.

(Optional) Disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

To use a separate event interface, you must enable an event-only interface on the Cloud-Delivered Firewall Management Center that is dedicated exclusively to event traffic. See the *Cisco Secure Firewall Management Center Administration Guide* .

Example:

```
> configure network management-interface enable management1
Configuration updated successfully
> configure network management-interface disable-management-channel management1
Configuration updated successfully
>
```

Step 4 Configure the IP address of the management interface and/or event interface:

If you do not specify the *management_interface* argument, then you change the network settings for the default management interface. When configuring an event interface, be sure to specify the *management_interface* argument. The event interface can be on a separate network from the management interface, or on the same network. If you are connected to the interface you are configuring, you will be disconnected. You can re-connect to the new IP address.

a) Configure the IPv4 address:

- Manual configuration:

  configure network ipv4 manual *ip_address netmask gateway_ip* [*management_interface*]

  Note that the *gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *gateway_ip* for use with

the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.
>
```

- DHCP (supported on the default management interface only):

  configure network ipv4 dhcp

b) Configure the IPv6 address:

- Stateless autoconfiguration:

  configure network ipv6 router [*management_interface*]

  Example:

  ```
  > configure network ipv6 router management0
  Setting IPv6 network configuration.
  Network settings changed.
  >
  ```

- Manual configuration:

  configure network ipv6 manual *ip6_address ip6_prefix_length* [*ip6_gateway_ip*] [*management_interface*]

  Note that the *ipv6_gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *ipv6_gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *ipv6_gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

  Example:

  ```
  > configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
  Setting IPv6 network configuration.
  Network settings changed.
  >
  ```

- DHCPv6 (supported on the default management interface only):

  configure network ipv6 dhcp

c) For IPv6, enable or disable ICMPv6 Echo Replies and Destination Unreachable messages. These messages are enabled by default.

configure network ipv6 destination-unreachable { **enable** | **disable** }

configure network ipv6 echo-reply { **enable** | **disable** }

You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the device management interfaces for testing purposes.

Example:

```
> configure network ipv6 destination-unreachable disable
> configure network ipv6 echo-reply disable
```

Step 5 Enable a DHCP server on the default management interface to provide IP addresses to connected hosts:

configure network ipv4 dhcp-server-enable *start_ip_address end_ip_address*

Example:

```
> configure network ipv4 dhcp-server-enable 10.10.10.200 10.10.10.254
DHCP Server Enabled
>
```

You can only configure a DHCP server when you set the management interface IP address manually. This command is not supported on the Firewall Management Center Virtual . To display the status of the DHCP server, enter **show network-dhcp-server** :

```
> show network-dhcp-server
DHCP Server Enabled
10.10.10.200-10.10.10.254
```

Step 6 Add a static route for the event-only interface if the Cloud-Delivered Firewall Management Center is on a remote network. Otherwise, all traffic will match the default route through the management interface.

configure network static-routes { **ipv4** | **ipv6** } **add** *management_interface destination_ip netmask_or_prefix gateway_ip*

For the default route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see Step 4, on page 1159).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully
> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully
>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes
---------------[ IPv4 Static Routes ]---------------
Interface                : management1
Destination              : 192.168.6.0
Gateway                  : 10.10.10.1
Netmask                  : 255.255.255.0
[…]
```

Step 7 Do these settings:

a) Set the hostname:

configure network hostname *name*

Example:

```
> configure network hostname farscape1.cisco.com
```

Syslog messages do not reflect a new hostname until after a reboot.

b) Set the search domains:

configure network dns searchdomains *domain_list*

Example:

```
> configure network dns searchdomains example.com,cisco.com
```

Set the search domain(s) for the device, separated by commas. These domains are added to hostnames when you do not specify a fully-qualified domain name in a command, for example, **ping system** . The domains are used only on the management interface, or for commands that go through the management interface.

c) Set up to 3 DNS servers, separated by commas:

configure network dns servers *dns_ip_list*

Example:

```
> configure network dns servers 10.10.6.5,10.20.89.2,10.80.54.3
```

d) Set the remote management port for communication with the Cloud-Delivered Firewall Management Center :

configure network management-interface tcpport *number*

Example:

```
> configure network management-interface tcpport 8555
```

The Cloud-Delivered Firewall Management Center and managed devices communicate using a two-way, TLS-1.3-encrypted communication channel, which by default is on port 8305. Do not change the management port when using multi-instance mode; only port 8305 is supported.

Note
We recommend that you keep the default settings for the remote management port, but if the management port conflicts with other communications on your network, you can choose a different port. If you change the management port, you must change it for *all* devices in your deployment that need to communicate with each other.

e) (Firewall Threat Defense only) Set the management or eventing interface MTU. The MTU is 1500 bytes by default.

configure network mtu [*bytes*] [*interface_id*]

- *bytes* —Sets the MTU in bytes. For the management interface, the value can be between 64 and 1500 if you enable IPv4, and 1280 to 1500 if you enable IPv6. For the eventing interface, the value can be between 64 and 9000 if you enable IPv4, and 1280 to 9000 if you enable IPv6. If you enable both IPv4 and IPv6, then the minimum is 1280. If you do not enter the *bytes* , you are prompted for a value.
- *interface_id* —Specifies the interface ID on which to set the MTU. Use the **show network** command to see available interface IDs, for example management0, management1, br1, and eth0, depending on the platform. If you do not specify an interface, then the management interface is used.

Example:

```
> configure network mtu 8192 management1
MTU set successfully to 1500 from 8192 for management1
Refreshing Network Config...
NetworkSettings::refreshNetworkConfig MTU value at start 8192
Interface management1 speed is set to '10000baseT/Full'
NetworkSettings::refreshNetworkConfig MTU value at end 8192
>
```

f) Configure an HTTP proxy. The device is configured to directly connect to the internet on ports TCP/443 (HTTPS) and TCP/80 (HTTP). You can use a proxy server, to which you can authenticate via HTTP

Digest. After issuing the command, you are prompted for the HTTP proxy address and port, whether proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Note
For proxy password on Firewall Threat Defense , you can use A-Z, a-z, and 0-9 characters only.

configure network http-proxy

Example:

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address: 10.100.10.10
Enter HTTP Proxy Port: 80
Use Proxy Authentication? (y/n) [n]: Y
Enter Proxy Username: proxyuser
Enter Proxy Password: proxypassword
Confirm Proxy Password: proxypassword
```

Step 8 If you change the device management IP address, then see the following tasks for Cloud-Delivered Firewall Management Center connectivity. Perform these tasks depending on how you identified the Cloud-Delivered Firewall Management Center during initial device setup using the **configure manager add** command :

- **IP address — No action.** If you identified the Cloud-Delivered Firewall Management Center using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in Cloud-Delivered Firewall Management Center to keep the information in sync; see Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center, on page 1167. This action can help reestablish the connection faster. If you specified an unreachable Cloud-Delivered Firewall Management Center IP address, then you must manually reestablish the connection using Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center, on page 1167
- **NAT ID only — Manually reestablish the connection.** If you identified the Cloud-Delivered Firewall Management Center using only the NAT ID, then the connection does not automatically reestablish. In this case, change the device management IP address in Cloud-Delivered Firewall Management Center according to Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center, on page 1167 .

Modify the Firewall Threat Defense data interface used for management at the CLI

This task allows you to specify a new data interface to replace the old interface when the management connection has been disrupted and you need to restore connectivity between the Firewall Threat Defense and the Cloud-Delivered Firewall Management Center.

If the management connection is active, make changes to an existing data interface using the Cloud-Delivered Firewall Management Center (see Modify the Firewall Threat Defense data interface used for management in the GUI, on page 1166). For initial setup of the data management interface, see the **configure network management-data-interface** command.

For high-availability pairs, perform all CLI steps on both units. Within the Cloud-Delivered Firewall Management Center, perform steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Note This topic applies to the data interface that you configured for Management, not the dedicated Management interface. If you want to change network settings for the Management interface, see Modify Firewall Threat Defense management interface settings at the CLI , on page 1158.

For information about the Firewall Threat Defense CLI, see the *Cisco Secure Firewall Threat Defense Command Reference*.

Before you begin

If you are changing the data management interface to a new interface, move the current interface cable to the new interface.

Procedure

Step 1 Connect to the device CLI.

Use the console port when executing these commands. If you are performing initial setup, then you may be disconnected from the Management interface. If you are editing the configuration due to a disrupted management connection and have SSH access to the dedicated management interface, you can use the SSH connection.

a) Log in with the **admin** username and password.

Step 2 Disable the interface so you can reconfigure its settings.

configure network management-data-interface disable

Note
If you only want to set a new IPv4 address on the same interface and not make any other changes, you can skip this step. Other changes require you to disable the interface first.

Example:

```
> configure network management-data-interface disable

 Configuration updated successfully..!!

Configuration disable was successful, please update the default route to point to a gateway
 on management interface using the command 'configure network'
```

Step 3 Configure the new data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

If you change the data management interface to a new interface on the same network, use the same settings as for the previous interface except the interface ID. In addition, for the **Do you wish to clear all the device configuration before applying ? (y/n) [n]:** option, choose **y**. This choice will clear the old data management interface configuration, so that you can successfully reuse the IP address and interface name on the new interface.

```
> configure network management-data-interface
```

```
Data interface to use for management: ethernet1/4
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]: y

Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

a) Limit data interface access to the Cloud-Delivered Firewall Management Center on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

Step 4 Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center, on page 1167.

The connection may be reestablished automatically, but disabling and reenabling the connection in the Cloud-Delivered Firewall Management Center will help the connection reestablish faster. Or you may need to update the device IP address in the Cloud-Delivered Firewall Management Center according to the linked procedure.

Step 5 Check that the management connection was reestablished.

sftunnel-status-brief

See the sample output for a connection that is up, with peer channel and heartbeat information:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
 '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Step 6 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and click **Edit** (). In the **Device** area, against the **Management** field, click **Refresh** next to **Manager Access - Configuration Details**.

The Cloud-Delivered Firewall Management Center detects the interface and default route configuration changes and blocks deployment to the device. When you change the data interface settings locally on the device, you must reconcile those changes in the Cloud-Delivered Firewall Management Center manually. You can view the discrepancies between the Cloud-Delivered Firewall Management Center and the device on the **Configuration** tab.

Step 7 Choose **Interfaces**, and make the changes.

a) Remove the IP address and name from the old data management interface and disable manager access for this interface.
b) Configure the new data management interface with the new settings (the ones you used at the CLI) and enable manager access for it.

Step 8 Under the **Routing** tab, click **Static Route**, and change the default route from the old data management interface to the new one.

Step 9 Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

The next time you deploy, the Cloud-Delivered Firewall Management Center configuration will overwrite any remaining conflicting settings on the Firewall Threat Defense. It is your responsibility to manually fix the configuration in the Cloud-Delivered Firewall Management Center before you re-deploy.

You will see expected messages of "Config was cleared" and "Manager access changed and acknowledged."

Modify the Firewall Threat Defense data interface used for management in the GUI

Configure the data interface IP address settings to change the management connection or update the interface used for manager access.

If the management connection is up but you want to change the IP address of the data interface used for manager access, follow these steps. For example, if you register a device using zero-touch provisioning, then you need to change the IP address to a static address before you can enable high availability.

You can alternatively change interface settings at the CLI, but we recommend using that method only if the management connection is down. Any changes you make at the CLI should be replicated in the GUI.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the device.

Step 2 Choose **Interfaces**.

Step 3 If you want to change the interface used for manager access:

a) Remove the IP address and name from the old data management interface and disable manager access for this interface.
b) Configure the new data management interface with the new settings and enable manager access for it.
c) If you use a static IP address, you are reminded to make sure you have a default route. Click **Yes**.
d) Click **OK** to exit the interface.
e) Click **Save** on the **Interfaces** page.

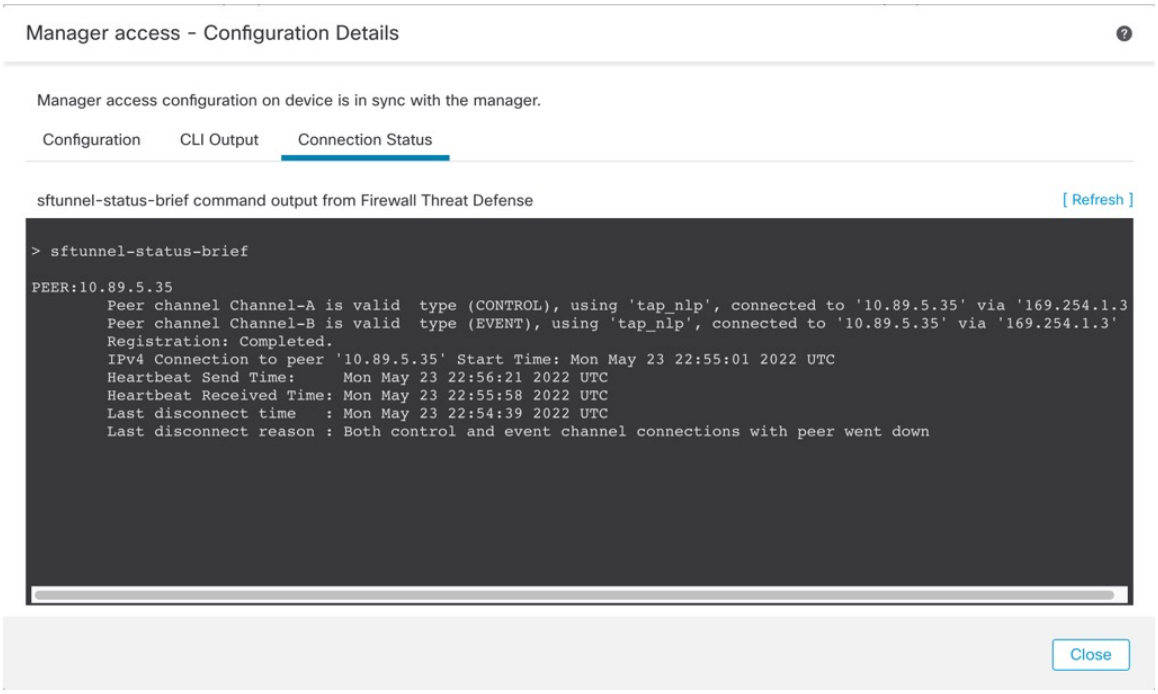
Step 4 If you only want to change the IP address:

a) Change the IP address.
b) For a static IP address, you are reminded to make sure you have a default route. Click **Yes**.
c) Click **OK** to exit the interface.
d) Click **Save** on the **Interfaces** page.

Step 5 Click the **Routing** tab, click **Static Route**, and then add or change the default or static route for the manager access interface.

Step 6 Deploy configuration changes.

The Cloud-Delivered Firewall Management Center will deploy the configuration changes over the current connection. After the deployment, the data interface will have a new IP address, so the management connection will need to be reestablished.



Step 7 Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center, on page 1167.

Step 8 Ensure the management connection is reestablished.

In the **Device** area, against the **Management** field, click **Manager Access Details: Configuration** and then click **Connection Status**.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 294: Connection status

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 1183.

Update the Hostname or IP Address in the Cloud-Delivered Firewall Management Center

This task allows you to manually update the hostname or IP address on the managing Cloud-Delivered Firewall Management Center when device network settings have been modified outside of the management interface.

If you edit the hostname or IP address of a device after you added it to the Cloud-Delivered Firewall Management Center (using the device's CLI, for example), you need to use this procedure to manually update the hostname or IP address on the managing Cloud-Delivered Firewall Management Center.

To change the device management IP address on the device, see Modify Firewall Threat Defense management interface settings at the CLI , on page 1158.

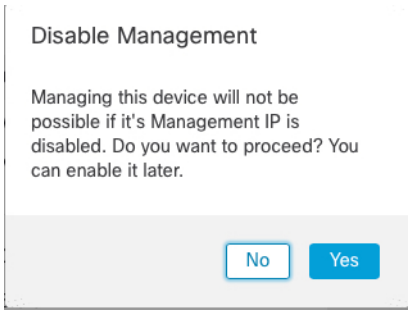
If you used only the NAT ID when registering the device, then the IP shows as **NO-IP** on this page, and you do not need to update the IP address/hostname.

If you used zero-touch provisioning to register the device on the outside interface, the hostname is automatically generated along with a matching DDNS configuration. You cannot edit the hostname in this case.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to modify management options, click **Edit** ( ).



Step 3 Click **Device** and view the **Management** area.

Step 4 Disable management temporarily by clicking the slider so it is disabled **Slider disabled** ( ).

Figure 295: Disable management

You are prompted to proceed with disabling management; click **Yes**.

Disabling management blocks the connection between the Cloud-Delivered Firewall Management Center and the device, but does **not** unregister the device from the Cloud-Delivered Firewall Management Center.

Step 5 Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** ( ).

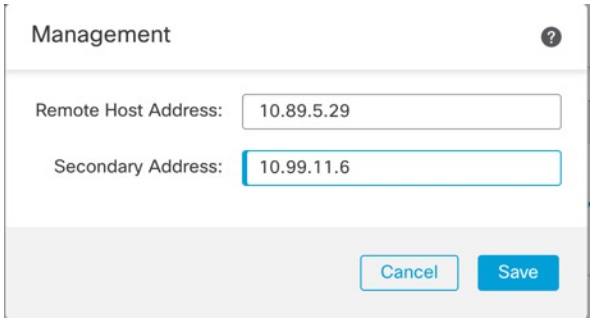


Figure 296: Edit management address

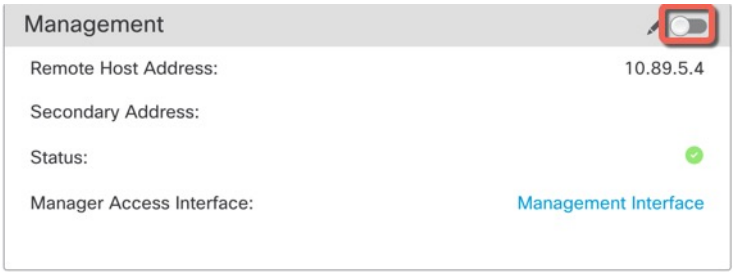
Step 6 In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field. Click **Save**.



For information about using a secondary manager access data interface, see Configure a redundant manager access data interface, on page 1153.

Figure 297: Management IP address

Step 7 Reenable management by clicking the slider so it is enabled **Slider enabled** ( ).

Figure 298: Enable management connection

Change the Cloud-Delivered Firewall Management Center IP Address

This task ensures the Cloud-Delivered Firewall Management Center IP address or hostname matches between the management center and device CLI, maintaining consistent configurations and network resiliency.

If you change the Cloud-Delivered Firewall Management Center IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the Cloud-Delivered Firewall Management Center IP

address or hostname on the device, in at least one case, you must perform this task for the connection to be reestablished: when you added the device to the Cloud-Delivered Firewall Management Center and you specified the NAT ID only. Even in other cases, we recommend keeping the Cloud-Delivered Firewall Management Center IP address or hostname up to date for extra network resiliency.

Procedure

Step 1 Change the Cloud-Delivered Firewall Management Center IP address.

Caution
Be careful when making changes to the Cloud-Delivered Firewall Management Center interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the Cloud-Delivered Firewall Management Center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** (⚙) > **Configuration** > **Management Interfaces**.
b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 2 At the Firewall Threat Defense CLI, view the Cloud-Delivered Firewall Management Center identifier.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
Management type           : Configuration
```

Step 3 At the Firewall Threat Defense CLI, edit the Cloud-Delivered Firewall Management Center IP address or hostname.

configure manager edit *identifier* {**hostname** {*ip_address* | *hostname*} | **displayname** *display_name*}

If the Cloud-Delivered Firewall Management Center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

The management connection will go down, and then reestablish. You can monitor the state of the connection using the **sftunnel-status** command.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 hostname 10.10.5.1
```

Change both Cloud-Delivered Firewall Management Center and Threat Defense IP addresses

You might want to change both Cloud-Delivered Firewall Management Center and Firewall Threat Defense IP addresses if you need to move them to a new network.

Procedure

Step 1 Disable the management connection.

For a high-availability pair or cluster, perform these steps on all units.

a) Choose **Devices** > **Device Management**.

b) Next to the device, click **Edit** ( ).

c) Click **Device**, and view the **Management** area.

d) Disable management temporarily by clicking the slider so it is disabled ( ).

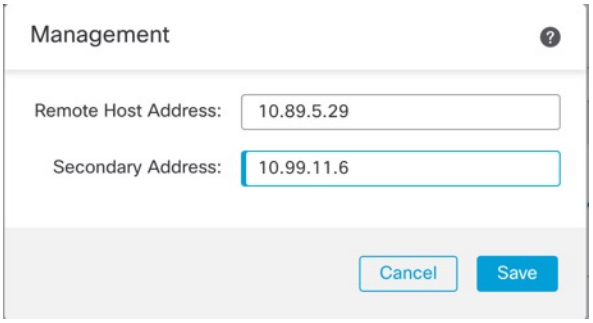
Figure 299: Disable Management

You are prompted to proceed with disabling management; click **Yes**.

Step 2 Change the device IP address in the Cloud-Delivered Firewall Management Center to the new device IP address.

You will change the IP address on the device later.

For a high-availability pair or cluster, perform these steps on all units.



a) Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** ( ).

Figure 300: Edit Management Address

b) In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field, and click **Save**.

Figure 301: Management IP Address

Step 3 Change the Cloud-Delivered Firewall Management Center IP address.

Caution
Be careful when making changes to the Cloud-Delivered Firewall Management Center interface to which you are connected. If you cannot re-connect because of a configuration error, you need to access the Cloud-Delivered Firewall Management Center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** (⚙) > **Configuration** > **Management Interfaces**.
b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 4 Change the manager IP address on the device.

For a high-availability pair or cluster, perform these steps on all units.

a) At the Firewall Threat Defense CLI, view the Cloud-Delivered Firewall Management Center identifier.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
Management type           : Configuration
```

b) Edit the Cloud-Delivered Firewall Management Center IP address or hostname.

configure manager edit *identifier* { **hostname** { *ip_address* | *hostname* } | **displayname** *display_name* }

If the Cloud-Delivered Firewall Management Center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

Example:

```
                                > configure manager edit
f7ffad78-bf16-11ec-a737-baa2f76ef602
```

```
hostname
10.10.5.1
```

Step 5 Change the IP address of the manager access interface at the console port.

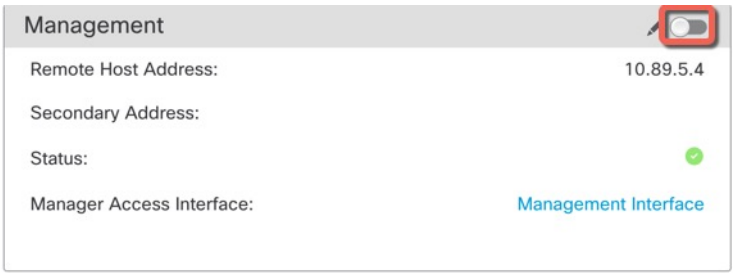
For a high-availability pair or cluster, perform these steps on all units.

If you use the dedicated Management interface:

configure network ipv4

configure network ipv6

If you use the dedicated Management interface:



configure network management-data-interface disable

configure network management-data-interface

Step 6 Re-enable management by clicking the slider ( ).

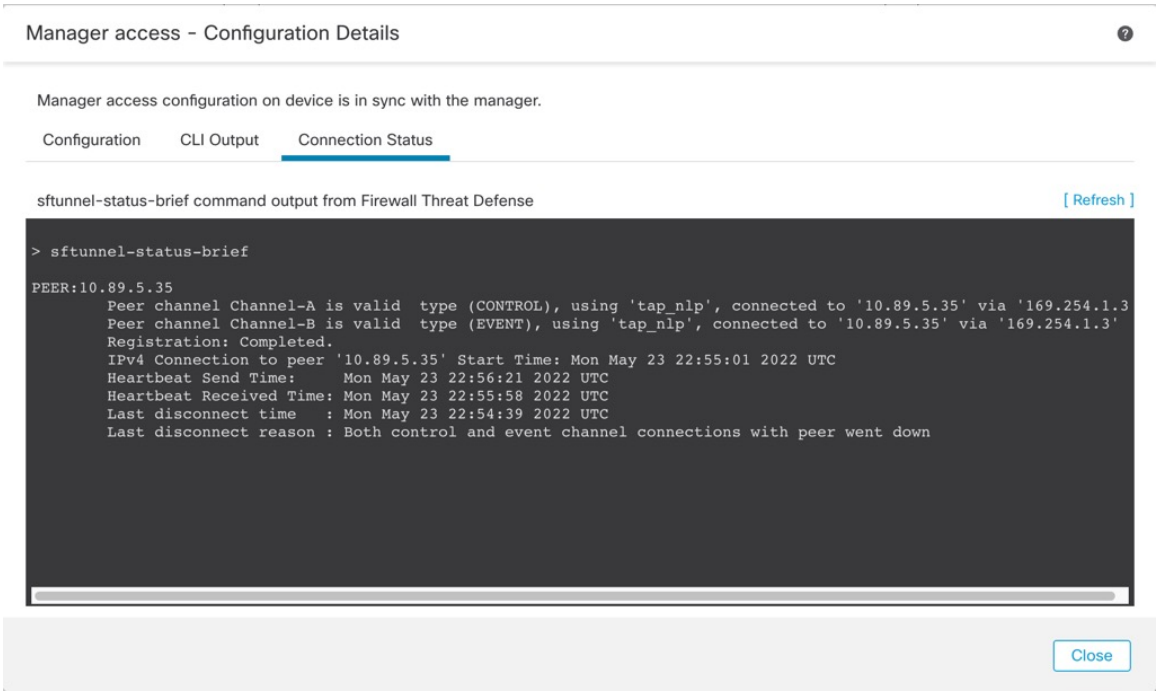
For a high-availability pair or cluster, perform these steps on all units.

Figure 302: Enable Management Connection

Step 7 (If you use a data interface for manager access) Refresh the data interface settings in the Cloud-Delivered Firewall Management Center.

For a high-availability pair, perform this step on both units.

a) Choose **Devices** > **Device Management**, and click **Manager Access - Configuration Details** , and then click **Refresh**.
b) Choose **Devices** > **Device Management**, and click the **Interfaces** tab and set the IP address to match the new address.
c) Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.



Step 8 Ensure the management connection is reestablished.

In the Cloud-Delivered Firewall Management Center, check the management connection status. Navigate to the **Devices** > **Device Management**, and click **Management** section under the **Device** tab. Then, click **Manager Access - Configuration Details** to view the **Connection Status** page.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

This status indicates a successful connection for a data interface and displays the internal "tap_nlp" interface.

Figure 303: Connection Status

Step 9 (For a high-availability Cloud-Delivered Firewall Management Center pair) Repeat configuration changes on the secondary Cloud-Delivered Firewall Management Center.

a) Change the secondary Cloud-Delivered Firewall Management Center IP address.
b) Specify the new peer addresses on both units.
c) Make the secondary unit the active unit.
d) Disable the device management connection.
e) Change the device IP address in the Cloud-Delivered Firewall Management Center.
f) Re-enable the management connection.

Change the manager access interface

After you register the device, you can change the manager access interface between the Management interface and a data interface.

Change the manager access interface from management to data

You can manage the Firewall Threat Defense from either the dedicated management interface or from a data interface. If you want to change the manager access interface after you added the device to the Cloud-Delivered Firewall Management Center , follow these steps to migrate from the Management interface to a data interface. To migrate the other direction, refer to Change the manager access interface from data to management, on page 1178 .

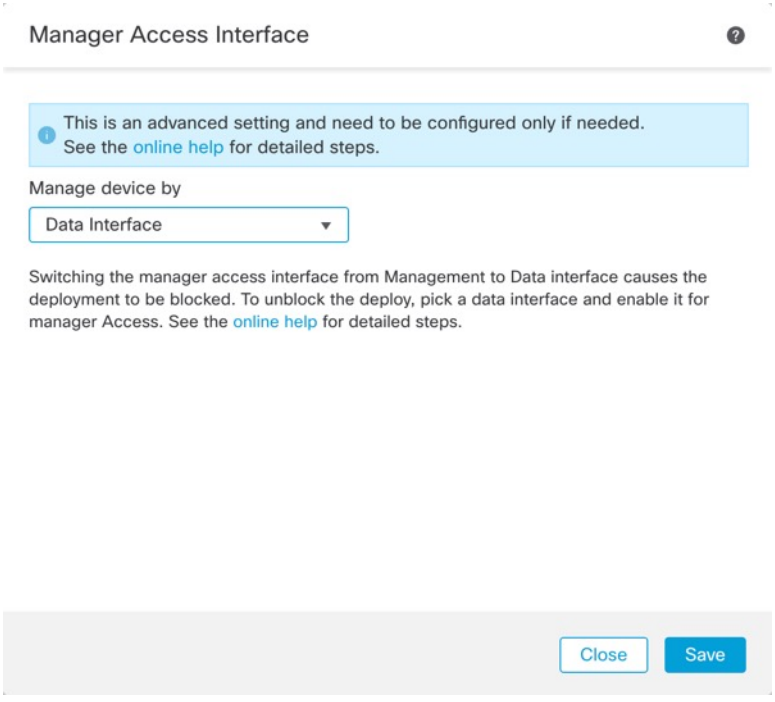
When you initiate the manager access migration from management to data, the Cloud-Delivered Firewall Management Center applies a block on deployment to the Firewall Threat Defense. To remove the block, enable manager access on the data interface.

Before you begin

For high-availability pairs:

- Ensure that you configure a standby IP address for data-managed interfaces before changing the manager access interface from management to data. For more information about configuring standby IP address, refer to Configure standby IP addresses and interface monitoring, on page 708.
- For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. After deploying the configuration changes, the standby unit synchronizes configuration and other state information from the active unit.
-

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. After deploying the configuration changes, the standby unit synchronizes configuration and other state information from the active unit.



Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** (✎) for the device. Click **Device** , and in the **Management** area, click the **Manager Access Interface** link.

The **Manager Access Interface** field shows the current Management interface. When you click the link, choose the new interface type, **Data Interface** , in the **Manage device by** drop-down list.

Figure 304: Manager Access Interface

b) Click **OK** and then **Close** .

You must now complete the remaining steps in this procedure to enable manager access on the data interface. The **Management** area now shows **Manager Access Interface: Data Interface** , and **Manager Access Details: Configuration** .

Figure 305: Manager Access

If you click **Configuration** , the **Manager Access - Configuration Details** dialog box opens. The **Manager Access Mode** shows a Deploy pending state.

Step 2 Enable manager access on the data interface (s) . Click **Interfaces** , click **Edit** ( ) for the interface, and then click **Manager Access** .

Check **Enable management access** and click **OK** . By default, all networks are allowed, but you can limit access as long as the Cloud-Delivered Firewall Management Center address is allowed.

If the manager access interface uses a static IP address, you are reminded to configure routing for it.

Click **Save** on the **Interfaces** page. See Configure routed mode interfaces, on page 1080 for more information about interface settings. You can enable manager access on one routed data interface , plus an optional secondary interface . Make sure these interfaces are fully configured with a name and IP address and that they are enabled.

If you use a secondary interface for redundancy, see Configure a redundant manager access data interface, on page 1153 for additional required configuration.

Step 3 (Optional) If you use DHCP for the interface, enable the web type DDNS method on the DDNS page. Navigate to **Devices** > **Device Management** , and then click **DDNS** under the **DHCP** tab.

See Configure Dynamic DNS, on page 1234 . DDNS ensures the Cloud-Delivered Firewall Management Center can reach the Firewall Threat Defense at its Fully-Qualified Domain Name (FQDN) if the FTD's IP address changes.

Step 4 Make sure the Firewall Threat Defense can route to the Cloud-Delivered Firewall Management Center through the data interface. Add a static route if necessary on the Static Route page. Navigate to **Devices** > **Device Management** and then click **Static Route** under the **Routing** tab.

See Add a static route, on page 1361 .

Step 5 (Optional) Configure DNS in a Platform Settings policy: choose **Devices** > **Platform Settings** , and click **DNS** . Apply the policy to this device.

See Configure DNS server settings, on page 1246 . DNS is required if you use DDNS. You may also use DNS for FQDNs in your security policies.

Step 6 (Optional) Enable SSH for the data interface in a Platform Settings policy, and apply it to this device at **Devices** > **Device Management** page. Click **Edit** ( ) for the device and then click **SSH Access** .

See Configure Secure Shell (SSH) access, on page 1262 . SSH is not enabled by default on the data interfaces, so if you want to manage the Firewall Threat Defense using SSH, you need to explicitly allow it.

Step 7 Deploy configuration changes.

You will see a validation error to confirm that you are changing the manager access interface. Check **Ignore warnings** and deploy again.

The Cloud-Delivered Firewall Management Center will deploy the configuration changes over the current Management interface. After the deployment, the data interface is now ready for use, but the original management connection to Management is still active.

Step 8 After deployment, perform these actions.

a) At the Firewall Threat Defense CLI (preferably from the console port), set the Management interface to use a static IP address and set the gateway to use the data interfaces. For high availability, perform this step on both units.

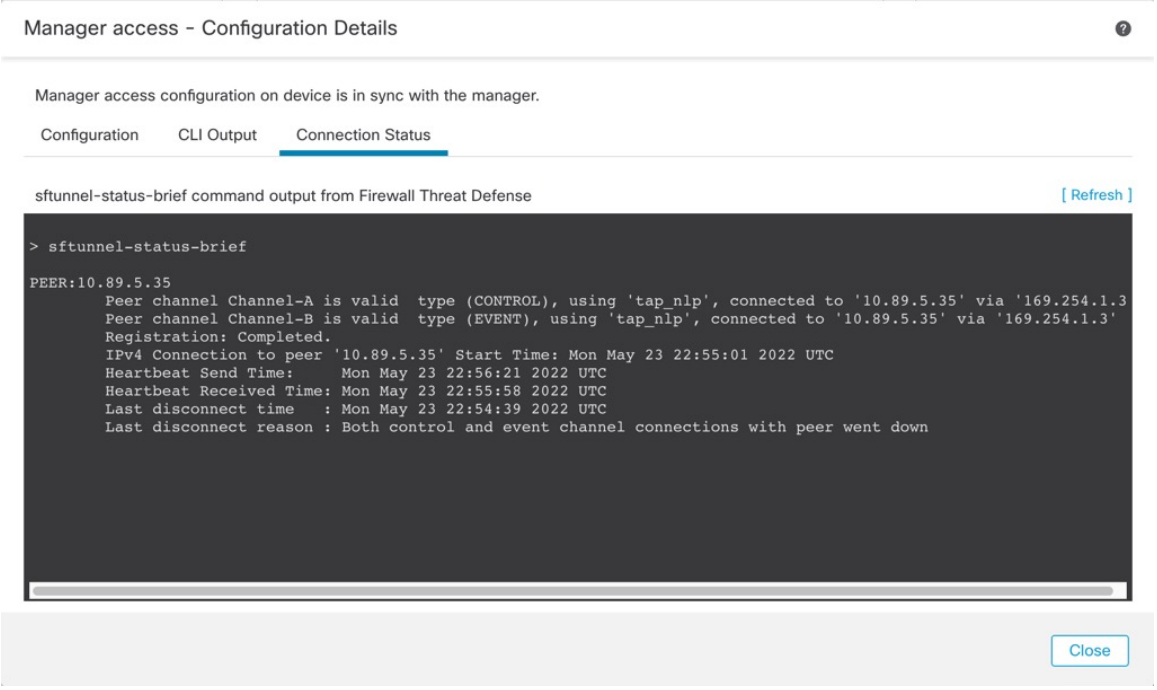
```
configure network
{
ipv4
 |
ipv6
}
manual
ip_address netmask
data-interfaces
```

- *ip_address netmask* —Although you do not plan to use the Management interface, you must set a static IP address, for example, a private address so that you can set the gateway to **data-interfaces** (see the next bullet). You cannot use DHCP because the default route, which must be **data-interfaces** , might be overwritten with one received from the DHCP server.
- **data-interfaces** —This setting forwards management traffic over the backplane so it can be routed through the manager access data interface.

We recommend that you use the console port instead of an SSH connection because when you change the Management interface network settings, your SSH session will be disconnected.

b) If necessary, re-cable the Firewall Threat Defense so it can reach the Cloud-Delivered Firewall Management Center on the data interface. For high availability, perform this step on both units.

c) In the Cloud-Delivered Firewall Management Center, disable the management connection for the Firewall Threat Defense in the **Devices** > **Device Management** page in the **Management** area under the **Device** tab, and then re-enable the connection.



Step 9 Ensure the management connection is reestablished.

In the **Devices** > **Device Management** page, click **Manager Access Details: Configuration** and then click **Connection Status** .

Alternatively, you can check at the Firewall Threat Defense CLI. Enter the **sftunnel-status-brief** command to view the management connection status.

This status indicates a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 306: Connection Status

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 1183 .

Change the manager access interface from data to management

This task enables you to migrate manager access from a data interface to the dedicated management interface, allowing you to manage the Firewall Threat Defense through the Management interface instead of a data interface.

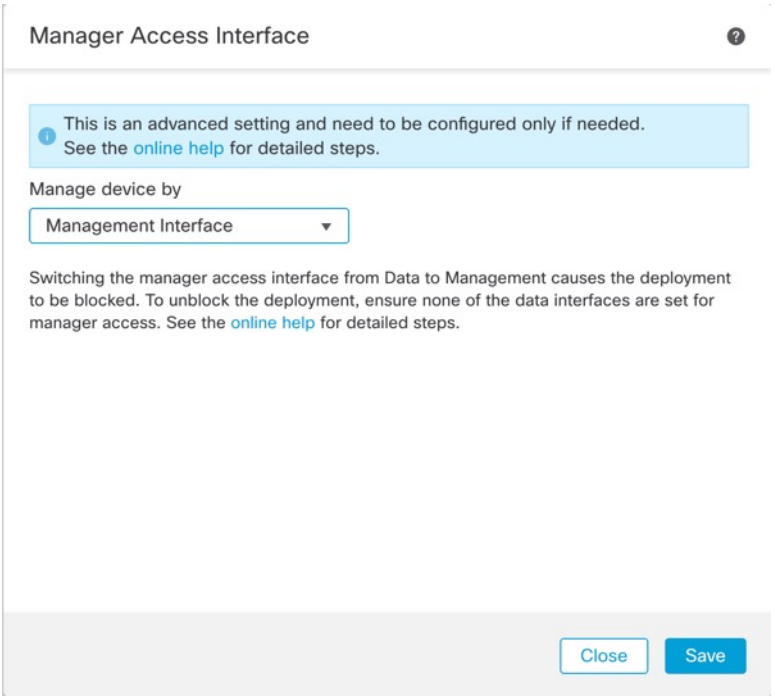
You can manage the Firewall Threat Defense from either the dedicated management interface or from a data interface. If you want to change the manager access interface after you added the device to the Cloud-Delivered Firewall Management Center, follow these steps to migrate from a data interface to the management interface. To migrate the other direction, see Change the manager access interface from management to data, on page 1174.

Initiating the manager access migration from data to management causes the Cloud-Delivered Firewall Management Center to apply a block on deployment to the Firewall Threat Defense. You must disable manager access on the data interface to remove the block.

Before you begin

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Follow these steps to disable manager access on a data interface, and also configure other required settings.



Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** (✎) for the device. Click **Device**, and in the **Management** area, click the link for **Manager Access Interface**.

The **Manager Access Interface** field shows the current management interface as data. When you click the link, choose the new interface type, **Management Interface**, in the **Manage device by** drop-down list.

Figure 307: Manager access interface

b) Click **Save**.

Click **OK** and then **Close**.

You must now complete the remaining steps in this procedure to enable manager access on the Management interface. The **Management** area now shows the **Manager Access Interface: Management Interface**.

Figure 308: Manager access

Step 2 Disable manager access on the data interface(s). Click **Interfaces**, click **Edit** (✎) for the interface, and then click **Manager Access**.

Uncheck **Enable management access** and click **OK**. Click **Save** on the **Interfaces** page. This step removes the block on deployment.

Step 3 If you have not already done so, configure DNS settings for the data interface in a Platform Setting policy, and apply it to this device at **Devices** > **Device Management** page. Click **Edit** (✎) for the device and then click **DNS**.

See Configure DNS server settings, on page 1246. The Cloud-Delivered Firewall Management Center deployment that disables manager access on the data interface will remove any local DNS configuration. If that DNS server is used in any security policy, such as an FQDN in an Access Rule, then you must re-apply the DNS configuration using the Cloud-Delivered Firewall Management Center.

Step 4 Deploy configuration changes.

The Cloud-Delivered Firewall Management Center will deploy the configuration changes over the current data interface.

Step 5 If necessary, re-cable the Firewall Threat Defense so it can reach the Cloud-Delivered Firewall Management Center on the Management interface. For High Availability, perform this step on both units.

Step 6 At the Firewall Threat Defense CLI, configure the Management interface IP address and gateway using a static IP address or DHCP. For high availability, perform this step on both units.

When you originally configured the data interface for manager access, the Management gateway was set to data-interfaces, which forwarded management traffic over the backplane so it could be routed through the manager access data interface. You now need to set an IP address for the gateway on the management network.

Static IP address:

configure network {**ipv4** | **ipv6**} **manual** *ip_address netmask gateway_ip*

DHCP:

configure network {**ipv4** | **ipv6**} **DHCP**

Step 7 In the Cloud-Delivered Firewall Management Center, disable the management connection for the Firewall Threat Defense in the **Devices** > **Device Management**, **Management** section under **Device** tab, and then reenable the connection.

Step 8 Ensure the management connection is reestablished.

In the Cloud-Delivered Firewall Management Center, check the management connection status on the **Devices** > **Device Management**, **Management** section under **Device** tab, **Status** field or view notifications in the Cloud-Delivered Firewall Management Center.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 1183.

Troubleshoot the management connection

This reference provides information to help diagnose and resolve management connection issues.

Manually Roll Back the configuration if the Cloud-Delivered Firewall Management Center loses Connectivity

Use this task to restore management connectivity when a configuration change deployed from the Cloud-Delivered Firewall Management Center affects network connectivity and you need to roll back to the last-deployed configuration.

If you use a data interface on the Firewall Threat Defense for manager access and deploy a configuration change from the Cloud-Delivered Firewall Management Center that affects network connectivity, you can roll back the configuration on the Firewall Threat Defense to the last-deployed configuration to restore management connectivity. Afterward, update the configuration settings in Cloud-Delivered Firewall Management Center to maintain network connectivity, and re-deploy. You can use the rollback feature even if you do not lose connectivity; it is not limited to this troubleshooting situation.

Alternatively, you can enable auto rollback of the configuration if you lose connectivity after a deployment; see Edit deployment settings, on page 1192.

See these guidelines:

- Only the previous deployment is available locally on the Firewall Threat Defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- Rollback is not supported immediately after high availability creation.
- The rollback only affects configurations that you can set in the Cloud-Delivered Firewall Management Center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the Firewall Threat Defense CLI. Note that if you changed data interface settings after the last Cloud-Delivered Firewall Management Center deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed Cloud-Delivered Firewall Management Center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

Step 1 At the Firewall Threat Defense CLI, roll back to the previous configuration.

configure policy rollback

Note
For a high availability pair, this command is allowed only on the active unit.

After the rollback, the Firewall Threat Defense notifies the Cloud-Delivered Firewall Management Center about the successful completion. The deployment screen In the Cloud-Delivered Firewall Management Center displays a banner indicating that the configuration was rolled back.

Note
If the rollback fails and the Cloud-Delivered Firewall Management Center management is restored, refer to https://www.cisco.com/c/en/us/support/docs/security/firepower-ngfw-virtual/215258-troubleshooting-firepower-threat-defense.html for common deployment problems. In some cases, the rollback may fail after the Cloud-Delivered Firewall Management Center management access is restored. Resolve any Cloud-Delivered Firewall Management Center configuration issues and redeploy from the Cloud-Delivered Firewall Management Center.

Example:

For the Firewall Threat Defense that uses a data interface for manager access:

```
> configure policy rollback

The last deployment to this FTD was on June 1, 2020 and its status was Successful.
Do you want to continue [Y/N]?

Y

Rolling back complete configuration on the FTD. This will take time.
.....................
Policy rollback was successful on the FTD.
Configuration has been reverted back to transaction id:
Following is the rollback summary:
.....................
.....................
>
```

Example:

For Firewall Threat Defenses in a high availability pair that use a data interface for Cloud-Delivered Firewall Management Center access:

```
> configure policy rollback

Checking Eligibility ....
============= DEVICE DETAILS =============
Device Version: 7.2.0
Device Type: FTD
Device Mode: Offbox
Device in HA: true
Is HA disabled: false
HA state: active - standby ready
==========================================
Device is eligible for policy rollback

```

Step 2 Check that the management connection was reestablished.

In Cloud-Delivered Firewall Management Center, check the management connection status on the Connection Status page. Navigate to **Devices** > **Device Management** and then navigate to **Management** area under the **Devices** tab. Then in the **Manager Access - Configuration Details** screen, click **Connection Status**.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 1183.

Troubleshoot Management Connectivity on a Data Interface

This topic helps you troubleshoot the loss of management connectivity when using a data interface for manager access instead of the dedicated Management interface.

If you use a data interface for manager access instead of the dedicated Management interface, exercise caution when changing the interface and network settings for the Firewall Threat Defense in the Cloud-Delivered Firewall Management Center to avoid disrupting the connection. If you change the management interface type after adding the Firewall Threat Defense to the Cloud-Delivered Firewall Management Center (switching between data and Management interfaces), misconfiguration of interfaces and network settings can result in loss of management connectivity.

Use the following methods to troubleshoot management connectivity:

- View management connection status: Check the status in the **Devices** > **Device Management** page or use **sftunnel-status-brief** at the CLI.
- View network information: Use **show network** to verify Management and manager access data interface settings.
- Check registration: Use **show managers** to confirm registration completion.
- Ping the manager: Use **ping** or **ping system** to test connectivity.
- Capture packets: Use **capture** on the `nlp_int_tap` interface to trace management traffic.
- Check interface status: Use **show interface detail** for the `nlp_int_tap` interface.
- Check routing and NAT: Use **show route** and **show nat** to verify routing and internal NAT rules.
- Check DDNS: Use **debug ddns** and related commands to verify DDNS updates.

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went
down
```

```
> show network
===============[ System Information ]===============
Hostname                  : FTD-4
Domains                   : cisco.com
DNS Servers               : 72.163.47.11
DNS from router           : enabled
Management port           : 8305
IPv4 Default route
Gateway                 : data-interfaces
...
```

Note At the Firewall Threat Defense CLI, check that the Cloud-Delivered Firewall Management Center registration was completed. Note that this command will not show the *current* status of the management connection.

Refer to https://cisco.com/go/fmc-reg-error for Cloud-Delivered Firewall Management Center log file information.

Troubleshoot management connectivity on a data interface in a High Availability pair

This topic provides troubleshooting steps for management connectivity issues on data interfaces in High Availability, covering scenarios involving interface connectivity failures and ISP changes.

The management connection between the active peer and the Security Cloud Control can be disrupted due to the following reasons:

- Connectivity issues on the data interface that is used for management on the active unit.
- Change in internet service provider (ISP).

Follow these procedures to restore connectivity based on the identified cause:

- Connectivity issues: Manually fail over to the standby unit and configure a new data interface for Security Cloud Control access.
- ISP change: Manually update the new network details on the active unit using CLI commands to restore device connectivity.

Data management interface on active unit has connectivity issues

1. In Security Cloud Control , manually switch the active unit to standby. See Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 710 .

   As an alternative, you can run the **no failover active** command on the active unit.

2. Next to the device high-availability pair you want to edit, click **Edit** ( ).
3. Choose **Routing** > **Static Route** and delete the static route defined for the old data management interface.
4. Click the **Interfaces** tab to remove the old interface configuration and configure the new data management interface.

Note Before removing the old data management interface information, remember the details if you want to use the same information.

5. Click the **High Availability** tab to update the **Monitored Interfaces** and **Standby IP Address** for the new interface.
6. Click **Save** and add the static route for the new data management interface under **Routing > Static Route** .
7. Deploy configuration changes. .
8. Re-cable the FTD when deployment reaches 90 percent so the Security Cloud Control reaches the device on the new interface.

Note After you re-cable, the deployment may fail if it timed out before re-establishing the management connection to the new interface. In that case, you must reinitiate the deployment after re-cabling for a successful deployment.

9. Verify the management connection status in Cloud-Delivered Firewall Management Center or via the **sftunnel-status-brief** command at the FTD CLI.

Internet service provider has changed

If you have changed your ISP, you can lose management connectivity, even though High Availability health is normal. Configure the new network details of the management interface using the CLI commands.

Note These commands are available only on the active unit and not on standby.

For information about the Firewall Threat Defense CLI, see the FTD command reference .

1. Connect to the device CLI and log in with the Admin username and password.
2. Use the **configure network management-data-interface** commands to update the IPv4 address, netmask, or gateway.

   Example:

```
            Configure network management-data-interface ipv4 manual 10.10.6.7
255.255.255.0 interface gig0/0
            Configuration updated successfully..!!
```

Note All other CLI commands of **configure network management-data-interface** are not supported on devices in a High Availability pair.

3. Verify the connection using **sftunnel-status-brief** .
4. In Security Cloud Control , navigate to **Security Devices > FTD**, select the device, and click **Refresh** in the **FMC Access Details** pane.
5. Click **Acknowledge** to remove the deployment block and reconcile the configuration changes.

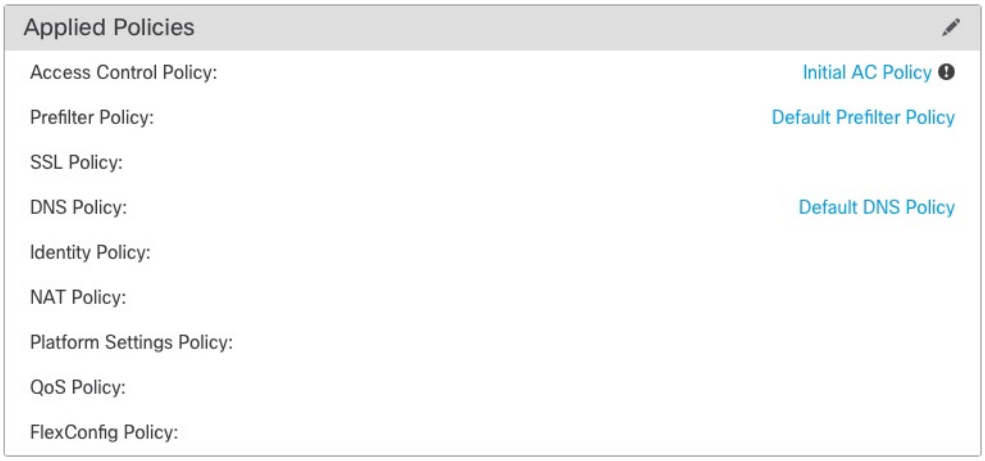
View inventory details

The **Inventory Details** section of the **Device** page shows chassis details such as the CPU and memory.

Figure 309: Inventory details

This section shows the chassis serial number. The firewall includes two serial numbers: the chassis serial number and the PCB (circuit board) serial number. The PCB serial number is shown in the System section. The Firewall Threat Defense Virtual does not have a chassis serial number.

Note For physical Firewall Threat Defense devices, the Memory field in **Inventory Details** shows only the data plane memory, not the total system memory.



To update information, click **Refresh** ( ).

Edit applied policies

This task allows you to assign or modify policies for an individual firewall device, including access control policies and other security policies that govern device behavior.

The **Applied Policies** section of the **Device** page displays the following policies applied to your firewall:

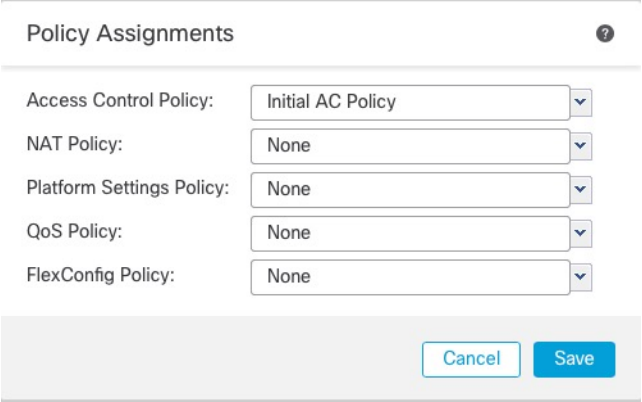
Figure 310: Applied policies

For policies with links, you can click the link to view the policy.

For the Access Control Policy, view the **Access Policy Information for Troubleshooting** dialog box by clicking the **Exclamation** ( ) icon. This dialog box shows how access rules are expanded into access control entries (ACEs).

Figure 311: Access policy information for troubleshooting

Procedure



Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **Applied Policies** section, click **Edit** ( ).

Figure 312: Policy assignments

Step 5 For each policy type, choose a policy from the drop-down menu. Only existing policies are listed.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Edit advanced settings

The **Advanced Settings** section of the **Device** page displays a table of advanced configuration settings, as described below. You can edit any of these settings.

Table 74: Advanced settings table fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.

Field	Description
Object Group Search	The state of object group search on the device. While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firepower Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules. **Note** By default, the **Object Group Search** is enabled when you add threat defense for the first time in the management center.
Interface Object Optimization	The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

These topics explain how to edit the advanced device settings.

Note For information about the Transfer Packets setting, see Edit general settings, on page 1133.

Configure automatic application bypass

Automatic Application Bypass (AAB) enables packet processing to continue when Snort detection becomes unavailable or exceeds processing time limits. This feature ensures network traffic flow continuity while providing diagnostic information for troubleshooting detection engine failures.

Automatic Application Bypass (AAB) allows packets to bypass detection if Snort is down or, for a Classic device, if a packet takes too long to process. AAB causes Snort to restart within ten minutes of the failure, and generates troubleshooting data that can be analyzed to investigate the cause of the Snort failure.

Caution AAB activation partially restarts the Snort process, which temporarily interrupts the inspection of a few packets.Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Note the following behavior:

Firewall Threat Defense Behavior: If Snort is down, then AAB is triggered after the specified timer duration. If Snort is up, then AAB is never triggered, even if packet processing exceeds the configured timer.

Classic Device Behavior: AAB limits the time allowed to process packets through an interface. You balance packet processing delays with your network's tolerance for packet latency.

The feature functions with any deployment; however, it is most valuable in inline deployments.

Typically, you use Rule Latency Thresholding in the intrusion policy to fast-path packets after the latency threshold value is exceeded. Rule Latency Thresholding does not shut down the engine or generate troubleshooting data.

If detection is bypassed, the device generates a health monitoring alert.

By default the AAB is disabled; to enable AAB follow these steps:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to edit advanced device settings, click **Edit** ( ).

Step 3 Click **Device**, then click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Automatic Application Bypass**.

Step 5 Enter a **Bypass Threshold** from 250 ms to 60,000 ms. The default setting is 3000 milliseconds (ms).

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Configure object group search

This task enables object group search on a Firewall Threat Defense device to reduce memory requirements for access control policies that include network or interface objects.

While operating, the Firewall Threat Defense device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Cloud-Delivered Firewall Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules.

Enabling object group search reduces memory requirements for access control policies that include network or interface objects. However, it is important to note that object group search might also decrease rule lookup performance and thus increase CPU utilization. You should balance the CPU impact against the reduced memory requirements for your specific access control policy. In most cases, enabling object group search provides a net operational improvement.

By default, the object group search is enabled for the threat defense devices that are added for the first time in the Cloud-Delivered Firewall Management Center. In the case of upgraded devices, if the device is configured with disabled object group search, then you need to manually enable it. You can enable it on one device at a time; you cannot enable it globally. We recommend that you enable it on a device to which you deploy access rules that use network or interface objects.

Note

- If you enable object group search and then configure and operate the device for a while, be aware that subsequently disabling the feature might lead to undesirable results.
- When you disable object group search, your existing access control rules will be expanded in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact.
- If your device is operating normally, do not disable the object group search after you have enabled it.

Before you begin

- Model support—Firewall Threat Defense
- We recommend that you also enable transactional commit on each device. From the device CLI, enter the **asp rule-engine transactional-commit access-group** command.
- Changing this setting can be disruptive to system operation while the device recompiles the ACLs. We recommend that you change this setting during a maintenance window.
- You can use FlexConfig to configure the **object-group-search threshold** command to enable a threshold to help prevent performance degradation. When operating with a threshold, for each connection, both the source and destination IP addresses are matched against network objects. If the number of objects matched by the source address times the number matched by the destination address exceeds 10,000, the connection is dropped. Configure your rules to prevent an excessive number of matches.

Follow these steps to configure object group search:

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the Firewall Threat Defense device where you want to configure the rule, click the **Edit** (✎).

Step 3 Click the **Device** tab, then click the **Edit** (✎) in the **Advanced Settings** section.

Step 4 Check **Object Group Search**.

Step 5 To have object group search work on interface objects in addition to network objects, check **Interface Object Optimization**.

If you do not select **Interface Object Optimization**, the system deploys separate rules for each source/interface pair, rather that use the security zones and interface groups used in the rules. This means the interface groups are not available for object group search processing.

Step 6 Click **Save**.

Configure interface object optimization

Interface object optimization enables the system to deploy a single rule per access control/prefilter rule instead of generating separate rules for each source/destination interface pair, simplifying device configuration and improving deployment performance.

During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source and destination interface pair. Enabling interface object optimization deploys a single rule per access control or prefilter rule. This approach simplifies device configuration and can improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce evice memory usage.

Interface object optimization is disabled by default. You can enable it on one device at a time; you cannot enable it globally.

Note If you disable interface object optimization, the system deploys existing access control rules without using interface objects. This process might take longer. If object group search is enabled, its benefits do not apply to interface objects, and the device's running configuration might show expanded access control rules. If this expansion requires more memory than is available, the device can become inconsistent, which may affect performance

Before you begin

Model support—Firewall Threat Defense

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the Firewall Threat Defense device where you want to configure the rule, click the **Edit** ( ).

Step 3 Under the **Device** tab, click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Interface Object Optimization**.

Step 5 Click **Save**.

Edit deployment settings

Configure the deployment settings to enable auto rollback of the deployment if the management connection fails as a result of the deployment. For example, if you use data for management center access and then you misconfigure the data interface.

The **Deployment Settings** section of the **Device** page displays information for managing automatic rollback configuration. As an alternative, you can manually roll back the configuration using the **configure policy rollback** command (see Manually Roll Back the configuration if the Cloud-Delivered Firewall Management Center loses Connectivity, on page 1181).

Figure 313: Deployment settings

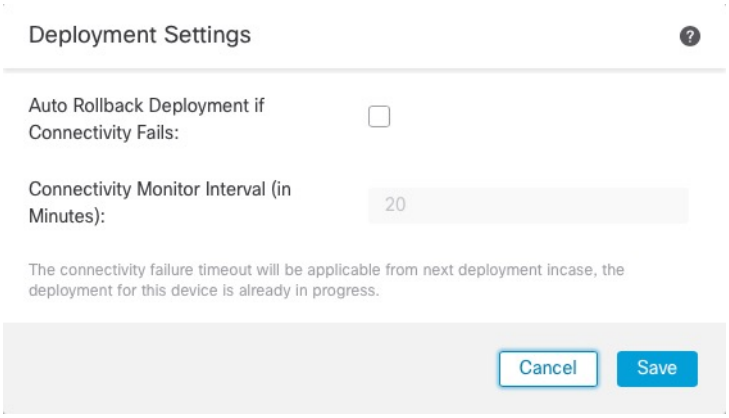
Table 75: Deployment settings

Field	Description
Auto Rollback Deployment if Connectivity Fails	Enabled or Disabled. You can enable auto rollback if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface.
Connectivity Monitor Interval (in Minutes)	Shows the amount of time to wait before rolling back the configuration.

Consider the following guidelines:

- Only the previous deployment is available locally on the Firewall Threat Defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- Rollback is not supported immediately after high availability creation.
- The rollback only affects configurations that you can set in the Cloud-Delivered Firewall Management Center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the Firewall Threat Defense CLI. Note that if you changed data interface settings after the last Cloud-Delivered Firewall Management Center deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed Cloud-Delivered Firewall Management Center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure



Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

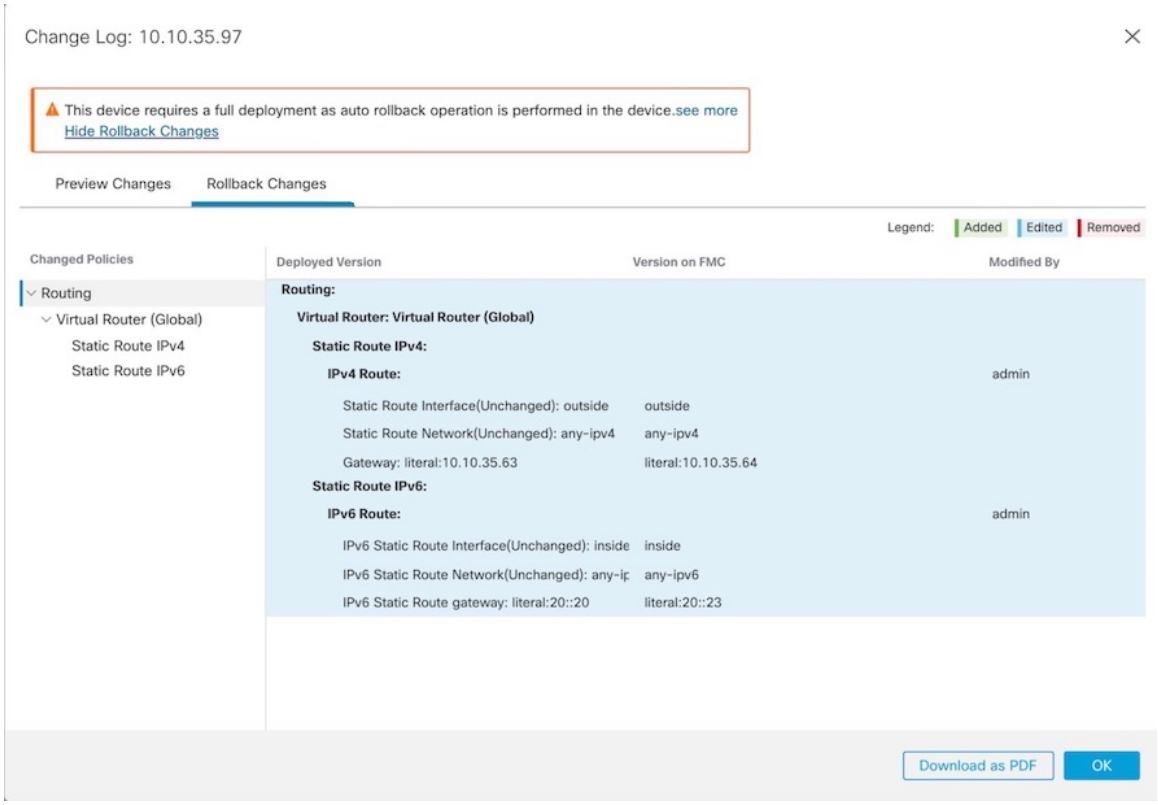
Step 3 Click **Device**.

Step 4 In the **Deployment Settings** section, click **Edit** ( ).

Figure 314: Deployment settings

Step 5 Check **Auto Rollback Deployment if Connectivity Fails** to enable auto rollback.

Step 6 Set the **Connectivity Monitor Interval (in minutes)** to configure the wait time before rolling back the configuration. The default is 20 minutes.



Step 7 If a rollback occurs, consider these next steps.

- If the auto rollback was successful, you see a success message instructing you to do a full deployment.
- Go to **Deploy** > **Advanced Deploy** page and click the **Preview** ( ) icon to view the parts of the configuration that were rolled back (see Deploy configuration changes, on page 202).

  To view the changes, click **Show Rollback Changes**.

  To hide the changes, click **Hide Rollback Changes**.

Figure 315: Rollback changes

- In the Deployment History Preview, you can view the rollback changes. See View deployment history, on page 210.

Step 8 Verify that the management connection was reestablished.

a. In Cloud-Delivered Firewall Management Center, check the management connection status on the connection status page.

b. Navigate to **Devices** > **Device Management** and then in **Management** area under the **Devices** tab, click **Connection Status** to view the **Connection Status** page.

c. At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 1183.

Edit cluster health monitor settings

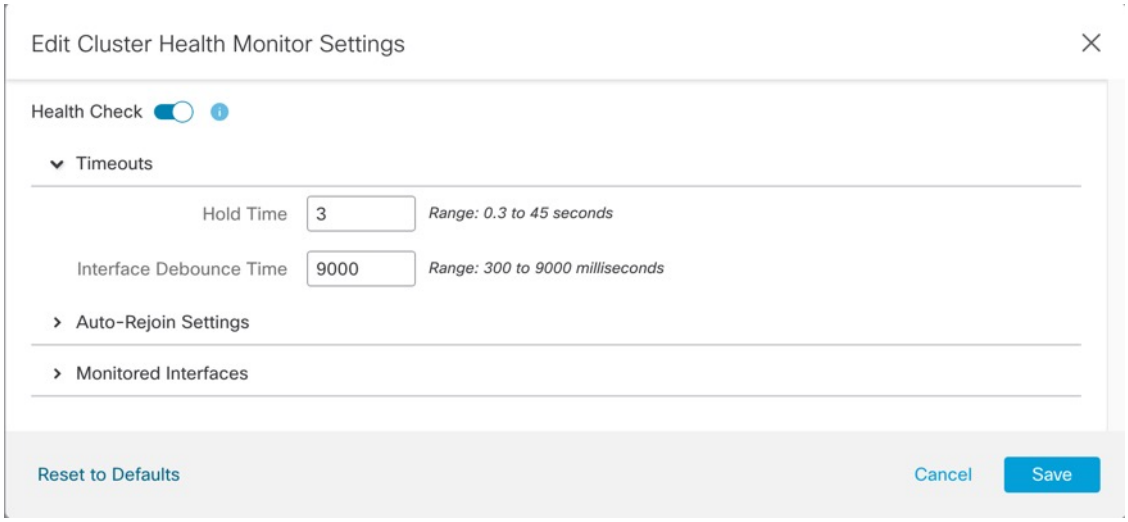
This task allows you to modify cluster health monitor settings to control how cluster nodes monitor system health and automatically rejoin the cluster after failures.

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings for monitoring cluster node health. You can monitor any port-channel ID, any single physical interface ID, and the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link. It is always monitored.

When a topology change occurs (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature. Also, disable interface monitoring for any interfaces that are disabled. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**.



Step 2 Next to the cluster you want to modify, click **Edit** ( ).

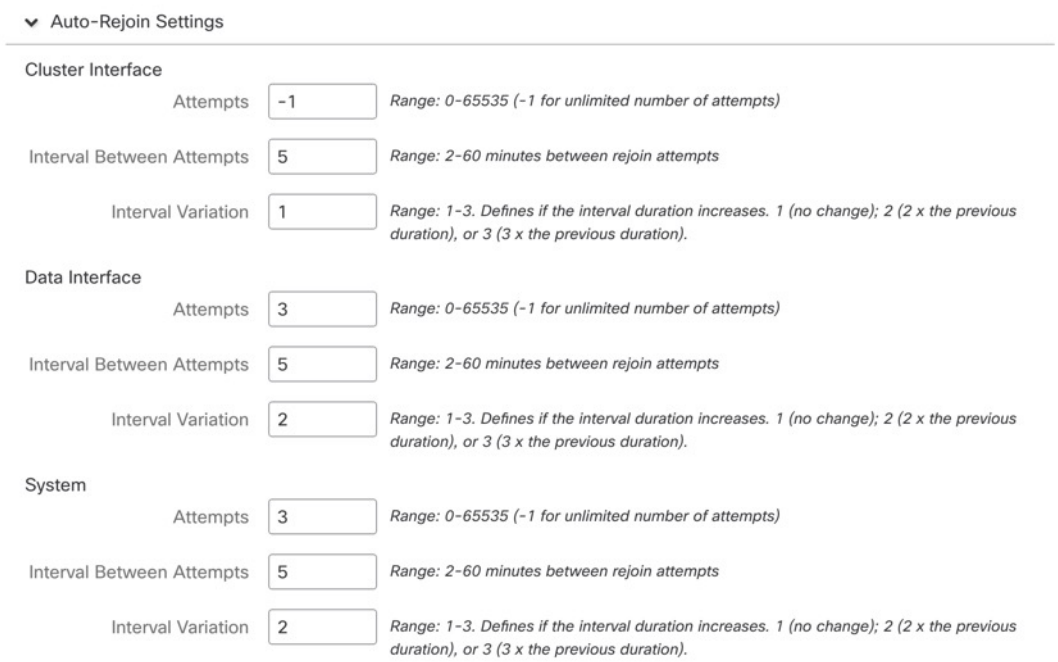
Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 316: Disable the system health check

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.



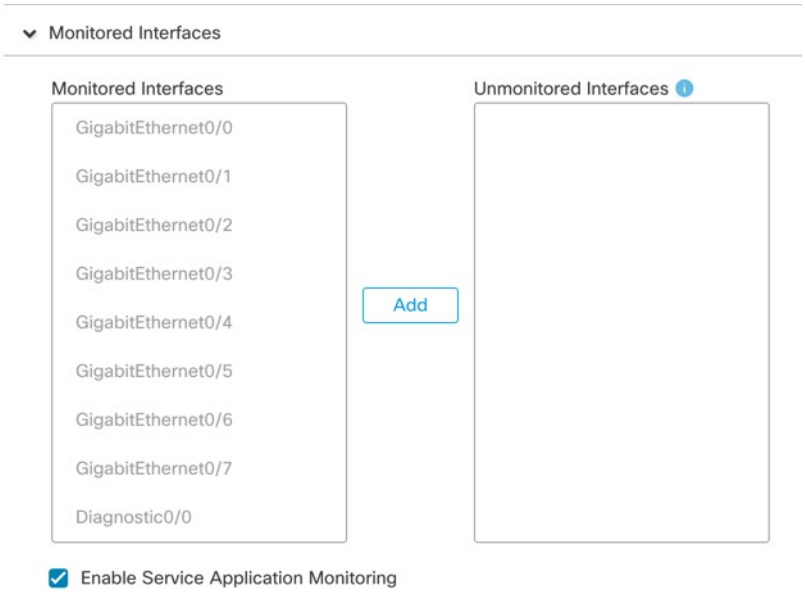
Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between 0.3 and 45 seconds. The default is 3 seconds.

- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the specified number of milliseconds before marking the interface as failed and removing the node from the cluster. If an EtherChannel transitions from a down state to an up state, such as after the switch reloads or enables an EtherChannel, a longer debounce time can prevent the interface from appearing failed on a cluster node if another cluster node bundles the ports more quickly.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 317: Configure Auto-Rejoin settings



Set values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 318: Configure monitored interfaces

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The time required to remove a member from the cluster depends on the type of interface and whether the node is established or is joining the cluster. By default, health check is enabled for all interfaces and the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Deploy configuration changes.

Hot swap an SSD

Hot swapping SSDs allows you to maintain system operation while replacing faulty drives, removing drives, or adding drives to form a RAID configuration.

If you have two SSDs, they form a RAID when you boot up. You can perform the following tasks at the Firewall Threat Defense CLI while the firewall is powered up:

- Hot swap one of the SSDs—If an SSD is faulty, you can replace it. Note that if you only have one SSD, you cannot remove it while the firewall is powered on.
- Remove one of the SSDs—If you have two SSDs, you can remove one.

- Add a second SSD—If you have one SSD, you can add a second SSD and form a RAID.

  When you use only one SSD in Secure Firewall devices, the **Drive State** will show as **degraded**.

Caution Do not remove an SSD without first removing it from the RAID using this procedure. You can cause data loss.

Procedure

Step 1 Remove one of the SSDs.

a) Remove the SSD from the RAID.

configure RAID remove-secure local-disk {**1** | **2**}

The **remove-secure** keyword removes the SSD from the RAID, disables the self-encrypting disk feature, and performs a secure erase of the SSD. If you only want to remove the SSD from the RAID and want to keep the data intact, you can use the **remove** keyword.

Example:

```
> configure raid remove-secure local-disk 2
```

b) Monitor the RAID status until the SSD no longer shows in the inventory.

show RAID

After the SSD is removed from the RAID, the **Operability** and **Drive State** will show as **degraded**. The second drive will no longer be listed as a member disk.

Example:

```
> show raid
Virtual Drive
ID:                         1
Size (MB):                  858306
Operability:                operable
Presence:                   equipped
Lifecycle:                  available
Drive State:                optimal
Type:                       raid
Level:                      raid1
Max Disks:                  2
Meta Version:               1.0
Array State:                active
Sync Action:                idle
Sync Completed:             unknown
Degraded:                   0
Sync Speed:                 none

RAID member Disk:
Device Name:                nvme0n1
Disk State:                 in-sync
Disk Slot:                  1
Read Errors:                0
```

```
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

Device Name:                nvme1n1
Disk State:                 in-sync
Disk Slot:                  2
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

> show raid

Unacknowledged Bad Blocks:
```

c) Physically remove the SSD from the chassis.

Step 2 Add an SSD.

a) Physically add the SSD to the empty slot.

b) Add the SSD to the RAID.

configure RAID add local-disk {**1** | **2**}

It can take several hours to complete syncing the new SSD to the RAID, during which the firewall is completely operational. You can even reboot, and the sync will continue after it powers up. Use the **show RAID** command to show the status.

If you install an SSD that was previously used on another system, and is still locked, enter the following command:

configure RAID add local-disk {**1** | **2**} *psid*

The *psid* is printed on the label attached to the back of the SSD. Alternatively, you can reboot the system, and the SSD will be reformatted and added to the RAID.

Disable the USB port

This reference explains how to disable the USB port functionality on the device for security or operational requirements.

By default, the type-A USB port is enabled. You might want to disable USB port access for security purposes. Disabling USB is supported on these models:

- Firepower 1000 Series
- Secure Firewall 200 Series
- Secure Firewall 3100
- Secure Firewall 4200

Guidelines

- Enabling or disabling the USB port requires a reboot .
- If the USB port is disabled and you downgrade to a version that does not support this feature, the port will remain disabled, and you cannot re-enable it without erasing the NVRAM (the FXOS local-mgmt **erase secure all** command).
- If you perform a ROMMON **factory-reset** or FXOS local-mgmt **erase secure** , the USB port will be re-enabled.
- For high availability or clustering , you must disable or re-enable the port individually on each unit.

Note This feature does not affect the USB console port, if present.

Disable the USB port on a device

Disable the USB port on a device to enhance security by preventing unauthorized data transfer or malicious USB device connections.

To disable the USB port on a device, you can do so at the Firewall Threat Defense CLI.

Procedure

Step 1 Disable the USB port.

system support USB configure disable

reboot

To re-enable the USB port, enter **system support USB configure enable**.

Example:

```
>system support usb configure disable
USB Port Admin State set to 'disabled'.
Please reboot the system to apply any control state changes.

>reboot
This command will reboot the system. Continue?
Please enter 'YES' or 'NO': YES
```

Step 2 View the port status.

system support USB show

The Admin State shows the USB port configuration. The Oper State shows the current operation. For example, if you disable the USB port but do not reload, the Admin State will show disabled while the Oper State would be enabled.

Example:

```
>system support usb show
USB Port Info
---------------
Admin State: disabled
Oper State: disabled
```

Disable the USB port in multi-instance mode

This task allows you to control USB port access on your device by enabling or disabling the port through the FXOS CLI.

To disable the USB port in multi-instance mode, you can do so at the FXOS CLI.

Procedure

Step 1 Disable the USB port and reboot for the change to take effect.

a) Disable the USB port.

scope fabric-interconnect

disable USB-port

commit buffer

b) Reboot the chassis.

connect local-mgmt

reboot

Example:

```
firepower-4245 /fabric-interconnect # disable usb-port
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:
device /fabric-interconnect* # commit buffer
```

```
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:yes
firepower-4245 /fabric-interconnect # connect local-mgmt
firepower-4245(local-mgmt)# reboot
Before rebooting, please take a configuration backup.
Do you still want to reboot? (yes/no):yes
Broadcast message from admin@firepower-4245 (Wed Feb 21 05:59:55 2024):
All shells being terminated due to system /sbin/reboot
```

Step 2 Enable the USB port and reboot for the change to take effect.

a) Enable the USB port.

scope fabric-interconnect

enable USB-port

commit buffer

b) Reboot the chassis.

connect local-mgmt

reboot

Example:

```
firepower-4245 /fabric-interconnect # enable usb-port
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:
device /fabric-interconnect* # commit buffer
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:yes
firepower-4245 /fabric-interconnect # connect local-mgmt
firepower-4245(local-mgmt)# reboot
Before rebooting, please take a configuration backup.
Do you still want to reboot? (yes/no):yes
Broadcast message from admin@firepower-4245 (Wed Feb 21 05:59:55 2024):
All shells being terminated due to system /sbin/reboot
```

Step 3 View the USB port status.

scope fabric-interconnect

show USB-port

The Admin State shows the USB port configuration. The Oper State shows the current operation. For example, if you disable the USB port but do not reload, the Admin State will show Disabled while the Oper State would will Enabled.

Example:

```
firepower-4245# scope fabric-interconnect
firepower-4245 /fabric-interconnect # show usb-port
Usb Port:
Equipment         Admin State Oper State
----------------- ----------- ----------
A                 Disabled    Disabled
```

Configure SNMP for FXOS

You can configure the Simple Network Management Protocol (SNMP) for the underlying FXOS operating system that controls low-level chassis functions. For SNMP for the Firewall Threat Defense, see Configure SNMP for a security device, on page 1264.

SNMP is an application-layer protocol that provides a message format for communication between SNMP managers and agents. SNMP provides a standardized framework and a common language used for the monitoring and management of devices in a network.

The SNMP framework consists of three parts:

- An SNMP manager—The system used to control and monitor the activities of network devices using SNMP.
- An SNMP agent—The software component within the chassis that maintains the data for the chassis and reports the data, as needed, to the SNMP manager. The chassis includes the agent and a collection of MIBs. To enable the SNMP agent and create the relationship between the manager and agent, enable and configure SNMP in the Cloud-Delivered Firewall Management Center.
- A managed information base (MIB)—The collection of managed objects on the SNMP agent.

The chassis supports SNMPv1, SNMPv2c and SNMPv3. Both SNMPv1 and SNMPv2c use a community-based form of security. SNMPv3 uses username and password for security.

Enable SNMP for FXOS

Enable SNMP and configure settings.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 Complete the following fields:

Name	Description
Admin State check box	Whether SNMP is enabled or disabled. Enable this service only if your system includes integration with an SNMP server.
Port field	The port on which the Firepower chassis communicates with the SNMP host. You cannot change the default port.

Name	Description
Community field	The default SNMPv1 or v2 community name or SNMP v3 username and password that the Firepower chassis includes on any trap messages it sends to the SNMP host. Enter a valid community string for SNMPv1 and SNMPv2: • Alphanumeric string between 1 and 32 characters and special characters ! (exclamation), - (hyphen), ~ (tilde), && (double ampersand), [ ] (square brackets), ^ (carat), ' (single quote), " (double quotes), and < > (angle brackets). • Do not use @ (at sign), \ (backslash), ? (question mark) or an empty space. • The string can also be in ASCII characters ranging 0x21 to 0x7E inclusive, excluding HTML interjection vectors, namely single quote ('), double quotes ("), and angle brackets (< >). Enter a valid username and password for SNMPv3: • Username can be alphanumeric string and can include @ (at sign), \ (backslash), . (period), _ (underscore), and - (hyphen). • The password restrictions are same as the community string restrictions. Note that if the **Community** field is already set, the text to the right of the empty field reads **Set: Yes**. If the **Community** field is not yet populated with a value, the text to the right of the empty field reads **Set: No**.
System Admin Name field	The contact person responsible for the SNMP implementation. Enter a string of up to 255 characters, such as an email address or a name and telephone number.
Location field	The location of the host on which the SNMP agent (server) runs. Enter an alphanumeric string up to 510 characters.

Step 4 Click **Save**.

What to do next

Create SNMP traps and users.

Create an SNMP Trap for FXOS

Create traps for SNMP.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 In the **SNMP Traps Configuration** area, click **Add**.

Step 4 In the **SNMP Trap Configuration** dialog box, complete the following fields:

Name	Description
Host Name field	The hostname or IP address of the SNMP host to which the Firepower chassis should send the trap.
Community field	The SNMP v1 or v2 community name or the SNMP v3 username the Firepower chassis includes when it sends the trap to the SNMP host. This must be the same as the community or username that is configured for the SNMP service. Enter an alphanumeric string between 1 and 32 characters. Do not use @ (at sign), \ (backslash), " (double quote), ? (question mark) or an empty space.
Port field	The port on which the Firepower chassis communicates with the SNMP host for the trap. Enter an integer between 1 and 65535.
Version field	The SNMP version and model used for the trap. This can be one of the following: • **V1** • **V2** • **V3**
Type field	If you select **V2** or **V3** for the version, the type of trap to send. This can be one of the following: • **Traps** • **Informs**
Privilege field	If you select **V3** for the version, the privilege associated with the trap. This can be one of the following: • **Auth**—Authentication but no encryption • **Noauth**—No authentication or encryption • **Priv**—Authentication and encryption

Step 5 Click **OK** to close the **SNMP Trap Configuration** dialog box.

Step 6 Click **Save**.

Create an SNMP user for FXOS

Create SNMP users.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 In the **SNMP Users Configuration** area, click **Add**.

Step 4 In the **SNMP User Configuration** dialog box, complete the following fields:

Name	Description
Username field	The username assigned to the SNMP user. Enter up to 32 letters or numbers. The name must begin with a letter and you can also specify _ (underscore), . (period), @ (at sign), and - (hyphen).
Auth Algorithm Type field	The authorization type: **SHA**.
Use AES-128 checkbox	If checked, this user uses AES-128 encryption. **Note** SNMPv3 does not support DES. If you leave the AES-128 box unchecked, no privacy encryption will be done and any configured privacy password will have no effect.
Authentication Password field	The password for the user.
Confirm field	The password again for confirmation purposes.
Encryption Password field	The privacy password for the user.
Confirm field	The privacy password again for confirmation purposes.

Step 5 Click **OK** to close the **SNMP User Configuration** dialog box.

Step 6 Click **Save**.

Configure alarms for the ISA 3000

You can configure the alarm system on a Cisco ISA 3000 device to alert you when undesirable conditions occur.

About alarms

You can configure the ISA 3000 to issue alarms for a variety of conditions. If any conditions do not match the configured settings, the system triggers an alarm, which is reported by way of LEDs, syslog messages, SNMP traps, and through external devices connected to the alarm output interface. By default, triggered alarms issue syslog messages only.

You can configure the alarm system to monitor the following:

- Power supply.
- Primary and secondary temperature sensors.
- Alarm input interfaces.

The ISA 3000 has internal sensors plus two alarm input interfaces and one alarm output interface. You can connect external sensors, such as door sensors, to the alarm inputs. You can connect external alarm devices, such as buzzers or lights, to the alarm output interface.

The alarm output interface is a relay mechanism. Depending on the alarm conditions, the relay is either energized or de-energized. When it is energized, any device connected to the interface is activated. A de-energized relay results in the inactive state of any connected devices. The relay remains in an energized state as long as alarms are triggered.

For information about connecting external sensors and the alarm relay, Refer to Alarms for the Cisco ISA 3000 chapter in Cisco ASA Series General Operations CLI Configuration Guide. see Cisco ISA 3000 Industrial Security Appliance Hardware Installation Guide.

Alarm input interfaces

You can connect the alarm input interfaces (or contacts) to external sensors, such as one that detects if a door is open.

Each alarm input interface has a corresponding LED. These LEDs convey the alarm status of each alarm input. You can configure the trigger and severity for each alarm input. In addition to the LED, you can configure the contact to trigger the output relay (to activate an external alarm), to send syslog messages, and to send SNMP traps.

The following table explains the statuses of the LEDs in response to alarm conditions for the alarm inputs. It also explains the behavior for the output relay, syslog messages, and SNMP traps, if you enable these responses to the alarm input.

Alarm Status	LED	Output Relay	Syslog	SNMP Trap
Alarm not configured	Off	—	—	—
No alarms triggered	Solid green	—	—	—
Alarm activated	Minor alarm—solid red Major alarm—flashing red	Relay energized	Syslog generated	SNMP trap sent
Alarm end	Solid green	Relay de-energized	Syslog generated	—

Alarm output interface

You can connect an external alarm, such as a buzzer or light, to the alarm output interface.

The alarm output interface functions as a relay and also has a corresponding LED, which conveys the alarm status of an external sensor connected to the input interface, and internal sensors such as the dual power supply and temperature sensors. You configure which alarms should activate the output relay, if any.

The following table explains the statuses of the LEDs and output relay in response to alarm conditions. It also explains the behavior for syslog messages, and SNMP traps, if you enable these responses to the alarm.

Alarm Status	LED	Output Relay	Syslog	SNMP Trap
Alarm not configured	Off	—	—	—
No alarms triggered	Solid green	—	—	—
Alarm activated	Solid red	Relay energized	Syslog generated	SNMP trap sent
Alarm end	Solid green	Relay de-energized	Syslog generated	—

Syslog alarms

By default, the system sends syslog messages when any alarm is triggered. You can disable syslog messaging if you do not want the messages.

For syslog alarms to work, you must also enable diagnostic logging. Choose **Devices** > **Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and configure destinations and settings on the **Syslog** page. For example, you can configure a syslog server, console logging, or internal buffer logging.

Without enabling a destination for diagnostic logging, the alarm system has nowhere to send syslog messages.

SNMP Alarms

You can optionally configure the alarms to send SNMP traps to your SNMP server. For SNMP trap alarms to work, you must also configure SNMP settings.

Choose **Devices** > **Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and enable SNMP and configure settings on the **SNMP** page.

Defaults for alarms

The following table specifies the defaults for alarm input interfaces (contacts), redundant power supply, and temperature.

	Alarm	Trigger	Severity	SNMP Trap	Output Relay	Syslog Message
Alarm Contact 1	Enabled	Closed State	Minor	Disabled	Disabled	Enabled
Alarm Contact 2	Enabled	Closed State	Minor	Disabled	Disabled	Enabled

	Alarm	Trigger	Severity	SNMP Trap	Output Relay	Syslog Message
Redundant Power Supply (when enabled)	Enabled	—	—	Disabled	Disabled	Enabled
Temperature	Enabled for the primary temperature alarm (default values of 92°C and -40°C for the high and low thresholds respectively) Disabled for the secondary alarm.	—	—	Enabled for primary temperature alarm	Enabled for primary temperature alarm	Enabled for primary temperature alarm

Prerequisites for alarms

Model support

Firewall Threat Defense on the ISA 3000.

Configure alarms for the ISA 3000

You use FlexConfig to configure alarms for the ISA 3000. The following topics explain how to configure the different types of alarms.

Configure alarm input contacts

If you connect the alarm input contacts (interfaces) to external sensors, you can configure the contacts to issue alarms based on the input from the sensor. In fact, the contacts are enabled by default to send syslog messages if the contact is closed, that is, if the electrical current stops flowing through the contact. You need to configure the contact only if the defaults do not meet your requirements.

The alarm contacts are numbered 1 and 2, so you need to understand how you have wired the physical pins to configure the correct settings. You configure the contacts separately.

Procedure

Step 1 Create the FlexConfig object to configure the alarm input contacts.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Configure_Alarm_Contacts.

- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the alarm contacts. The following steps explain the commands.

c) Configure a description for the alarm contact.

alarm contact {**1** | **2**} **description** *string*

For example, to set the description of contact 1 to "Door Open," enter the following:

```
alarm contact 1 description Door Open
```

d) Configure the severity for the alarm contact.

alarm contact {**1** | **2** | **any**} **severity** {**major** | **minor** | **none**}

Instead of configuring one contact, you can specify **any** to change the severity for all contacts. The severity controls the behavior of the LED associated with the contact.

- **major**—The LED blinks red.
- **minor**—The LED is solid red. This is the default.
- **none**—The LED is off.

For example, to set the severity of contact 1 to Major, enter the following:

```
alarm contact 1 severity major
```

e) Configure the trigger for the alarm contact.

alarm contact {**1** | **2** | **any**} **trigger** {**open** | **closed**}

Instead of configuring one contact, you can specify **any** to change the trigger for all contacts. The trigger determines the electrical condition that signals an alert.

- **open**—The normal condition for the contact is closed, that is, the electrical current is running through the contact. An alert is triggered if the contact becomes open, that is, the electrical current stops flowing.
- **closed**—The normal condition for the contact is open, that is, the electrical current does not run through the contact. An alert is triggered if the contact becomes closed, that is, the electrical current starts running through the contact. This is the default.

For example, you connect a door sensor to alarm input contact 1, and its normal state has no electrical current flowing through the alarm contact (it is open). If the door is opened, the contact is closed and electrical current flows through the alarm contact. You would set the alarm trigger to closed so that the alarm goes off when the electrical current starts flowing.

```
alarm contact 1 trigger closed
```

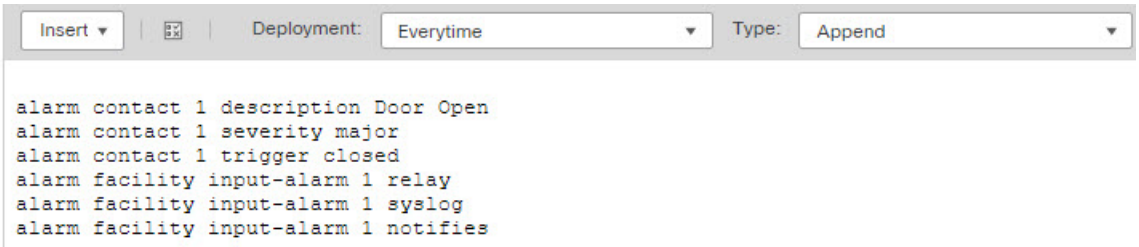
f) Configure the actions to take when the alarm contact is triggered.

alarm facility input-alarm {**1** | **2**} {**relay** | **syslog** | **notifies**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.

For example, to enable all actions for the alarm input contact 1, enter the following:



```
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

g) Verify that the object body contains the commands you want.

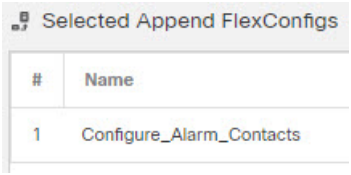
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

The object body should look similar to the following:

h) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the alarm contact FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the alarm contact commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1342.

Configure power supply alarms

The ISA 3000 has two power supplies. By default, the system operates in single-power mode. However, you can configure the system to operate in dual mode, where the second power supply automatically provides power if the primary power supply fails. When you enable dual-mode, the power supply alarm is automatically enabled to send syslog alerts, but you can disable the alert altogether, or also enable SNMP traps or the alarm hardware relay.

The following procedure explains how to enable dual mode, and how to configure the power supply alarms.

Procedure

Step 1 Create the FlexConfig object to configure the power supply alarm.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Power_Supply_Alarms.

- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the power supply alarms. The following steps explain the commands.

c) Enable dual power supply mode.

power-supply dual

For example:

```
power-supply dual
```

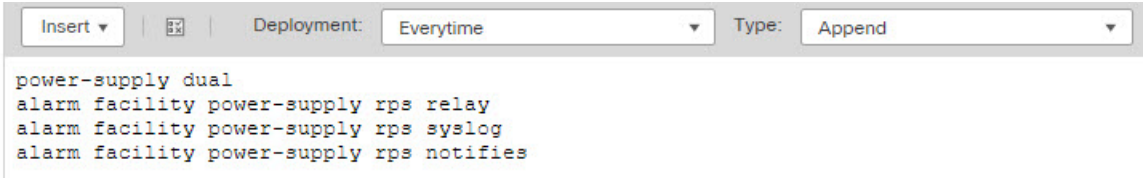
d) Configure the actions to take when the power supply alarm is triggered.

alarm facility power-supply rps {**relay** | **syslog** | **notifies** | **disable**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.
- **disable**—Disable the power supply alarm. Any other actions configured for the power supply alarm are inoperable.

For example, to enable all actions for the power supply alarm, enter the following:



```
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

e) Verify that the object body contains the commands you want.

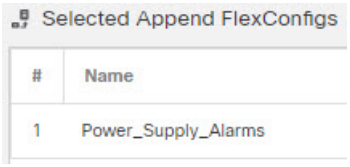
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

The object body should look similar to the following:

f) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the power supply alarm FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the power supply alarm commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1342.

Configure temperature alarms

You can configure alarms based on the temperature of the CPU card in the device.

You can set a primary and secondary temperature range. If the temperature drops below the low threshold, or exceeds the high threshold, the alarm is triggered.

The primary temperature alarm is enabled by default for all alarm actions: output relay, syslog, and SNMP. The default settings for the primary temperature range is -40°C to 92°C.

The secondary temperature alarm is disabled by default. You can set the secondary temperature within the range -35°C to 85°C.

Because the secondary temperature range is more restrictive than the primary range, if you set either the secondary low or high temperature, that setting disables the corresponding primary setting, even if you configure non-default values for the primary setting. You cannot enable two separate high and two separate low temperature alarms.

Thus, in practice, you should configure the primary only, or the secondary only, setting for high and low.

Procedure

Step 1 Create the FlexConfig object to configure the temperature alarms.

a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Configure_Temperature_Alarms.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the temperature alarms. The following steps explain the commands.

c) Configure the acceptable temperature range.

alarm facility temperature {**primary** | **secondary**} {**low** | **high**} *temperature*

The temperature is in Celsius. The allowed range for the primary alarm is -40 to 92, which is also the default range. The allowed range for the secondary alarm is -35 to 85. The low value must be lower than the high value.

For example, to set a more restrictive temperature range of -20 to 80, which falls within the allowed range for the secondary alarm, configure the secondary alarm as follows:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
```

d) Configure the actions to take when the temperature alarm is triggered.

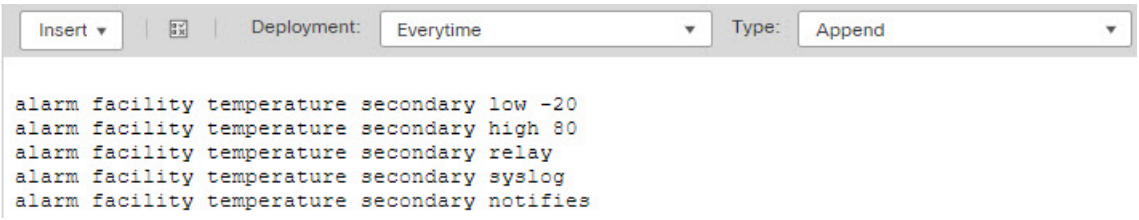
alarm facility temperature {**primary** | **secondary**} {**relay** | **syslog** | **notifies**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message.

- **notifies**—Send an SNMP trap.

For example, to enable all actions for the secondary temperature alarm, enter the following:



```
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

e) Verify that the object body contains the commands you want.

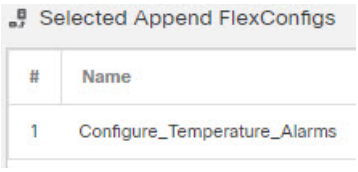
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

The object body should look similar to the following:

f) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the temperature alarms FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the

preview. Note that you will also see commands generated from other changes you have made to managed features. For the temperature alarms commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1342.

Turn off the external alarm

If you are using an external alarm that is attached to the alarm output, and the alarm is triggered, you can turn off the external alarm from the device CLI using the **clear facility-alarm output** command. This command de-energizes the output pin and also turns off the output LED.

Monitoring alarms

The following topics explain how to monitor and manage alarms.

Monitoring alarm status

You can use the following commands in the CLI to monitor alarms.

- **show alarm settings**

  Shows the current configuration for each possible alarm.

- **show environment alarm-contact**

  Shows information about the physical status of the input alarm contacts.

- **show facility-alarm relay**

  Shows information about the alarms that have triggered the output relay.

- **show facility-alarm status** [**info** | **major** | **minor**]

  Shows information on all alarms that have been triggered. You can limit the view by filtering on **major** or **minor** status. The **info** keyword provides the same output as using no keyword.

Monitoring syslog messages for alarms

Depending on the type of alarms you configure, you might see the following syslog messages.

Dual Power Supply Alarms

- %FTD-1-735005: Power Supply Unit Redundancy OK
- %FTD-1-735006: Power Supply Unit Redundancy Lost

Temperature Alarms

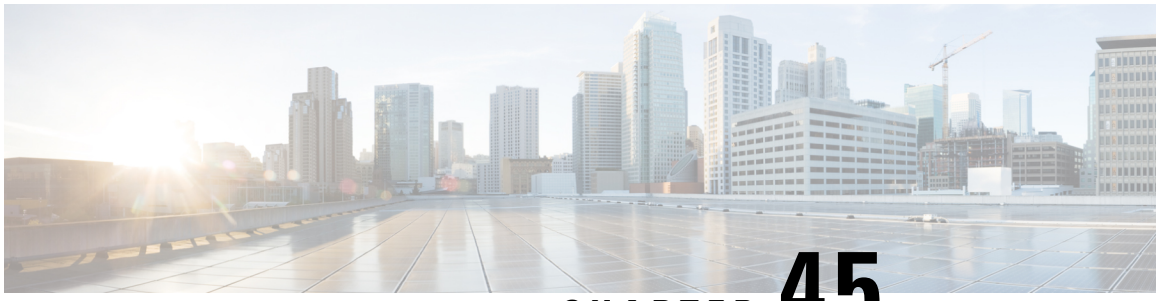
In these alarms, *Celsius* is replaced by the temperature detected on the device, in Celsius.

- %FTD-6-806001: Primary alarm CPU temperature is High *Celsius*
- %FTD-6-806002: Primary alarm for CPU high temperature is cleared
- %FTD-6-806003: Primary alarm CPU temperature is Low *Celsius*
- %FTD-6-806004: Primary alarm for CPU Low temperature is cleared
- %FTD-6-806005: Secondary alarm CPU temperature is High *Celsius*
- %FTD-6-806006: Secondary alarm for CPU high temperature is cleared
- %FTD-6-806007: Secondary alarm CPU temperature is Low *Celsius*
- %FTD-6-806008: Secondary alarm for CPU Low temperature is cleared

Alarm Input Contact Alarms

In these alarms, *description* is the description for the contact that you configured.

- %FTD-6-806009: Alarm asserted for ALARM_IN_1 *alarm_1_description*
- %FTD-6-806010: Alarm cleared for ALARM_IN_1 *alarm_1_description*
- %FTD-6-806011: Alarm asserted for ALARM_IN_2 *alarm_2_description*
- %FTD-6-806012: Alarm cleared for ALARM_IN_2 *alarm_2_description*



History for Device Settings

Provides a comprehensive reference of feature introductions, command modifications, and interface updates related to device settings and management.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Recovery-config mode for emergency on-device configuration and out-of-band configuration detection on the Cloud-Delivered Firewall Management Center	20250219	7.7.0	If you lose the management connection to your device, you can make select configuration changes directly at the device CLI to: • Restore the management connection if you are using a data interface for manager access • Make select policy changes that can't wait until the connection is restored After the management connection is restored, the Cloud-Delivered Firewall Management Center will detect the configuration changes on the device. It does not automatically update the device configuration in the Cloud-Delivered Firewall Management Center ; you must view the configuration differences, acknowledge that the device configuration is different, and then manually make the same changes in the Cloud-Delivered Firewall Management Center before you deploy. New/modified diagnostic CLI (**system support diagnostic-cli**) command: **configure recovery-config** New/modified screens: **Devices** > **Device Management** , click **Edit** ( ) , then **Device** > **Health** > **Out of Band Status**
High availability is supported with redundant manager access data interfaces	20250219	7.7.0	You can now use redundant manager access data interfaces with high availability.
Cluster health monitor settings.	20221213	Any	You can now edit cluster health monitor settings. New/modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Redundant manager access data interface.	20221213	7.3.0	When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces. New/modified screens: • **Devices** > **Device Management** > **Device** > **Management** • **Devices** > **Device Management** > **Device** > **Interfaces** > **Manager Access**
Policy rollback support for high availability devices.	20220609	7.2.0	The **configure policy rollback** command is supported for high availability devices.
Auto rollback of a deployment that causes a loss of management connectivity.	20220609		You can now enable auto rollback of the configuration if a deployment causes the management connection between the management center and the threat defense to go down. Previously, you could only manually rollback a configuration using the **configure policy rollback** command. New/modified screens: • **Devices** > **Device Management** > **Device** > **Deployment Settings** • **Deploy** > **Advanced Deploy** > **Preview** • **Deploy** > **Deployment History** > **Preview**
Object group search is enabled by default for access control rules.	20220609	7.2.0	The **Object Group Search** setting is enabled by default for managed devices starting with Version 7.2.0. This option is in the **Advanced Settings** section when editing device settings on the Device Management page.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Import and export device configurations.	20220609	7.2.0	You can export the device-specific configuration, and you can then import the saved configuration for the same device in the following use cases: • Moving the device to a different FMC. • Restore an old configuration. • Reregistering a device. New/modified screens: **Devices** > **Device Management** > **Device** > **General**
Update the FMC IP address on FTD.	20220609	7.0.3	If you change the FMC IP address, you can now use the FTD CLI to update the device. New/modified commands: **configure manager edit**
Alarms for the Cisco ISA 3000 series.	6.7	Any	Configuring alarms for the Cisco ISA 3000 series was validated using FlexConfig. You should be able to configure the alarms in older releases that support FlexConfig, except for the dual power supply alarms. Supported platforms: Secure Firewall Threat Defense

CHAPTER 45

DHCP and DDNS

The following topics explain DHCP and DDNS services and how to configure them on Threat Defense devices.

- About DHCP and DDNS services, on page 1223
- Requirements and prerequisites for DHCP and DDNS, on page 1225
- Guidelines for DHCP and DDNS services, on page 1225
- Configure the DHCPv4 server, on page 1227
- DHCPv6 stateless server configuration, on page 1229
- Configure the DHCP relay agent, on page 1233
- Configure Dynamic DNS, on page 1234
- History for DHCP and DDNS, on page 1239

About DHCP and DDNS services

This topic describes the DHCP server, DHCP relay agent, and DDNS update.

DHCPv4 servers

A DHCPv4 server provides network configuration parameters, such as IP addresses, to DHCP clients.

- delivers configuration parameters directly to DHCP clients attached to Firewall Threat Defense device interfaces, and
- uses UDP port communication for client-server messaging.

DHCPv4 server communication details

The DHCP communication uses specific network protocols and port assignments:

- IPv4 DHCP client: Uses broadcast rather than multicast address to reach the server and listens for messages on UDP port 68
- DHCP server: Listens for messages on UDP port 67

DHCP options

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. The configuration parameters are carried in tagged items that are stored in the Options field of the DHCP message and the data are also called options. Vendor information is also stored in Options, and all of the vendor information extensions can be used as DHCP options.

Common DHCP options

Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.
- DHCP option 66 gives the IP address or the hostname of a single TFTP server.
- DHCP option 3 sets the default route.

A single request might include both options 150 and 66. In this case, the DHCP server provides values for both options in the response if they are already configured on the Firewall Threat Defense.

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients. DHCP option 15 is used for the DNS domain suffix. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

Domain name configuration precedence

You can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

DHCPv6 stateless server

A DHCPv6 stateless server is a DHCP IPv6 configuration that

- provides information such as DNS server or domain name when clients send Information Request (IR) packets,
- accepts IR packets but does not assign addresses to clients, and
- works in conjunction with StateLess Address Auto Configuration (SLAAC) and Prefix Delegation features.

DHCPv6 stateless server operation

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 prefix delegation client, on page 1093), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

DHCP relay agents

A DHCP relay agent forwards DHCP requests received on an interface to one or more DHCP servers.

DHCP relay agent operation

DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the Firewall Threat Defense device because it does not forward broadcast traffic. The DHCP relay agent lets you configure the interface of the Firewall Threat Defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another device.

Requirements and prerequisites for DHCP and DDNS

This reference provides the model support and user role requirements necessary for configuring DHCP and DDNS functionality.

Model support

Firewall Threat Defense

User roles

- Admin
- Access Admin
- Network Admin

Guidelines for DHCP and DDNS services

Context mode restrictions

DHCPv6 stateless server is not supported in multiple context mode.

Firewall mode restrictions

Consider these firewall mode limitations when configuring DHCP and DDNS services:

- DHCP Relay is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCP Server is supported in transparent firewall mode on a bridge group member interface. In routed mode, the DHCP server is supported on the BVI interface, not the bridge group member interface. The BVI must have a name for the DHCP server to operate.
- DDNS is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCPv6 stateless server is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.

Clustering limitations

DHCPv6 stateless server is not supported with clustering.

IPv6 support

DHCPv4 server guidelines

Follow these guidelines when configuring DHCPv4 server:

- The maximum available DHCP pool is 256 addresses.
- You can configure a DHCP server on any interface with a name and IP address, such as a physical interface, a subinterface, or a BVI in routed mode.
- Do not select an interface that uses DHCP or PPPoE to obtain it's address as a DHCP server interface.
- You can configure only one DHCP server on each interface. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure an interface as a DHCP client if that interface also has DHCP server enabled; you must use a static IP address.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- The Firewall Threat Defense does not support DHCP clients behind DHCP relay servers; the client must be directly connected to the Firewall Threat Defense.
- The DHCP server does not support BOOTP requests.

DHCPv6 server guidelines

Consider these guidelines when configuring DHCPv6 server:

- The DHCPv6 Stateless server cannot be configured on an interface where the DHCPv6 address, Prefix Delegation client, or DHCPv6 relay is configured.

DHCP relay guidelines

Follow these guidelines when configuring DHCP relay:

- You can configure a maximum of 10 DHCPv4 relay servers per virtual router, global (VRF) and interface-specific servers combined, with a maximum of 4 servers per interface.
- You can configure a maximum of 10 DHCPv6 relay servers per virtual router. Interface-specific servers for IPv6 are not supported.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- Do not select an interface that uses DHCP or PPPoE to obtain it's address as a DHCP relay interface.
- DHCP relay services are not available in transparent firewall mode or in routed mode on the BVI or bridge group member interface. You can, however, allow DHCP traffic through using an access rule. To allow DHCP requests and replies through the Firewall Threat Defense, you need to configure two access rules, one that allows DCHP requests from the inside interface to the outside (UDP destination port 67), and one that allows the replies from the server in the other direction (UDP destination port 68).
- For IPv4, clients must be directly-connected to the Firewall Threat Defense and cannot send requests through another relay agent or a router. For IPv6, the Firewall Threat Defense supports packets from another relay server.
- The DHCP clients must be on different interfaces from the DHCP servers to which the Firewall Threat Defense relays requests.
- You cannot enable DHCP Relay on an interface in a traffic zone.

DDNS service configuration

The firewall's DDNS supports only DynDNS service. Hence, ensure that the DDNS is configured with update URL in the following syntax:

https://*username***:***password***@***provider-domain***/***path***?hostname=<h>&myip=<a>**.

Configure the DHCPv4 server

Configure a DHCPv4 server to automatically assign IP addresses, DNS servers, domain names, and other network configuration parameters to DHCP clients on your network.

The DHCPv4 server provides dynamic IP address allocation and network configuration to clients. You can configure global server settings, interface-specific pools, and advanced DHCP options to customize the service for your network requirements.

Before you begin

Follow these steps to configure the DHCPv4 server:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **DHCP** > **DHCP Server**.

Step 3 Configure these DHCP server options:

- **Ping Timeout**—The amount of time in milliseconds that Firewall Threat Defense device waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.

  To avoid address conflicts, the Firewall Threat Defense device sends two ICMP ping packets to an address before assigning that address to a DHCP client.

- **Lease Length**—The amount of time in seconds that the client may use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).

- (Routed mode) **Auto-configuration**—Enables DHCP auto configuration on the Firewall Threat Defense device. Auto-configuration enables the DHCP server to provide the DHCP clients with the DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. Otherwise, you can disable auto configuration and add the values yourself in Step 4.

- (Routed mode) **Interface**—Specifies the interface to be used for auto configuration. For a device with virtual routing capability, this interface can only be a global virtual router interface.

Step 4 To override auto-configured settings, do the following:

- Enter the domain name of the interface. For example, your device may be in the Your_Company domain.
- From the drop-down list, choose the DNS servers (primary and secondary) configured for the interface. To add a new DNS server, see Create a network object, on page 2985.
- From the drop-down list, choose the WINS servers (primary and secondary) configured for the interface. To add a new WINS server, see Create a network object, on page 2985.

Step 5 Select **Server**, click **Add**, and configure the following options:

- **Interface**—Choose the interface from the drop-down list. In transparent mode, specify a named bridge group member interface. In routed mode, specify a named routed interface or a named BVI; do not specify the bridge group member interface. Note that each bridge group member interface for the BVI must also be named for the DHCP server to operate.
- **Address Pool**—The range of IP addresses from lowest to highest that is used by the DHCP server. The range of IP addresses must be on the same subnet as the selected interface and cannot include the IP address of the interface itself.
- **Enable DHCP Server**—Enables the DHCP server on the selected interface.

Step 6 Click **OK** to save the DHCP server configuration.

Step 7 (Optional) Select **Advanced**, click **Add**, and specify the type of information you want the option to return to the DHCP client:

- **Option Code**—The Firewall Threat Defense device supports the DHCP options listed in RFC 2132, RFC 2562, and RFC 5510 to send information. All DHCP options (1 through 255) are supported except for 1, 12, 50–54, 58–59, 61, 67, and 82. See DHCPv4 servers, on page 1223for more information on DHCP option codes.

  Note
  The Firewall Threat Defense device does not verify that the option type and value that you provide match the expected type and value for the option code, as defined in RFC 2132. For more information about option codes and their associated types and expected values, see RFC 2132.

- **Type**—DHCP option type. Available options include **IP**, **ASCII**, and **HEX**. If you chose IP, you must add IP addresses in the IP Address fields. If you chose ASCII, you must add the ASCII value in the ASCII field. If you chose HEX, you must add the HEX value in the HEX field.
- **IP Address 1** and **IP Address 2**—The IP address(es) to be returned with this option code. To add a new IP address, see Create a network object, on page 2985.
- **ASCII**—The ASCII value that is returned to the DHCP client. The string cannot include spaces.
- **HEX**—The HEX value that is returned to the DHCP client. The string must have an even number of digits and no spaces. You do not need to use a 0x prefix.

Step 8 Click **OK** to save the option code configuration.

Step 9 Click **Save** on the DHCP page to save your changes.

a) To view DHCP bindings, use **show dhcpd binding**.

Example:

```
> show dhcpd binding
IP Address Client-id         Lease Expiration  Type
10.0.1.100 0100.a0c9.868e.43 84985 seconds     automatic
```

DHCPv6 stateless server configuration

The DHCPv6 stateless server configuration enables the Firewall Threat Defense to provide network information such as the DNS server or domain name to clients using StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature. When clients send Information Request (IR) packets to Firewall Threat Defense, they receive this information.

Create a DHCP IPv6 pool

Create a DHCP IPv6 pool to define the parameters sent in IR messages from the DHCPv6 server to clients.

Create a DHCP IPv6 pool for use with the DHCPv6 server. The DHCPv6 server provides information such as the DNS server or domain name when they clients send Information Request (IR) packets to the Firewall Threat Defense. The DHCP IPv6 pool defines the parameters to sent in IR messages.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

Procedure

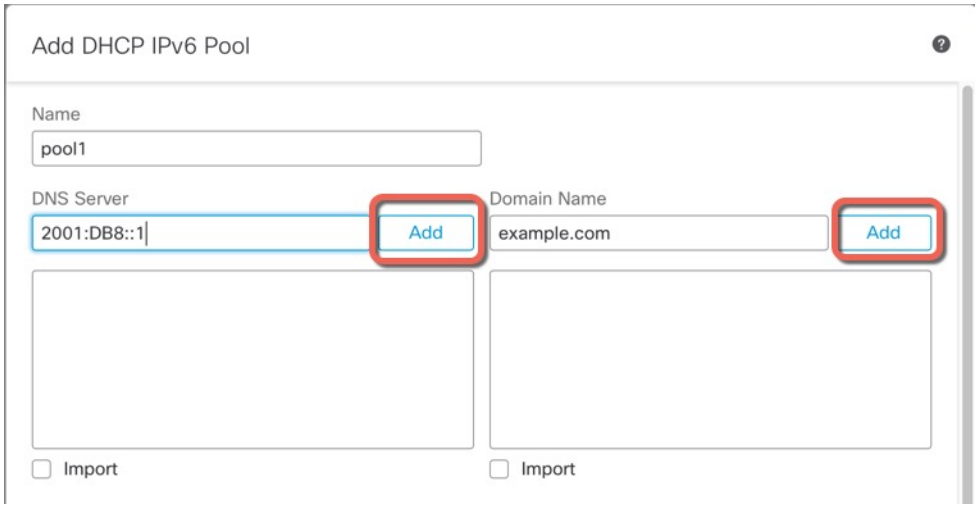
Step 1 Choose **Objects** > **Object Management** > **DHCP IPv6 Pool**.

Step 2 Click **Add** ( ).

Step 3 Configure the **DNS Server** and **Domain Name**.

You can either manually define the values and click **Add**, or you can check **Import** to use one or more parameters that the Firewall Threat Defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

Figure 319: Manually define values



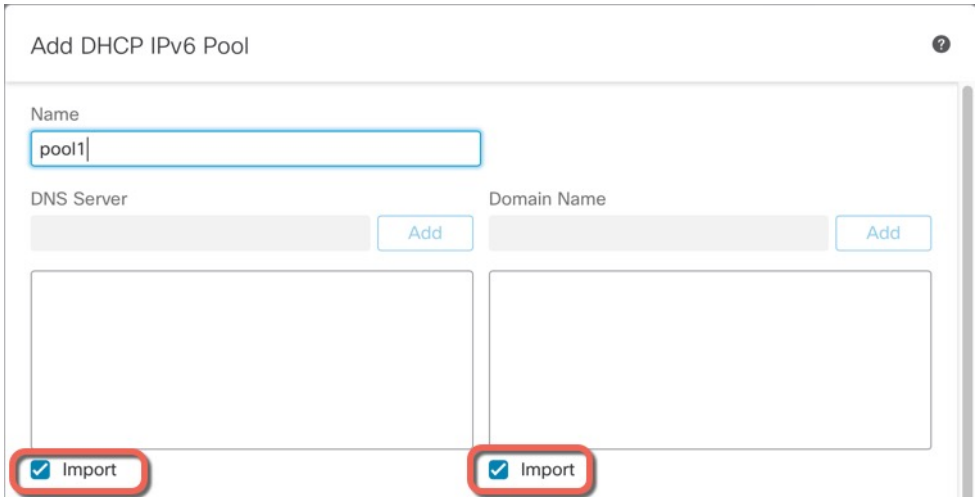


Figure 320: Import values

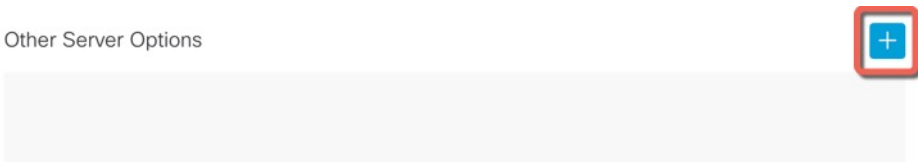
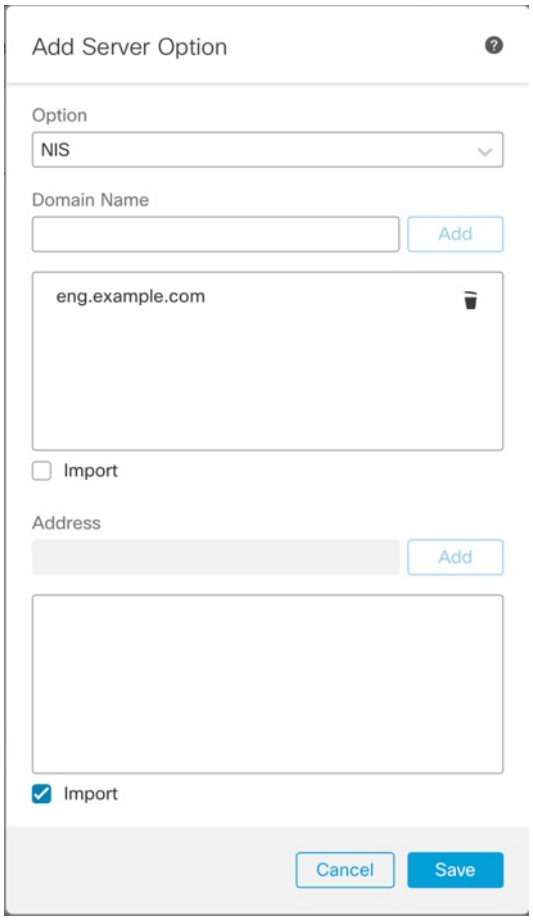


Step 4 Define **Other Server Options**.

You can define the domain name and IP address for these servers:

- NIS
- NISP
- SIP
- SNTP



a) Click **Add** ( ).

Figure 321: Other server options

b) Choose the server type under **Option**, and either manually define the **Domain Name** and **Address**, or check **Import**.

Figure 322: Define server domain name and address

Import uses one or more parameters that the Firewall Threat Defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

c) Click **Save**.

d) Repeat for each server type.

Step 5 Click **Save**.

Step 6 Use this pool with the DHCPv6 server. See Enable the DHCPv6 stateless server, on page 1232.

Enable the DHCPv6 stateless server

This task enables the DHCPv6 stateless server to provide configuration information to IPv6 autoconfiguration clients without assigning addresses. The server responds to Information Request (IR) packets with DNS server addresses, domain names, and other configuration parameters.

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 prefix delegation client, on page 1093), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

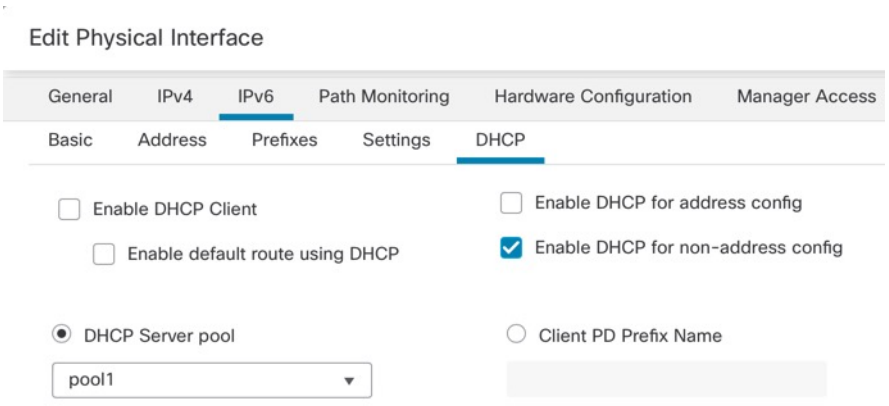
This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

Before you begin

Add a DHCP IPv6 Pool object. See Create a DHCP IPv6 pool, on page 1229. This object defines the server parameters included in the IR messages.

Follow these steps to enable the DHCPv6 stateless server:

Procedure



Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **IPv6** page, and then click **DHCP**.

Step 4 Click **DHCP Server Pool**, and choose the object you created earlier.

Figure 323: Enable the DHCPv6 server

Step 5 Check **Enable DHCP for non-address config** to inform SLAAC clients about the DHCPv6 server.

This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure the DHCP relay agent

Configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers when DHCP clients and servers are on different network segments.

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the Firewall Threat Defense device because it does not forward broadcast traffic.

You can remedy this situation by configuring the interface of the Firewall Threat Defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

Note DHCP Relay is not supported in transparent firewall mode.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **DHCP** > **DHCP Relay**.

Step 3 In the **IPv4 Relay Timeout** and **IPv6 Relay Timeout** fields, enter the amount of time in seconds that the Firewall Threat Defense device waits to time out the DHCP relay agent. Valid values range from 1 to 3600 seconds. The default value is 60 seconds.

The timeout is for address negotiation through the local DHCP Relay agent.

Step 4 (Optional) Check **Trust All Information** to set all client interfaces as trusted.

You can configure interfaces as trusted interfaces to preserve DHCP Option 82. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the Firewall Threat Defense DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then the Firewall Threat Defense will drop that packet by default. You can preserve Option 82 and forward the packet by identifying an interface as a trusted interface.

Step 5 On **DHCP Relay Agent**, click **Add**, and configure these options:

- **Interface**—The interface connected to the DHCP clients.
- **Enable IPv4 Relay**—Enables IPv4 DHCP Relay for this interface.
- **Set Route**—(For IPv4) Changes the default gateway address in the DHCP message from the server to that of the Firewall Threat Defense device interface that is closest to the DHCP client, which relayed the original DHCP request. This action allows the client to set its default route to point to the Firewall Threat Defense device even if the DHCP server specifies a different router. If there is no default router option in the packet, the Firewall Threat Defense device adds one containing the interface address.
- **Enable IPv6 Relay**—Enables IPv6 DHCP Relay for this interface.

Step 6 Click **OK** to save the DHCP relay agent changes.

Step 7 On **DHCP Servers**, click **Add**, and configure these options:

Add the IPv4 and IPv6 server addresses as separate entries, even if they belong to the same server.

- **Server**—The IP address of the DHCP server. Chose an IP address from the drop-down list. To add a new one, see Create a network object, on page 2985
- **Interface**—The interface to which the specified DHCP server is attached. The DHCP Relay agent and the DHCP server cannot be configured on the same interface.

Step 8 Click **OK** to save the DHCP server changes.

Step 9 Click **Save** on the DHCP page to save your changes.

Configure Dynamic DNS

When an interface uses DHCP IP addressing, the assigned IP address can change when the DHCP lease is renewed. When the interface needs to be reachable using a fully qualified domain name (FQDN), the IP address change can cause the DNS server resource records (RRs) to become stale. Dynamic DNS (DDNS) provides a mechanism to update DNS RRs whenever the IP address or hostname changes. You can also use DDNS for static or PPPoE IP addressing.

DDNS updates these RRs on the DNS server: the A RR includes the name-to-IP address mapping, while the PTR RR maps addresses to names.

The Firewall Threat Defense supports these DDNS update methods:

- Standard DDNS—The standard DDNS update method is defined by RFC 2136.

  With this method, the Firewall Threat Defense and the DHCP server use DNS requests to update the DNS RRs. The Firewall Threat Defense or DHCP server sends a DNS request to its local DNS server for information about the hostname and, based on the response, determines the main DNS server that owns the RRs. The Firewall Threat Defense or DHCP server then sends an update request directly to the main DNS server. See these typical scenarios.

  - The Firewall Threat Defense updates the A RR, and the DHCP server updates the PTR RR.

    Typically, the Firewall Threat Defense "owns" the A RR, while the DHCP server "owns" the PTR RR, so both entities need to request updates separately. When the IP address or hostname changes,

the Firewall Threat Defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request a PTR RR update.

- The DHCP server updates both the A and PTR RR.

  Use this scenario if the Firewall Threat Defense does not have the authority to update the A RR. When the IP address or hostname changes, the Firewall Threat Defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request an A and PTR RR update.

You can configure different ownership depending on your security needs and the requirements of the main DNS server. For example, for a static address, the Firewall Threat Defense should own the updates for both records.

- Web—The Web update method uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

  With this method when the IP address or hostname changes, the Firewall Threat Defense sends an HTTP request directly to a DNS provider with which you have an account.

The **DDNS** page also supports setting DHCP server settings relating to DDNS.

Note DDNS is not supported on the BVI or bridge group member interfaces.

Before you begin

- Configure a DNS server group on **Objects** > **Object Management** > **DNS Server Group**, and then enable the group for the interface on **Devices** > **Platform Settings**, create or edit a Threat Defense policy and click **DNS**. See Configure DNS server settings, on page 1246.
- Configure the device hostname. You can configure the hostname when you perform the Firewall Threat Defense initial setup, or by using the **configure network hostname** command. If you do not specify the hostname per interface, then the device hostname is used.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **DHCP** > **DDNS**.

Step 3 Standard DDNS method: Configure a DDNS update method to enable DNS requests from the Firewall Threat Defense.

You do not need to configure a DDNS update method if the DHCP server will perform all requests.

a) On **DDNS Update Methods**, click **Add**.
b) Set the **Method Name**.
c) Click **DDNS**.
d) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.

e) Set the **Update Records** you want the Firewall Threat Defense to update.

This setting only affects the records you want to update directly from the Firewall Threat Defense; to determine the records you want the DHCP server to update, configure the DHCP client settings per interface or globally. See, Step 5, on page 1236.

- **Not Defined**—Disables DNS updates from the Firewall Threat Defense.
- **Both A and PTR Records**—Sets the Firewall Threat Defense to update both A and PTR RRs. Use this option for static or PPPoE IP addressing.
- **A Records**—Sets the Firewall Threat Defense to update the A RR only. Use this option if you want the DHCP server to update the PTR RR.

f) Click **OK**.

g) Assign this method to the interface in Step 5, on page 1236.

Step 4 Web method: Configure a DDNS update method to enable HTTP update requests from the Firewall Threat Defense.

a) On **DDNS Update Methods**, click **Add**.

b) Set the **Method Name**.

c) Click **Web**.

d) Set the **Web Update Type** to update IPv4, IPv6, or both types of addresses.

e) Set the **Web URL**. Specify the update URL. Check with your DNS provider for the URL required.

Use this syntax:

https://*username***:***password***@***provider-domain***/***path***?hostname=<h>&myip=<a>**

Example:

https://jcrichton:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>

f) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.

g) Click **OK**.

h) Assign this method to the interface in Step 5, on page 1236.

i) The web type method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection. See, Step 9, on page 1238.

Step 5 Configure interface settings for DDNS, including setting the update method, DHCP client settings, and the hostname for this interface.

a) On **DDNS Interface Settings**, click **Add**.

b) Choose the **Interface** from the drop-down list.

c) Choose the **Method Name** that you created on the **DDNS Update Methods** page.

(Standard DDNS method) You do not need to assign a method if you want the DHCP server to perform all updates.

d) Set the **Host Name** for this interface.

If you do not set the hostname, the device hostname is used. If you do not specify an FQDN, then the default domain from the DNS server group is appended (for static or PPPoE IP addressing) or the domain name from the DHCP server is appended (for DHCP IP addressing).

e) Standard DDNS method: Configure the **DHCP Client requests DHCP server to update requests** to determine which records you want the DHCP server to update.

The Firewall Threat Defense sends DHCP client requests to the DHCP server. Note that the DHCP server must also be configured to support DDNS. The server can be configured to honor the client requests, or it can override the client (in which case, it will reply to the client so the client does not also try to perform updates that the server is performing).

For static or PPPoE IP addressing, these settings are ignored.

Note
You can also set these values globally for all interfaces on the **DDNS** page. The per-interface settings take precedence over the global settings.

- **Not Selected**—Disables DDNS requests to the DHCP server. Even if the client does not request DDNS updates, the DHCP server can be configured to send updates anyway.
- **No Update**—Requests the DHCP server not to perform updates. This setting works in conjunction with a DDNS update method with **Both A and PTR Records** enabled.
- **Only PTR**—Requests that the DHCP server perform the PTR RR update. This setting works in conjunction with a DDNS update method with **A Records** enabled. Use this setting to enable DHCP option 81.
- **Both A and PTR Records**—Requests that the DHCP server perform both A and PTR RR updates. This setting does not require a DDNS update method to be associated with the interface.

f) Click **OK**.

Note
The **Dynamic DNS Update** settings relate to DHCP server settings when you enable a DHCP server on the Firewall Threat Defense. See, Step 6, on page 1237 for more information.

Step 6 If you enable the DHCP server on an Firewall Threat Defense, you can configure DHCP server settings for DDNS.

To enable the DHCP server, see Configure the DHCPv4 server, on page 1227). You can configure the server behavior when DHCP clients use the standard DDNS update method. If the server performs any updates, then if the client lease expires (and is not renewed), the server will request that the DNS server remove the RRs for which it was responsible.

a) You can configure server settings globally or per interface. For global settings, refer to the main **DDNS** page. For per-interface settings, refer to the **DDNS Interface Settings** page. Interface settings take precedence over global settings.
b) Configure which DNS RRs you want the DHCP server to update under **Dynamic DNS Update**.

- **Not Selected**—DDNS updates are disabled, even if the client requests them.
- **Only PTR**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will only update the PTR RR. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.
- **Both A and PTR Records**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will update both the A and PTR RRs. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN

option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.

c) To override the update actions requested by the DHCP client, check **Override DHCP Client Requests**.

The server will reply to the client that the request was overridden, so the client does not also try to perform updates that the server is performing.

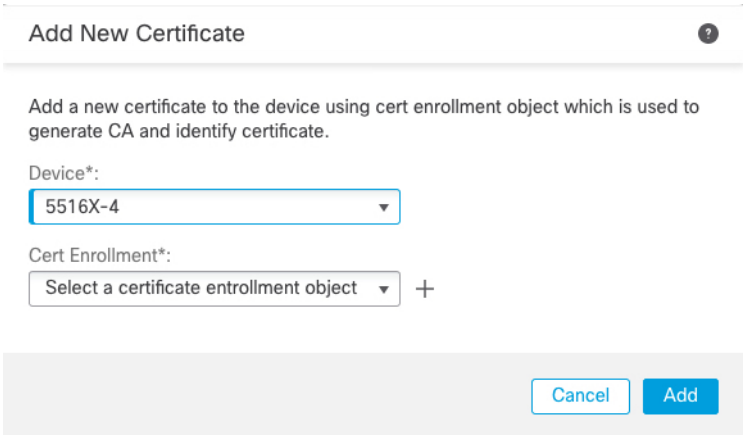
Step 7 (Optional) Configure general DHCP client settings. These settings are not related to DDNS, but are related to how the DHCP client behaves.

a) On the **DDNS** page, check **Enable DHCP Client Broadcast** to request that the DHCP server broadcast the DHCP reply (DHCP option 1).

b) To force a MAC address to be stored inside a DHCP request packet for option 61 instead of the default internally generated string, on **DDNS** > **DHCP Client ID Interface**, choose the interface from the **Available Interfaces** list, and then click **Add** to move it to the **Selected Interfaces** list.

Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned. This setting does not directly relate to DDNS, but is a general DHCP client setting.

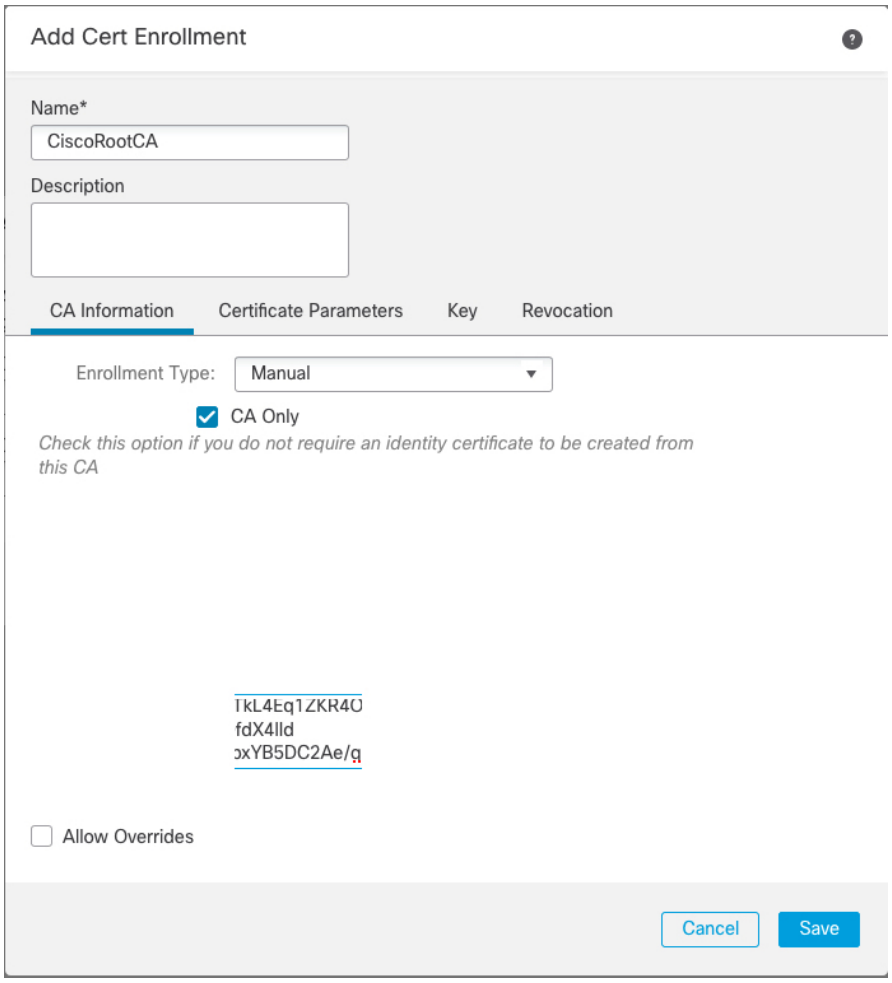
Step 8 Click **Save** on the Device page to save your changes.



Step 9 The Web method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection.

This example shows how to add a DDNS server's CA as a trustpoint.

a) Obtain the DDNS server CA certificate. This procedure shows a manual import using PEM format, but you can also use PKCS12.

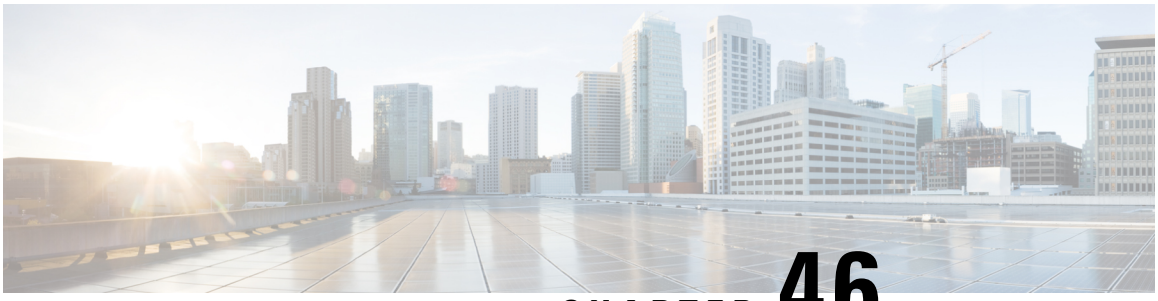


b) In Cloud-Delivered Firewall Management Center, choose **Devices** > **Certificates**, and click **Add**.

c) Select a **Device**, and click **Add** (+).

The **Add Cert Enrollment** dialog box appears.

d) Enter these fields, and click **Save**:



- Enter a **Name**.
- Choose **Enrollment Type** > **Manual**.
- Click **CA Only**.
- Paste in the CA text from step 9.a, on page 1238.

e) Click **Save**.

History for DHCP and DDNS

This reference provides the release history for DHCP and DDNS features, including version requirements and implementation details for Secure Firewall Management Center and Threat Defense devices.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Configure DHCP relay trusted interfaces from the Cloud-Delivered Firewall Management Center web interface.	20240203	Any	You can now use the Cloud-Delivered Firewall Management Center web interface to configure interfaces as trusted interfaces to preserve DHCP Option 82. If you do this, these settings override any existing FlexConfigs, although you should remove them. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the Firewall Threat Defense DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then Firewall Threat Defense will drop that packet by default. You can preserve Option 82 and forward the packet by identifying an interface as a trusted interface. New/modified screens: **Devices** > **Device Management** > **Add/Edit Device** > **DHCP** > **DHCP Relay** See: Configure the DHCP Relay Agent
DHCPv6 Stateless Server	20221213	7.3.0	The Firewall Threat Defense now supports a light DHCPv6 stateless server when using the DHCPv6 Prefix Delegation client. The Firewall Threat Defense provides other information such as the domain name to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. New/modified screens: • **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **DHCP** • **Objects** > **Object Management** > **DHCP IPv6 Pool** New/modified commands: **show ipv6 DHCP**

CHAPTER 46

Platform Settings

Platform settings for Firewall Threat Defense devices configure a range of unrelated features whose values you might want to share among several devices. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

Note In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 devices).

- Platform settings policies, on page 1242
- List requirements and prerequisites for platform settings policies, on page 1242
- Manage platform settings policies, on page 1243
- Configure ARP inspection, on page 1244
- Configure a banner, on page 1245
- Configure DNS server settings, on page 1246
- Configure external authentication, on page 1249
- Enable a virtual-router-aware interface for platform external authentication, on page 1255
- Configure fragment settings, on page 1256
- Configure HTTP access, on page 1257
- Configure ICMP access, on page 1258
- Configure NetFlow, on page 1260
- Configure Secure Shell (SSH) access, on page 1262
- Configure an SMTP server, on page 1264
- Configure SNMP for a security device, on page 1264
- Configure SSL settings, on page 1278
- Syslog, on page 1283
- Configure timeouts, on page 1301
- Synchronize time on FTD devices, on page 1303
- Configure a time zone for a device, on page 1304
- Configure UCAPL/CC compliance, on page 1305
- Configure a performance profile, on page 1306

Platform settings policies

A platform settings policy is a shared set of features or parameters that

- define aspects of managed devices that are likely to be similar to other managed devices in a deployment, such as time settings and external authentication,
- enable configuration of multiple managed devices at once, providing consistency and streamlining management efforts, and
- apply changes to all managed devices where the policy is used, requiring creation and application of shared policies even for device-specific settings.

Platform settings policy reference information

Use platform settings policies to enforce security requirements, such as displaying a login banner message, and to manage device configurations efficiently.

- You can set a “No Unauthorized Use” message for appliance logins using platform settings policies.
- You can apply multiple platform settings policies to a single Cloud-Delivered Firewall Management Center to accommodate different mail relay hosts or access lists.

Platform settings policy example

Your organization’s security policies may require that appliances display a “No Unauthorized Use” message when a user logs in. With platform settings, you can set the login banner once in a platform settings policy.

Multiple platform settings policy example

If your organization has different mail relay hosts that you use for different circumstances or if you want to test different access lists, you can create several platform settings policies and switch between them, rather than editing a single policy.

List requirements and prerequisites for platform settings policies

You must meet specific requirements and prerequisites before you configure Platform Settings Policies, including supported domains and user roles.

Supported domains

Any

User roles

Admin

Access Admin

Network Admin

Manage platform settings policies

Manage platform settings policies to control device configurations and assignments within your environment. This task allows you to create, edit, or delete policies for supported device types.

Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** ( ), **Edit** ( ), or **Delete** ( ) the policy.

Caution
You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is a good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose a device type from the drop-down list:

- **Firepower Settings** to create a shared policy for managed Classic devices.
- **Threat Defense Settings** to create a shared policy for managed Firewall Threat Defense devices.

b) Enter a **Name** for the new policy and optionally, a **Description**.

c) Optionally, choose the **Available Devices** where you want to apply the policy and click **Add** (or drag and drop) to add the selected devices. You can enter a search string in the **Search** field to narrow the list of devices.

d) Click **Save**.

- When you have selected a device and if the device is already applied with a policy, the **Confirm PFS Overwrite** dialog appears. To override the applied policy, click **OK**. The selected device is applied with the new policy.
- The system creates the policy and opens it for editing.

Step 4 To change the target devices for a policy, click **Edit** ( ) next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.

b) To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add**. You can also drag and drop.

c) To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

d) Click **OK**.

After completing these steps, platform settings policies are created, edited, or deleted as needed, and device assignments are updated accordingly.

What to do next

- Deploy configuration changes.

Configure ARP inspection

Configure ARP inspection to ensure that only valid ARP packets are accepted on your network, reducing the risk of ARP spoofing and related attacks.

- Apply ARP inspection policies to specific interfaces and security zones.
- Add static ARP entries for enhanced control and security.

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the Firewall Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the Firewall Threat Defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the Firewall Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Management interface never floods packets even if this parameter is set to flood.

Use this task when you need to protect your network from ARP spoofing by validating ARP packets and controlling ARP traffic on selected interfaces and zones.

Use ARP inspection in environments where network security is a priority and static ARP entries are needed.

Before you begin

Make sure you have device access and permission to edit platform settings and ARP inspection policies.

- Have the list of interfaces and security zones where ARP inspection will be applied.

- Prepare the static ARP entries that you intend to add.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **ARP Inspection**.

Step 3 Add entries to the ARP inspection table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the desired options.

- **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.
- **Flood Enabled**—Floods ARP requests that do not match static ARP entries to all interfaces except the originating or dedicated management interface. By default, this behavior is enabled.

  If you choose not to flood ARP requests, only requests that match static ARP entries are allowed.
- **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, type the interface name into the field in the Selected Security Zone list and click **Add**. The device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Add static ARP entries according to Add a static ARP entry, on page 1111.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ARP inspection is enabled on the selected interfaces and security zones. Only valid ARP packets are accepted, and static ARP entries are enforced. The policy is active after deployment.

Configure a banner

Configure a banner to display messages to users when they connect to the device command line interface (CLI). This helps inform users and discourage unauthorized access.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Banner**.

Step 3 Configure the banner.

These are some tips and requirements for banners.

- Use only ASCII characters. You can add line returns (press Enter), but do not use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables **$(hostname)** or **$(domain)**.
- Although banners do not have an absolute length restriction, Telnet or SSH sessions close if the system does not have enough memory to process banner messages.
- Create a banner that discourages unauthorized access by avoiding the words "welcome" or "please," which may seem inviting. The sample banner provided discourages intruders.

```
You have logged in to a secure device.
If you are not authorized to access this device,
log out immediately or risk criminal charges.
```

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The system displays the banner to users when they connect to the device CLI. The changes occur after you deploy the policy.

Configure DNS server settings

Configure DNS server settings to enable hostname resolution for data traffic on managed devices. This task allows you to set up DNS server groups, trusted DNS services, and interface-specific DNS lookups. These configurations support features such as access control rules, NAT, and application detection.

- Set up DNS server groups for resolving FQDNs used in data traffic.
- Configure trusted DNS servers for DNS snooping and application-based PBR.
- Enable DNS lookups on specific interfaces to control routing behavior.

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. Data DNS settings apply to services that use FQDNs, such as access control rules and remote access VPN. Special management traffic uses separate DNS settings configured via CLI commands. This procedure applies only to data DNS servers. For management DNS settings, see the CLI **configure network dns servers** and **configure network dns searchdomains** commands.

Managed devices use routing lookups to determine the correct interface for DNS server communications. The system selects the routing table based on the interfaces enabled for DNS. Multiple DNS server groups can be configured to resolve different DNS domains, allowing internal and external DNS resolution as needed.

Trusted DNS servers

You can configure trusted DNS services for DNS snooping. DNS snooping is used to map the application domains to IPs in order to detect the application on the first packet. You can also include the already configured servers in DNS group, DHCP pool, DHCP relay and DHCP client as trusted DNS servers.

For application-based PBR, configure trusted DNS servers. Ensure DNS traffic passes through Firewall Threat Defense in clear text format (because encrypted DNS is not supported) for domain resolution and application detection.

Before you begin

- Ensure you have created one or more DNS server groups. For more information, see Create a DNS server group object, on page 2965.
- Ensure you have created interface objects to connect to the DNS servers.
- Ensure that the managed device has appropriate static or dynamic routes to access the DNS servers.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit a Threat Defense policy.

Step 2 Click **DNS**, and then click the **DNS Settings** tab.

Step 3 Check **Enable DNS name resolution by device**.

Step 4 Configure the DNS server groups.

a) Do any of these actions in the DNS server group list:

- To add a group, click **Add**. You cannot add another group once there are 30 filter domains configured within the existing list of server groups.
- To edit a group, click **Edit** ( ) next to the group.
- To remove a group, click **Delete** ( ) next to the group. When you remove a group, you do not delete the DNS server group object. You remove it only from this list.

b) When adding or editing a group, configure the following settings, then click **OK**:

- **Select DNS Group**—Select an existing DNS server group object, or click **+** to create a new one.
- **Make as default**—Select this option to make this group the default group. Any DNS resolution request that does not match the filters for other groups will be resolved using the servers in this group.
- **Filter Domains**—For non-default groups only, enter a list of domain names separated by commas, such as example.com,example.net. Do not include spaces.

  The group is used only for DNS resolutions for these domains. You can enter up to 30 separate domains across all groups in this DNS platform settings policy. Each domain name can contain up to 127 characters.

  Note that these filter domains are not related to the default domain name for the group. The filter list can be different from the default domain.

Step 5 (Optional) Enter the **Expiry Entry Timer** and **Poll Timer** values in minutes.

These options apply to FQDNs specified in network objects only and do not apply to FQDNs used in other features.

- **Expire Entry Timer** specifies the minimum time-to-live (TTL) value for the DNS entry, in minutes. If the expiration timer is longer than the entry's TTL, the TTL is increased to the expire entry time value.

If the TTL is longer than the expiration timer, the expire entry time value is ignored. Upon expiration, the entry is removed from the DNS lookup table. When you remove an entry, the device recompiles the table. Frequent removals can increase the processing load on the device. Some DNS entries can have very short TTL (as short as three seconds); use this setting to virtually extend the TTL. The default is 1 minute. The range is 1 to 65535 minutes.

For systems running 7.0 or earlier, the expiration time is actually added to the TTL; it does not specify a minimum value.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN defined in a network object. An FQDN is resolved periodically when either the poll timer has expired or the TTL of the resolved IP entry has expired, whichever occurs first.

Step 6 Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used.

Enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The Firewall Threat Defense always uses a route lookup to determine the source interface. Management-only interfaces other than the dedicated Management interface cannot be used.

- No interfaces selected—This setting enables DNS lookups on all interfaces. The Firewall Threat Defense checks the data routing table only.
- Specific interfaces selected but not the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces. The Firewall Threat Defense checks the data routing table only.
- Specific interfaces selected plus the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces and the Management interface. The Firewall Threat Defense checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Only the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on Management. The Firewall Threat Defense checks only the management-only routing table.

Step 7 Configure Trusted DNS servers.

a) Click the **Trusted DNS Servers** tab.
b) By default, the existing DNS servers that are configured in DHCP pool, DHCP relay, DHCP client, or DNS server group are included as trusted DNS servers. If you want to exclude any of them, uncheck the appropriate check boxes.
c) To add trusted DNS servers, under **Specify DNS Servers**, click **Edit**.
d) In the **Select DNS Servers** dialog box, either choose a host object as the trusted DNS server or directly specify the IP address of the trusted DNS server:

1. To choose existing host objects, under **Available Host Objects**, select the required host object and click **Add** to include it to **Selected DNS Servers**. For information on adding the host objects, see Create a network object, on page 2985.
2. To directly provide the IP address (IPv4 or IPv6) of the trusted DNS server, enter the address in the given text field, and click **Add** to include it to **Selected DNS Servers**.
3. Click **Save**. The added DNS servers are displayed in the **Trusted DNS Servers** page.

Note
You can configure a maximum of 12 DNS servers per policy.

To search for a DNS server that was added, using either the host name or the IP address, use the search field under **Specify DNS Servers**.

Step 8 Click **Save**.

What to do next

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions, see Create a network object, on page 2985.

Configure external authentication

Configure external authentication to allow management users to be authenticated using an LDAP or RADIUS server, as specified in an external authentication object. Centralized user management also enhances security for device access.

Note You must have administrator privileges to perform this task.

When you enable external authentication for management users, the Firewall Threat Defense verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

Sharing External Authentication Objects

External authentication objects can be used by the Cloud-Delivered Firewall Management Center and Firewall Threat Defense devices. You can share the same object between the Cloud-Delivered Firewall Management Center and devices. Alternatively, create separate objects. Note that the Firewall Threat Defense supports defining users on the RADIUS server, while the Cloud-Delivered Firewall Management Center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the Firewall Threat Defense, but if you want to define users on the RADIUS server, you must create separate objects for the Firewall Threat Defense and the Cloud-Delivered Firewall Management Center.

Note The timeout range is different for the Firewall Threat Defense and the Cloud-Delivered Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1 to 30 seconds for LDAP, and 1 to 300 seconds for RADIUS). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Assigning External Authentication Objects to Devices

For the Cloud-Delivered Firewall Management Center, enable the external authentication objects directly on **System** (⚙) > **Users** > **External Authentication**; this setting only affects Cloud-Delivered Firewall Management Center usage, and it does not need to be enabled for managed device usage. For Firewall Threat Defense devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access. Be sure that both the Firewall Threat Defense and the Cloud-Delivered Firewall Management Center can reach the LDAP server, even if you are not sharing

the object. The Cloud-Delivered Firewall Management Center is essential to retrieving the user list and downloading it to the device.

Firewall Device Supported Fields

Only a subset of fields in the external authentication object are used for Firewall Threat Defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the Cloud-Delivered Firewall Management Center, those fields will be used. This procedure only covers the supported fields for the Firewall Threat Defense. For other fields, see *Configure External Authentication for the Cloud-Delivered Firewall Management Center* in the *Cisco Secure Firewall Management Center Administration Guide*.

Usernames

Usernames must be Linux-valid usernames and be lowercase only, using alphanumeric characters plus period (.) or hyphen (-). Special characters such as at sign (@) and slash (/) are not supported. You cannot add these default internal users for external authentication—**root, daemon, bin, sys, sync, games, man, lp, mail, news, uucp, proxy, www-data, backup, list, irc, gnats, ntp, lldpd, bind, dhcp, qemu, rpcuser, rpc, sshd, radiusd, messagebus, admin, mysql, www, sfrna, snorty, sfsnort, sfremediation, nobody, samdme, extuser, p2puser, rloginUser**. You can only add external users (as part of the External Authentication object) in the Cloud-Delivered Firewall Management Center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the Cloud-Delivered Firewall Management Center.

If you previously configured the same username for an internal user using the **configure user add** command, the Firewall Threat Defense first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Privilege Level

LDAP users always receive Config privileges. You can define RADIUS users as either config or basic users.

Before you begin

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see Configure Secure Shell (SSH) access, on page 1262.
- Inform RADIUS users of the following behavior to set their expectations appropriately:
  - The first time an external user logs in, Firewall Threat Defense creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start the session. The user will see a message similar to this: "New external username identified. Please log in again to start a session."
  - If the user's Service-Type attribute is not defined or incorrectly configured in the RADIUS server and you use the RADIUS-defined users for authentication, the user will see a message similar to this: "Your username is not defined with a service type that is valid for this system. You are not authorized to access the system?".

    In some cases, the SSH clients close the CLI window on an unsuccessful SSH connection, even before displaying the failure message. Hence, ensure that the user's Service-Type attribute is correctly defined in the RADIUS server.
  - Similarly, if the user’s Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to this: "Your authorization privilege has changed. Please log in again to start a session."

- The server used for external authentication must be reachable by the Cloud-Delivered Firewall Management Center; otherwise, users' authentication will fail.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **External Authentication**, and then click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System** > **Users** > **External Authentication**.

Step 3 Click **Add External Authentication Object**.

Step 4 Configure an LDAP Authentication Object.

Step 5 Configure a RADIUS Authentication Object.

Step 6 Return to **System** (⚙) > **Users** > **External Authentication**.

Step 7 Click **Refresh** (↻) to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

Step 8 Click **Slider enabled** (⬭) next to the External Authentication object you want to use. You can only enable one object.

Step 9 Click **Save**; deploy configuration changes (see Deploy configuration changes, on page 202).

After completing this task, external authentication is enabled for management users. The system verifies user credentials with the configured LDAP or RADIUS server and grants access based on the authentication object and user privileges.

Configure an LDAP External Authentication Object

Configure external authentication to allow management users to be authenticated using an LDAP server.

Note You must have administrator privileges to perform this task.

Procedure

Step 1 In the **External Authentication Object** page, select **LDAP** from the **Authentication Method** drop-down list and enter appropriate values in these fields:

a) Enter a **Name**.

b) (Optional) Enter **Description**.

Step 2 Choose a **Server Type** from the drop-down list.

Step 3 For the **Primary Server** enter these values:

a) Enter a **Host Name/IP Address**.

Note
If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

b) Change the **Port** from the default.

Step 4 Enter the **Backup Server** parameters.

Step 5 Enter **LDAP-Specific Parameters**.

- **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
- (Optional) **Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
- **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
- **Password** and **Confirm Password**—Enter and confirm the password for the user.
- (Optional) **Show Advanced Options**—Configure the following advanced options.
  - **Encryption**—Click **None**, **TLS**, or **SSL**.

    Note
    If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

  - **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.
  - (Not Used) **User Name Template**—Not used by the Firewall Threat Defense.
  - **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

    Note
    The timeout range is different for the Firewall Threat Defense and the Cloud-Delivered Firewall Management Center, so if you share an object, be sure not to exceed the Firewall Threat Defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the Firewall Threat Defense external authentication configuration will not work.

Step 6 (Optional) Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.

Step 7 Set the **CLI Access Filter**.

Choose one of these methods:

- To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Step 8 Click **Save**.

Step 9 For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

a) Choose **System** (⚙) > **Users** > **External Authentication**.

b) Click **Refresh** (↻) next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Theat Defense Platform Settings will also show that it is "Out-of-Date on *x* targeted devices."

c) Deploy configuration changes; see Deploy configuration changes, on page 202.

Configure a RADIUS Authentication Object

Configure external authentication to allow management users to be authenticated using a RADIUS server

Note You must have administrator privileges to perform this task.

Procedure

Step 1 In the **External Authentication Object** page, select **RADIUS** from the **Authentication Method** drop-down list and enter appropriate values in these fields:

a) Check the **Enabled Message Authenticator** check box to require the Message-Authenticator attribute in all RADIUS responses, ensuring that every response from the RADIUS server is securely verified by the Firewall Threat Defense.

This feature is enabled by default for new RADIUS servers. We recommend you enable it for existing servers after the upgrade. Disabling message authenticators may expose your firewalls to potential attacks. Ensure that your RADIUS server has the Message-Authenticator configuration.

b) Define users on the RADIUS server using the Service-Type attribute.

This is the list of supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step Configure external authentication, on page 1249). To use the same RADIUS server for the Firewall Threat Defense and Cloud-Delivered Firewall Management Center while using the Service-Type attribute method for the Firewall Threat Defense, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the Cloud-Delivered Firewall Management Center), and the other object leaves the **CLI Access Filter** empty (for use with Firewall Threat Defenses).

c) Enter a **Name** and optional **Description**.

Step 2 For the **Primary Server**, enter a **Host Name/IP Address**.

Note
If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

Step 3 (Optional) Change the **Port** from the default.

Step 4 Enter a **RADIUS Secret Key**.

Step 5 (Optional) Enter the **Backup Server** parameters.

Step 6 Enter **RADIUS-Specific Parameters**.

- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
- **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.

Step 7 (Optional) Enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter `jchrichton, aerynsun, rygel`.

You may want to use the **CLI Access Filter** method for Firewall Threat Defense so you can use the same external authentication object with Firewall Threat Defense and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note
If you want to only define users on the RADIUS server, you must leave this section empty.

Step 8 Click **Save**.

Enable a virtual-router-aware interface for platform external authentication

Enable a virtual-router-aware data interface for external authentication of the platform to allow Authentication, Authorization, and Accounting (AAA) management traffic to be routed through the data interface instead of the default management interface.

Authentication, Authorization, and Accounting (AAA) for the Firewall Threat Defense device is managed through the management interface of the device. You can also enable virtual-router-aware data interface, data sub-interface, port-channel, or sub port-channel to manage AAA for the Firewall Threat Defense device. When enabled, the AAA route lookup is in the Virtual Routing and Forwarding (VRF) routing domain, and the AAA management traffic is forwarded to the data interfaces. These server configuration are supported when using virtual-router-aware data interfaces for AAA:

- RADIUS or LDAP servers for external authentication
- FQDN, IPv4, or IPv6 server addresses

To use a virtual-router-aware interface for external authentication of a Firewall Threat Defense device, modify its external authentication policy by associating the authentication servers with the virtual-router-aware interface of the device.

Before you begin

- Ensure that you have configured the required Virtual Routing and Forwarding (VRF) interface with a static route for the device. For information about configuring a VRF interface, see Configure a virtual router, on page 1387, and for information about adding a static route, see Add a static route, on page 1361.
- Ensure that security zones or interface groups with a single virtual-router-aware interface exists. For information about creating security zones and interface groups, see Create security zone and interface group objects, on page 1002.
- If the primary authentication server is configured with the FQDN of the server, ensure that the backup authentication server, if configured, is also with its FQDN. In addition, configure the DNS server in the

threat defense device's management interface. For information about the DNS server configuration, see Configure DNS.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **External Authentication** and edit the external authentication policy.

Step 3 In the **External Authentication** dialog box, the available security zone and interface groups are listed. To associate a virtual-router-aware interface with the external authentication servers, select the security zone or interface group having a single virtual-router-aware interface, and then do the following:

a) To associate the interface object with the primary authentication server, click **Add to Primary Server**.

b) (Optional) To associate the interface object with the backup authentication server, click **Add to Backup Server**. If the **Add to Backup Server** button is inactive, it means that a backup server for external authentication is not configured in the device.

Step 4 Click **OK**.

Step 5 Save and deploy the changes.

Configure fragment settings

Configure fragment settings to manage the handling of fragmented IP packets on your Firewall Threat Defense device. These settings help prevent Denial of Service (DoS) attacks and ensure applications that require packet fragmentation operate properly.

- Set limits for the number of fragments per packet and for fragments awaiting reassembly.
- Set the timeout for fragment reassembly.
- Allow fragments only if your network applications require them.

By default, the Firewall Threat Defense device allows up to 24 fragments per IP packet. It also allows up to 200 fragments awaiting reassembly. Applications such as NFS over UDP may require fragmented packets, but attackers often use fragmented packets in Denial of Service (DoS) attacks.

These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced** > **Security Configuration**. Select **Devices** > **Device Management**, edit a Firewall Threat Defense device, and select **Interfaces** to edit interface properties.

- Allow fragments only if required by your network applications.
- Override the default settings for specific interfaces when your configuration requires it.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Fragment Settings**.

Step 3 Configure the available options. To use the default settings, click **Reset to Defaults**.

- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default value is 200 fragments. (One fragment equals one packet segment.)
- **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to one to disallow fragments.
- **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is five seconds. If all fragments are not received within this time, all fragments are discarded.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Deploy the policy to activate the new fragment settings on assigned devices. Monitor device performance and change fragment settings as needed.

Configure HTTP access

You can enable the HTTPS server to provide a health check mechanism for a cloud load balancer, for example, for the Firewall Threat Defense Virtual on AWS using an Application Load Balancer.

Use HTTPS with the Firewall Threat Defense only as described for health checks and management. You cannot configure the Firewall Threat Defense through a web interface in this management mode.

Configure HTTP access only on data interfaces, including interfaces you set as management-only. Use only data interfaces for HTTP access, not the dedicated Management interface. The Management interface is separate from the other interfaces on the device. Use the Management interface only to set up and register your device to the Cloud-Delivered Firewall Management Center. It has a separate IP address and static routing.

Configure HTTPS access as described in this section. An access rule for the host IP address is not required.

Use HTTPS only on a reachable interface. If your HTTPS host is on the outside interface, initiate the management connection directly to it.

Before you begin

- Configure HTTPS and AnyConnect VPN module of Cisco Secure Client on separate TCP ports if both features are required on the same interface. For example, assign a different port to HTTPS, such as port 4443.
- Create network objects to define the hosts or networks that are allowed for HTTPS connections. You can add these objects as part of this procedure. If you plan to use object groups for IP addresses, ensure the groups exist in the rules. Select **Objects** > **Object Management** to configure objects.

Note Use the **any-ipv4** or **any-ipv6** network object group instead of the system-provided **any** object.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **HTTP Access**.

Step 3 Check the **Enable HTTP Server** check box to enable the HTTP server.

Step 4 (Optional) Change the HTTP port. The default is 443.

Step 5 Identify the interfaces and IP addresses that allow HTTP connections.

Allow HTTP connections only from specific interfaces and client IP addresses by configuring this table. You may use network addresses instead of individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make HTTP connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow HTTP connections. For interfaces not in a zone, type the interface name into the field under the selected **Selected Zones/Interfaces** list. Then click **Add**. The device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After you complete this task, the device enables HTTP access on the specified interfaces and IP addresses. Use secure connections for health checks or management.

Configure ICMP access

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The Firewall Threat Defense does not respond to ICMP echo requests directed to a broadcast address.
- The Firewall Threat Defense only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

Before you begin

Make sure the required objects exist before you configure rules. Select **Objects** > **Object Management** to configure objects. Create network objects or groups to specify the hosts or networks, and port objects to specify the ICMP message types you want to control.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **ICMP Access**.

Step 3 Configure ICMP rules.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **Action**—Whether to permit (allow) or deny (drop) matching traffic.
- **ICMP Service**—The port object that identifies the ICMP message type.
- **Network**—The network object or groupthat identifies the hosts or networks whose access you are controlling.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces that you are protecting. If an interface is not in a zone, type the interface name into the field beneath the **Selected Zones/Interfaces** list, and click **Add**. A device applies these rules only if it includes the selected interfaces or zones.

c) Click **OK**.

Step 4 (Optional.) Set rate limits on ICMPv4 Unreachable messages.

- **Rate Limit**—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
- **Burst Size**—Sets the burst rate, between 1 and 10. The system sends this number of replies, but subsequent replies are not sent until the rate limit is reached.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ICMP access rules take effect after you deploy the policy to the assigned devices. Your configuration permits or denies ICMP traffic for the hosts or networks you specified.

Configure NetFlow

Configure NetFlow to enable the collection and export of IP network traffic information from your device interfaces. This allows you to analyze traffic patterns, bandwidth usage, and identify sources and causes of network congestion.

The NetFlow feature enables you to collect IP network traffic information as it enters or exits an interface. The collected traffic information is sent as records to a NetFlow Collector server or NetFlow Analyzer. You can analyze the data from NetFlow and determine information such as source and destination of traffic, class of service, traffic pattern, bandwidth usage, type of traffic, traffic volume, and the causes of congestion.

With the native NetFlow configuration support, the traffic information collection that was enabled through syslogs flow exports has to be disabled.

NetFlow provides the option to configure the flow exporter and collectors along with flow event types that must be monitored.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **NetFlow**.

Step 3 Enable the **Enable Flow Export** toggle to enable NetFlow data export.

Step 4 Configure the general NetFlow parameters that control the frequency of events pushed to the collector.

a) **Active Refresh Interval**—For active connections, specify the time interval (in minutes) between flow-update events.

b) **Delay Flow Create**—Specify the delay (in seconds) before sending a flow-create event. If you do not enter any value, there is no delay and the flow-create event is exported as soon as the flow is created.

c) **Template Timeout Rate**—Specify the time interval (in minutes) at which the template records are sent to the collectors.

Step 5 Click **Add Collector** to configure the collector. See Add a collector in NetFlow, on page 1260.

Step 6 Click **Add Traffic Class** to configure the traffic class. See Add a traffic class to NetFlow, on page 1261.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, NetFlow will be enabled and configured on your device. Traffic data will be exported to the configured collector, allowing you to analyze network traffic patterns and usage.

Add a collector in NetFlow

Use this task when you need to export NetFlow data from Cisco Threat Defense devices to a collector for traffic analysis and monitoring.

This configuration is applicable to Cisco Threat Defense policies with NetFlow enabled.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **NetFlow**.

Step 3 Enable the **Enable Flow Export** toggle to enable NetFlow data export.

Step 4 Click **Add Collector** to configure the collector. You can configure a maximum of five collectors.

Step 5 From the **Host** dropdown list, choose the collector host IP address (IPv4 only) of the NetFlow event collector or server to which the NetFlow packets must be sent. Alternatively, you can click the (+) icon to create a new network host.

Step 6 In the **Port** field, enter the UDP port on the collector to which the NetFlow packets must be sent.

Step 7 From **Available Interfaces or Interface Groups**, choose the interface or interface group through which the collector must be reached. You can choose multiple interfaces or interface groups. The Interface Group object can contain only one interface for a given device. A collector can be reached only through one interface. The object can include a virtual-router-aware interface. Loopback interface is not supported in NetFlow.

You can click the (+) icon to create a new interface group.

Step 8 Click **Add** to add the interfaces you chose. Alternatively, you can also enter the interface name and click **Add** to add the interface.

Step 9 Click **OK**.

Add a traffic class to NetFlow

Use this task when you need to monitor, filter, and export specific types of network traffic using NetFlow on a Threat Defense device. Adding a traffic class helps you focus on relevant traffic for security or operational analysis.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **NetFlow**.

Step 3 Click the **Enable Flow Export** toggle to export NetFlow data.

Step 4 Click **Add Traffic Class** to configure the traffic class.

Step 5 In the **Name** field, enter the name of the traffic class that must match the NetFlow events.

Step 6 In the **Type** field, choose the traffic class to filter the type of traffic you want to capture:

- **Default**—The traffic class that is matched if none of the traffic classes matches the traffic.
- **Access List**—The specific traffic class that must match the traffic captured for the NetFlow events.

Step 7 If you select **Access List** as the **Type**, then select the access list object from the **Access List Object** drop-down list.

Note

You can also click the (+) icon to create a new extended access list object. See Configure an extended ACL object, on page 2949.

Step 8 In **Event Types**, check the checkboxes for the different NetFlow events that you want to capture and send to the collectors.

Step 9 Click **OK**.

Configure Secure Shell (SSH) access

If you enabled Cloud-Delivered Firewall Management Center access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more *data* interfaces on the Firewall Threat Defense.

Note SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

Data vs. Management SSH

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Cloud-Delivered Firewall Management Center. SSH for data interfaces shares the internal and external user lists with SSH for the Management interface. Other settings are configured separately. For data interfaces, enable SSH and access lists using this screen. SSH traffic for data interfaces uses the regular routing configuration. Routing for the Management interface configured during setup or at the CLI is not used.

For the Management interface, to configure an SSH access list, see the **configure SSH-access-list** command in the *Cisco Secure Firewall Threat Defense Command Reference*. To configure a static route, see the **configure network static-routes** command. By default, you configure the default route through the Management interface at initial setup.

Interface Access

You can SSH only to a reachable interface(including an interface in a user-defined virtual router); for example, if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface. When you enable SSH in a user-defined virtual router, and you want VPN users to access SSH, be sure to terminate the VPN on the same virtual router. If the VPN is terminated on another virtual router, then you must configure route leaks between the virtual routers.

Ciphers and Key Exchange

SSH supports the following ciphers and key exchange:

- Encryption—aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr

- Integrity—hmac-sha2-256
- Key exchange—dh-group14-sha256

SSH Stack

The Firewall Threat Defense uses the CiscoSSH stack, which is based on OpenSSH. CiscoSSH supports FIPS compliance and regular updates, including updates from Cisco and the open source community.

Maximum Attempts

After you make three consecutive failed attempts to log into the CLI using SSH, the device terminates the SSH connection.

Before you begin

- You can configure SSH internal users at the CLI using the **configure user add** command; see Add an internal user at the CLI, on page 183. By default, there is an **admin** user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring **External Authentication** in platform settings. See Configure external authentication, on page 1249.
- You need network objects that define the hosts or networks permitted to make SSH connections to the device. You can add objects during the procedure. If you want to use object groups to identify a group of IP addresses, make sure the required groups already exist in the rules. Select **Objects** > **Object Management** to configure objects.

Note You cannot use the system-provided **any** network object. Instead, use **any-ipv4** or **any-ipv6**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **SSH Access**.

Step 3 Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.
b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. You can also add loopback interfaces and virtual-router-aware interfaces. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure an SMTP server

Configure an SMTP server to enable email alerts in Syslog. Ensure the source email address configured for Syslog is a valid account on the SMTP servers.

Before you begin

Ensure that the network objects for the primary and secondary SMTP server addresses exist. Define the objects using **Objects** > **Object Management**. You can also create these objects when you edit the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **SMTP Server**.

Step 3 Select the network objects that identify the **Primary Server IP Address** and optionally, the **Secondary Server IP Address**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, email alerts can be sent through Syslog using the specified SMTP servers.

Configure SNMP for a security device

Configure SNMP monitoring to allow network management stations to monitor the health and status of Cisco security devices. This task enables centralized visibility and management of devices using SNMP.

- Enable SNMP so that SNMP management stations can monitor devices.
- SNMP versions 1, 2c, and 3, including traps and read access, are supported. SNMP write access is not supported.

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

SNMPv3 supports read-only users and encryption with DES(deprecated), 3DES, AES256, AES192, and AES128.

The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption and that were created using a version earlier than 6.5, you can continue to use those users for Firewall Threat Defense devices running versions 6.6 or earlier. However, you cannot edit those users and retain DES encryption or create new users with DES encryption. If your Cloud-Delivered Firewall Management Center manages any Firewall Threat Defense devices running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those Firewall Threat Defense devices will fail.

Note

- You can configure SNMP only on Routed and Diagnostic interfaces.
- To create an alert to an external SNMP server, access **Policies** > **Actions** > **Alerts**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **SNMP**.

Step 3 Enable SNMP, and configure basic options.

- **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
- **Read Community String**, **Confirm**—Enter the password used by a SNMP management station when sending requests to the Firewall Threat Defense device. The SNMP community string (also known as password) is a shared secret among the SNMP management stations and the network nodes. The security device uses this password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.
- **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Location**—Enter the location of this security device (for example, Building 42, Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Port**—Enter the UDP port on which incoming requests will be accepted. The default is 161.

Step 4 (SNMPv3 only.) Add SNMPv3 users, on page 1271.

Step 5 Add SNMP hosts, on page 1274.

Step 6 Configure SNMP traps, on page 1276.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

SNMP protocol

SNMP protocol is an application-layer protocol that

- facilitates the exchange of management information between network devices, and
- is part of the TCP/IP protocol suite.

SNMP protocol support and access

Firewall Threat Defense provides support for network monitoring using SNMP Versions 1, 2c, and 3, and supports the use of all three versions simultaneously. The SNMP agent runs on the Firewall Threat Defense interface. You can monitor network devices using management systems (NMSs) such as OpenView network management system. Firewall Threat Defense supports SNMP read-only access with a GET request. SNMP does not support write access or the SNMP SET request, so you cannot make changes with SNMP.

You can configure the Firewall Threat Defense to send traps, which are messages sent to the management station when certain events occur. These messages are called event notifications. You can also use the NMS to browse Management Information Bases (MIBs) on the security devices. MIBs are collections of definitions, and the Firewall Threat Defense maintains a database of values for each definition. To browse a MIB, issue a series of GET-NEXT or GET-BULK requests from the NMS to the MIB tree to get values.

The SNMP agent sends a notification to your management station when a specified event occurs, such as a network link going up or down. The notification includes an SNMP OID, which identifies the source device. The agent also replies when your management station requests information.

List SNMP terminology

This reference lists and defines the terms that are commonly used when working with SNMP.

Table 76: SNMP terminology

Term	Description
Agent	The SNMP server running on the Secure Firewall Threat Defense. The SNMP agent has these features: • responds to requests for information and actions from the network management station. • ontrols access to its Management Information Base, the collection of objects that the SNMP manager can view or change. • does not allow SET operations.
Browsing	Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.
Management Information Bases (MIBs)	Standardized data structures for collecting information about packets, connections, buffers, failovers, and other items. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur.
Network management stations (NMSs)	The PCs or workstations SET up to monitor SNMP events and manage devices.

Term	Description
Object identifier (OID)	The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.
Trap	Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as link-up, link-down, cold-start, warm-start, authentication events, or syslog messages. **coldStart**—The coldStart trap occurs when the SNMP agent starts after the SNMP configuration. This trap also occurs when the agent starts after a system reboot. **Note** For cluster and HA nodes, after a reload, if the interface reboot time exceeds 5 minutes (preset threshold), the trap is dropped. When the cluster and HA nodes have rebooted successfully, all other traps are sent as expected. The **SNMP-server enable traps SNMP coldstart** command is used to enable and disable transmission of these traps.

Describe MIBs and traps

MIBs are either standard or enterprise-specific. Standard MIBs are created by the IETF and described in various RFCs. Traps report significant events, such as errors or failures, on a network device. SNMP traps can be defined in standard or enterprise-specific MIBs. The IETF also creates standard traps, documented in various RFCs. SNMP traps are compiled into ASA software.

If needed, you can also download RFCs, standard MIBs, and standard traps from these locations:

http://www.IETF.org/

Browse the SNMP Object Navigator to look up Cisco MIBs, traps, and OIDs from this location:

https://snmp.cloudapps.cisco.com/Support/SNMP/do/BrowseOID.do?local=en

In addition, download Cisco OIDs by FTP from this location:

ftp://FTP.cisco.com/pub/mibs/oid/oid.tar.gz

List of supported tables and objects in MIBs

This reference lists the supported tables and objects for the specified MIBs, including details for each MIB such as counters, OIDs, and descriptions.

Remote Access VPN polling

Table 77: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
Active Sessions	crasNumSessions (1.3.6.1.4.1.9.9.392.1.3.1)	The number of currently active sessions.
Users	crasNumUsers (1.3.6.1.4.1.9.9.392.1.3.3)	The number of users who have active sessions.

Counter	OID	Description
Peak Sessions	crasNumPeakSessions (1.3.6.1.4.1.9.9.392.1.3.41)	The number of peak RA sessions since system up.

Site-to-site VPN tunnel polling

Table 78: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
LAN to LAN Sessions	crasL2LNumSessions (1.3.6.1.4.1.9.9.392.1.3.29)	The number of currently active LAN to LAN sessions.
Peak LAN to LAN Sessions	crasL2LPeakConcurrentSessions (1.3.6.1.4.1.9.9.392.1.3.31)	The number of peak concurrent LAN to LAN sessions since the system is up.

Connection polling

Table 79: CISCO-FIREWALL-MIB

Counter	OID	Description
Active Connections	cfwConnectionActive (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.6)	The number of connections currently in use by the entire firewall.
Peak Connections	cfwConnectionPeak (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.7)	The highest number of connections in use at any one time since system startup.
Connections Per Second	cfwConnectionPerSecond (1.3.6.1.4.1.9.9.147.1.2.2.3)	The current connections per second rate on the firewall.
Peak Connections Per Second	cfwConnectionPerSecondPeak (1.3.6.1.4.1.9.9.147.1.2.2.4)	The highest number of connections per second on the firewall since system startup.

NAT translation polling

Table 80: CISCO-NAT-EXT-MIB

Counter	OID	Description
Active Translations	cneAddrTranslationNumActive (1.3.6.1.4.1.9.9.532.1.1.1.1)	The total number of address translation entries that are currently available in the NAT device. This indicates the aggregate of the translation entries created from both the static and dynamic address translation mechanisms.
Peak Active Translations	cneAddrTranslationNumPeak (1.3.6.1.4.1.9.9.532.1.1.1.2)	The maximum number of address translation entries that are active at any one time since system startup. This value indicates the high watermark of address translation entries active at any one time since system startup. This object includes the translation entries created from both the static and dynamic address translation mechanisms.

Routing table entries polling

Table 81: IP-FORWARD-MIB

Counter	OID	Description
Active Translations	inetCidrRouteNumber (1.3.6.1.2.1.4.24.6)	The total number of current inetCidrRouteTable entries that are valid.

Interface duplex status polling

Table 82: CISCO-IF-EXTENSION-MIB

Counter	OID	Description
Duplex Status	cieIfDuplexCfgStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.20)	This object specifies the configured duplex status for the given interface.
Detected Duplex Status	cieIfDuplexDetectStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.21)	This object specifies the detected duplex status for the given interface.

Snort 3 intrusion EVENT rate polling

Table 83: CISCO-UNIFIED-FIREWALL-MIB

Counter	OID	Description
Snort 3 Intrusion event Rate	cufwAaicIntrusionEvtRate (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The rate at which intrusion events were recorded by Snort on this firewall, averaged over the last 300 seconds.

BGP peer-flap trap notification

Table 84: BGP4-MIB

Counter	OID	Description
BGP Peer-flap	bgpBackwardTransition (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The BGPBackwardTransition event is generated when the BGP FSM moves from a higher numbered state to a lower numbered state.

CPU utilization polling

Table 85: CISCO-PROCESS-MIB

Counter	OID	Description
CPU Total Utilization	cpmCPUTotal1minRev (1.3.6.1.4.1.9.9.109.1.1.1.1.7.1)	Total system CPU utilization for the last one minute.

Counter	OID	Description
Individual CPU Core Utilization	Associated parameters and values of cpmCPUTotal1minRev 1.3.6.1.4.1.9.9.109.1.1.1.1.7.2 to 1.3.6.1.4.1.9.9.109.1.1.1.1.7.(n+1)	Individual CPU core utilization values for the last one minute, where 'n' represents the number of cores. Examples: • 3.6.1.4.1.99.109.1.1.1.1.7.(n+2) - Aggregate system CPU utilization % (This value is the same as the system CPU usage from .3.6.1.4.1.99.109.1.1.1.1.7.1 in single context mode). • 3.6.1.4.1.99.109.1.1.1.1.7.(n+3) - Snort average CPU utilization % (total aggregate value of all snort instances) • 3.6.1.4.1.99.109.1.1.1.1.7.(n+4) - System PROCESS average % (average of "Sysproc" cores)

Note The SNMP OIDs 1.3.6.1.2.1.25.3.3 and 1.3.6.1.2.1.25.3.4 pertaining to CPU monitoring (hrProcessorTable and hrNetworkTable) were removed on ASA FirePOWER. You can view and MONITOR the CPU health details of the device only through its device manager.

In ENTITY-MIB, two new vendor OIDs were added for the dual EPM 2X100G and 4X200G cards of Secure Firewall 4200 for slot 2 and slot 3—cevFPRNM4X200Gng and cevFPRNM2X100Gng.

Add SNMPv3 users

Add SNMPv3 users to provide secure, authenticated, and encrypted SNMP management access to your device. This task ensures that only authorized users can access SNMPv3 features using specified authentication and encryption algorithms.

You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

Note If you add a new cluster unit or replace a High Availability unit when using SNMPv3 with clustering or High Availability, SNMPv3 users are not replicated to the new unit. Remove the users, add them again, and redeploy your configuration to replicate users to the new unit.

For a successful SNMPv3 user authentication, the authentication key size should be equal to or larger than the encryption key size. For example, a user authentication using SHA-1 with AES256 fails, whereas authentication using SHA256 with AES256 succeeds.

The authentication algorithm options are MD5 (deprecated, pre-6.5 only), SHA, SHA224, SHA256, and SHA384.

Note The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTD devices running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

The encryption algorithm options are DES (deprecated, pre-6.5 only), 3DES, AES256, AES192, and AES128.

Note The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **SNMP** > **Users** tab.

Step 3 Click **Add** and completed the following:

a) Select the security level for the user from the **Security Level** drop-down list.

- **Auth**—Authentication but No Privacy, which means that messages are authenticated.
- **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.
- **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.

b) Enter the name of the SNMP user in the **Username** field. Usernames must be 32 characters or fewer.

c) From the **Encryption Password Type** drop-down list, choose one of these options:

- **Clear text**—The Firewall Threat Defense device encrypts the password when you deploy the policy. In High Availability or cluster deployments, choose this option so that each unit localizes the SNMPv3 key with its own SNMP engineID.
- **Encrypted**—The Firewall Threat Defense device directly deploys the precomputed localized key in hexadecimal format.

Note
Do not choose **Encrypted** for SNMPv3 users in High Availability or cluster deployments. An encrypted SNMPv3 password is a localized key that is generated from a specific SNMP engineID. Each High Availability or cluster unit has a unique SNMP engineID. If you deploy a localized key generated for one unit to its peer, SNMPv3 polling to the peer fails with an authentication error.

Choose **Clear text** so that each unit localizes the key during deployment.

d) In the **Auth Algorithm Type** drop-down list, select the type of authentication you want to use: SHA, SHA224, SHA256, or SHA384.

Note
The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTD devices running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your Cloud-Delivered Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those Firewall Threat Defenses will fail.

e) In the **Authentication Password** field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

Note
The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

f) In the **Encryption Type** drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

Note
To use AES or 3DES encryption, you must have the appropriate license installed on the device.

Note
The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for Firewall Threat Defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your Cloud-Delivered Firewall Management Center manages any Firewall Threat Defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those Firewall Threat Defenses will fail.

g) Enter the password to use for encryption in the **Encryption Password** field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows. Each xx is one octal.:

- AES 128 requires 16 octals
- AES 192 requires 24 octals
- AES 256 requires 32 octals
- 3DES requires 32 octals
- DES can be any size

Note
For all passwords, the length must be 256 characters or fewer.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing these steps, SNMPv3 users are added with the specified authentication and encryption settings. The device is now configured for secure SNMPv3 management access.

Add SNMP hosts

Define SNMP hosts and their communication parameters to enable SNMP management stations to access and monitor the device. This task allows you to specify which hosts are permitted and how they communicate with the device.

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the Firewall Threat Defense device.

You can add up to 8192 hosts. Only 128 of this number can be for traps.

Note In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 FTDs).

Before you begin

Ensure that the network objects that define the SNMP management stations exist. Select **Device** > **Object Management** to configure network objects.

Note The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Choose **SNMP** > **Hosts** tab.

Step 3 Click **Add** and completed the following:

a) In the **IP Address** field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.

The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.

b) Select the appropriate SNMP version from the **SNMP version** drop-down list.

c) (SNMPv3 only.) Select the username of the SNMP user that you configured from the **User Name** drop-down list.

Note
You can associate up to 23 SNMP users per SNMP host.

d) (SNMPv1, 2c only.) In the **Read Community String** field, enter the community string that you have already configured, for read access to the device. Re-enter the string to confirm it.

Note
This string is required, only if the string used with this SNMP station is different from the one already defined in the **Enable SNMP Server** section.

e) Select the type of communication between the device and the SNMP management station. You can select both types. Choose from:

- **Poll**—The management station periodically requests information from the device.
- **Trap**—The device sends trap events to the management station as they occur.

Note
When the SNMP host IP address is either an IPv4 range or an IPv4 subnet, you can configure either **Poll** or **Trap**, not both.

f) In the **Port** field, enter a UDP port number for the SNMP host. The default value is 162. The valid range is 1 to 65535.

g) Select the interface type for communication between the device and the SNMP management station under the **Reachable By** options. You can select either the Management interface of the device or an available security zone/named interface. Choose from:

- **Device Management Interface**—Communication between the device and the SNMP management station occurs over the Management interface.
  - When you choose this interface for SNMPv3 polling, all configured SNMPv3 users are allowed to poll and are not restricted to the user chosen in 3.c, on page 1275. Here, SNMPv1 and SNMPv2c are not allowed from an SNMPv3 host.

- When you choose this interface for SNMPv1 and SNMPv2c polling, the polling is not restricted at all to the version selected in 3.b, on page 1275.

- **Security Zones or Named Interface**—Communication between the device and the SNMP management station occurs over a security zone or interface.
  - Search for zones in the **Available Zones** field.
  - Add the zones that contain the interfaces through which the device communicates with the management station to the **Selected Zone/Interface** field. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. You can also choose a loopback interface and virtual-router-aware interfaces. The host will be configured on a device only if the device includes the selected interfaces or zones.

Note
VTI tunnel interfaces are not supported for SNMP.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure SNMP traps

Use SNMP traps to configure event notifications for Firewall Threat Defense. Traps are unsolicited notifications sent from the device to the management station for certain events, such as linkup, linkdown, and syslog event generation. Each SNMP trap includes an object ID (OID) for your device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy to one of these models. For example, not all models have field-replaceable units, so the **Field Replaceable Unit Insert/Delete** trap will not be configured on those models.

SNMP traps are defined in standard MIBs or in enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. The Firewall Threat Defense software includes SNMP traps.

If needed, you can download RFCs, standard MIBs, and standard traps from http://www.IETF.org/.

Browse the complete list of CISCO MIBs, traps, and OIDs using the SNMP Object Navigator on the Cisco website: SNMP Object Navigator.

In addition, download CISCO OIDs by FTP: ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **SNMP** > **SNMP Traps** to configure SNMP traps (event notifications) for the Firewall Threat Defense device.

Step 3 Select the appropriate Enable Traps options. You can select either or both options.

a) Check **Enable All SNMP Traps** to select all traps in the subsequent four sections.
b) Check **Enable All Syslog Traps** to enable transmission of trap-related syslog messages.

Note
SNMP traps are of higher priority than other notification messages because they are expected to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process to consume excess resources in the agent and in the network, causing the system to hang. If you notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog traps. You can also limit the rate at which syslog messages are generated by severity level or message ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP class; see Configure syslog rate limits, on page 1296.

Step 4 The event-notification traps in the **Standard** section are enabled by default for an existing policy:

- **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string.
- **Link Up** – One of the device's communication links has become available (it has "come up"), as indicated in the notification.
- **Link Down** – One of the device's communication links has failed, as indicated in the notification.
- **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered.
- **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.

Step 5 Select the desired event-notification traps in the **Entity MIB** section:

- **Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.)
- **Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification
- **Configuration Change** – There has been a hardware change, as indicated in the notification

Step 6 Select the desired event-notification traps in the **Resource** section:

- **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached.

Step 7 Select the desired event-notification traps in the **Other** section:

- **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold.
- **CPU Rising Threshold** – This notification is generated when rising CPU utilization exceeds a predefined threshold for a configured period of time. Check this option to enable CPU rising threshold notifications:
  - **Percentage** – The default value is 70% for the high threshold notification; the range is 10 to 94%. The critical threshold is 95%.
  - **Period** – The default monitoring period is 1 minute; the range is 1 to 60 minutes.

- **Memory Rising Threshold** – This notification is generated when rising memory utilization exceeds a predefined threshold, thus reducing available memory. Check this option to enable memory rising threshold notifications:
  - **Percentage** – The default value is 70% for the high threshold notification; the range is 50 to 95%.
- **Failover** – This notification is generated when there is a change in the failover state as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Cluster** – This notification is generated when there is a change in the cluster health as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Peer Flap** – This notification is generated when there is BGP route flapping, a situation in which BGP systems send an excessive number of update messages to advertise network reachability information.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, SNMP traps are configured on the Firewall Threat Defense device, and event notifications will be sent to the management station for the selected events. This enables proactive monitoring and timely response to device events.

Configure SSL settings

This task enables you to configure SSL settings for remote access VPN sessions, allowing you to specify protocol versions, security levels, and available algorithms to ensure secure communication.

You must have administrator privileges and be in a leaf domain to perform this task.

Make sure that you are running a fully licensed version of the Cloud-Delivered Firewall Management Center. The SSL Settings are disabled if you are running Cloud-Delivered Firewall Management Center in evaluation mode. SSL Settings are also disabled if the licensed Cloud-Delivered Firewall Management Center version does not meet the export-compliance criteria. If you are using Remote Access VPN with SSL, your Smart Account must have the strong-crypto features enabled. For more information, see *License Types and Restrictions* in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Ensure you have administrator privileges and are in a leaf domain. Verify that you are running a fully licensed version of the management center with strong-crypto features enabled if using Remote Access VPN with SSL.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit a Firewall Threat Defense policy.

Step 2 Select **SSL**.

Step 3 Add entries to the **Add SSL Configuration** table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the required security configurations from the drop-down list.

- **Protocol Version**—Specifies the TLS protocols to be used while establishing remote access VPN sessions.
- **Security Level**—Indicates the kind of security positioning you would like to set up for the SSL.

Step 4 Select the **Available Algorithms** based on the protocol version that you select and click **Add** to include them for the selected protocol. For more information, see Configure SSL settings, on page 1279.

The algorithms are listed based on the protocol version that you select. Each security protocol identifies a unique algorithm for setting up the security level.

Step 5 Click **OK** to save the changes.

What to do next

Select **Deploy** > **Deployment** and click **Deploy** to deploy the policy to the assigned devices.

Configure SSL settings

The Firewall Threat Defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. The SSL Settings window lets you configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL.

Note Though you configure Cloud-Delivered Firewall Management Center and Firewall Threat Defense to operate in a security certifications (UCAPL, CC, or FIPS) compliance mode, the Cloud-Delivered Firewall Management Center allows configuration of unsupported ciphers. For example, in a FIPS enabled mode, management center allows configuring DH Group 5 which is not FIPS-compliant. However, VPN tunnel does not negotiate due to the non-compliant cipher usage.

Configure the SSL Settings at this location:

Devices > **Platform Settings**, and then click **SSL**.

Fields

Minimum SSL Version as Server—Specify the minimum SSL/TLS protocol version that the Firewall Threat Defense device uses when acting as a server. For example, when it functions as a Remote Access VPN Gateway.

TLS Version—Select one of these TLS versions from the drop-down list:

TLS V1	Accepts SSLv2 client hellos and negotiates TLSv1 (or greater).
TLSV1.1	Accepts SSLv2 client hellos and negotiates TLSv1.1 (or greater).
TLSV1.2	Accepts SSLv2 client hellos and negotiates TLSv1.2 (or greater).
TLSV1.3	Accepts SSLv2 client hellos and negotiates TLSv1.3 (or greater).

Note TLS 1.3 in remote access VPN requires Cisco Secure Client, Version 5.0 and above.

DTLS Version—Select the DTLS versions from the drop-down list, based on the selected TLS version. By default, DTLSv1 is configured on Firewall Threat Defense devices, you can choose the DTLS version as per your requirement.

Note Ensure that the TLS protocol version is higher than or equal to the DTLS protocol version selected. TLS protocol versions support these DTLS versions:

TLS V1	DTLSv1
TLSV1.1	DTLSv1
TLSV1.2	DTLSv1, DTLSv1.2
TLSV1.3	DTLSv1, DTLSv1.2

Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group1 - 768-bit modulus, Group2 - 1024-bit modulus, Group5 - 1536-bit modulus, Group14 - 2048-bit modulus, 224-bit prime order, and Group24 - 2048-bit modulus, 256-bit prime order. The default is Group1.

Elliptical Curve Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group19 - 256-bit EC, Group20 - 384-bit EC, and Group21 - 521-bit EC. The default value is Group19.

TLSv1.2 adds support for these ciphers:

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- RSA-AES128-GCM-SHA256

- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256

Note
ECDSA and DHE ciphers are the highest priority.

TLSv1.3 adds support for these ciphers:

- TLS_AES_128_GCM_SHA256
- TLS_CHACHA20_POLY1305_SHA256
- TLS_AES_256_GCM_SHA384

The SSL configuration table can be used to specify the protocol version, security level, and Cipher algorithms that you want to support on the Secure Firewall Threat Defense devices.

Protocol Version—Lists the protocol version that the Secure Firewall Threat Defense device supports and uses for SSL connections. Available protocol versions are:

- Default
- TLSV1
- TLSV1.1
- TLSV1.2
- TLSV1.3
- DTLSv1
- DTLSv1.2

Security Level—Lists the cipher security levels that Firewall Threat Defense device supports and uses for SSL connections.

If you have Firewall Threat Defense devices with evaluation license, the security level is Low by default. With Firewall Threat Defense smart license, the default security level is High. You can choose one of these options to configure the required security level:

- **All** includes all ciphers, including NULL-SHA.
- **Low** includes all ciphers, except NULL-SHA.
- **Medium** includes all ciphers, except NULL-SHA, DES-CBC-SHA, RC4-SHA, and RC4-MD5 (this is the default).
- **FIPS** includes all FIPS-compliant ciphers, except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA, TLS_CHACHA20_POLY1305_SHA256.
- **High** includes only AES-256 with SHA-2 ciphers and applies to TLS version 1.2 and the *default* version.
- **Custom** includes one or more ciphers that you specify in the Cipher algorithms/custom string box. This option provides you with full control of the cipher suite using OpenSSL cipher definition strings.

Cipher Algorithms/Custom String—Lists the cipher algorithms that the Firewall Threat Defense device supports and uses for SSL connections. For more information about ciphers using OpenSSL, see https://www.openssl.org/docs/apps/ciphers.html

Ciphers supported by TLSv1.2 only

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- DHE-RSA-AES256-SHA256
- AES256-SHA256
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- DHE-RSA-AES128-SHA256
- AES128-SHA256

Note ECDSA and DHE ciphers are the highest priority.

Ciphers not supported by TLSv1.1 or TLSv1.2

- RC4-SHA
- RC4-MD5

- DES-CBC-SHA
- NULL-SHA

Syslog

Logging information

Logging information can help you identify and isolate network or device configuration problems.

- System logging (syslog) can be enabled for Firewall Threat Defense devices.
- Some security events can be sent to a syslog server.

Syslog messages

A syslog message is a log event that

- collects messages from devices to a server running a syslog daemon
- enables aggregation of logs and alerts for centralized management, and
- provides protected long-term storage for logs, supporting troubleshooting and incident handling.

System log configuration details

Devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and either stores them in files or prints them, based on a simple configuration file.

Table 86: System logs for Secure Firewall Threat Defense

Logs related to	Details	Configure in
Device and system health, network configuration	This syslog configuration generates messages for features running on the data plane, that is, features that are defined in the CLI configuration that you can view with the **show running-config** command. This includes features such as routing, VPN, data interfaces, DHCP server, NAT, and so forth. Data plane syslog messages are numbered, and they are the same as those generated by devices running ASA software. However, Secure Firewall Threat Defense does not necessarily generate every message type that is available for ASA Software. For information on these messages, see *Cisco Secure Firewall Threat Defense syslog messages* at https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html. This configuration is explained in these topics.	**Platform settings**

Logs related to	Details	Configure in
Security events	This syslog configuration generates alerts for file and malware, connection, Security Intelligence, and intrusion events.	**Platform settings** and the **Logging** in an access control policy
(All devices) Policies, rules, and events	This syslog configuration generates alerts for access control rules, intrusion rules, and other advanced services as described in *Configurations supporting alert responses* in the *Cisco Secure Firewall Management Center Administration Guide*. These messages are not numbered. For information on configuring this type of syslog, see *Creating a syslog alert response* in the *Cisco Secure Firewall Management Center Administration Guide*.	**alert responses** and the **Logging** in an access control policy

You can set up multiple syslog servers and control the messages and events sent to each server. You can also configure varied destinations, such as console, email, or internal buffer.

Syslog message severity levels

The syslog message severity levels define the importance of system messages.

Table 87: Syslog message severity levels

Level Number	Severity Level	Description
0	**emergencies**	You cannot use the system.
1	**alert**	You need to take immediate action.
2	**critical**	The system has critical conditions to be addressed.
3	**error**	Error conditions.
4	**warning**	The system has warnings you should review.
5	**notification**	The system reports significant events you should monitor.
6	**informational**	Informational messages only.
7	**debugging**	The system generates only debugging messages Log at this level only temporarily, when debugging issues. This log level can generate many messages, which might affect system performance.

Note Firewall Threat Defense does not generate syslog messages with a severity level of zero (emergencies).

Syslog message filters

Syslog message filter criteria

You can direct syslog messages to an output destination according to these criteria:

- Syslog message ID number

  (This does not apply to syslog messages for security events such as connection and intrusion events.)

- Syslog message severity level
- Syslog message class (equivalent to a functional area)

  (This rule does not apply to syslog messages for security events, including connection and intrusion events.)

You can create a message list with specific criteria, which you can then specify as the output destination is set. Alternatively, you can configure the Firewall Threat Defense device to send a particular message class to each type of output destination independently of the message list.

(Message lists do not apply to syslog messages for security events such as connection and intrusion events.)

Syslog message classes and associated message ID numbers

Note This topic does not apply to messages for security events (connection, intrusion, etc.)

You can use syslog message classes in two ways:

- Specify an output location for an entire category of syslog messages.
- Create a message list that specifies the message class.

Use the syslog message class to categorize syslog messages by type, such as features or functions of the device. For example, use the RIP class for RIP routing.

Syslog messages in the same class have the same three initial digits in their message ID numbers. For example, the syslog messages for the VPN client feature use ID numbers 611101 to 611323.

Most ISAKMP syslog messages include prepended objects that identify the tunnel. When available, these objects appear before the descriptive text of a syslog message. If the object is unknown when the syslog message is generated, the heading and value combination is omitted.

The objects are prefixed in this manner:

Group = *groupname*, Username = *user*, IP = *IP_address*

The term 'group' here refers to the tunnel-group configuration. The username is from the local database or AAA server. The IP address is the public IP address of the remote access client or Layer 2 peer.

See the message classes and the range of message ID numbers in each class in this table.

Table 88: Syslog message classes and associated message ID numbers

Class	Definition	Syslog Message ID Numbers
auth	User Authentication	109, 113
—	Access Lists	106
—	Application Firewall	415
—	Botnet Traffic Filtering	338
bridge	Transparent Firewall	110, 220
ca	PKI Certification Authority	717
citrix	Citrix Client	723
—	Clustering	747
—	Card Management	323
config	Command Interface	111, 112, 208, 308
csd	Secure Desktop	724
cts	Cisco TrustSec	776
dap	Dynamic Access Policies	734
EAP, eapoudp	EAP or EAPoUDP for Network Admission Control	333, 334
EIGRP	EIGRP Routing	336
email	E-mail Proxy	719
—	Environment Monitoring	735
ha	Failover	101, 102, 103, 104, 105, 210, 311, 709
—	Identity-based Firewall	746
ids	Intrusion Detection System	400, 733
—	IKEv2 Toolkit	750, 751, 752
IP	IP Stack	209, 215, 313, 317, 408
ipaa	IP Address Assignment	735
ips	Intrusion Protection System	400, 401, 420
—	IPv6	325
—	Licensing	444

Class	Definition	Syslog Message ID Numbers
MDM-proxy	MDM Proxy	802
NAC	Network Admission Control	731, 732
nacpolicy	NAC Policy	731
nacsettings	NAC Settings to apply NAC Policy	732
—	NAT and PAT	305
—	Network Access Point	713
NP	Network Processor	319
—	NP SSL	725
OSPF	OSPF Routing	318, 409, 503, 613
—	Password Encryption	742
—	Phone Proxy	337
RIP	RIP Routing	107, 312
rm	Resource Manager	321
—	Smart Call Home	120
session	User Session	106, 108, 201, 202, 204, 302, 303, 304, 305, 314, 405, 406, 407, 500, 502, 607, 608, 609, 616, 620, 703, 710
SNMP	SNMP	212
—	ScanSafe	775
SSL	SSL Stack	725
svc	SSL VPN Client	722
sys	System	199, 211, 214, 216, 306, 307, 315, 414, 604, 605, 606, 610, 612, 614, 615,701, 711, 741
—	Threat Detection	733
tag-switching	Service Tag Switching	779
transactional-rule-engine-tre	Transactional Rule Engine	780
uc-IMS	UC-IMS	339
vm	VLAN Mapping	730

Class	Definition	Syslog Message ID Numbers
vpdn	PPTP and L2TP Sessions	213, 403, 603
VPN	IKE and IPsec	316, 320, 402, 404, 501, 602, 702, 713, 714, 715
vpnc	VPN Client	611
vpnfo	VPN Failover	720
vpnlb	VPN Load Balancing	718
—	VXLAN	778
webfo	WebVPN Failover	721
webvpn	WebVPN and Secure Client	716

Guidelines for logging

Restrictions for IPv6 logging

- IPv6 is supported. Syslog message can be sent using TCP or UDP.
- Ensure that the interface configured for sending syslogs is enabled, IPv6 capable, and the syslog server is reachable through the designated interface.
- You cannot use IPv6 for secure logging.

Syslog server configuration guidelines

- The syslog server must run a server program called syslogd. Windows includes a syslog server as part of its operating system.
- The syslog server operates based on the syslog-ng process of the firewall system. Do not use external configuration files, such as the *scwx.conf* file from SecureWorks. Because these files are not compatible with the device, using them causes parsing errors and the syslog-ng process fails.
- You can configure up to 16 syslog servers.
- Assign only one list or class to each syslog server and location.
- Do not configure Cloud-Delivered Firewall Management Center as a primary syslog server. The Cloud-Delivered Firewall Management Center can log some syslogs. However, it does not have adequate storage provision to accommodate large amounts of information from connection events for every sensor, especially when multiple sensors are used and all send syslogs.
- The syslog server should be reachable through the Firewall Threat Defense device. Configure the device to deny ICMP unreachable messages on the interface through which the syslog server is reachable, and to send syslogs to the same server. Enable logging for all severity levels. To prevent the syslog server from crashing, suppress the generation of syslogs 313001, 313004, and 313005.
- To view logs generated by the Firewall Threat Defense device, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the Firewall Threat

Defense device generates messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately.

- The Firewall Threat Defense syslog supports one-way TLS for secure logging. It does not support client certificate authentication, trustpoint configuration for syslog, or mutual TLS (X.509 certificate authentication).

Interfaces for syslog configuration

- Determining the egress interface for the syslog:
  - If the specified management-only interface has management-access enabled, the management center will perform route table lookups and determine the egress interface (could be data or management) based on best routing logic.
  - If you configure a management-only interface as logging host, that does not have management-access enabled, the management center will use the interface regardless of routing table entries.

    Thus, for the management center to always uses a dedicated management path for syslog traffic, configure the management interface without management-access, and then specify the interface in the logging host:

    ```
    interface <management-interface>
    management-only ----->Do not include management-access
    logging host <management-interface> <syslog-server-ip>
    ```

- When the syslog rate exceeds 50,000 messages per second, ensure that a data interface is used as egress interface rather than a management interface.
- Configure the data interface as the syslog source interface for production monitoring and auditing. Use the management interface only for temporary testing. This approach ensures optimal syslog reliability and prevents rate-limiting on the management interface.

TCP and UDP connections for syslog

- If you use TCP as the transport protocol, the system opens 4 connections to the syslog server to ensure that messages are not lost. If you collect messages from many devices and the combined connection overhead is too much for the server, use UDP instead.
- The number of UDP connections for syslog is directly related to the number of CPUs on the hardware platform and the number of syslog servers you configure. At any point in time, there can be as many UDP syslog connections as there are CPUs times the number of configured syslog servers. The global UDP connection idle timeout applies to these sessions, and the default duration is two minutes. You can adjust this setting to close sessions more quickly, but the timeout applies to all UDP connections, not just syslog. This is the intended behavior.
- When the Firewall Threat Defense device sends syslogs via TCP, the connection takes about one minute to initiate after the syslogd service restarts.
- When the TCP logging host goes down, it takes approximately six minutes to change its connection status from *Connected* to *Not connected*. Logging relies on TCP to detect the channel state; until then, logging sends the logs through the channel. During this time, when you execute the **show log**, the output would display the TCP logging host as connected. Once the TCP channel is closed, the TCP logging host state is updated to *Not connected*.

Configure syslog logging for Firewall Threat Defense devices

This task enables you to configure syslog logging for Firewall Threat Defense devices, allowing you to monitor and manage system events efficiently.

Syslog logging helps track security events and system activity on your devices. If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages.

See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291 for more information about platform settings that apply to security event syslog messages.

Before you begin

See requirements in Guidelines for logging, on page 1288.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **Syslog** from the table of contents.

Step 3 Click **Logging Setup** to enable logging, specify FTP server settings, and specify Flash usage. For more information, see Configure logging and basic settings, on page 1291.

Step 4 Click **Logging Destinations** to enable logging to specific destinations and to specify filtering on message severity level, event class, or on a custom event list. For more information, see Enable logging destinations, on page 1293.

You must enable a logging destination to see messages at that destination.

Step 5 Click **E-mail Setup** to specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages. For more information, see Configure syslog messages to be sent to an e-mail address, on page 1294.

Step 6 Click **Events List** to define a custom event list that includes an event class, a severity level, and an event ID. For more information, see Create a custom event list, on page 1295.

Step 7 Click **Rate Limit** to specify the volume of messages being sent to all configured destinations and define the message severity level to which you want to assign rate limits. For more information, see Configure syslog rate limits, on page 1296.

Step 8 Click **Syslog Settings** to specify the logging facility, enable the inclusion of a time stamp, and enable other settings to set up a server as a syslog destination. For more information, see Configure syslog settings, on page 1297.

Step 9 Click **Syslog Servers** to specify the IP address, protocol used, format, and security zone for the syslog server that is designated as a logging destination. For more information, see Configure a syslog server, on page 1298.

Configure only a public syslog server. If you configure a local syslog server, health alerts sent to syslog are not delivered.

After you complete these steps, your Firewall Threat Defense device sends system events to the specified destinations for monitoring and analysis.

Firewall Threat Defense platform settings that apply to security event syslog messages

Security events include connection, Security Intelligence, intrusion, and file and malware events. Some syslog settings configured on the **Syslog** page and its tabs apply to syslog messages for security events. However, most settings only apply to messages for events related to system health and networking. This reference lists the settings that apply to syslog messages for security events.

Settings that apply to syslog messages for security events:

- **Logging Setup** tab:
  - **Send syslogs in EMBLEM format**
- **Syslog Settings** tab:
  - **Enable Timestamp on Syslog Messages**
  - **Timestamp Format**
  - **Enable Syslog Device ID**
- **Syslog Servers** tab:
  - All options on the **Add Syslog Server** form and the list of configured servers.

Configure logging and basic settings

Enable logging and configure syslog settings so the system generates and manages logs for data plane events. This setup ensures log data is archived and available for analysis or reporting.

Perform this task when you need to generate syslog messages for data plane events and manage log storage on your device. You can manipulate saved logging data. You can also specify actions for certain syslog messages, extract data for reporting, or track statistics using scripts.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291.

Before you begin

- Determine where logs should be stored, such as an FTP server or flash memory.
- Understand the desired logging level (critical, alerts, emergencies, errors, etc)
- Identify if logging should be enabled on standby or failover units.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Logging Setup** in your device's configuration interface.

Step 3 Enable logging and configure basic logging settings.

- **Enable Logging**—Turns on the data plane system logging.
- **Enable Logging on the Failover Standby Unit**—Turns on logging for the standby device, if available.
- **Send syslogs in EMBLEM format**—Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages. EMBLEM is not compatible with TCP.

  The EMBLEM syslog format is a Cisco-specific convention that is built upon the RFC 3164 and RFC 5424 standards. When EMBLEM is enabled, the syslog message prints a colon (:) after the <PRI> field, which differs from the RFC 5424 format.

  Note
  Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in Cloud-Delivered Firewall Management Center, if you want to display the PRI value in the syslog messages of the managed Firewall Threat Defense device, ensure to enable the EMBLEM format. Also, the device ID does not appear in EMBLEM-formatted syslog messages.

- **Send debug messages as syslogs**—Redirects debug trace output to the syslog. The syslog message number is 711001 and the default logging level is set to debug. To view these messages, ensure logging is enabled at the console and configured for the debug syslog message number and level.
- **Memory Size of Internal Buffer**—Specify the size of the internal buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 52428800 bytes.

Step 4 (Optional) Configure the syslog message logging to the Security Cloud Control.

a) Click the **All Logs** radio button to enable logging all the troubleshooting syslog messages corresponding to the selected severity level or click the **VPN Logs** radio button to enable logging only the VPN troubleshooting messages corresponding to the selected severity level.

b) Choose the syslog severity level for the logging messages in the **Logging Level** drop-down list.

- The logging level for **All Logs** is set to **critical** by default. You can choose to send syslog messages with severity levels **critical**, **alerts**, or **emergencies** to the Cloud-Delivered Firewall Management Center.
- The logging level for the VPN messages is set to **errors** by default.

  VPN troubleshooting syslogs can add excessive load on the Cloud-Delivered Firewall Management Center. Hence, enable this option with caution. Also, when you configure a device with site-to-site or remote access VPN, it automatically enables sending VPN syslogs to the management center by default. We recommend that you limit the logging level to **error** and above to restrict the excessive flow of syslogs to the Cloud-Delivered Firewall Management Center, especially in case of RAVPN, where multiple devices are involved.

For information on the levels, see Syslog message severity levels, on page 1284.

Step 5 (Optional) Save log buffer contents to an FTP server before the buffer is overwritten.

- Enable **FTP Server Buffer Wrap** and enter the necessary destination information in the following fields.
- **IP Address**—Select the host network object that contains the IP address of the FTP server.
- **User Name**—Enter the username to use when connecting to the FTP server.
- **Path**—Enter the path, relative to the FTP root, where the buffer contents should be saved.
- **Password/ Confirm**—Enter and confirm the password used to authenticate the username to the FTP server.

Step 6 (Optional) Save log buffer contents to flash memory before overwriting.

- Check the **Flash** checkbox
- Specify **Maximum flash to be used by logging (KB)** (range: 4-8044176 KB).
- Specify **Minimum free space to be preserved (KB)** (range: 0-8044176 kilobytes.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Logging is enabled and syslog messages are generated and stored based on your configuration. Log data is archived as specified and is accessible for further analysis or reporting.

Enable logging destinations

Enable logging destinations to ensure that syslog messages are received at the specified destination. This task allows you to control which messages are sent by applying message filters to each destination.

To see messages at a logging destination, enable the destination and specify a message filter.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291.

Before you begin

Before you begin, ensure you have access to the system and the necessary permissions to configure logging destinations.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Logging Destinations**.

Step 3 Click **Add** to enable a destination and apply a logging filter, or edit an existing destination.

Step 4 In the **Logging Destinations** dialog box, select a destination and configure the filter for that destination:

a) Choose the destination to enable in the **Logging Destination** drop-down list. You can create one filter for each destination. Examples include Console, E-Mail, Internal buffer, SNMP trap, SSH Sessions, and Syslog servers.

Note
Console and SSH session logging works in the diagnostic CLI only. Enter **system support diagnostic-CLI**.

b) In **Event Class**, choose the filter that will apply to all classes not listed in the table.

You can configure these filters:

- **Filter on severity** —Select the severity level. Messages at this level or higher are sent to the destination
- **Use Event List** —Select the event list that defines the filter. You create these lists on the **Event Lists** page.
- **Disable Logging** —Prevents messages from being sent to this destination.

c) To create filters for each event class, click **Add** for a new filter or edit an existing filter. Select the event class and severity level to limit messages in that class. Click **OK** to save the filter.

For an explanation of the event classes, see Syslog message classes and associated message ID numbers, on page 1285.

d) Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing this task, the selected logging destinations will receive syslog messages according to the filters you have configured.

Configure syslog messages to be sent to an e-mail address

Enable syslog messages to be delivered as e-mails to designated recipients so administrators receive important system notifications directly through e-mail.

You can set up a list of recipients for syslog messages to be sent as e-mails.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291.

Before you begin

- Configure an SMTP server on the platform settings page
- Configure logging and basic settings, on page 1291
- Setup Email as the Logging Destination

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Email Setup**.

Step 3 Specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

Step 4 Click **Add** to enter a new e-mail address recipient of the specified syslog messages.

Step 5 Set the desired severity level for syslog messages for each recipient.

The severity filter ensures only messages of the specified level and higher are sent via e-mail. For information on the levels, see Syslog message severity levels, on page 1284.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Syslog messages are sent as e-mails to the specified recipients according to the configured severity level.

Create a custom event list

Create a custom event list to control which syslog messages are sent to a logging destination. This allows you to filter messages based on event class, severity, and message identifier for more granular control.

An event list is a custom filter you can apply to a logging destination, allowing greater control over which messages are sent. Normally, you filter messages for a destination based solely on severity. Using an event list, you can fine-tune filters using event class, severity, and message ID.

Creating a custom event list is a two-step process. You create a custom list in the **Event Lists**, and then use the event list to define the logging filter for the various types of destination, in the **Logging Destinations**.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291.

Before you begin

Ensure you have access to the system where syslog event lists can be configured.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Events List**.

Step 3 Click **Add** to create a new list or click an existing list to edit.

a) Enter a unique name for the event list in the **Name** field; avoid spaces.

b) Set criteria to filter messages by severity or event class, select the **Severity/Event Class** tab and add or edit entries.

For information on the available classes see Syslog message classes and associated message ID numbers, on page 1285.

For information on the levels, see Syslog message severity levels, on page 1284.

Certain event classes do not apply to devices in transparent mode. If you configure these options, the system does not use or deploy them.

c) To identify messages specifically by message ID, select the **Message ID** and add or edit the IDs.

You can enter a range of IDs using a hyphen, for example, 100000-200000. Each message ID you enter must contain six digits. For information on how the initial three digits map to features, see Syslog message classes and associated message ID numbers, on page 1285.

For specific message numbers, see Cisco ASA Series Syslog Messages.

d) Click **OK** to save the event list.

Step 4 Click **Logging Destinations** and add or edit the destination that should use the custom event list filter.

See Enable logging destinations, on page 1293.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The system creates the custom event list and applies it to the logging destination you select.

Configure syslog rate limits

Limit the rate at which syslog messages are generated, reducing log flooding and ensuring that important messages are not lost.

Syslog message generation can overwhelm logging systems if not managed properly. Configure rate limits for severity levels or specific message IDs to ensure efficient log management. When limits set for severity level and message ID conflict, the message ID limit takes precedence.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most Firewall Threat Defense platform settings do not apply to these messages. See Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Rate Limit**.

Step 3 To limit message generation by severity level, click **Logging Level** > **Add**, then configure these options:

- **Logging Level**—Specify the severity level for the rate limit. For information on the levels, see Syslog message severity levels, on page 1284.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

Step 4 Click **OK**.

Step 5 To limit message generation by syslog message ID, click **Syslog Level** > **Add**, then configure these options:

- **Syslog ID**—Specify the syslog message ID to be rate limited. For specific message numbers, see Cisco ASA Series Syslog Messages.
- **Number of messages**—Enter the maximum number of messages allowed in the specified interval.
- **Interval**—Set the interval (in seconds) for the rate limit counter to reset.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Syslog message generation is limited based on configured severity levels or message IDs, preventing excessive log messages and supporting efficient log management.

Configure syslog settings

Configure syslog settings to manage how syslog messages are generated and sent to external syslog servers. You can specify the facility code, timestamp, device ID, and control message severity and suppression.

General syslog settings let you choose what information is included in syslog messages sent to syslog servers. This information includes the facility code, timestamp, device ID, severity levels, and message suppression. If you configure devices to send syslog messages about security events (such as connection and intrusion events), some settings do not apply to messages that relate to security events. See *Threat Defense Platform Settings That Apply to Security Event Syslog Messages* in the *Cisco Secure Firewall Management Center Administration Guide*.

Before you begin

Make sure you have access to the device and the permissions needed to change syslog settings.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Syslog Settings**.

Step 3 Choose a system log facility from the **Facility** list as required by your syslog server.

Most UNIX systems use the default LOCAL4(20). Change the facility if your network devices use the same codes. In most cases, you do not need to set the facility value for security event logs.

Step 4 Select the **Enable timestamp on each syslog message** check box to include the date and time a message was generated in the syslog message.

Step 5 Select the desired **Timestamp Format**:

- **Legacy (MMM dd yyyy HH:mm:ss)**: Default format without a timezone (always UTC).
- **RFC 5424 (yyyy-MM-ddTHH:mm:ssZ)**: Uses ISO 8601 with “Z” indicating UTC.

Step 6 To add a device identifier at the start of messages, check the **Enable Syslog Device ID** check box and select the identifier type:

- **Interface**—Use the IP address of a specific interface.

  Note
  VTI tunnel interfaces are not supported for Syslog.

- **User Defined ID**—Enter a custom text string (up to 16 characters).
- **Host Name**—Use the device's hostname.

Step 7 Use the Syslog Message table to adjust severity or suppress messages:

Change a message's severity level or disable its generation if necessary. By default, syslog entries for NetFlow are enabled and appear in the table.

a) To suppress redundant messages due to NetFlow, select **Netflow Equivalent Syslogs**.

   This adds the messages to the table as suppressed messages.

   Note
   If any of these syslog equivalents are already in the table, your existing rules are not overwritten.

b) To add a rule, click **Add**.
c) Select the message number (Syslog ID) to change, from the **Syslog ID** drop-down list.
d) Choose the new severity level from the **Logging Level** drop-down list or select **Suppressed** to disable the generation of the message. Usually, you do not change both the severity level and disable the message. However, you can modify both fields if you want.
e) Click **OK** to add the rule to the table.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes.

Configure a syslog server

This task enables you to configure a syslog server for your device, allowing you to collect and monitor system-generated messages for security and operational visibility.

To configure a syslog server to handle messages generated from your system, perform this task.

If you want this syslog server to receive security events such as connection and intrusion events, see also Firewall Threat Defense platform settings that apply to security event syslog messages , on page 1291.

Note In version 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, you must use separate Platform Settings policies for merged and unmerged devices. This requirement also applies to version 7.3 and earlier, and to some Firewall Threat Defense devices upgraded to version 7.4.

Before you begin

- See requirements in Guidelines for logging, on page 1288.
- Make sure your devices can reach your syslog collector on the network.
- Ensure that only a public syslog server is configured. If you configure a local syslog server, health alerts will not be sent to syslog.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Syslog** > **Syslog Server**.

Step 3 Check the **Allow user traffic to pass when TCP syslog server is down (Recommended)** check box, to allow traffic if any syslog server that is using the TCP protocol is down.

Note

- This option is enabled by default. Unless required, we recommend that you allow connections through the threat defense device when the external TCP syslog server is unreachable by the device.
- When the **Allow user traffic to pass when TCP syslog server is down** option is disabled in Cloud-Delivered Firewall Management Center version 6.2.x or earlier, it remains in the Disabled state even after upgrading to version 6.3 or later. You must manually enable this option.
- If this option is disabled and more than one TCP syslog server is configured on the device, user traffic is allowed if at least one server is reachable by thethreat defense device. This option only blocks traffic when none of the configured TCP syslog servers are reachable. The device generates a syslog message that describes the root cause of denied traffic.

```
%FTD-3-414003: TCP Syslog Server intf : IP_Address /port not responding. New connections
are denied based on logging permit-hostdown policy
```

Step 4 In the **Message queue size (messages)** field, enter the queue size for storing syslog messages on the security appliance when the syslog server is busy. The minimum is 1 message. The default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).

If the number of messages exceeds the configured queue size, the excess messages are dropped, resulting in missing syslog entries. To determine the ideal queue size, you need to identify the available block memory. Use the **show blocks** command to know the current memory utilization. For more information on the command and its attributes, see *Cisco Secure Firewall ASA Series Command Reference Guide*. Contact Cisco TAC for assistance.

Step 5 Click **Add** to add a new syslog server.

a) In the **IP Address** drop-down list, select a network host object containing the IP address of the syslog server.

b) Choose the protocol, either TCP or UDP, and enter the port number used for communication between the Firewall Threat Defense device and the syslog server.

UDP is faster and uses fewer resources than TCP on the device.

The default port for UDP is 514. You must manually configure port 1470 for TCP. Valid non-default port values for either protocol are 1025 through 65535.

c) Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

The EMBLEM syslog format is a Cisco-specific convention that is built upon the RFC 3164 and RFC 5424 standards. Hence, when EMBLEM is enabled, the syslog message prints colon (:) after <PRI> field.

Note
Syslog messages in RFC5424 format typically displays the priority value, referred to as PRI. However, in Cloud-Delivered Firewall Management Center, only when you enable logging in Cisco EMBLEM format, the PRI value in the syslog messages of the managed Firewall Threat Defense is displayed. Also, the device ID does not appear in EMBLEM-formatted syslog messages.

d) Check the **Enable Secure Syslog** check box to encrypt the connection between the device and server using SSL or TLS over TCP.

Note
You must select TCP as the protocol and its port value ranging between 1025 and 65535 to use this option. Upload the certificate required to communicate with the syslog server on the **Devices** > **Certificates** page. Then, upload the certificate from the Firewall Threat Defense device to the syslog server to complete the secure relationship and allow it to decrypt the traffic. The **Enable Secure Syslog** option is not supported on the device Management interface.

e) Select **Device Management Interface** or **Security Zones or Named Interfaces** to communicate with the syslog server.

- **Device Management Interface**: Send syslogs out of the Management interface. We recommend that you use this option when configuring syslog on Snort events.

  Note
  The **Device Management Interface** option does not support the **Enable Secure Syslog** option.

- **Security Zones or Named Interfaces**: Select the interfaces from the list of **Available Zones** and click **Add**. You can also add virtual-router-aware interfaces.

  Important
  The Firewall Threat Defense data plane (Lina) syslog messages cannot be sent out through the diagnostic interface. Configure other interfaces or the Management interface (Br1/Management0) to send out the data plane syslog messages.

f) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes.

Configure timeouts

Configure timeout values for console sessions and protocol connections in a Threat Defense policy to manage session durations and optimize device resource usage.

You can set the global idle timeout durations for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool.

You can also set a timeout for console sessions on the device.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Timeouts**.

Step 3 Configure the timeouts you want to change.

For any setting, select **Custom** to specify your own value or **Default** to use the system default value. In most cases, the maximum timeout is 1193 hours.

You can disable some timeouts by selecting **Disable**.

- **Console Timeout**—The idle time until a connection to the console is closed, range is 0 or 5 to 1440 minutes. The default is 0, which means the session does not time out. If you change the value, existing console sessions will continue to use the previous timeout value. The updated timeout will apply only to new connections.
- **Translation Slot (xlate)**—The idle time until a NAT translation slot is freed. This duration must be at least 1 minute. The default is 3 hours.
- **Connection (Conn)**—The idle time until a connection slot is freed. This duration must be at least 5 minutes. The default is 1 hour.
- **Half-Closed**—The idle time until a TCP half-closed connection closes. A connection is considered half-closed if both the FIN and FIN-ACK have been seen. If only the FIN has been seen, the regular connection timeout applies. The minimum is 30 seconds. The default is 10 minutes.
- **UDP**—The idle time until a UDP connection closes. This duration must be at least 1 minute. The default is 2 minutes.
- **ICMP**—The idle time after which general ICMP states are closed. The default (and minimum) is 2 seconds.

- **RPC/Sun RPC**—The idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes.

  In a Sun RPC-based connection, if the parent connection is deleted or times out, a new child connection might not be treated as part of the parent–child relationship. As a result, the new connection could be evaluated according to the system's policy or rules. After the parent connection times out, existing child connections remain valid only until their own timeout value is reached.

- **H.225**—The idle time until an H.225 signaling connection closes. The default is 1 hour. To close a connection immediately after all calls are cleared, a timeout of 1 second (0:0:1) is recommended.
- **H.323**—The idle time after which H.245 (TCP) and H.323 (UDP) media connections close. The default (and minimum) is 5 minutes. Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.
- **SIP**—The idle time until a SIP signaling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.
- **SIP Media**—The idle time until a SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes. The SIP media timer is used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.
- **SIP Disconnect**—The idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 0:10:0. The default is 2 minutes (0:2:0).
- **SIP Invite**—The idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 00:30:0. The default is 3 minutes (0:3:0).
- **SIP Provisional Media**—The timeout value for SIP provisional media connections, between 1 and 30 minutes. The default is 2 minutes.
- **Floating Connection**—When multiple routes exist to a network with different metrics, the system uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To make it possible to use better routes, set the timeout to a value between 0:0:30 and 1193:0:0. This timer does not apply to connections through virtual tunnel interfaces (VTI). If a connection through a VTI gets stuck, you must manually clear it.
- **Xlate PAT**—The idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.
- **TCP Proxy Reassembly**—The idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).
- **ARP Timeout**—The number of seconds between ARP table rebuilds, from 60 to 4294967. The default is 14,400 seconds (4 hours).

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

The configured timeout values are applied to the Threat Defense policy. Sessions and protocol connections will now use the specified timeout durations after you deploy the policy.

Synchronize time on FTD devices

Use a Network Time Protocol (NTP) server to synchronize the clock settings on your devices. We recommend you configure all Firewall Threat Defenses managed by a Cloud-Delivered Firewall Management Center to use the same NTP server as the Cloud-Delivered Firewall Management Center. The Firewall Threat Defense gets its time directly FROM the configured NTP server. If the Firewall Threat Defense's configured NTP servers are not reachable for any reason, it synchronizes its time with the Cloud-Delivered Firewall Management Center.

The device supports NTPv4.

Note If you are deploying Firewall Threat Defense on the Firepower 4100/9300 chassis, you must configure NTP on the Firepower 4100/9300 chassis so that Smart Licensing will work properly and to ensure proper timestamps on device registrations. You should use the same NTP server for the Firepower 4100/9300 chassis and the Cloud-Delivered Firewall Management Center.

Before you begin

- If your organization has one or more NTP servers that your Firewall Threat Defense can reach, use the same NTP server or servers for your devices that you have configured for Time Synchronization on the **System** (⚙) > **Configuration** page on your Cloud-Delivered Firewall Management Center.
- If you selected **Use the authenticated NTP server only** when configuring NTP server or servers for the Cloud-Delivered Firewall Management Center, for your devices use only the NTP server or servers that are configured to authenticate with the Cloud-Delivered Firewall Management Center. (The managed devices will use the same NTP servers as the Cloud-Delivered Firewall Management Center, but their NTP connections will not use authentication.)
- If your device cannot reach an NTP server or your organization does not have one, use the **Via NTP FROM Management Center** option as discussed in this procedure.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Time Synchronization**.

Step 3 Configure one of these clock options:

- **Via NTP FROM Management Center**—(Default). The managed device gets time FROM the NTP servers you configured for the Cloud-Delivered Firewall Management Center (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of these are true, the managed device synchronizes time FROM the Cloud-Delivered Firewall Management Center:
  - The Cloud-Delivered Firewall Management Center's NTP servers are not reachable by the device.
  - The Cloud-Delivered Firewall Management Center has no unauthenticated servers.

- **Via NTP FROM**—If your Cloud-Delivered Firewall Management Center is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as NTP.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in **System** (⚙) > **Configuration** > **Time Synchronization**. If the NTP servers are not reachable, the Cloud-Delivered Firewall Management Center acts as an NTP server.

When multiple NTP servers are configured, the device uses the NTP server that is deemed appropriate based on the criteria defined in RFC. Thus, the status "Being used" for a specific NTP server indicates that the server is currently used by the device.

Step 4 Click **Save**.

After completing these steps, the FTD device synchronizes its clock with the configured NTP server or, if unavailable, with the management center, ensuring accurate time for logs and system operations.

What to do next

- Deploy configuration changes.

Configure a time zone for a device

By default, your device uses the UTC time zone. To set a different time zone for the device, use this procedure.

The time zone you specify is used only in policies that use time-based policy application.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit a Firewall Threat Defense policy.

You can also create time zone objects from the **Objects** > **Object Management** > **Time Zone** page.

Step 2 Create a new time zone object by clicking **+**.

Step 3 Select the time zone.

Step 4 Click **Save**.

What to do next

- Create time range objects, select applicable time ranges in access control and prefilter rules, and assign the parent policies to devices associated with the correct time zone.
- Deploy configuration changes.

Configure UCAPL/CC compliance

Configure Unified Capabilities Approved Products List (UCAPL) or Common Criteria (CC) compliance to ensure your Secure Firewall Threat Defense device meets security certifications and export-controlled feature requirements.

Use this task when you need to enable security certifications compliance for your device. This is required for export-controlled features and may be necessary for regulatory or organizational compliance.

For more information about this setting and how to enable it for the Cloud-Delivered Firewall Management Center, see the *Cisco Secure Firewall Management Center Administration Guide*.

Caution After you enable this setting, disabling it is not possible. To return the appliance to standard mode, reimage the appliance.

Before you begin

- Secure Firewall Threat Defense devices cannot use an evaluation license; your Smart Software Manager account must be enabled for export-controlled features.
- Secure Firewall Threat Defense devices must be deployed in routed mode.
- You must have administrative privileges to perform this task.
- Security certifications compliance mode cannot be changed if the Firewall Threat Defense device is in high availability. Change the security certifications compliance mode before you create the high availability pair.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Click **UCAPL/CC Compliance**.

Step 3 To *permanently* enable security certifications compliance on the appliance, you have two choices:

- To enable security certifications compliance in Common Criteria mode, choose **CC** from the drop-down list.
- To enable security certifications compliance in Unified Capabilities Approved Products List (UCAPL) mode, choose **UCAPL** from the drop-down list.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

After completing these steps, your device operates in the selected compliance mode (UCAPL or CC), and the policy is enforced once deployed.

Configure a performance profile

Configure the performance profile to control how CPU cores are allocated between the data plane and Snort processes on supported devices. This configuration optimizes device performance for VPN, improves intrusion prevention, or balances the workload.

The performance profile determines how the CPU cores on the device are assigned to two of the main system processes: the data plane (Lina) and Snort. The data plane handles VPN connections, routing, and basic layer 3/4 processing. Snort provides advanced inspection for intrusion and malware prevention, URL filtering, application filtering, and other deep packet inspection features.

If you use both basic and advanced features, keep the performance profile unchanged. The system is designed to provide a balanced assignment of cores to these processes. This assignment differs based on the hardware model.

However, if you use the device primarily for VPN, or for intrusion and other advanced inspection, you can skew the performance profile so that more cores are assigned to the more heavily used features. This change can improve system performance.

Before you begin

- These settings apply to systems running release 7.3+ only.
- Performance profile is supported on these device types:
  - Firepower 4100/9300
  - Secure Firewall 3100/4200 (7.4+)
  - Secure Firewall Threat Defense Virtual
- Changing the performance profile is not supported on units in a cluster or high-availability group, or those configured for multi-instance.
- The minimum number for core allocation is 2. Cores are assigned in even numbers based on the selected performance profile.

Procedure

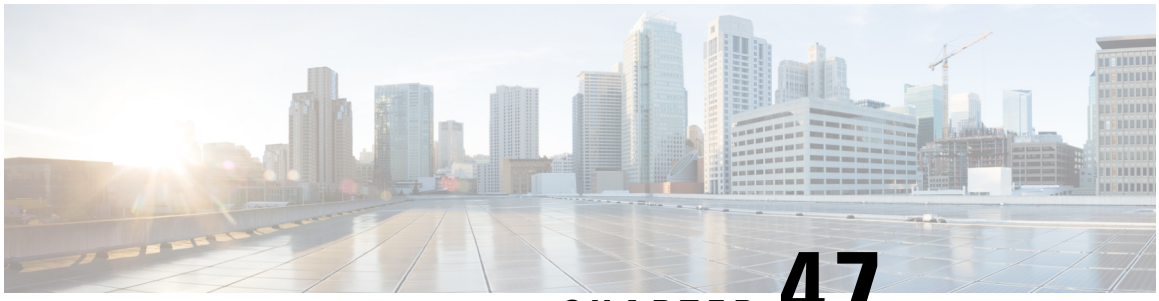
Step 1 Choose **Devices** > **Platform Settings** and create or edit the Firewall Threat Defense policy.

Step 2 Select **Performance Profile**.

Step 3 Select a profile:

- **Default**—This is the recommended setting and is the best option if you configure both VPN and intrusion inspection.
- **VPN Heavy with prefilter fastpath**—If you primarily use the device as a VPN endpoint or headend, and you configure rules in the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. The allocation is 90% data plane, 10% Snort.
- **VPN Heavy with inspection**—If you primarily use the device as a VPN endpoint or headend, but do not use the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of

CPU cores to the data plane. This option assumes that you leave intrusion inspection, URL filtering, and other advanced functions that use Snort, to a different device in the network. The allocation is 60% data plane, 40% Snort.



- **IPS Heavy**—If you do not configure VPN, but you do use the device for intrusion prevention, you can choose this option to assign the majority of CPU core to the Snort process. The allocation is 30% data plane, 70% Snort.

Step 4 Click **Save**.

Step 5 Deploy the policy to apply your configuration.

Step 6 After deployment completes, reboot each affected device to apply the new core assignments.

After completing these steps, the device will use the selected performance profile and allocate CPU cores according to your configuration. The new core assignments take effect after you reboot the device.

CHAPTER 47

FlexConfig policies

These topics describe how to configure and deploy FlexConfig policies.

- FlexConfig policy overview, on page 1309
- Requirements and prerequisites for FlexConfig policies, on page 1330
- Guidelines and limitations for FlexConfig, on page 1331
- Customize device configuration with FlexConfig policies, on page 1331
- Examples for FlexConfig, on page 1346
- Migrate FlexConfig policies, on page 1352

FlexConfig policy overview

A FlexConfig policy is a container of an ordered list of FlexConfig objects that

- includes a series of Apache Velocity scripting language commands, ASA software configuration commands, and variables that you define
- contains FlexConfig objects that are essentially programs that generate a sequence of ASA commands that will then be deployed to the assigned devices, and
- configures the related feature on the Firewall Threat Defense device.

FlexConfig policy usage and limitations

Firewall Threat Defense uses ASA configuration commands to implement some features, but not all features. There is no unique set of Firewall Threat Defense configuration commands. Instead, the point of FlexConfig is to allow you to configure features that are not yet directly supported through Cloud-Delivered Firewall Management Center policies and settings.

Caution We recommend using FlexConfig policies only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through FlexConfig policies may cause unintended results with other configured features.

Contact the Cisco Technical Assistance Center for support concerning FlexConfig policies that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other features. FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for the Cloud-Delivered Firewall Management Center support. When in doubt, do not use FlexConfig policies.

Recommended usage for FlexConfig policies

Use FlexConfig policies in two main scenarios to ensure proper firewall configuration and functionality.

- You are converting from ASA to Firewall Threat Defense, and there are compatible features you are using (and need to continue using) that Cloud-Delivered Firewall Management Center does not directly support. In this case, use the **show running-config** command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Experiment with the object's deployment settings (once/every time and append/prepend) to get the right setting. Verify by comparing **show running-config** output on the two devices.
- You are using Firewall Threat Defense but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

The system includes a set of predefined FlexConfig objects that represent tested configurations. If the feature you need is not represented by these objects, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control. The ASA implements these functions using separate features. Many features are not configured using CLI commands, so not every policy appears in the output of the **show running-config** command.

Note At all times, keep in mind that there is not a one-to-one overlap between ASA and Firewall Threat Defense. Do not attempt to completely recreate an ASA configuration on a Firewall Threat Defense device. You must carefully test any feature that you configure using FlexConfig.

CLI commands in FlexConfig objects

A managed device uses ASA configuration commands to configure some features. Although not all ASA features are compatible with the device, some features can work on the managed device but you cannot configure them through Cloud-Delivered Firewall Management Center policies. You can use FlexConfig objects to specify the CLI required to configure these features.

ASA documentation resources

When using FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig policies do not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

- ASA CLI configuration guides explain how to configure a feature. Find the guides at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-installation-and-configuration-guides-list.html
- ASA command references provide additional information sorted by command name. Find the references at https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-command-reference-list.html

Determine the ASA software version and current CLI configuration

Determine the ASA software version and examine the current CLI-based configuration to identify which ASA CLI configuration guides to use for instructions on configuring a feature.

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the Firewall Threat Defense device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a Firewall Threat Defense configuration. Many Firewall Threat Defense policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and Firewall Threat Defense configuration.

To view this information, make an SSH connection to the device's management interface and issue the following commands:

- **show version system** and look for the Cisco Adaptive Security Appliance Software Version number. (If you issue the command through the Cloud-Delivered Firewall Management Center CLI tool, omit the **system** keyword.)
- **show running-config** to view the current CLI configuration.
- **show running-config all** to include all the default commands in the current CLI configuration.

You can also issue these commands from within Cloud-Delivered Firewall Management Center using this procedure.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Step 2 Click the name of the device targeted by the FlexConfig policy.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

Step 3 Click **View System and Troubleshoot Details**.

Step 4 Click **Advanced Troubleshooting**.

Step 5 Click **Threat Defense CLI**.

Step 6 Choose the **Device**, then choose **show** as the command, and type **version** or one of the other commands as the parameter.

Step 7 Click **Execute**.

For version, search the output for the Cisco Adaptive Security Appliance Software Version number.

You can select the output and press Ctrl+C, then paste it into a text file for later analysis.

Prohibited CLI commands

The purpose of FlexConfig is to configure features that are available on ASA devices that you cannot configure on Firewall Threat Defense devices using Cloud-Delivered Firewall Management Center.

Thus, you are prevented from configuring ASA features that have equivalents in Cloud-Delivered Firewall Management Center. The following table lists some of these prohibited command areas.

In addition, some **clear** commands are prohibited because they overlap with managed policies, and can delete part of the configuration for a managed policy.

The FlexConfig object editor prevents you from including prohibited commands in the object.

Prohibited CLI Command	Description
AAA	Configuration blocked.
AAA-Server	Configuration blocked.
Access-list	Advanced ACL, Extended ACL, and Standard ACL are blocked. Ethertype ACL is allowed. You can use standard and extended ACL objects defined in the object manager inside the template as variables.
ARP Inspection	Configuration blocked.
As-path Object	Configuration blocked.
Banner	Configuration blocked.
BGP	Configuration blocked.
Clock	Configuration blocked.
Community-list Object	Configuration blocked.
Copy	Configuration blocked.
Delete	Configuration blocked.
DHCP	Configuration blocked.
Enable Password	Configuration blocked.

Prohibited CLI Command	Description
Erase	Configuration blocked.
Fragment Setting	Blocked, except for **fragment reassembly**.
Fsck	Configuration blocked.
HTTP	Configuration blocked.
ICMP	Configuration blocked.
Interface	Only **nameif**, **mode**, **shutdown**, **ip address** and **mac-address** commands are blocked.
Multicast Routing	Configuration blocked.
NAT	Configuration blocked.
Network Object/Object-group	Network object creation in the FlexConfig object is blocked, but you can use network objects and groups defined in the object manager inside the template as variables.
NTP	Configuration blocked.
OSPF/OSPFv3	Configuration blocked.
pager	Configuration blocked.
Password Encryption	Configuration blocked.
Policy-list Object	Configuration blocked.
Prefix-list Object	Configuration blocked.
Reload	You cannot schedule reloads. The system does not use the **reload** command to restart the system, it uses the **reboot** command.
RIP	Configuration blocked.
Route-Map Object	Route-map object creation in the FlexConfig object is blocked, but you can use route map objects defined in the object manager inside the template as variables.
Service Object/Object-group	Service object creation in the FlexConfig object is blocked, but you can use port objects defined in the object manager inside the template as variables.

VPN	Configuration blocked.

Template scripts

You can use scripting language to control processing within a FlexConfig object. Scripting language instructions are a subset of commands supported in the Apache Velocity 1.3.1 template engine. The Apache Velocity engine is a Java-based scripting language that supports looping, if/else statements, and variables.

To learn how to use the scripting language, see the *Velocity Developer Guide* at http://velocity.apache.org/engine/devel/developer-guide.html.

FlexConfig variables

You can use variables in a FlexConfig object in cases where part of a command or processing instruction depends on runtime information rather than static information. During deployment, the variables are replaced with strings obtained from other device configurations, depending on the type of variable.

FlexConfig variable types

Variables are replaced with strings based on the type of variable.

- Policy object variables are replaced with strings obtained from objects defined in Cloud-Delivered Firewall Management Center.
- System variables are replaced with information obtained from the device itself or from policies configured for it.
- Processing variables are loaded with the contents of policy object or system variables as during script execution. For example, in a loop, you iteratively load one value from a policy object or system variable into a processing variable, then use the processing variable to form a command string or perform another action. These processing variables do not show up in the Variables list within a FlexConfig object. Also, you do not add them using the **Insert** menu in the FlexConfig object editor.
- Secret key variables are replaced with the single string defined for the variable within the FlexConfig object.

Variables start with the $ character, except for secret keys, which start with the @ character. For example, $ifname is a policy object variable in this command, whereas @keyname is a secret key.

```
interface $ifname
key @keyname
```

Note The first time you insert a policy object or system variable, you must do so through the **Insert** menu in the FlexConfig object editor. This action adds the variable to the **Variables** list at the bottom of the FlexConfig object editor. You must type in the variable string on subsequent uses, even when using system variables. If you are adding a processing variable, which does not have an object or system variable assignment, do not use the **Insert** menu. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Whether a variable is resolved as a single string, a list of strings, or a table of values depends on the type of policy object or system variable you assign to the variable. (Secret keys always resolve to a single string.) You must understand what will be returned in order to process the variables correctly.

Variable processing

At runtime, a variable can resolve to any of these: a single string; a list of strings of the same type; a list of strings of different types; or a table of named values. Variables that resolve to multiple values can have a determinate or indeterminate length. To process the values correctly, you must understand what will be returned.

The main possibilities include these scenarios.

Single value variables

If a variable always resolves to a single string, use the variable directly without modification in the FlexConfig script.

For example, the predefined text variable tcpMssBytes always resolves to a single value (which must be numeric). The **Sysopt_basic** FlexConfig then uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, *tcpMssMinimum*.

Implementation methods

The implementation of single value variables depends on the variable type:

- **Standard text variables**: Use the variable directly in the FlexConfig script. For example, the predefined text variable tcpMssBytes always resolves to a single numeric value.
- **Secret key variables**: Always use the **Insert** menu to add the variable, even for second and subsequent uses. These variables do not show up in the Variables list within the FlexConfig object.
- **Policy object variables for network objects**: Equate to a single IP address specification (host address, network address, or address range). You must know what type of address to expect because ASA commands require specific address types.

Note Policy object variables for network objects also equate to a single IP address specification, either a host address, network address, or address range. However, in this case, you must know what type of address to expect, because the ASA commands require specific address types. For example, if a command requires a host address, using a network object variable that points to an object that contains a network address will result in an error during deployment.

TCP MSS configuration using single value variables

The **Sysopt_basic** FlexConfig uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, tcpMssMinimum:

```
#if($tcpMssMinimum == "true")
  sysopt connection tcpmss minimum $tcpMssBytes
#else
  sysopt connection tcpmss $tcpMssBytes
#end
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $tcpMssBytes, but you would type in the variable directly on the #else line.

Multiple value variables with same type values

Several policy object and system variables resolve to multiple values of the same type. For example, an object variable that points to a network object group resolves to a list of the IP addresses within the group. Similarly, the system variable $SYS_FW_INTERFACE_NAME_LIST resolves to a list of interface names.

You can also create text objects for multiple values of the same type. For example, the predefined text object enableInspectProtocolList can contain more than one protocol name.

Processing characteristics

Multiple value variables that resolve to a list of items of the same type are frequently of indeterminate length. For example, you cannot know beforehand how many interfaces on a device are named, as users can configure or unconfigure interfaces at any time.

You would typically use a loop to process multiple value variables of the same type. For example, the predefined FlexConfig **Default_Inspection_Protocol_Enable** uses a #foreach loop to go through the enableInspectProtocolList object and process each value.

```
policy-map global_policy
    class inspection_default
    #foreach ( $protocol in $enableInspectProtocolList)
    inspect $protocol
    #end
```

In this example, the script assigns each value in turn to the $protocol variable, which is then used in an ASA **inspect** command to enable the inspection engine for that protocol. In this case, you simply type in $protocol as a variable NAME. You do not use the **Insert** menu to add it, because you are not assigning an object or system value to the variable. However, you must use the **Insert** menu to add $enableInspectProtocolList.

The system loops through the code between #foreach and #end until there are no values remaining in $enableInspectProtocolList.

Multiple value variables with different types

You can create multiple value text objects and have each value serve a different purpose. For example, the predefined **netflow_Destination** text object should include three values in this order: interface name, destination IP address, and UDP port number.

Objects defined in this way should have a determinate number of values to make them easier to process.

Processing multiple value variables

Use the get method to process these objects. Type **.get(*n*)** at the end of the object name, replacing *n* with an index into the object. Start counting at 0, even though the text object lists its values starting at 1.

NetFlow destination configuration example

The predefined **netflow_Destination** text object should have 3 values, in order, interface name, destination IP address, and UDP port number.

The Netflow_Add_Destination object uses this line to add the 3 values from netflow_Destination to the ASA **flow-export** command:

```
flow-export destination $netflow_Destination.get(0) $netflow_Destination.get(1)
$netflow_Destination.get(2)
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of $netflow_Destination, and then add **.get(0)**. But you would type in the variable directly for the **$netflow_Destination.get(1)** and **$netflow_Destination.get(2)** specifications.

Multiple value variables that resolve to a table of values

Some system variables return a table of values. These variables include the string MAP in their names. For example, $SYS_FTD_ROUTED_INTF_MAP_LIST is one such variable. The routed interface map returns data in a table of values. Line breaks have been added for clarity.

Variable structure and processing

These variables return data that includes a table of named values for each item. For example, the ROUTED interface MAP returns data that looks like this (line returns added for clarity):

```
[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]
```

In the above example, information is returned for 4 interfaces. Each interface includes a table of named values. For example, intf_hardwarare_id is the name of the interface hardware name property, and returns strings such as GigabitEthernet0/0.

This type of variable is typically of indeterminate length, so you need to use looping to process the values. You also need to add the property name to the variable name to indicate which value to retrieve.

IS-IS interface configuration

For example, IS-IS configuration requires that you add the ASA **ISIS** command to an interface that has a logical name in interface configuration mode. However, you enter that mode using the interface's hardware name. Thus, you need to identify which interfaces have logical names, then configure just those interfaces using their hardware names. The ISIS_Interface_Configuration predefined FlexConfig does this using an if/then structure nested in a loop. In this code, you can see that the #foreach scripting command loads each interface MAP into the $INTF variable, then the #if statement keys off the intf_logical_name value in the MAP ($INTF.intf_logical_name), and if the value is in the LIST defined in the isisIntfList predefined text variable, enters the interface command using the intf_hardwarare_id value ($INTF.intf_hardwarare_id). You would need to edit the isisIntfList variable to add the names of the interfaces on which to configure IS-IS.

```
#foreach ($intf in $SYS_FTD_ROUTED_INTF_MAP_LIST)
 #if ($isIsIntfList.contains($intf.intf_logical_name))
  interface $intf.intf_hardwarare_id
   isis
   #if ($isIsAddressFamily.contains("ipv6"))
   ipv6 router isis
   #end
 #end
#end
```

Evaluate device variable results

To evaluate what a variable will return by creating a simple FlexConfig object that processes variables and shows their resolved values in a configuration preview.

This method allows you to test and analyze variable resolution without deploying potentially invalid configuration commands to devices.

Procedure

Step 1 Create a simple FlexConfig object that processes an annotated list of variables.

Example:

```
Following is a network object group variable for the
IPv4-Private-All-RFC1918 object:

$IPv4_Private_addresses

Following is the system variable SYS_FW_MANAGEMENT_IP:

$SYS_FW_MANAGEMENT_IP

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

$SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

$SYS_FTD_ROUTED_INTF_MAP_LIST
```

```
Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

$SYS_FW_INTERFACE_NAME_LIST
```

Step 2 Assign the FlexConfig object to a FlexConfig policy.

Step 3 Assign the policy to a device.

Step 4 Save the policy.

Step 5 Preview the configuration for that device.

The preview shows the resolved values.

Step 6 Select the preview text, copy it, then paste the output into a text file for analysis.

Example:

```
###Flex-config Prepended CLI ###

###CLI generated from managed features ###

###Flex-config Appended CLI ###
Following is an network object group variable for the
IPv4-Private-All-RFC1918 object:

[10.0.0.0, 172.16.0.0, 192.168.0.0]

Following is the system variable SYS_FW_MANAGEMENT_IP:

192.168.0.171

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

[dns, ftp, h323 h225, h323 ras, rsh, rtsp, sqlnet, skinny, sunrpc,
xdmcp, sip, netbios, tftp, icmp, icmp error, ip-options]

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

[outside, inside, management]
```

Note

Do not deploy this FlexConfig to the device, however, because it will not contain any valid configuration commands. You would get deployment errors. After obtaining the preview, delete the FlexConfig object from the FlexConfig policy and save the policy.

You can analyze the resolved variable values in the text file to understand what each variable returns for the device.

FlexConfig policy object variables

A policy object variable is associated with a specific policy object configured in the Object Manager. When you insert a policy object variable in a FlexConfig object, you give the variable a name and select the object associated with it.

Policy object variable types

Although you can give the variable the exact same name as the associated object, the variable itself is not the same thing as the associated object. You must use the **Insert** > **Insert Policy Object** > ***Object Type*** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the object. Simply typing in the name of the object preceded by a $ sign does not create a policy object variable.

You can create variables to point to these types of objects. Ensure that you create the right type of object for each variable. To create objects, go to the **Objects** > **Object Management** page.

- **Text Objects**—For text strings, which can include IP addresses, numbers, and other free-form text such as interface or zone names. Select **FlexConfig** > **Text Object** from the table of contents, then click **Add Text Object**. You can configure these objects to contain a single value or multiple values. These objects are highly flexible and built specifically for use within FlexConfig objects. For detailed information, see Configure FlexConfig text objects, on page 1337.
- **Network**—For IP addresses. You can use network objects or groups. Select **Network** from the table of contents, then select **Add Network** > **Add Object** or **Add Group**. If you use a group object, the variable returns a list of each IP address specification within the group. Addresses can be host, network, or address ranges, depending on the object contents. See Networks, on page 2982.
- **Security Zones**—For interfaces within a security zone or interface group. Select **Interface** from the table of contents, then select **Add** > **Security Zone** or **Interface Group**. A security zone variable returns a list of the interfaces within that zone or group for the device being configured. See Interfaces, on page 2980.
- **Standard ACL Object**—For standard access control lists. A standard ACL variable returns the name of the standard ACL object. Select **Access List** > **Standard** from the table of contents, then click **Add Standard Access List Object**. See Access lists, on page 2948.
- **Extended ACL Object**—For extended access control lists. An extended ACL variable returns the name of the extended ACL object. Select **Access List** > **Extended** from the table of contents, then click **Add Extended Access List Object**. See Access lists, on page 2948.
- **Route Map**—For route map objects. A route map variable returns the name of the route map object. Select **Route Map** from the table of contents, then click **Add Route Map**. See Configure a route map, on page 3017.

FlexConfig system variables

System variables are replaced with information obtained from the device itself or from policies configured for it. To add a variable for the first time in the FlexConfig script and establish its association with the system variable, use the **Insert** > **Insert System Variable** > ***Variable NAME*** menu in the FlexConfig object editor. Typing the system variable name with a preceding $ sign does not create a system variable in the context of the FlexConfig object.

Before using a variable, check the typical value it returns. Refer to Evaluate device variable results, on page 1318.

Table 89: System variables

NAME	Description
SYS_FW_OS_MODE	The operating system MODE of the device. Possible values are ROUTED or TRANSPARENT.
SYS_FW_OS_MULTIPLICITY	Whether the device is running in SINGLE or multiple context MODE. Possible values are SINGLE, MULTI, or NOT_APPLICABLE.
SYS_FW_MANAGEMENT_IP	The MANAGEMENT IP address of the device
SYS_FW_HOST_NAME	The device hostname
SYS_FTD_INTF_POLICY_MAP	A MAP with INTERFACE NAME as key and POLICY-MAP as value. This variable returns nothing if there are no INTERFACE-based service policies defined on the device.
SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST	The LIST of protocols for which inspection is ENABLED.
SYS_FTD_ROUTED_INTF_MAP_LIST	A LIST of ROUTED INTERFACE maps on the device. Each MAP includes a set of named values related to ROUTED INTERFACE configuration.
SYS_FTD_SWITCHED_INTF_MAP_LIST	A LIST of SWITCHED INTERFACE maps on the device. Each MAP includes a set of named values related to SWITCHED INTERFACE configuration.
SYS_FTD_INLINE_INTF_MAP_LIST	A LIST of INLINE INTERFACE maps on the device. Each MAP includes a set of named values related to INLINE set INTERFACE configuration.
SYS_FTD_PASSIVE_INTF_MAP_LIST	A LIST of PASSIVE INTERFACE maps on the device. Each MAP includes a set of named values related to PASSIVE INTERFACE configuration.
SYS_FTD_INTF_BVI_MAP_LIST	A LIST of Bridge Virtual INTERFACE maps on the device. Each MAP includes a set of named values related to BVI configuration.
SYS_FW_INTERFACE_HARDWARE_ID_LIST	A LIST of the HARDWARE names for interfaces on the device, such as GigabitEthernet0/0.

NAME	Description
SYS_FW_INTERFACE_NAME_LIST	A LIST of logical names for interfaces on the device, such as inside.
SYS_FW_INLINE_INTERFACE_NAME_LIST	A LIST of logical names for interfaces configured as PASSIVE or ERSPAN PASSIVE.
SYS_FW_NON_INLINE_INTERFACE_NAME_LIST	A LIST of logical names for interfaces that are NOT part of INLINE sets, such as all ROUTED interfaces.

Predefined FlexConfig objects

The predefined FlexConfig objects provide tested configurations for select features. Use these objects if you need to configure these features, which otherwise cannot be configured using the management center. Note that some objects might become obsolete as features are added to the GUI.

This table lists the available objects. Make note of the associated text objects. You must edit these text objects to customize the behavior of the predefined FlexConfig object. The text objects make it possible for you to customize the configuration using the IP addresses and other attributes required by your network and device.

If you need to modify a predefined FlexConfig object, copy the object, make changes to the copy, and save it with a new name. You cannot directly edit a predefined FlexConfig object.

Although you might be able to configure other ASA-based features using FlexConfig, the configuration of those features has not been tested. If an ASA feature overlaps with something that you can configure in Cloud-Delivered Firewall Management Center policies, do not attempt to configure it through FlexConfig.

For example, Snort inspection includes the HTTP protocol, so do not enable ASA-style HTTP inspection. You cannot add **http** to the enableInspectProtocolList object; this restriction prevents you from misconfiguring your device. Instead, configure the access control policy to perform application or URL filtering, as needed, to implement your HTTP inspection requirements.

Table 90: Predefined FlexConfig objects

FlexConfig Object Name	Description	Associated Text Objects
Default_Inspection_Protocol_Disable	Disables protocols in the global_policy default policy map.	disableInspectProtocolList
Default_Inspection_Protocol_Enable	Enables protocols in the global_policy default policy map.	enableInspectProtocolList
Inspect_IPv6_Configure	Configures IPv6 inspection in the global_policy policy map, logging and dropping traffic based on IPv6 header contents.	IPv6RoutingHeaderDropLogList, IPv6RoutingHeaderLogList, IPv6RoutingHeaderDropList.
Inspect_IPv6_UnConfigure	Clears and disables IPv6 inspection.	—
ISIS_Configure	Configures global parameters for IS-IS routing.	isIsNet, isIsAddressFamily, isISType

FlexConfig Object Name	Description	Associated Text Objects
ISIS_Interface_Configuration	Interface level IS-IS configuration.	isIsAddressFamily, IsIsIntfList Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST
ISIS_Unconfigure	Clears the IS-IS router configuration on the device.	—
ISIS_Unconfigure_All	Clears the IS-IS router configuration from the device, including the router assignment from the device interface.	—
NGFW_TCP_NORMALIZATION	Modifies the default TCP normalization configuration.	—
Policy_Based_Routing	To use this example configuration, copy it, modify the interface name, and use the r-map-object text object to identify a route map object in the object manager.	—
Policy_Based_Routing_Clear	Clears Policy Based Routing configurations from the device.	—
Sysopt_AAA_radius	Ignores the authentication key in RADIUS accounting responses.	—
Sysopt_AAA_radius_negate	Negates the Sysopt_AAA_radius configuration.	—
Sysopt_basic	Configures sysopt wait time , maximum segment size for TCP packets, and detailed traffic statistics.	tcpMssMinimum, tcpMssBytes
Sysopt_basic_negate	Clears sysopt_basic detailed traffic statistics, wait time, and TCP maximum segment size.	—
Sysopt_clear_all	Clears all sysopt configurations from the device.	—
Sysopt_noproxyarp	Configures noproxy-arp CLIs.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_noproxyarp_negate	Clears Sysopt_noproxyarp configurations.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_Preserve_Vpn_Flow	Configures syopt preserve VPN flow.	—
Sysopt_Preserve_Vpn_Flow_negate	Clears the Sysopt_Preserve_Vpn_Flow configuration.	—
Sysopt_Reclassify_Vpn	Configures sysopt reclassify vpn.	—

FlexConfig Object Name	Description	Associated Text Objects
Sysopt_Reclassify_Vpn_Negate	Negates sysopt reclassify vpn.	—
Threat_Detection_Clear	Clear the threat detection TCP Intercept configuration.	—
Threat_Detection_Configure	Configure threat detection statistics for attacks intercepted by TCP Intercept.	threat_detection_statistics
Wccp_Configure	This template provides an example for configuring WCCP.	isServiceIdentifier, serviceIdentifier, wccpPassword
Wccp_Configure_Clear	Clears WCCP configurations.	—

Deprecated FlexConfig objects

This table lists objects that configure features you can now configure natively in the GUI. Discontinue using these objects at the earliest convenience.

Table 91: Deprecated predefined FlexConfig objects

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.3	DHCPv6_Prefix_Delegation_Configure	Configure one outside (Prefix Delegation client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation. To use this template, copy it and modify the variables. Associated text objects: pdoutside, pdinside Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	Interface IPv6 Settings.
7.3	DHCPv6_Prefix_Delegation_UnConfigure	Removes the DHCPv6 prefix delegation configuration.	Interface IPv6 Settings.
6.3	Default_DNS_Configure	Configure the Default DNS group, which defines the DNS servers that can be used when resolving fully-qualified domain names on the data interfaces. Associated text objects: defaultDNSNameServerList, defaultDNSParameters	Platform settings.

Deprecated Version	FlexConfig Object	Description	Now Configure In
6.3	DNS_Configure	Configure DNS servers in a non-default DNS server group. Copy the object to change the name of the group.	**DNS Server Group** in the object manager.
6.3	DNS_UnConfigure	Removes the DNS server configuration performed by Default_DNS_Configure and DNS_Configure. Copy the object to change the DNS server group names if you altered DNS_Configure.	**DNS Server Group** in the object manager.
7.2	Eigrp_Configure	Configures EIGRP routing next-hop, auto-summary, router-id, eigrp-stub. Associated text objects: eigrpAS, eigrpNetworks, eigrpDisableAutoSummary, eigrpRouterId, eigrpStubReceiveOnly, eigrpStubRedistributed, eigrpStubConnected, eigrpStubStatic, eigrpStubSummary	For all EIGRP objects, see EIGRP, on page 1479. The system does allow you to deploy post-upgrade, but also warns you to redo your EIGRP configurations. To help you with this process, we provide a command-line migration tool.
7.2	Eigrp_Interface_Configure	Configures EIGRP interface authentication mode, authentication key, hello interval, hold time, split horizon. Associated text objects: eigrpIntfList, eigrpAS, eigrpAuthKey, eigrpAuthKeyId, eigrpHelloInterval, eigrpHoldTime, eigrpDisableSplitHorizon Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	
7.2	Eigrp_Unconfigure	Clears EIGRP configuration for an autonomous system from the device.	
7.2	Eigrp_Unconfigure_all	Clears all EIGRP configurations.	
7.4	Netflow_Add_Destination	Creates and configures a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Clear_Parameters	Restores Netflow export global default settings.	Platform settings.

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.4	Netflow_Delete_Destination	Deletes a Netflow export destination. Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Set_Parameters	Sets global parameters for Netflow export. Associated text objects: netflow_Parameters	Platform settings.
6.3	TCP_Embryonic_Conn_Limit	Configures embryonic connection limits to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_limit	Service policy.
6.3	TCP_Embryonic_Conn_Timeout	Configures embryonic connection timeouts to protect against SYN Flood Denial of Service (DoS) attacks. Associated text objects: tcp_conn_misc, tcp_conn_timeout	Service policy.
7.2	VxLAN_Clear_Nve	Removes the NVE 1 configured when VxLAN_Configure_Port_And_Nve is used from the device.	For all VxLAN objects, see Configure VXLAN Interfaces, on page 1062. If you configured VXLAN interfaces with FlexConfig in a previous version, they continue to work. In fact, FlexConfig takes precedence in this case—if you redo your VXLAN configurations in the web interface, remove the FlexConfig settings.
7.2	VxLAN_Clear_Nve_Only	Clears the NVE configured on the interface when deployed.	
7.2	VxLAN_Configure_Port_And_Nve	Configures VLAN port and NVE 1. Associated text objects: vxlan_Port_And_Nve	

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.2	VxLAN_Make_Nve_Only	Sets an interface for NVE only. Associated text objects: vxlan_Nve_Only Also uses system variables SYS_FTD_ROUTED_MAP_LIST and SYS_FTD_SWITCHED_INTF_MAP_LIST	
7.2	VxLAN_Make_Vni	Creates a VNI interface. After deploying this you have to unregister and re-register the device to properly discover the VNI interface. Associated text objects: vxlan_Vni	

Predefined text objects

There are several predefined text objects. These objects are associated with variables used in the predefined FlexConfig objects. In most cases, you must edit these objects to add values if you use the associated FlexConfig object, or you will see errors during deployment. Although some of these objects contain default values, others are empty.

For information on editing text objects, refer to Configure FlexConfig text objects, on page 1337.

Name	Description	Associated FlexConfig Object
defaultDNSNameServerList (Deprecated.)	The DNS server IP address to configure in the Default DNS group. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
defaultDNSParameters (Deprecated.)	The parameters to control DNS behavior for the default DNS server group. The object contains separate entries, in order, for retries, timeout, expire-entry-timer, poll-timer, domain-name. Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
disableInspectProtocolList	Disables protocols in the default policy map (global_policy).	Disable_Default_Inspection_Protocol
dnsNameServerList	The DNS server IP address to configure in a user-defined DNS group.	DNS_Configure

Name	Description	Associated FlexConfig Object
dnsParameters	The parameters to control DNS behavior for a non-default DNS server group. The object contains separate entries, in order, for retries, timeout, domain-name, name-server-interface.	DNS_Configure
enableInspectProtocolList	Enables protocols in the default policy map (global_policy). You are prevented from adding protocols whose inspection conflicts with Snort inspection.	Enable_Default_Inspection_Protocol
IPv6RoutingHeaderDropList	The list of IPv6 routing header types that you want to disallow. IPv6 inspection drops packets that contain these headers without logging the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderDropLogList	The list of IPv6 routing header types that you want to disallow and log. IPv6 inspection drops packets that contain these headers and sends a syslog message about the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderLogList	The list of IPv6 routing header types that you want to allow but log. IPv6 inspection allows packets that contain these headers, but sends a syslog message about the existence of the header.	Inspect_IPv6_Configure
isIsAddressFamily	The IPv4 or IPv6 address family.	ISIS_Configure ISIS_Interface_Configuration
IsIsIntfList	List of logical interface names.	ISIS_Interface_Configuration
isIsISType	IS Type (level-1, level-2-only or level-1-2).	ISIS_Configure
isIsNet	Network entity.	ISIS_Configure
isServiceIdentifier	When false, uses the standard **web-cache** service identifier.	Wccp_Configure
netflow_Destination	Defines a single NetFlow export destination's interface, destination, and UDP port number.	Netflow_Add_Destination
netflow_Event_Types	Defines the types of events to be exported for a destination as any subset of: **all**, **flow-create**, **flow-defined**, **flow-teardown**, **flow-update**.	Netflow_Add_Destination

Name	Description	Associated FlexConfig Object
netflow_Parameters	Provides the NetFlow export global settings: active refresh interval (number of minutes between flow update events), delay (flow create delay in seconds; default 0 = command will not appear), and template time-out rate in minutes.	Netflow_Set_Parameters
PrefixDelegationInside	Configures the inside interface for DHCPv6 prefix delegation. The object includes multiple entries, in order, interface name, IPv6 suffix with prefix length, and prefix pool name.	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
PrefixDelegationOutside	Configure the outside DHCPv6 prefix delegation client. The object includes multiple entries, in order, interface name and IPv6 prefix length	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
serviceIdentifier	Dynamic WCCP service identifier number.	Wccp_Configure
tcp_conn_limit (Deprecated.)	Parameters used for configuring the TCP embryonic connection limits. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit
tcp_conn_misc (Deprecated.)	Parameters used for configuring the TCP embryonic connection settings. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit, TCP_Embryonic_Conn_Timeout
tcp_conn_timeout (Deprecated.)	Parameters used for configuring the TCP embryonic connection timeouts. Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Timeout
tcpMssBytes	Maximum segment size in bytes.	Sysopt_basic
tcpMssMinimum	Checks whether to set maximum segment size (MSS), which is set only if this flag is true.	Sysopt_basic

Name	Description	Associated FlexConfig Object
threat_detection_statistics	Parameters used for threat detection statistics for TCP Intercept.	Threat_Detection_Configure
vxlan_Nve_Only	Parameters for configuring NVE-only on interface: • logical name of interface • IPv4 address (optional for routed interface) • IPv4 netmask (optional for routed interface)	VxLAN_Make_Nve_Only
vxlan_Port_And_Nve	Parameters used for configuring ports and NVE for VXLAN: • vxlan port • source interface (logical name) • type (peer or mcast) • Peer IP Address or default-mcast-group	VxLAN_Configure_Port_And_Nve
vxlan_Vni	Parameters used for creating VNI: • Interface number (1-10000) • segment-id (1-16777215) • nameif (Logical Name of the interface) • type (routed or transparent) • IP address (used in case of routed mode device) or bridge-group number (used in case of transparent mode device) • netmask (If device is in routed mode) or unused	VxLAN_Make_Vni
wccpPassword	WCCP password.	Wccp_Configure

Requirements and prerequisites for FlexConfig policies

This topic outlines the model support, domain requirements, and user role prerequisites required to configure and deploy FlexConfig policies.

Guidelines and limitations for FlexConfig

Be cautious with FlexConfig deployments, as configuration mistakes trigger rollbacks that can disrupt your network.

- If you make a mistake in the FlexConfig policy, the system will roll back all changes included in the deployment attempt that includes the failed FlexConfig. Because rollback due to a failed deployment includes clearing the configuration, this can be disruptive to your network.
- Consider timing deployments that include FlexConfig changes to non-business hours. Also, consider isolation the deployment so it includes just FlexConfig changes, and no other policy updates.

When you use the VxLAN_Make_VNI object, you must deploy the same FlexConfig to all units in a cluster or high availability pair before you form the cluster or high availability pair. The Management Center requires the VXLAN interfaces to match on all devices before forming the cluster or high availability pair.

The **webvpn keepout** command must be configured only within the global webvpn configuration mode. The webvpn group-policy attributes or username attributes configuration modes do not support the **keepout** command. Do not include the **keepout** command in a group-policy FlexConfig object.

If you configure any service that applies to connections, such as SIP inspection, go to the device CLI and enter the **clear conn** command to clear connections. When the connections are rebuilt, the new configuration is applied to the sessions.

QoS rules and service policy rules (in the access control policy) are translated to commands on the firewall. This includes creating policy maps. There can be only one policy map per interface. The system automatically combines QoS and service policy configurations in a single policy map per interface.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps in the configuration. For more powerful firewalls, such as the Firepower 4100, you can create up to 128. Be careful not to exceed this limit, or deployment will fail. You can view the device configuration from the CLI or use the deployment transcript to see how rules are translated to commands.

Customize device configuration with FlexConfig policies

Use FlexConfig policies to customize the configuration of a Firewall Threat Defense device when standard configuration methods are insufficient.

Before using FlexConfig, try to configure all the policies and settings you need using the other features in Cloud-Delivered Firewall Management Center. FlexConfig is a method of last resort to configure ASA-based

features that are compatible with Firewall Threat Defense but which are not otherwise configurable in Cloud-Delivered Firewall Management Center.

Before you begin

Follow these steps to customize device configuration with FlexConfig policies:

Procedure

Step 1 Determine the CLI command sequence that you want to configure.

If you have a functioning configuration on an ASA device, use **show running-config** to get the sequence of commands that you need. Make adjustments to items such as interface names and IP addresses as needed.

If this is for a new feature, it is best to try to implement it on an ASA device in a lab setting to verify that you have the correct command sequence.

For more information, see the following topics:

- Recommended usage for FlexConfig policies, on page 1310
- CLI commands in FlexConfig objects, on page 1310

Step 2 Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.

Examine the predefined FlexConfig objects to determine if any will be able to generate the commands you need. Click **View** () to see the object contents. If an existing object is close to what you want, start by making a copy of the object, and then edit the copy. See Predefined FlexConfig objects, on page 1322.

Examining the objects will also give you an idea of the structure, command syntax, and expected sequencing for a FlexConfig object.

Note
If you find any objects that you will use, either directly or as copies, examine the Variables list at the bottom of the object. Make note of the variable names, except those in all capitals that start with SYS, which are system variables. These variables are text objects that you will probably need to edit and define overrides for, especially if the default value column shows the object has no value.

Step 3 If you need to create your own FlexConfig objects, determine what variables you will need and create the associated objects.

The CLI you need to deploy might contain IP addresses, interface names, port numbers, and other parameters that you might want to adjust over time. These are best isolated into variables, which point to objects that contain the necessary values. You might also need variables for strings that are part of the configuration and could change over time.

Also, determine if you need different values for each device to which you will assign the policy. For example, you might want to configure the feature on three devices, but you might need to specify a different interface name or IP address on a given command for each of these devices. If you need to customize the object for each device, ensure that you enable overrides when creating the object and then define the override values per device.

See the list of topics for an explanation of the various types of variables and how to configure the related objects when necessary.

- FlexConfig variables, on page 1314

- FlexConfig policy object variables, on page 1320
- FlexConfig system variables, on page 1321
- Configure FlexConfig text objects, on page 1337

Step 4 If you are using the predefined FlexConfig objects, edit the text objects used as variables.

See Configure FlexConfig text objects, on page 1337.

Step 5 (If necessary) Configure FlexConfig objects, on page 1333.

You need to create objects only if the predefined objects cannot do the job.

Step 6 Configure the FlexConfig policy, on page 1339.

a) Set target devices for a FlexConfig policy, on page 1340.

You can also assign the policy to devices when you create the policy. The policy must have at least one assigned device before you can preview it.

b) Preview the FlexConfig policy, on page 1341.

You must save changes before you can preview the policy.

Verify that the generated commands are the ones intended, and that all variables are resolving correctly.

Step 7 Choose **Deploy** > **Deployment** in the menu bar.

a) Select the devices assigned to the policy, and click **Deploy**.

Wait for deployment to complete.

Step 8 Verify the deployed configuration, on page 1342.

Step 9 (If necessary) Remove features configured using FlexConfig, on page 1344.

Unlike other types of policy, simply unassigning a FlexConfig from a device might not remove the related configuration. If you want to remove a FlexConfig-generated configuration, follow the cited procedure.

If you are removing a feature because it is now directly supported by the product, check Convert from FlexConfig to managed feature, on page 1345.

Configure FlexConfig objects

Before you begin

Keep the following in mind:

- FlexConfig objects translate into commands that are then deployed to the device. These commands are already issued in global configuration mode. Therefore, do not include the **enable** and **configure terminal** commands as part of the FlexConfig object.
- Determine what types of variables you will need, and create any policy objects that you will require. You cannot create objects for variables while editing a FlexConfig object.
- Ensure that your commands do not conflict in any way with the VPN or access control configuration on the devices.

- If there is more than one set of commands for an interface, only the last set of commands is deployed. Therefore, we recommend you not use beginning and ending commands to configure interfaces. For an example of configuring interfaces, refer to the ISIS_Interface_Configuration predefined FlexConfig object.

There are several predefined FlexConfig objects that you can use directly, or you can make copies if you need to edit them. You can also create your own objects from scratch. A FlexConfig object's content can range from a single simple command string to elaborate CLI command structures that use variables and scripting commands to deploy commands whose content can differ from device to device or deployment to deployment.

You can also create FlexConfig policy objects when defining FlexConfig policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object** .

Step 2 Do one of the following:

- Click **Add FlexConfig Object** to create a new object.
- Click **Edit** ( ) to edit an existing object.
- Click **View** ( ) to see the contents of a predefined object.
- If you want to edit a predefined object, click **Clone** ( ) to create a new object with the same contents.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 In the object body area, enter the commands and instructions to produce the required configuration.

The object content is a sequence of scripting commands and configuration commands that generate a valid ASA software command sequence. The Firewall Threat Defense device uses ASA software commands to configure some features. For more information on scripting and configuration commands, refer to:

- Template scripts, on page 1314
- CLI commands in FlexConfig objects, on page 1310

You can use variables to supply information that can be known only at runtime, or which can differ from device to device. You simply type in processing variables, but you must use the **Insert** menu to add variables that are associated with policy objects or system variables, or which are secret keys. For a complete discussion of variables, refer to FlexConfig variables, on page 1314 .

- To insert system variables, choose **Insert** > **Insert System Variable** > ***Variable Name*** . For a detailed explanation of these variables, see FlexConfig system variables, on page 1321 .
- To insert policy object variables, choose **Insert** > **Insert Policy Object** > ***Object Type*** , selecting the appropriate type of object. Then, give the variable a name (which can be the same name as the associated policy object), select the object to associate with the variable, and click **Save** . For a detailed explanation of these types, see FlexConfig policy object variables, on page 1320 . For more detail on the procedure, see Add a policy object variable to a FlexConfig object, on page 1336 .
- To insert secret key variables, choose **Insert** > **Secret Key** and define the variable name and value. For more detail on the procedure, see Configure secret keys, on page 1337 .

Note
You must use the **Insert** menu to create a new policy object or system variable. However, for subsequent uses of that variable, you must type it in, $ included. This is also true for system variables: the first time you use it, add it from the **Insert** menu. Then, type it out for subsequent uses. If you use the **Insert** menu more than once for a system variable, the system variable is added to the Variables list multiple times, and the FlexConfig will not validate, meaning you cannot save your changes. For processing variables (those not associated with a policy object or system variable), simply type in the variable. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

Step 5 Choose the deployment frequency and type.

- **Deployment** —Whether to deploy the commands in the object **Once** or **Everytime** . The only way to choose the right option is to test the results of deployment.

  Start by selecting **Everytime** . Then, after you attach the object to a FlexConfig policy, deploy the configuration. After a successful deployment, come back to the FlexConfig policy and preview the configuration for one of the assigned devices as described in Preview the FlexConfig policy, on page 1341 . If the section labeled `###CLI generated from managed features ###` contains commands that clear or negate the commands in the object, and the `###Flex-config Appended CLI ###` section contains the commands to reconfigure the feature, you know that **Everytime** is the right option.

  Even if you do not see negate commands, make some minor change to the device configuration, then run another deployment. If the deployment completes successfully, you can check the deployment transcript (see Verify the deployed configuration, on page 1342). If you see that the commands were issued again (even when they were already configured) without error, then you can keep **Everytime** .

  Change to **Once** only if the system does not first negate the commands in the object before issuing them again, or if the deployment results in errors that are specific to the command. In some cases, the system does not allow you to issue a command that is already configured, but this is the exception.

  Some additional tips:

  - If the FlexConfig object points to system-managed objects such as network or ACL objects, choose **Everytime** . Otherwise, updates to the objects might not get deployed.
  - Use **Once** if the only thing you do in the object is to clear a configuration. Then, remove the object from the FlexConfig policy after the next deployment.

- **Type** —Select one of the following:
  - **Append** —(The default.) Commands in the object are put at the end of the configurations generated from the Cloud-Delivered Firewall Management Center policies. You must use Append if you use policy object variables, which point to objects generated from managed objects. If commands generated for other policies overlap with those specified in the object, you should select this option so your commands are not overwritten. This is the safest option.
  - **Prepend** —Commands in the object are put at the beginning of the configurations generated from the Cloud-Delivered Firewall Management Center policies. You would typically use prepend for commands that clear or negate a configuration.

Step 6 (Optional.) Click **Validate** () above the object body to check the integrity of the script.

The object is always validated when you click **Save**. You cannot save an invalid object.

Step 7 Click **Save** .

What to do next

- If an active policy references your object, deploy configuration changes.

Add a policy object variable to a FlexConfig object

Insert variables into a FlexConfig policy object that are associated with other types of policy object, allowing the variables to resolve to the names or content of the associated object when the FlexConfig is deployed to a device.

You can insert variables into a FlexConfig policy object that are associated with other types of policy object. When the FlexConfig is deployed to a device, these variables resolve to the names or content of the associated object.

Use the following procedure for the first use of a policy object variable in a FlexConfig object. If you need to refer to the object again, type in the variable (including the $ sign). To understand how to use these variables, see Variable processing, on page 1315.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig objects, on page 1333.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Insert Policy Object** > ***Object Type***, selecting the appropriate type of object.

Step 2 Enter a name for the variable, and optionally, a description.

The name must be unique within the context of the FlexConfig object. It cannot include spaces. You are allowed to use the exact same name as the object associated with the variable.

Step 3 Select the object to associate with the variable and click **Add** to move it to the **Selected Object** list.

You can associate a variable with a single object only.

Note
For text objects, you can select any of the predefined objects as needed. However, many of these objects have no default values. You must update the objects to add the required values either directly or as overrides for the device to which you will deploy the FlexConfig object. Trying to deploy a FlexConfig without updating these objects typically results in deployment errors.

Step 4 Click **Save**.

The variable appears in the Variables list at the bottom of the FlexConfig object editor.

Configure secret keys

Secret keys allow you to mask sensitive information such as passwords in FlexConfig objects, preventing the dissemination of sensitive information while providing special treatment for these variables.

A secret key is any single-string variable whose content you want to mask, such as passwords. The system provides special treatment for these variables to help you prevent the dissemination of sensitive information.

Secret key variables do not show up in the Variables list in the FlexConfig object.

Unlike other types of variables, you can use the **Insert** command every time you need to insert a given secret key variable. With respect to processing, these variables behave like single-value text object variables; see Single value variables, on page 1315.

Note Any data defined in a secret key variable is masked from users except when previewing a FlexConfig policy. In addition, if you export a FlexConfig policy, the content of any secret key variable is erased. When you import the policy, you will need to manually edit each secret key variable to enter the data.

Before you begin

For information on editing a FlexConfig Object, see Configure FlexConfig objects, on page 1333.

Procedure

Step 1 While editing a FlexConfig Policy Object, choose **Insert** > **Secret Key**.

Step 2 In the **Insert Secret Key** dialog box, do any of the following:

- To create a new key, click **Add Secret Key**, then fill in the following information and click **Add**.
  - **Secret Key Name**—The name of the variable. This name appears in the FlexConfig object prefixed with @.
  - **Password**, **Confirm Password**—The secret string, which is masked with asterisks as you type.
- To insert a secret key variable in the FlexConfig object, select the check box for the variable.
- To edit the value of a secret key variable, click **Edit** ( ) for the variable. Make your changes and click **Add**.
- To delete a secret key variable, click **Delete** ( ) for the variable.

Step 3 Click **Save**.

Configure FlexConfig text objects

Use text objects in FlexConfig objects as the target of policy object variables. During deployment, variables that point to text objects are replaced by the content of the text object.

Use text objects in FlexConfig objects as the target of policy object variables. You can use variables to supply information that can be known only at runtime, or which can differ from device to device. During deployment, variables that point to text objects are replaced by the content of the text object.

Text objects contain free-form strings, which can be keywords, interface names, numbers, IP addresses, and so forth. The content depends on how you will use the information within a FlexConfig script.

Before creating or editing a text object, determine exactly what content you will need. This includes how you intend to process the object, which will help you decide between creating a single string or multiple string object. Read the following topics:

- FlexConfig variables, on page 1314
- Variable processing, on page 1315

Procedure

Step 1 Choose **Objects** > **Object Management** > **FlexConfig** > **Text Object**.

Step 2 Do one of the following:

- Click **Add Text Object** to create a new object.
- Click **Edit** ( ) to edit an existing object. You are allowed to edit the predefined text objects, which is required if you intended to use the predefined FlexConfig objects.

Step 3 Enter a **Name** and optionally, a description for the object.

Step 4 (New objects only.) Choose a **Variable Type** from the drop-down list:

- **Single**—If the object should contain a single text string.
- **Multiple**—If the object should contain a list of text strings.

You cannot change the variable type after you save the object.

Step 5 If the variable type is **Multiple**, use the up and down arrows to specify a **Count**.

Rows are added or removed from the object as you change the number.

Step 6 Add content to the object.

You can either click in the text box next to a variable number and type in a value, or you can set up device overrides for each device that will be assigned a FlexConfig object that uses the text object. You can also do both, in which case the values configured in the base object act as default values in cases where an override does not exist for a given device.

When editing predefined objects, it is a good practice to use device overrides, so that the system defaults remain in place for other users who might need to use the object in different FlexConfig policies. The approach you take depends on the requirements of your organization.

Tip
Some predefined objects require multiple values where each value serves a specific purpose. Read the description text carefully to determine the expected values in the object. In some cases, the instructions specify that you must use overrides instead of changing the base values. In the case of enableInspectProtocolList, you are prevented from entering protocols whose inspection is incompatible with Snort inspection.

If you decide to use device overrides, do the following.

a) Check the check box of **Allow Overrides**.
b) Expand the Overrides area (if necessary) and click **Add**.

   If an override already exists for the device, click edit for the override to change it.

c) On **Targets** in the Add Object Override dialog box, select the device for which you are defining values and click **Add** to move it to the Selected Devices list.
d) Click **Override**, adjust the **Count** as needed, then click in the variable fields and type in the values for the device.
e) Click **Add**.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Configure the FlexConfig policy

Configure a FlexConfig policy to manage device configurations using shared policies that can be assigned to multiple devices.

A FlexConfig policy contains two ordered lists of FlexConfig objects, one prepended list and one appended list. For an explanation of prepend/append, see Configure FlexConfig objects, on page 1333.

FlexConfig policies are shared policies that you can assign to multiple devices.

Procedure

Step 1 Choose **Devices** > **FlexConfig**.

Step 2 Do one of the following:

- Click **New Policy** to create a new FlexConfig Policy. You are prompted to enter a name. Optionally, select devices in the Available Devices list and click **Add to Policy** to assign devices. Click **Save**.
- Click **Edit** () to edit an existing Policy. You can change the name or description by clicking them in edit mode.
- Click **Copy** () to create a new policy with the same contents. You are prompted for a name. Device assignments are not retained for the copy.
- Click delete to remove a policy you no longer need.

Step 3 Select the FlexConfig objects required for the policy from the **Available FlexConfig** list and click > to add them to the policy.

Objects are automatically added to the prepended or appended list based on the deployment type specified in the FlexConfig object.

To remove a selected object, click **Delete** ( ) next to an object.

Step 4 For each selected object, click **View** ( ) next to the object to identify the variables used in the object.

Except for system variables, which start with SYS, you need to ensure that the objects associated with the variables are not empty. A blank or brackets with nothing between them, [ ], indicate an empty object. You will need to edit these objects before deploying the policy.

Note
If you use object overrides, those values will not show up in this view. Thus, an empty default value does not necessarily mean that you have not updated the object with the required values. Previewing the configuration will show whether the variables resolve correctly for a given device. See Preview the FlexConfig policy, on page 1341.

Step 5 Click **Save**.

What to do next

- Set target devices for the policy; see Set target devices for a FlexConfig policy, on page 1340.
- Deploy configuration changes.

Set target devices for a FlexConfig policy

This task allows you to assign or change device assignments for a FlexConfig policy after creation.

When you create a FlexConfig policy, you can select the devices that use the policy. You can subsequently change device assignments for the policy as described below.

Note Normally, when you unassign a policy from a device, the system automatically removes the associated configuration upon the next deployment. However, because FlexConfig objects are scripts for deploying customized commands, simply unassigning a FlexConfig policy from a device does not remove the commands that were configuring by the FlexConfig objects. If your intention is to remove FlexConfig-generated commands from a device's configuration, refer to Remove features configured using FlexConfig, on page 1344.

Procedure

Step 1 Choose **Devices** > **FlexConfig** and edit a FlexConfig policy.

Step 2 Click **Policy Assignments**.

Step 3 On **Targeted Devices**, build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**. You can assign the policy to devices, high availability pairs, and clustered devices.
- Delete—Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.

Step 4 Click **OK** to save your selection.

Step 5 Click **Save** to save the FlexConfig policy.

What to do next

- Deploy configuration changes.

Preview the FlexConfig policy

The FlexConfig policy preview allows you to validate and troubleshoot your configuration before deployment. It translates FlexConfig objects into CLI commands and resolves variables based on device-specific configurations.

Preview a FlexConfig policy to see how the FlexConfig objects get translated into CLI commands. The preview shows the commands that will be generated for a selected device from the scripts and variables used in the FlexConfig objects. The variables are resolved based on the configuration for the device, so you get a clear idea of what will be deployed.

Use the preview to look for potential problems in the FlexConfig objects. Correct the objects until the preview shows the expected results.

You must preview the configuration separately for each device, because the variables can resolve differently based on the device configuration.

Procedure

Step 1 Choose **Devices** > **FlexConfig** and edit a FlexConfig policy.

Step 2 If there are any pending changes, click **Save**.

The preview shows results only for those FlexConfig objects that were in the most recently saved version of the policy. You must save the policy to see a preview of newly-added objects.

Step 3 Click **Preview Config**.

Step 4 Choose a device from the **Select Device** drop-down list.

The system retrieves information from the device and configured policies, and determines what CLI commands will be generated on the next deployment to the device. You can select the output and use Ctrl+C to copy it to the clipboard, where you can paste it into a text file for further analysis.

The preview includes the following sections:

- Flex-config Prepended CLI—These are the commands generated by FlexConfigs that are prepended to the configuration.
- CLI generated from managed features—These are commands generated for policies configured in the Cloud-Delivered Firewall Management Center. Commands are generated for new or changed policies since the last successful deployment to the device. These commands do not represent all commands needed to implement the assigned policies. No commands in this section are generated from FlexConfig objects.

- Flex-config Appended CLI—These are the commands generated by FlexConfigs that are appended to the configuration.

Step 5 Click **Close** to close the preview dialog.

Verify the deployed configuration

This task helps you confirm that your FlexConfig policy deployment completed successfully and that the device configuration matches your expectations.

After you deploy a FlexConfig policy to a device, verify that the deployment was successful and that the resulting configuration is what you expected. Also, verify that the device is performing as expected.

Procedure

Step 1 To verify that deployment was successful:

Check the deployment status and review any error messages or warnings.

- Click **Notifications** in the menu bar, which is unnamed between **Deploy** and **System**.

  The icon looks like one of the following, and it might include a number if there are errors:

  - **Indicates No Warnings** — Indicates no warnings or errors are present on the system.
  - Indicates **One or More Warnings** — Indicates one or more warnings and no errors are present on the system.
  - **Indicates One or More Errors** — Indicates one or more errors and any number of warnings are present on the system.

- On **Deployments**, verify that the deployment was successful.
- To see more detailed information, especially for failed deployments, click **Show History**.
- Select the deployment job in the list of jobs in the left column.

  Jobs are listed in reverse chronological order, with the most recent job at the top of the list.

- Click download in the **Transcript** column for the device in the right column.

  The deployment transcript includes commands sent to the device, and any responses returned from the device. These response can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands that you sent through FlexConfig. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

  Note
  There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

  For example, the following sequence shows that Cloud-Delivered Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything. Messages relevant to FlexConfig are in the CLI Apply section of the transcript.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

Step 2 Verify that the deployed configuration includes the expected commands.

You can do this by making an SSH connection to the device's management IP address. Use the **show running-config** command to view the configuration.

Alternatively, use the CLI tool within Cloud-Delivered Firewall Management Center.

- Choose **System** (⚙) > **Health** > **Monitor** and click the name of the device.

  You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

- Click **Advanced Troubleshooting**.
- Click **Threat Defense CLI**.
- Select **show** as the command, and type **running-config** as the parameter.
- Click **Execute**.

  The running configuration appears in the text box. You can select the configuration and press Ctrl+C, then paste it into a text file for later analysis.

Step 3 Verify that the device is performing as expected.

Use the **show** commands related to the feature to see detailed information and statistics. For example, if you enabled additional protocol inspections, the **show service-policy** command provides this information. The exact commands to use are feature-dependent and should be mentioned in the ASA configuration guide and command reference you used to learn how to configure the feature.

If commands that show statistics indicate that numbers are not changing (for example, hit counts, connection counts, and so forth), the configuration might be valid but not meaningful. If you know that traffic is going through the device that should show up in statistics, look for what is missing in your configuration. For example, NAT or access rules might be dropping or changing traffic before a feature can act on it.

You can use the **show** commands from an SSH session or through the Cloud-Delivered Firewall Management Center CLI tool.

However, if the **show** command that you need to use is not available directly within the Firewall Threat Defense CLI, you will need make an SSH connection to the device to use the commands. From the CLI, enter the following command sequence to enter Privileged EXEC mode within the diagnostic CLI. From there, you should be able to enter these otherwise unsupported **show** commands.

```
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.
firepower> enable
Password: <press enter, do not enter a password>
firepower#
```

Remove features configured using FlexConfig

This task allows you to manually remove configuration commands that were deployed using FlexConfig when unassigning the FlexConfig policy from a device might not remove all of the configuration.

If you decide you need to remove a set of configuration commands you configured using FlexConfig, you might need to manually remove that configuration. Unassigning the FlexConfig policy from a device might not remove all of the configuration.

To manually remove the configuration, you create new FlexConfig objects to clear or negate the configuration commands.

Before you begin

To determine if you need to manually remove some or all of the configuration generated by an object:

1. Examine the configuration preview, as described in Preview the FlexConfig policy, on page 1341. If the **###CLI generated from managed features ###** section contains the clear or negate commands to remove all of the commands in the FlexConfig object, then you can simply remove the object from the FlexConfig policy, save, and redeploy.
2. Remove the object from the FlexConfig policy, save the change, then preview the configuration again. If the **###CLI generated from managed features ###** section still does not include the required clear or negate commands, you must follow this procedure to manually remove the configuration.

Follow these steps to remove features configured using FlexConfig:

Procedure

Step 1 Choose **Objects** > **Object Management** and create the FlexConfig Objects to clear or negate the configuration commands.

If a feature has a **clear** command that can remove all configuration settings, then use that command. For example, the predefined ISIS_Unconfigure_All object contains a single command that removes all ISIS-related configuration commands:

```
clear configure router isis
```

If there is not a **clear** command for the feature, you need to use the **no** form of each command you want to remove. For example, the predefined Sysopt_basic_negate object removes the commands configured through the predefined Sysopt_basic object.

```
no sysopt traffic detailed-statistics
```

```
no sysopt connection timewait
```

You would typically configure a FlexConfig object that removes configurations as a prepended, deploy once object.

Step 2 Choose **Devices** > **FlexConfig** and create a new FlexConfig policy or edit the existing policy.

If you want to preserve the FlexConfig policy that deploys the configuration commands, create a new policy specifically for negating the commands, and assign the devices to the policy. Then, add the new FlexConfig objects to the policy.

If you want to completely remove the FlexConfig configuration objects from all devices, you can simply delete those commands from the existing FlexConfig policy and replace them with the objects that negate the configuration.

Step 3 Click **Save** to save the FlexConfig policy.

Step 4 Click **Preview Config** and verify that the clear and negation commands are generating correctly.

Step 5 Choose **Deploy** > **Deployment** in the menu bar, select the device, and click **Deploy**.

Wait for deployment to complete.

Step 6 Verify that the commands were removed.

View the running configuration on the device to confirm that the commands are removed. For more detailed information, see Verify the deployed configuration, on page 1342.

Step 7 While editing the FlexConfig policy, click **Policy Assignments** and remove the device. Optionally, remove the FlexConfig Objects from the policy.

Assuming that the FlexConfig policy simply removes the unwanted configuration commands, there is no need to keep the policy assigned to the device after the removal is complete.

However, if the FlexConfig policy retains options that you still want configured on the device, remove the negation objects from the policy. They are no longer needed.

Convert from FlexConfig to managed feature

This procedure converts deprecated FlexConfig commands to newly supported managed features after a software upgrade.

Each software release adds managed features to the product. These are features you configure directly through policies controlled outside of FlexConfig. This can deprecate FlexConfig commands that you are currently using. Your configurations are not automatically converted. After the upgrade, you cannot assign or create FlexConfig objects using the newly deprecated commands. After upgrading software, examine your FlexConfig policies and objects.

If a feature configured through FlexConfig becomes available as a managed feature, convert the configuration to the managed feature instead of using FlexConfig. In most cases, your existing FlexConfig configurations continue to work after the upgrade, and you can still deploy. However, using deprecated commands may cause deployment issues in certain situations. Configuring a feature in both the GUI and FlexConfig is not supported.

Note Use the migration tool instead of this procedure if the tool supports the feature configuration you are migrating.

Procedure

Step 1 Remove the FlexConfig, as explained in Remove features configured using FlexConfig, on page 1344.

Step 2 Configure the settings in the newly supported managed feature.

The release notes have a list of new features for the release.

Examples for FlexConfig

This topic provides a collection of practical examples for implementing FlexConfig policies.

Configure precision time protocol (ISA 3000)

The Precision Time Protocol (PTP) is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. These device clocks are generally of varying precision and stability. The protocol is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

A PTP system is a distributed, networked system consisting of a combination of PTP and non-PTP devices. PTP devices include ordinary clocks, boundary clocks and transparent clocks. Non-PTP devices include network switches, routers and other infrastructure devices.

You can configure the Firewall Threat Defense device to be a transparent clock. The Firewall Threat Defense device does not synchronize its clock with the PTP clocks. The Firewall Threat Defense device will use the PTP default profile, as defined on the PTP clocks.

When you configure the PTP devices, you define a domain number for the devices that are meant to function together. Thus, you can configure multiple PTP domains, and then configure each non-PTP device to use the PTP clocks for one specific domain.

Before you begin

Determine the domain number configured on the PTP clocks that the device should use. This example assumes the PTP domain number is 10. Also, determine the interfaces through which the system can reach the PTP clocks in the domain.

These are the guidelines for configuring PTP.

- This feature is only available on the Cisco ISA 3000 appliance.
- Cisco PTP supports multicast PTP messages only.
- PTP is available only for IPv4 networks, not for IPv6 networks.
- PTP configuration is supported on physical Ethernet data interfaces, whether stand-alone or bridge group members. It is not supported on the management interface, subinterfaces, EtherChannels, Bridge Virtual Interfaces (BVI), or any other virtual interfaces.

- PTP flows on VLAN subinterfaces are supported, assuming the appropriate PTP configuration is present on the parent interface.
- You must ensure that PTP packets are allowed to flow through the device. PTP traffic is identified by UDP destination ports 319 and 320, and destination IP address 224.0.1.129, so any access control rule that allows this traffic should work.
- In Routed firewall mode, you must enable multicast routing for PTP multicast groups. In addition, if an interface on which you enable PTP is **not** in a bridge group, you must configure the interface to join the IGMP multicast group 224.0.1.129. If the physical interface is a bridge group member, you do not configure it to join the IGMP multicast group.

Follow these steps to configure Precision Time Protocol on an ISA 3000 device:

Procedure

Step 1 (Routed mode only) Enable Multicast routing, and configure the IGMP group for the interfaces.

In Routed mode, you must enable Multicast routing. In addition, for stand-alone physical interfaces, that is, those that are not bridge group members, you must also configure the interface to join the 224.0.1.129 IGMP group. You cannot configure bridge group members to join an IGMP group, but PTP configuration on bridge group members will work without the IGMP join.

Perform this procedure for each device on which you will configure PTP.

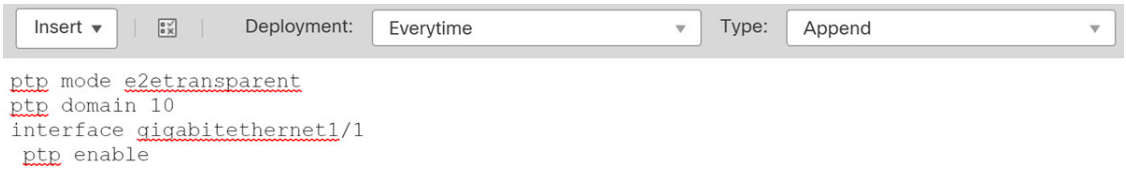
Note
Write down the hardware names of each PTP-clock-facing interface on each device, for example, GigabitEthernet1/1.

a) Choose **Devices** > **Device Management**, and edit the device.
b) Click **Routing**.
c) Choose **Multicast Routing** > **IGMP**.
d) Check the **Enable Multicast Routing** check box.
e) Click **Join Group**.
f) Click **Add**, and in the **Add IGMP Join Group Parameters** dialog box, configure the following options and click **OK**.
   - **Interface**—Select the PTP-clock-facing stand-alone interface.
   - **Join Group**—Click **+** to add a new network object. Create a Host object with the address 224.0.1.129. When configuring additional interfaces, simply select this object. (See Create a network object, on page 2985.)

   Repeat this step for each PTP-clock-facing stand-alone interface on the device.
g) Click **Save** on the Routing page.

Step 2 Create the FlexConfig object to enable PTP globally and on the interface.

This procedure assumes that the PTP-clock-facing interface is the same on every device you are configuring. If you have used different interfaces on different devices, you need to create separate objects for each distinct combination. For example, if you use GigabitEthernet1/1 on devices A and B, GigabitEthernet1/2 on devices



C and D, and both GigabitEthernet1/1 and 1/2 on devices E and F, you need 3 separate FlexConfig objects, and subsequently, 3 separate FlexConfig policies (explained in the next step).

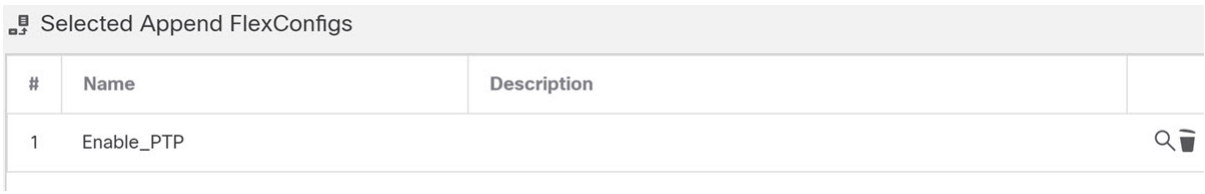
a) Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.
b) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Enable_PTP.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features. This ensures that any other changes you make to interface configuration are configured before these commands.
- **Object body**—In the object body, type the commands needed to configure PTP globally and on each PTP-clock-facing interface. For example, the commands needed for the global configuration for PTP domain 10 and the interface configuration on GigabitEthernet1/1 are:

```
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

The object body should look similar to the following:

Step 3 Create the FlexConfig policy and assign it to the devices.



If you created multiple FlexConfig objects for different combinations of PTP-clock-facing interfaces, you need to create separate FlexConfig policies for each object, and assign those policies to the correct devices based on the interfaces you need to configure. Repeat this procedure for each group of devices.

a) Choose **Devices** > **FlexConfig**.
b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the PTP FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.
e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the PTP FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the PTP commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
 ptp enable
```

Step 4 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1342.

Step 5 Verify the PTP configuration on each device.

From an SSH or Console session into each device, verify the PTP settings:

```
> show ptp clock
 PTP CLOCK INFO
  PTP Device Type: End to End Transparent Clock
  Operation mode: One Step
  Clock Identity: 34:62:88:FF:FE:1:73:81
  Clock Domain: 10
  Number of PTP ports: 4
> show ptp port
 PTP PORT DATASET: GigabitEthernet1/1
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 1
  PTP version: 2
  Port state: Enabled

 PTP PORT DATASET: GigabitEthernet1/2
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 2
  PTP version: 2
  Port state: Disabled

 PTP PORT DATASET: GigabitEthernet1/3
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 3
  PTP version: 2
  Port state: Disabled

 PTP PORT DATASET: GigabitEthernet1/4
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 4
```

```
PTP version: 2
Port state: Disabled
```

Configure automatic hardware bypass for power failure (ISA 3000)

Configure automatic hardware bypass to ensure network traffic continues to flow between interface pairs during power outages on ISA 3000 devices.

You can enable hardware bypass so that traffic continues to flow between an interface pair during a power outage. Supported interface pairs are copper interfaces GigabitEthernet 1/1 and 1/2; and GigabitEthernet 1/3 and 1/4. If you have a fiber Ethernet model, only the copper Ethernet pair (GigabitEthernet 1/1 and 1/2) supports hardware bypass.

When hardware bypass is active, traffic passes between these interface pairs at layer 1. The Firewall Threat Defense CLI will see the interfaces as being down. No firewall functions are in place, so make sure you understand the risks of allowing traffic to pass through the device.

In CLI Console or an SSH session, use the **show hardware-bypass** command to monitor the operational status.

Before you begin

For hardware bypass to work:

- You must place the interface pairs in the same bridge group.
- You must attach the interfaces to access ports on the switch. Do not attach them to trunk ports.

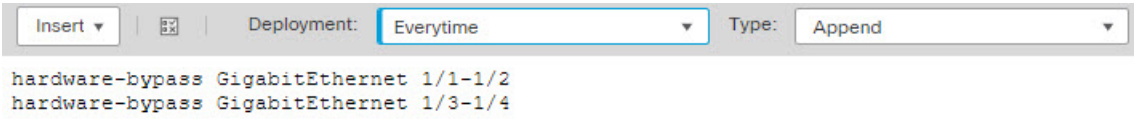
We recommend that you disable TCP sequence number randomization globally using the Threat Defense Service Policy attached to the access control policy assigned to the device. By default, the ISA 3000 rewrites the initial sequence number (ISN) of TCP connections passing through it to a random number. When hardware bypass is activated, the ISA 3000 is no longer in the data path and does not translate the sequence numbers. The receiving client receives an unexpected sequence number and drops the connection, so the TCP session needs to be re-established. Even with TCP sequence number randomization disabled, some TCP connections will have to be re-established because of the link that is temporarily down during the switchover.

Follow these steps to configure automatic hardware bypass for power failure:

Procedure

Step 1 Create the FlexConfig object to enable automatic bypass.

a. Choose **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object**.



b. Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

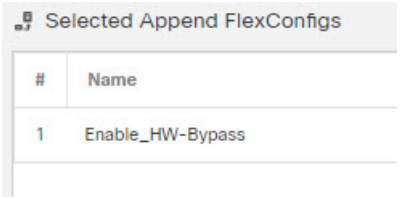
- **Name**—The object name. For example, Enable_HW-Bypass.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.

- **Object body**—In the object body, type the commands needed to enable automatic hardware bypass. For example, the commands needed for both possible interface pairs:

```
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

The object body should look similar to the following:

Step 2 Create the FlexConfig policy and assign it to the devices.



a. Choose **Devices** > **FlexConfig**.

b. Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c. Select the hardware bypass FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d. Click **Save**.

e. If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f. Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the hardware bypass FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the hardware bypass commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the deployed configuration, on page 1342.

What to do next

If you want to manually invoke hardware bypass or manually turn it off, you need to create two FlexConfig objects:

- One that manually starts bypass, which would contain one or both of the following commands, depending on whether you want to invoke bypass for both pairs:

```
hardware-bypass manual GigabitEthernet 1/1-1/2
hardware-bypass manual GigabitEthernet 1/3-1/4
```

- One that manually turns off bypass, which would contain one or both of the following commands:

```
no hardware-bypass manual GigabitEthernet 1/1-1/2
no hardware-bypass manual GigabitEthernet 1/3-1/4
```

You would then need to add one or the other object to the FlexConfig policy, and deploy changes, to either turn bypass on or off. You would also need to immediately remove the object from the FlexConfig policy after deployment. If you manually invoke bypass, you would then need to repeat the process to turn it off again. Thus, using this manual method requires frequent and careful editing of the FlexConfig policy and additional deployments.

Migrate FlexConfig policies

This task migrates ECMP, VXLAN, and EIGRP policies from FlexConfig objects to the management center UI to enable direct policy management.

Attention This section on migrating FlexConfig policies is applicable only for migrating ECMP, VXLAN, and EIGRP policies.

The ECMP, VXLAN, and EIGRP policies were configured using the FlexConfig objects and policies in earlier versions of the Cloud-Delivered Firewall Management Center. You can now directly configure these policies in the management center UI. When you are upgrading the management center from earlier versions, the FlexConfig configuration is retained. However, to manage the policies from the UI, you must redo the configuration in the corresponding **Device (Edit)** > **Routing** page and remove the configuration from FlexConfig. To automate creation of the policies in the UI, Cloud-Delivered Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. However, it does not remove the migrated policies from the FlexConfig. For post-migration procedure, refer to Step 7, on page 1353.

Before you begin

- Ensure that the deployed FlexConfig policy is up-to-date and not out-of-date. The migration option will be available only if the policy is up-to-date on at least 1 device. Migration does not take place for those devices that have out-of-date policies.
- If the policy is configured in both FlexConfig and the management center:
  - Migration will not be initiated if the policy is already configured at **Device (Edit)** > **Routing**.
  - During deployment, the management center displays an error message. Example EIGRP migration error message—*EIGRP is configured through FlexConfig object and also under Device Listing ->Routing EIGRP for the device. Maintain the EIGRP configuration in either Routing EIGRP or FlexConfig.*
- If the network objects used in the policy exist in the management center, during migration, they are reused. During migration, when a network object that is matching the IP configuration is not available, a new network object is created as *bb* appended with a timestamp and integer, like ***bb_<timestamp>_<integer>***. For more than one such network object, the integer variable in the name would be incremented by one.

Follow these steps to migrate FlexConfig policies:

Procedure

Step 1 Choose **Devices** > **FlexConfig**, click **Edit** (✎) against the FlexConfig policy that you want to migrate.

Step 2 Click **Migrate Config**.

Note
Once migration starts, both **Migrate Config** and FlexConfig **Edit** options are not available.

The **Migrate Config** option is not available, when:

- There are no applicable FlexConfig CLIs to be migrated.
- The FlexConfig policy is not associated with any FlexConfig objects.
- There are no devices that are associated with the FlexConfig policy.

Step 3 In the **Migrate Flex Configuration** dialog box, select the device to which you wish to migrate the configuration, and then click **Ok**.

The migration progress is displayed as task notification. When the migration is complete, click the *View Details* link and download the migration report (PDF format).

Step 4 To view the policy changes, choose **System** (⚙) > **Monitoring** > **Audit** and click on the *Flex Config Migration* message.

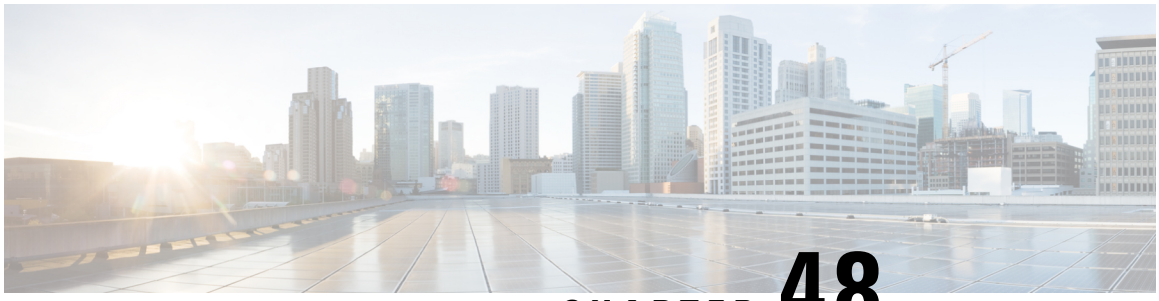
Step 5 To view the FlexConfig migration report, choose **System** (⚙) > **Monitoring** > **Audit** and click on the *Flex Config Migration* message. To view the complete migration report, click the **Report** icon.

Step 6 Verify the migrated configuration settings in the corresponding **Device (Edit)** > **Routing**. page.

Step 7 To remove the specific policy config from FlexConfig for the device, in the management center, do the following:

a) Identify the migrated FlexConfig policy for the device.

b) Use the copy option and create duplicate of the FlexConfig policy.
c) Remove the corresponding CLI objects from the duplicated FlexConfig policy.
d) Associate the device to the duplicated FlexConfig policy.



Step 8 Save and deploy the configuration.

PART XIII

Routing

- Static and Default Routes, on page 1357
- Virtual Routers, on page 1375
- ECMP, on page 1431
- Bidirectional Forwarding Detection Routing, on page 1441
- OSPF, on page 1447
- EIGRP, on page 1479

CHAPTER 48

Static and Default Routes

This chapter describes how to configure static and default routes on the Firewall Threat Defense.

- Static and default routes overview, on page 1357
- Requirements and prerequisites for static routes, on page 1360
- Guidelines for static and default routes, on page 1360
- Add a static route, on page 1361
- Reference for routing, on page 1362

Static and default routes overview

To route traffic to a non-connected host or network, define a route to the host or network, using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, which is typically the next-hop router.

Default routes

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the Firewall Threat Defense sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

Default route configuration requirements

You should always define a default route.

The Firewall Threat Defense has separate routing tables for data interfaces and for management-only interfaces (including the special Linux Management interface). You can only add a default route for the data routing table. The Firewall Threat Defense automatically adds a default route in the management-only routing table that sends traffic to the Linux Management interface, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the Firewall Threat Defense CLI **configure network static-routes** command.

Note The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

Static routes

You might want to use static routes in the following cases:

Use cases for static routes

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the Firewall Threat Defense.
- You are using a feature that does not support dynamic routing protocols.
- Virtual routers use static routes to create route leaks. Route leaks enable flow of traffic from an interface of a virtual router to another interface in another virtual router. For more information, see Virtual router interconnection, on page 1378.

Route to null0 interface to drop unwanted traffic

Access rules let you filter packets based on the information contained in their headers. A static route to the null0 interface is a complementary solution to access rules. You can use a null0 route to forward unwanted or undesirable traffic so the traffic is dropped.

Performance and routing benefits

Using static null0 routes provides a favorable performance profile. You can also use static null0 routes to prevent routing loops. BGP can leverage the static null0 route for Remotely Triggered Black Hole routing.

Note Though routing traffic to a null0 interface to blackhole it helps to drop unwanted traffic, this method increases the `no-route` ASP drops.

Route priorities

- Routes that identify a specific destination take precedence over the default route.
- When multiple routes exist to the same destination (either static or dynamic), then the administrative distance for the route determines priority. Static routes are set to 1, so they typically are the highest priority routes.
- When you have multiple static routes to the same destination with the same administrative distance, see Equal-cost multi-path routing, on page 1371.
- For traffic emerging from a tunnel with the Tunneled option, this route overrides any other configured or learned default routes.

Transparent firewall mode and bridge group routes

For traffic that originates on the Firewall Threat Defense device and is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the Firewall Threat Defense device knows out of which bridge group member interface to send traffic. Traffic that originates on the Firewall Threat Defense device might include communications to a syslog server or SNMP server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. For transparent mode, you cannot specify the BVI as the gateway interface; only member interfaces can be used. For bridge groups in routed mode, you must specify the BVI in a static route; you cannot specify a member interface. Refer to MAC address and route lookups, on page 159 for more information.

Static route tracking

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and configure a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

Static route tracking implementation

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the Firewall Threat Defense device goes down.

The Firewall Threat Defense device implements static route tracking by associating a static route with a monitoring target host on the destination network that the Firewall Threat Defense device monitors using ICMP echo requests. If an echo reply is not received within a specified time period, the host is considered down, and the associated route is removed from the routing table. An untracked backup route with a higher metric is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. You can choose any network object as the target, but consider using one of these options:

- The address of the ISP gateway (for dual ISP support)
- The address of the next hop gateway (if you are concerned about gateway availability)
- A server on the target network, such as a syslog server, with which the Firewall Threat Defense device needs to communicate
- A persistent network object on the destination network

Note A PC that may be shut down at night is not a good choice.

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

Requirements and prerequisites for static routes

Requirement	Description
Model support	Firewall Threat Defense
Supported domains	Any
User roles	Admin Network Admin

Guidelines for static and default routes

Firewall mode and bridge groups

Configure static routes according to your firewall mode and interface requirements.

- In transparent mode, static routes must use the bridge group member interface as the gateway; you cannot specify the BVI.
- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- Static route tracking is not supported for bridge group member interfaces or on the BVI.

Supported network address

Ensure your network addresses meet static route requirements.

- Static route tracking is not supported for IPv6.
- The Firewall Threat Defense does not support Class E routing, so a Class E network is not routable in static routes.

Clustering

Consider these limitations for clustering and multiple context mode configurations.

- In clustering, static route tracking is only supported on the control node.

Network object group

You cannot use a range of network objects or a network object group having a range of IP addresses in a static route.

ASP and RIB Route Entries

All routes and its distance installed on the device are captured in the ASP routing table. This is common for all static and dynamic routing protocols. Only the best distance route is captured in the RIB table.

Add a static route

A static route defines where to send traffic for specific destination networks. You should at a minimum define a default route. A default route is simply a static route with 0.0.0.0/0 as the destination IP address.

To configure routes for redundant manager access data interfaces, see Configure a redundant manager access data interface, on page 1153.

Procedure

Step 1 To configure routes for redundant manager access data interfaces, see Configure a redundant manager access data interface, on page 1153.

Step 2 Click **Routing**.

Step 3 (May be required) From the virtual routers drop-down list, select the virtual router for which you are configuring a static route.

Step 4 Select **Static Route**.

Step 5 Click **Add Routes**.

Step 6 Click **IPv4** or **IPv6** depending on the type of static route that you are adding.

Step 7 Choose the **Interface** to which this static route applies.

For transparent mode, choose a bridge group member interface name. For routed mode with bridge groups, you can choose either the bridge group member interface for the BVI name. To "black hole" unwanted traffic, choose the **Null0** interface.

For a device using virtual routing, you can select an interface that belongs to another virtual router. You can create such a static route if you want to leak traffic from this virtual router into the other virtual router. For more information, see Virtual router interconnection, on page 1378.

Step 8 In the **Available Network** list, choose the destination network.

To define a default route, create an object with the address 0.0.0.0/0 and select it here.

Note
Although you can create and choose a Network Object Group containing a range of IP addresses, the Cloud-Delivered Firewall Management Center does not support using ranges in static routes.

Step 9 In the **Gateway** or **IPv6 Gateway** field, enter or choose the gateway router that is the next hop for this route. You can provide an IP address or a Networks/Hosts object.

When you are using static-route configuration for virtual routers to leak routes, do not specify the next hop gateway.

Step 10 In the **Metric** field, enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1.

The metric is a measurement of the "expense" of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. The metric is used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connected routes. The default

administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static route takes precedence. Connected routes always take precedence over static or dynamically discovered routes.

Step 11 (Optional) For a default route, click the **Tunneled** checkbox to define a separate default route for VPN traffic.

You can define a separate default route for VPN traffic if you want your VPN traffic to use a different default route than your non VPN traffic. For example, traffic incoming from VPN connections can be easily directed towards internal networks, while traffic from internal networks can be directed towards the outside. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the device that cannot be routed using learned or static routes, is sent to this route. You can configure only one default tunneled gateway per device. ECMP for tunneled traffic is not supported.

Step 12 (IPv4 static route only) To monitor route availability, enter or choose the name of an SLA (service level agreement) Monitor object that defines the monitoring policy, in the **Route Tracking** field.

See Configure an SLA monitor, on page 3034.

Step 13 Click **Ok**.

Reference for routing

This section describes underlying concepts of how routing behaves within the Firewall Threat Defense.

Path determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which include route information. Route information varies depending on the routing algorithm used.

Path determination process

Routing algorithms fill routing tables with a variety of information. Destination or next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the next hop on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can include other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

Supported route types

There are several route types that a router can use. The Firewall Threat Defense device uses the following route types:

- Static Versus Dynamic
- Single-Path Versus Multipath
- Flat Versus Hierarchical
- Link-State Versus Distance Vector

Static versus dynamic routing algorithms

Static routing algorithms are actually table mappings established by the network administrator. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Dynamic routing algorithms

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a default route for a router to which all unrouteable packets are sent), for example, can be designated to act as a repository for all unrouteable packets, ensuring that all messages are at least handled in some way.

Single-path versus multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are substantially better throughput and reliability, which is generally called load sharing.

Flat versus hierarchical routing

Some routing algorithms operate in a flat space, while others use routing hierarchies.

In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from non-backbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more non-backbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas.

In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

Link-state versus distance vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables.

Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, link-state algorithms are used in conjunction with OSPF routing protocols.

Supported internet protocols for routing

The Firewall Threat Defense device supports several internet protocols for routing. Each protocol is briefly described in this section.

The device supports these internet routing protocols:

- **Enhanced Interior Gateway Routing Protocol (EIGRP)**

  EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperation with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

- **Open Shortest Path First (OSPF)**

  OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

- **Routing Information Protocol (RIP)**

  RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

- **Border Gateway Protocol (BGP)**

  BGP is an interautonomous system routing protocol. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP). Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

Routing tables

The Firewall Threat Defense uses separate routing tables for data traffic (through-the-device) and for management traffic (from-the-device). This section describes how the routing tables work. For information about the management routing table, see also Routing table for management traffic, on page 1370.

How the routing table is populated

The Firewall Threat Defense routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the Firewall Threat Defense device can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner.

Route selection criteria

When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

  For example, if the RIP and OSPF processes discovered the following routes:

  - RIP: 192.168.32.0/24
  - OSPF: 192.168.32.0/19

  Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the Firewall Threat Defense device learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

  Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the Firewall Threat Defense device learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the Firewall Threat Defense uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because

the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the Firewall Threat Defense.

Table 92: Default Administrative Distance for Supported Routing Protocols

Route Source	Default Administrative Distance
Connected interface	0
VPN route	1
Static route	1
EIGRP Summary Route	5
External BGP	20
Internal EIGRP	90
OSPF	110
IS-IS	115
RIP	120
EIGRP external route	170
Internal and local BGP	200
Unknown	255

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the Firewall Threat Defense receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the Firewall Threat Defense chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

A VPN advertised route (V-Route/RRI)) is equivalent to a static route with the default administrative distance 1. But it has a higher preference as with the network mask 255.255.255.255.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the Firewall Threat Defense would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the Firewall Threat Defense on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

Backup Dynamic and Floating Static Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the Firewall Threat Defense. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

How forwarding decisions are made

A forwarding decision is a network routing process that

- determines the appropriate interface for packet transmission based on destination address matching in the routing table
- prioritizes routes with longer network prefix lengths when multiple matches exist, and
- directs packets through default routes when no specific routing table entries match the destination.

Forwarding decision process

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

Note When a route change occurs, the Threat Defense re-evaluates the forwarding decision of established connections the next time a packet is seen on the flow.

The resulting behavior is determined by your configuration:

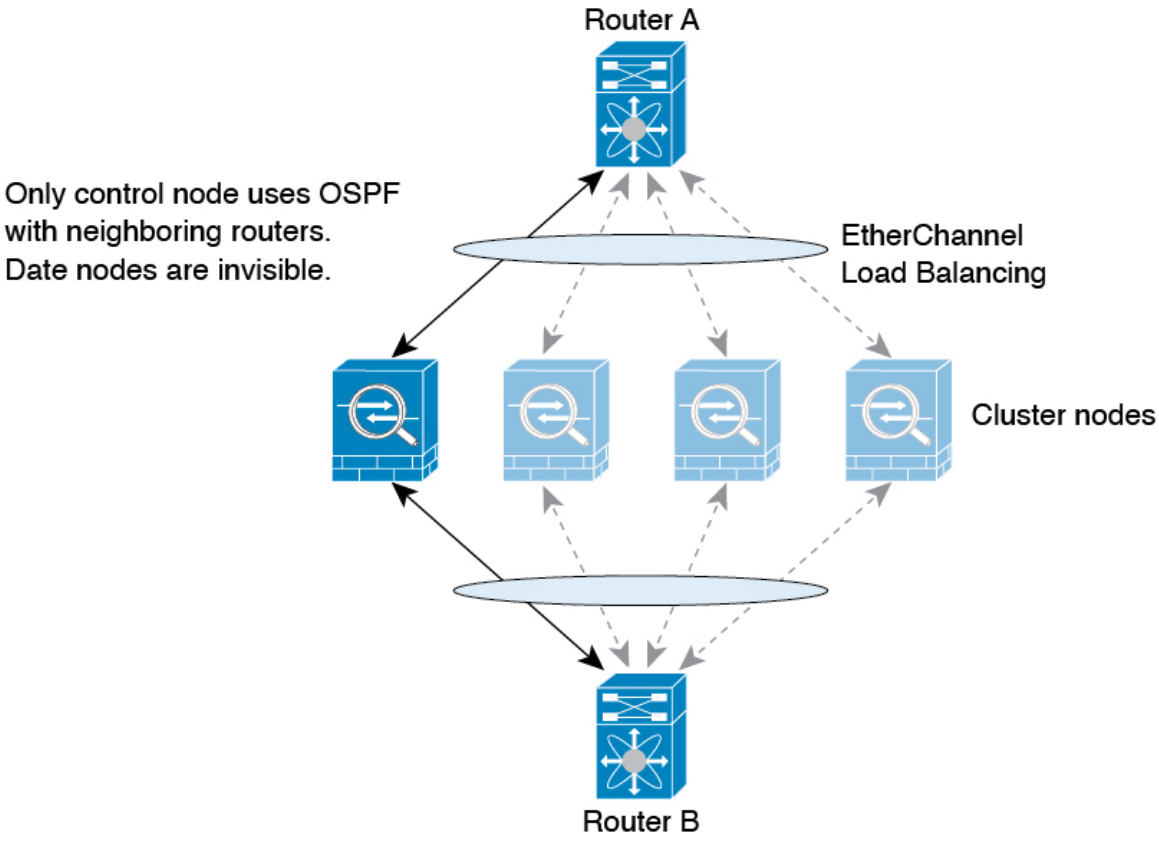
Configuration	Behavior	Outcome
Default (timeout floating-conn 0, no ECMP zone)	Retains the original egress path initially.	If that path can no longer resolve the destination, the flow is torn down after the conn-holddown period (default 15s) rather than waiting for an idle timeout.
Floating-Connection (timeout floating-conn configured)	Identifies a new optimal path on a different interface (outside the same ECMP zone).	The flow is torn down after the floating-conn timeout to allow for a fresh connection. Note: May trigger %FTD-6-110003 syslog messages.
ECMP Zone (Both interfaces in the same ECMP zone)	Dynamically updates the flow's egress interface.	The flow is switched to the new path atomically and non-disruptively.

Longest prefix match example

For example, a packet destined for 192.168.32.1 arrives on an interface with these routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits verses 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.



Dynamic routing and High availability

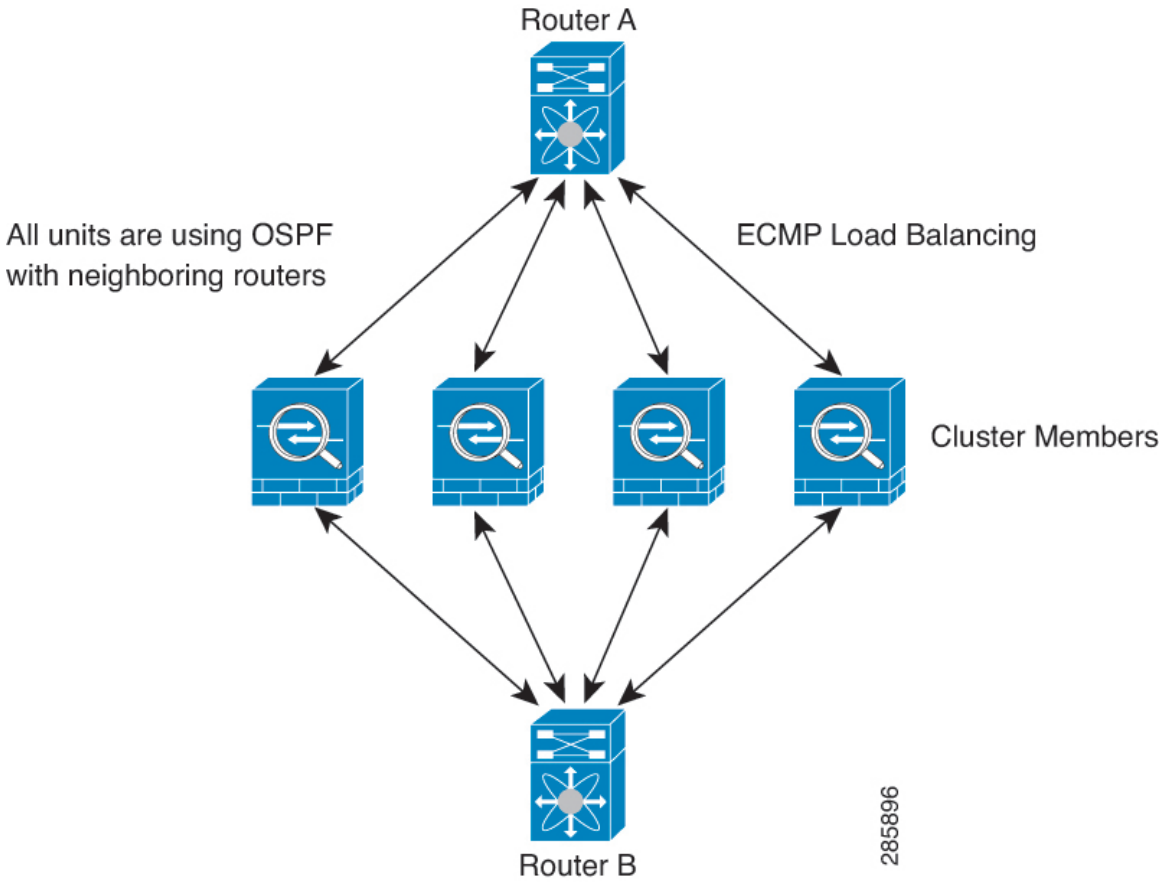
Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit. This means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active in an active/standby ready High availability pair, it will already have an identical routing table as that of the former active unit because routes are synchronized as a part of the High availability bulk synchronization and continuous replication processes.

Dynamic routing in Clustering

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 324: Dynamic Routing in Spanned EtherChannel Mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.



The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

Dynamic routing in individual interface mode

Learn how dynamic routing functions in individual interface mode, where each cluster node operates as a standalone router. Understand how to configure unique router IDs and manage traffic zones to ensure effective load balancing and prevent asymmetric routing in your network environment.

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 325: Dynamic Routing in Individual Interface Mode

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

EIGRP does not form neighbor relationships with cluster peers in individual interface mode.

Note If the cluster has multiple adjacencies to the same router for redundancy purposes, asymmetric routing can lead to unacceptable traffic loss. To avoid asymmetric routing, group all of these node interfaces into the same traffic zone. See Create an ECMP zone, on page 1433.

Routing table for management traffic

The Firewall Threat Defense device includes the following routing tables for from-the-device management traffic:

- Linux Management routing table—Special management traffic sourced from the Management interface such as Cloud-Delivered Firewall Management Center communication, licensing communication, and database updates always uses the Linux Management routing table.
- Data routing table—All from-the-device traffic (as well as all through traffic) uses the data routing table by default. All regular data interfaces are part of this routing table. Most services let you choose a specific interface, so only routes associated with that interface are used.
- Management-only routing table—The Management interface and all data interfaces that you set to management-only are part of this routing table. To send from-the-device traffic from any of these interfaces, you must choose a specific management-only interface when you configure the service. An exception is for DNS lookups and ICMP (ping and traceroute): in these cases, the Firewall Threat Defense will use data and then fall back to management automatically if a route is not found. You can add static routes for management-only interfaces, but not for the special Management interface. The Firewall Threat Defense device automatically adds a default route for Management that forwards traffic to Linux, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the Firewall Threat Defense CLI **configure network static-routes** command.

Note The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

Note For devices that have not yet merged the Management and legacy Diagnostic interfaces, see refer to pre-7.3 versions of this guide.

Equal-cost multi-path routing

The Firewall Threat Defense supports Equal-Cost Multi-Path (ECMP) routing.

ECMP routing implementation

You can have up to 8 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```

In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

ECMP Across Multiple Interfaces Using Traffic Zones

If you configure traffic zones to contain a group of interfaces, you can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Similarly, your dynamic routing protocol can automatically configure equal cost routes. The Firewall Threat Defense load-balances traffic across the interfaces with a more robust load balancing mechanism.

When a route is lost, the device seamlessly moves the flow to a different route.

Routing GRE traffic

In Firewall Threat Defense, Generic Routing Encapsulation (GRE) traffic is managed using bi-directional flows. This means that each GRE session is represented by a single flow entry that handles both inbound and outbound traffic between endpoints. With bi-directional flows, only one route lookup is performed and both directions are mapped to the same interface. As a result, the system cannot make independent routing decisions for each direction, which may lead to sub-optimal routing in some scenarios.

About route maps

Route maps are used when redistributing routes into an OSPF, RIP, EIGRP or BGP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route map characteristics

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, and each has a permit or deny result. Evaluation of an ACL or a route map consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms. Criteria matches and match interpretation are dictated by the way that they are applied and the feature that uses them. The same route map applied to different features might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.
- Each ACL ends with an implicit deny statement, by design convention. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Route maps that are applied to *redistribution* behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained a deny statement at the end.

Permit and deny clauses

Route maps can have permit and deny clauses. The deny clause rejects route matches from redistribution. You can use an ACL as the matching criterion in the route map.

Route map and ACL clause interaction rules

Because ACLs also have permit and deny clauses, the following rules apply when a packet matches the ACL:

- ACL permit + route map permit: routes are redistributed.
- ACL permit + route map deny: routes are not redistributed.
- ACL deny + route map permit or deny: the route map clause is not matched, and the next route-map clause is evaluated.

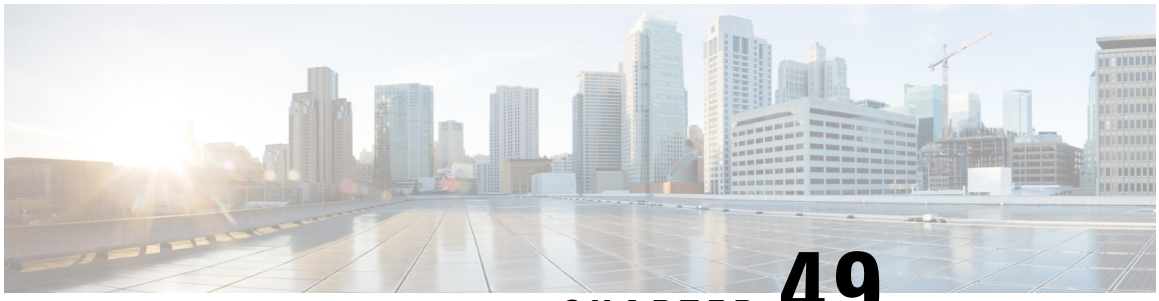
Match and set clause values

Each route map clause has two types of values:

- A match value selects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

Route map evaluation process

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeeds, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the set commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found that matches the route or until the end of the route map is reached.



A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several match entries are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a match entry refers to several objects in one entry, either of them should match (the logical OR algorithm is applied).
- If a match entry is not present, all routes match the clause.
- If a set entry is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note Do not configure a set entry in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a match or set entry does perform an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

CHAPTER 49

Virtual Routers

This chapter describes underlying concepts about virtual routers and on how virtual routing behaves within the Secure Firewall Threat Defense.

- Virtual routers and virtual routing and forwarding (VRF), on page 1375
- Maximum number of virtual routers by device model, on page 1381
- Requirements and prerequisites for virtual routers, on page 1383
- Guidelines and limitations for virtual routers, on page 1383
- Manage virtual routers, on page 1386
- Create a virtual router, on page 1386
- Monitor virtual routers, on page 1390
- Configuration examples for virtual routers, on page 1390

Virtual routers and virtual routing and forwarding (VRF)

A virtual router is a network virtualization feature that

- maintains separate routing tables for groups of interfaces
- provides clean separation in the traffic flowing through the device, and
- implements the "light" version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP).

Virtual router capabilities and configuration

Virtual routers provide support to two or more distinct customers over a common set of networking equipment. You can also use virtual routers to provide more separation for elements of your own network, for example, by isolating a development network from your general purpose corporate network.

When you create a virtual router, you assign interfaces to the router. You can assign a given interface to one, and only one, virtual router. You would then define static routes, and configure routing protocols such as OSPF or BGP, for each virtual router. You would also configure separate routing processes over your entire network, so that routing tables on all participating devices are using the same per-virtual-router routing process and tables. Using virtual routers, you create logically-separated networks over the same physical network to ensure the privacy of the traffic that runs through each virtual router.

Because the routing tables are separate, you can use the same, or overlapping, address spaces across the virtual routers. For example, you could use the 192.168.1.0/24 address space for two separate virtual routers, supported by two separate physical interfaces.

Note that there are separate management and data routing tables per virtual router. For example, if you assign a management-only interface to a virtual router, then the routing table for that interface is separate from the data interfaces assigned to the virtual router.

Virtual routers and dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router. For more information, refer to Virtual Routers and Dynamic VTI, on page 1749.

Virtual router applications

Virtual router applications are network implementation scenarios that

- isolate networks on shared resources through dedicated routing tables
- enable common security policy management across different departments or networks, and
- provide shared internet access for different departments or networks.

Global and user-defined virtual routers

This reference provides information about global and user-defined virtual routers, including their characteristics and the features supported by each type.

Global virtual routers

For a device with virtual routing capability, system creates a global virtual router by default. The system assigns all interfaces in your network to the global virtual router. A routed interface can belong to either a user-defined virtual router or a global virtual router. When you upgrade Firewall Threat Defense to a version which has virtual router capability, all its existing routing configuration becomes part of the global virtual router.

User-Defined virtual routers

A user-defined virtual router is the one defined by you. You can create more than one virtual router on a device. However, anytime, an interface can be assigned to only one user-defined virtual router. While some of the device features are supported on user-defined virtual routers, few of the features are supported only on the global virtual routers. User-defined virtual routers support route-based site-to-site VPN (static VTI) (static and dynamic VTI).

Supported features and monitoring policies

You can configure these features on the global virtual router only:

- OSPFv3
- RIP

- EIGRP
- IS-IS
- Multicast Routing
- Policy Based Routing (PBR)

ISIS and PBR are supported through Flex Config in Cloud-Delivered Firewall Management Center (see Predefined FlexConfig objects, on page 1322). Configure only global virtual router interfaces for these features.

DHCP server auto-configuration uses WINS/DNS server that is learned from an interface. This interface can only be a global virtual router interface.

You can configure these features separately for each user-defined virtual router:

- Static routes and their SLA monitors
- OSPFv2
- BGPv4/v6
- Integrated Routing and Bridging (IRB)
- SNMP

These features are used by the system when querying or communicating with the remote system (from-the-box traffic). These features use interfaces in the global virtual router only. That means, if you configure an interface for the feature, it must belong to the global virtual router. As a rule, anytime, if the system must look up a route to reach an external server for its own management purposes, it does the route lookup in the global virtual router.

- DNS server when used to resolve fully qualified names used in access control rules, or for resolving names for the **ping** command. If you specify **any** as the interface for a DNS server, the system considers interfaces in the global virtual router only.
- AAA server or identity realm when used with VPN. You can configure VPN on interfaces in the global virtual router only. Thus, the external AAA servers that are used for VPN, such as Active Directory, must be reachable through an interface in the global virtual router.
-

Virtual-router-aware policies

Virtual-router-aware policies are security policies that

- apply to interfaces from a single virtual router only
- use security zones whose memberships are constrained to interfaces assigned to a specific virtual router, and
- prevent policies from affecting all interfaces across all virtual routers when that is not desired.

Virtual router policy behavior

When you create a virtual router, the routing table for that virtual router is automatically separated from the global virtual router or any other virtual router. However, security policies are not automatically virtual-router-aware.

For example, if you write an access control rule that applies to "any" source or destination security zone, then the rule will apply to all interfaces across all virtual routers. This might in fact be exactly what you want. For example, all of your customers might want to block access to the same list of objectionable URL categories.

But, if you need to apply a policy to one of the virtual routers but not others, you need to create security zones that contain interfaces from that single virtual router only. Then, use the virtual-router-constrained security zones in the source and destination criteria of the security policy.

By using security zones whose memberships are constrained to the interfaces assigned to a single virtual router, you can write virtual-router-aware rules in these policies:

- Access control policy.
- Intrusion and file policies.
- SSL decryption policy.
- Identity policy and user-to-IP address mappings. If you use overlapping address spaces in virtual routers, ensure that you create separate realms for each virtual router and apply them correctly in the identity policy rules.

If you use overlapping address spaces in your virtual routers, you should use security zones to ensure that the right policies get applied. For example, if you use the 192.168.1.0/24 address space in two separate virtual routers, an access control rule that simply specifies the 192.168.1.0/24 network will apply to traffic in both virtual routers. If that is not the desired outcome, you can limit the application of the rule by also specifying the source/destination security zones for just one of the virtual routers.

Virtual router interconnection

Virtual router interconnection is a routing mechanism that

- enables traffic routing between virtual routers through route leaking,
- supports both manual static routes and dynamic BGP configurations, and
- allows network segmentation while maintaining controlled inter-segment communication.

Route leaking methods

You can configure the device to route traffic between virtual routers. This process of route leaking can be done manually by setting up static routes or dynamically through BGP settings.

Static route leaking involves manual configuration:

You can configure static routes to route traffic between virtual routers.

For example, if you have the outside interface in the global virtual router, you can set up static default routes in each of the other virtual routers to send traffic to the outside interface. Then, any traffic that cannot be routed within a given virtual router gets sent to the global router for subsequent routing.

Static routes between virtual routers are known as route leaks, because you are leaking traffic to a different virtual router. When you are leaking routes, say, VR1 routes to VR2, you can initiate connections from VR2 to VR1 only. For traffic to flow from VR1 to VR2, you must configure the reverse route. When you create a static route to an interface in another virtual router, you do not need to specify a gateway address. Simply select the destination interface.

For inter-virtual-router routes, the system does destination interface look-up in the source virtual router. Then, it looks up the MAC address of the next hop in the destination virtual router. Thus, the destination virtual router must have either a dynamic (learned) or static route for the selected interface for the destination address.

Configuring NAT rules that use source and destination interfaces in different virtual routers can also allow traffic to route between virtual routers. If you do not select the option for NAT to do a route lookup, the rule will simply send traffic out the destination interface with a NATed address whenever destination translation happens. However, the destination virtual router should have a route for the translated destination IP address so that next-hop lookup can succeed.

Though NAT rule leaks traffic from one virtual router to another, to ensure correct routing, we recommend that you configure a static route leak between these virtual routers for the translated traffic. Without the route leak, sometimes the rule may not match the traffic you expect it to match, and the translation may not be applied.

Virtual routing does not support a cascading or chain of route leaks. For example, assume that your Firewall Threat Defense has VR1, VR2, and VR3 virtual routers; VR3 is directly connected to a network - 10.1.1.0/24. Now, assume you configure a route leak in VR1 for network 10.1.1.0/24 through interface in VR2 and in VR2 define a route leak for 10.1.1.0/24 through VR3. This chain of route leaks will not allow traffic to hop from VR1 to VR2 and then exit from VR3. In case of route leaks, the route lookups first determine egress interface from input Virtual Router's routing table and then looks at the output of Virtual Router's routing table for next hop lookup. From both the lookups, egress interface should match. In our example, the egress interfaces will not be the same and hence the traffic does not pass through.

Use static inter VRF route with caution when the destination network is not a direct-connected subnet of the upstream (outgoing) VR. For example, assume two VRs - VR1 and VR2. While VR1 handles the outgoing traffic which gets the default route from its external peer through BGP or any dynamic routing protocol, and VR2 handles the incoming traffic which is configured with static inter VRF default route with VR1 as the next-hop. When VR1 loses the default route from its peer, VR2 will not able to detect that its upstream (outgoing) VR lost the default route and the traffic is still sent toward VR1 which will eventually get dropped without notifications. In this scenario, we recommend that you configure VR2 with dynamic route leak through BGP.

You can implement an inter-virtual-router route leak by exporting routes from a source virtual router (say VR1) to the source BGP table using route target extended community and then importing the same route target extended community from the source BGP table into the destination BGP table, which in turn is used by the destination virtual router (say, VR2). You can use the route maps for filtering the routes. The routes of global virtual router can also be leaked to user-defined virtual routers and vice versa. The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

For details on configuring BGP route leaking, see Configure BGP route import and export, on page 1509.

BGP route leaking guidelines:

- Ensure that all the routes required for recursion are imported and present in the routing table of the ingress virtual router.
- ECMP is supported per virtual router. Hence, do not configure an ECMP across different virtual routers. The overlapping prefixes imported from different virtual routers cannot form an ECMP. That is, when you attempt to import routes with overlapping addresses from two different virtual routers to other virtual

routers (a global virtual router or n user-defined virtual router), only one route (as per BGP best path algorithm, the first route that was advertised) is imported to the respective virtual routing table. For example, if a network 10.10.0.0/24, connected to VR1 is advertised through BGP to a global virtual router first, and later another network with the same address 10.10.0.0/24, connected to VR2 is also advertised through BGP to global virtual router, only the VR1 network route is imported to the global virtual routing table.

- OSPFv3 is not supported on user-defined virtual routers. Hence, do not configure BGPv6 to leak OSPFv3 user-defined virtual routers to global virtual router. However, you can configure BGPv6 to leak OSPFv3 global virtual router routes to user-defined virtual router through redistribution.
- It is recommended to keep VTI interface, protected internal interfaces (loopback interface if supported for VTI) to be part of same virtual router to prevent the need for route leak.

Best practice for overlapping IP addresses

Virtual router creates multiple instances of routing tables that are independent, thereby, the same or overlapping IP addresses can be used without conflicts. Firewall Threat Defense allows the same network to be part of two or more virtual routers. This involves multiple policies to be applied at the interface or at the virtual router level.

Limitations with overlapping IP addresses

When using an overlapping IP address in multiple virtual routers, to ensure proper application of the policy, you have to modify policies or rules for some of the features. Such features require you to use more specific interface either by splitting existing security zone or using new interface group as the need be.

- Network Map—Modify the network discovery policy to exclude some overlapping IP segments to ensure that there is no overlapping IP address being mapped.
- Identity Policy—The identity feed source cannot differentiate among virtual routers; to overcome this limitation, map overlapping address spaces or virtual routers in different realms.
- Access Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- Prefilter Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- QoS/Rate Limit—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.
- SSL Policy—Apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments.

Unsupported features with overlapping IP addresses

These features are not supported with overlapping IP addresses:

- ISE SGT-based Rule in AC Policy—The static security group tag (SGT) to IP address mappings downloaded from Cisco Identity Services Engine (ISE) are not virtual-router-aware. Set up separate ISE systems per virtual router if you need to create different SGT mappings per virtual router. This is not necessary if you intend to map the same IP addresses to the same SGT number in each virtual router.
- Overlapping DHCP server pools are not supported across virtual routers.

- Events and Analytics—Many of the Cloud-Delivered Firewall Management Center analytics are dependent on network map and identity mappings which cannot differentiate if the same IP address belongs to two different end hosts. Hence, these analytics are not accurate when there are overlapping IP segments existing in same device but different virtual routers.

Other than few exceptions, the routing functions and most of the NGFW and IPS capability does not get impacted by the overlapping IP addresses.

Configuring SNMP on user-defined virtual routers

In addition to supporting SNMP on the management interface and Global virtual router data interfaces, Secure Firewall Threat Defense now allows you to configure SNMP host on user-defined virtual routers.

Summary

The key components involved in configuring SNMP on user-defined virtual routers are:

- Device interfaces: Physical or logical interfaces that need to be configured and enabled
- Virtual router: User-defined virtual router configured on specific interfaces
- SNMP hosts: Network management stations that receive SNMP polling and traps
- Secure Firewall Threat Defense: The target device where configurations are deployed

Workflow

The SNMP configuration on user-defined virtual routers involves these stages:

1. Configure device interfaces.
2. Configure virtual router on an interface.
3. Configure SNMP hosts on a virtual router interface.

Note SNMP is not virtual router-aware. Hence, while configuring SNMP server on the user-defined virtual router, ensure that the network address is not an overlapping IP address.

4. Deploy configurations to Secure Firewall Threat Defense.

   On successful deployment, the SNMP polling and traps are sent to the Network Management Station through the virtual router interface.

Maximum number of virtual routers by device model

The maximum number of virtual routers you can create depends on the device model. The following table shows the maximum supported virtual routers per model. You can confirm the maximum for your system by entering the **show vrf counters** command, which displays the maximum number of user-defined virtual routers for your platform (not including the global virtual router). The numbers below include both user and global routers. For Firepower 4100/9300 devices, these values apply to native mode.

For platforms that support multi-instance capability, such as the Firepower 4100/9300, determine the maximum number of virtual routers per container instance by dividing the maximum virtual routers by the number of cores on the device, and then multiplying by the number of cores assigned to the instance, rounding down to the nearest whole number. For example, if the platform supports a maximum of 100 virtual routers, and it has 70 cores, then each core would support a maximum of 1.43 virtual routers (rounded). Thus, an instance assigned 6 cores would support 8.58 virtual routers, which rounds down to 8, and an instance assigned 10 cores would support 14.3 virtual routers (rounding down, 14).

Device Model	Maximum Virtual Routers
Secure Firewall 220	5
Firepower 1010	5
Firepower 1120	5
Firepower 1140	10
Firepower 1150	10
Secure Firewall 1210CE	5
Secure Firewall 1210CP	5
Secure Firewall 1220CX	10
Secure Firewall 1230	10
Secure Firewall 1240	10
Secure Firewall 1250	15
Firepower 2110	10
Firepower 2120	20
Firepower 2130	30
Firepower 2140	40
Secure Firewall 3105	10
Secure Firewall 3110	15
Secure Firewall 3120	25
Secure Firewall 3130	50
Secure Firewall 3140	100
Firepower 4112	60
Firepower 4115	80
Firepower 4125	100

Device Model	Maximum Virtual Routers
Firepower 4145	100
Secure Firewall 4215	100
Secure Firewall 4225	100
Secure Firewall 4245	100
Firepower 9300 appliance, all models	100
Firewall Threat Defense Virtual, all platforms	30
ISA 3000	10

Guidelines and limitations for virtual routers

Firewall mode guidelines

Use virtual routers on routed firewall mode only.

Interface guidelines

Configure interfaces for virtual routers according to these guidelines:

- Assign an interface to only one virtual router.
- A virtual router can have any number of interfaces that are assigned to it.
- Assign only routed interfaces with logical names and VTIs to a user-defined virtual router.
- If you want to change a virtual router interface to a non-routed mode, remove the interface from the virtual router, and then change its mode.
- You can assign an interface to a virtual router, either from a global virtual router or from another user-defined virtual router.
- Do not assign these interfaces to a user-defined virtual router:
  - Members of EtherChannel.
  - Members of Redundant interfaces.
  - Members of BVI.
- VTI is a route-based VPN. When the tunnel is established, control the traffic that uses VTI for encryption through routing. Static routing, as well as dynamic routing with BGP, OSPFv2/v3, or EIGRP is supported.
- Do not use interfaces that belong to user-defined virtual routers in policy-based site-to-site or remote access VPNs.
- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

Follow these precautions when moving interfaces between virtual routers:

- If a route using the interface that is being moved or its virtual router is deleted, exist in source or destination virtual router table, remove the routes before the interface movement or virtual router deletion.
- As separate routing tables are maintained for each virtual router, when an interface is moved from one virtual router to another virtual router, be it global or user-defined, the system removes the IP address configured on the interface temporarily. All existing connections on the interface are terminated. Thus, moving interfaces between virtual routers have drastic effect on the network traffic. Hence take precautionary measures before you move interfaces.

Global virtual router guidelines

Consider these guidelines for global virtual routers:

- The interfaces which are named and not part of other virtual routers, are part of the global virtual router.
- Do not remove routed interfaces from global virtual router.
- Do not modify global virtual router.
- Generally, after configuring interfaces, if you un-register and register back to same or another Cloud-Delivered Firewall Management Center, interface configuration is imported back from device.

With virtual router support, there is a restriction—the IP address for only global virtual router interfaces is retained.

Clustering guidelines

Consider these limitations when using virtual routers with clustering:

- When the control unit link fails due to failure of its interfaces, the unit removes all leaked routes of its interfaces from the global routing table and propagates the inactive connected and static routes to other units of the cluster. This results in removal of those leaked routes from the routing table in other units. These removal takes place prior to another unit becoming a new control unit, which takes approximately 500 ms. When another unit becomes the new control unit, these routes are learned and added back to the routing tables through BGP convergence. Thus, till the convergence time, approximately one minute, the leaked routes are not available for the routing events to take place.
- When a control role change occurs in a cluster, the leaked routes learnt through BGP is updated with the best ECMP path. However, the non-best ECMP path is removed from the cluster routing table only after the BGP reconvergence timer elapses, that is 210 seconds. Thus, till the BGP reconvergence timer elapse, the old, non-best ECMP path persist as preferred route for routing events.

Additional guidelines

Follow these additional guidelines when configuring virtual routers:

- While configuring BGP for virtual routers, you can redistribute the routes belonging to different protocols within the same virtual routers. For example, OSPF VR2 routes cannot be imported into BGP VR1. You can only redistribute OSPF VR2 into BGP VR2, and then configure a route leak between BGP VR2 and BGP VR1.
- Do not use IPv6 ACL for filtering the routes in the route map. Only prefix list is supported.
- Security Intelligence Policy—The Security Intelligence policy is not virtual-router-aware. If you add an IP address, URL, or DNS name to the block list, it is blocked for all virtual routers. This limitation is applicable on the interface having security zones.
- NAT Rules—Do not mix interfaces in NAT rules. In virtual routing, if the specified source and destination interface objects (interface groups or security zones) have interfaces that belong to different virtual routers, the NAT rule diverts traffic from one virtual router through another virtual router. The NAT does the route lookup in the virtual router table for the inbound interface only. If necessary, define static routes in the source virtual router for the destination interface. If you leave the interface as **any**, the rule applies to all interfaces regardless of virtual router membership.
- DHCP Relay—Interconnecting virtual routers for DHCP relay is not supported. For example, if DHCP relay client is enabled on VR1 interface and DHCP relay server is enabled on VR2 interface, the DHCP requests will not be forwarded outside of VR2 interface.
- Recreating a deleted virtual router—When you recreate a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to recreate a deleted virtual router successively, use a different name for the new virtual router.

Manage virtual routers

When you click **Manage Virtual Routers** on the Virtual Routers pane, the Manage Virtual Routers page appears. This page displays the existing virtual routers on the device and the associated interfaces. On this page, you can **Add Virtual Router** (+) to the device. You can also **Edit** (✎) and **Delete** (🗑) user-defined virtual routers. You cannot edit or remove a global virtual router. You can only **View** (🔍) the details of a global virtual router.

Create a virtual router

Create a virtual router to enable network segmentation and manage routing configurations independently within the firewall device.

Virtual routers allow you to segment network traffic and create separate routing domains within a single firewall device, providing enhanced network management and security isolation.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

Step 4 Click **Add Virtual Router** (+).

Step 5 In the Add Virtual Router box, enter a name and description for the virtual router.

Note
If you are creating a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to create a deleted virtual router successively, use a different name for the new virtual router.

Step 6 Click **Ok**.

The Routing page appears, displaying the newly created virtual router page.

The virtual router is successfully created and appears in the routing configuration interface, ready for further configuration.

What to do next

- Configure a Virtual Router.

Configure a virtual router

Configure a virtual router to assign interfaces and set up routing policies for network traffic management and routing capabilities on your device.

You can assign interfaces to a user-defined virtual router and configure the routing policies for the device. Though you cannot manually add or remove interfaces for a global virtual router, you can configure the routing policies for the device interfaces.

Before you begin

- To configure routing policies for a user-defined virtual router, add a router. See Create a virtual router, on page 1386.
- All routing configuration settings of a non-virtual routing capable device are also available for a global virtual router. For information on the settings, see Routing Settings.
- Only limited routing protocols are supported for a user-defined virtual router.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, from the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.

For information on the modifications to the routing page, see Modifications to the Cloud-Delivered Firewall Management Center web interface routing page.

Step 2 From the drop-down list, select the desired virtual router.

Step 3 In the **Virtual Router Properties** page, modify the description as needed.

Step 4 To add interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.

Remember these guidelines:

- Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.
- Only interfaces of global virtual routers are available for assigning; the **Available Interfaces** box lists only interfaces that are not assigned to any other user-defined virtual routers. You can assign physical interfaces, subinterfaces, redundant interfaces, bridge groups, VTIs, and EtherChannels to a virtual router, but not their member interfaces. Because the member interfaces cannot be named, they cannot be used in virtual routing.

  You can assign the diagnostic interface to the global virtual router only.

Step 5 To save the interface settings, click **Save**.

Step 6 To configure the routing policy for the virtual router, click the respective names to open the corresponding settings page:

- **OSPF**—Only OSPFv2 is supported on the user-defined virtual router. All other settings for OSPFv2 are as applicable as for a non-virtual-router-aware interface, except that **Interface** allows you to select only the interfaces of the virtual router that you are configuring. You can define the OSPFv3 and OSPFv2 routing policies for a global virtual router. For information on the OSPF settings, see OSPF, on page 1447.

- **RIP**—You can configure RIP routing policies only for a global virtual router. For information on RIP settings, see RIP, on page 1513.
- **BGP**—This page displays the BGP general settings that you have configured in **Settings**:
  - You cannot modify any of those general settings on this page, except for the router ID settings. You can override the router ID settings that were defined in the **Settings** page by editing them on this page.
  - To configure other BGP IPv4 or IPv6 settings, you must enable the BGP option in **BGP** page under **General Settings**.
  - BGP configuration for both IPv4 and IPv6 address family are supported for global router and the user-defined virtual router.

  For information on configuring BGP settings, see BGP, on page 1491.
- **Static Route**—Use this setting to define where to send traffic for a specific destination network. You can also use this setting to create an inter-virtual-router static route. You can create a leak of connected or static route by using the interfaces of user-defined or global virtual routers. **FMC prefixes** to an interface to indicate that it is belonging to another virtual router and can be used for a route leak. For the route leak to be successful, do not specify next hop gateway.

  The Static Route table displays the virtual router whose interface is used for a route leak in the **Leaked from Virtual Router** column. If it is not a route leak, the column displays N/A.

  Irrespective of which virtual router the static route belongs, a Null0 interface is listed along with the interfaces of the same virtual router to which the static route belongs.

  For information on static route settings, see Static and Default Routes, on page 1357.
- **Multicast**—You can configure multicast routing policies only for a global virtual router. For information on multicast settings, see Multicast, on page 1521.

Step 7 To save the routing policy settings, click **Save**.

The virtual router is configured with the assigned interfaces and routing policies you specified.

What to do next

- Modify a virtual router.
- Remove a virtual router.

Modify a virtual router

This task allows you to update the configuration settings of virtual routers to meet changing network requirements.

You can modify the description and other routing policies of a virtual router.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the assigned interfaces are displayed in the **Virtual Routers** page.

Step 4 To modify a virtual router, click **Edit** ( ) against the desired virtual router.

Note
You cannot modify the general settings of the global virtual router. Hence, edit is not available for the global router; instead a **View** ( ) is provided to view the settings.

Step 5 To save the changes, click **Save**.

The virtual router configuration is updated with your changes.

What to do next

- Remove a virtual router.

Remove Virtual Routers

Remove virtual routers when they are no longer needed or when consolidating routing configurations. This helps maintain a clean and efficient network routing structure.

Virtual routers provide network segmentation and routing isolation. When removing virtual routers, all associated interfaces automatically move to the global virtual router, and all routing policies are deleted.

Before you begin

- You cannot delete the Global virtual router. Hence, the delete option is not available for the Global virtual router.
- You can remove multiple virtual routers at a time.
- All the routing policies of the deleted virtual router are also deleted.
- All the interfaces of the deleted virtual router move to the global virtual router.
- If there are any restrictions on the movement of interfaces, such as overlapping IPs, route conflicts, and so on, you can remove the router only after resolving the conflicts.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the mapped interfaces are displayed in the **Virtual Routers** page.

Step 4 To remove a virtual router, click **Delete** ( ) against the desired virtual router.

Step 5 To remove multiple routers, holding the CTRL key, click the virtual routers that you want to delete. Right-click, and then click **Delete**.

Step 6 To save the changes, click **Save**.

The selected virtual routers are removed from the device configuration. All interfaces from the deleted virtual routers are automatically moved to the global virtual router, and all associated routing policies are permanently deleted.

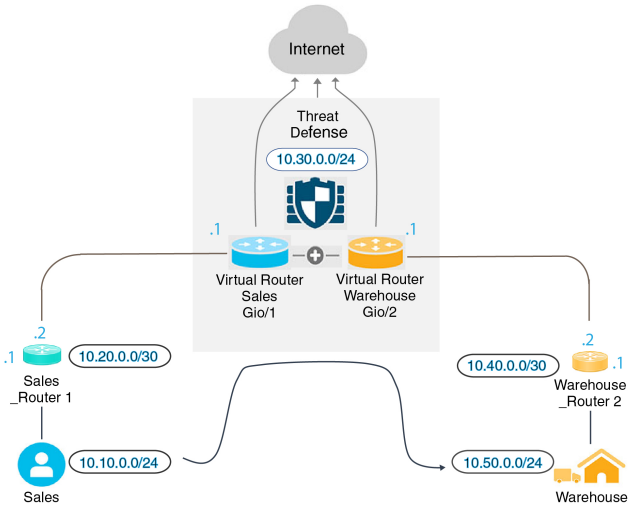
Monitor virtual routers

To monitor and troubleshoot virtual routers, log into the device CLI and use these commands:

- **show vrf**: Displays the details of the virtual routers and their associated interfaces.
- **show route vrf** <*vrf_name*>: Displays the routing details of a virtual router.
- **show run router BGP all**: Displays the BGP routing details of all virtual router.
- **show run router BGP vrf** <*vrf_name*>: Displays the BGP routing details of a virtual router.
- **show crypto ipsec sa/show crypto ikev2 sa**: Displays the details of the tunnel and the associated virtual router.
- You can monitor the tunnels in the Site-to site monitoring dashboard (**Overview > Site to Site VPN**).

  In the **Tunnel Status** widget, hover over a topology, click View and click **Packet Tracer** to view and troubleshoot the threat defense VPN tunnels.

Configuration examples for virtual routers



Route to a distant server through virtual routers

This task enables network separation while maintaining connectivity to servers across different virtual routing domains. You can create multiple virtual routers to maintain separate routing tables for groups of interfaces and interconnect them to reach hosts that are multiple hops away.

In virtual routing, you can create multiple virtual routers to maintain separate routing tables for groups of interfaces, thereby achieve network separation. In some scenarios, you may need to access a server that is reachable only through a separate virtual router. This example provides the procedure that interconnects virtual routers to reach to a host that is multiple hops away.

Consider an example, where a member of the sales department of a garment company wants to look up at the stock maintained by the warehousing department of its factory unit. In a virtual routing environment, you need to leak route between virtual routers where destination (warehousing department) is multiple hops away from sales department. This route leaking is done by adding multihop route leak, where, you configure a static route in Sales virtual router(source) to an interface in Warehouse virtual router (destination). As the destination network is multi-hop away, you also need to configure the Warehouse virtual router with the route to the destination network, namely 10.50.0.0/24.

Figure 326: Interconnecting two virtual routers - an example

Before you begin

This example assumes that you have already configured Sales_Router1 to route traffic from 10.20.0.1/30 interface to 10.50.0.5/24.

Follow these steps to route to a distant server through virtual routers:

Procedure

Step 1 Configure the inside interface (Gi0/1) of the device to be assigned to Sales virtual router.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.

b) Edit the Gi0/1 interface.

- **Name**—For this example, VR-Sales.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.30.0.1/24.

c) Click **Ok**.
d) Click **Save**.

Step 2 Configure the inside interface (Gi0/2) of the device to be assigned to Warehouse virtual router.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.
b) Edit the Gi0/2 interface.
   - **Name**—For this example, VR-Warehouse.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP**.
   - **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address (10.30.0.1/24), as you are yet to create user-defined virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 3 Create Sales and Warehouse virtual routers and assign their interfaces.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**.
c) Click **Add Virtual Router** and create Sales.
d) Click **Add Virtual Router** and create Warehouse.
e) Select Sales from virtual router drop-down, in **Virtual Router Properties**, add VR-Sales as **Selected Interface** and save.
f) Select Warehouse from virtual router drop-down, in **Virtual Router Properties**, add VR-Warehouse as **Selected Interface** and save.

Step 4 Revisit the VR-Warehouse interface configuration.

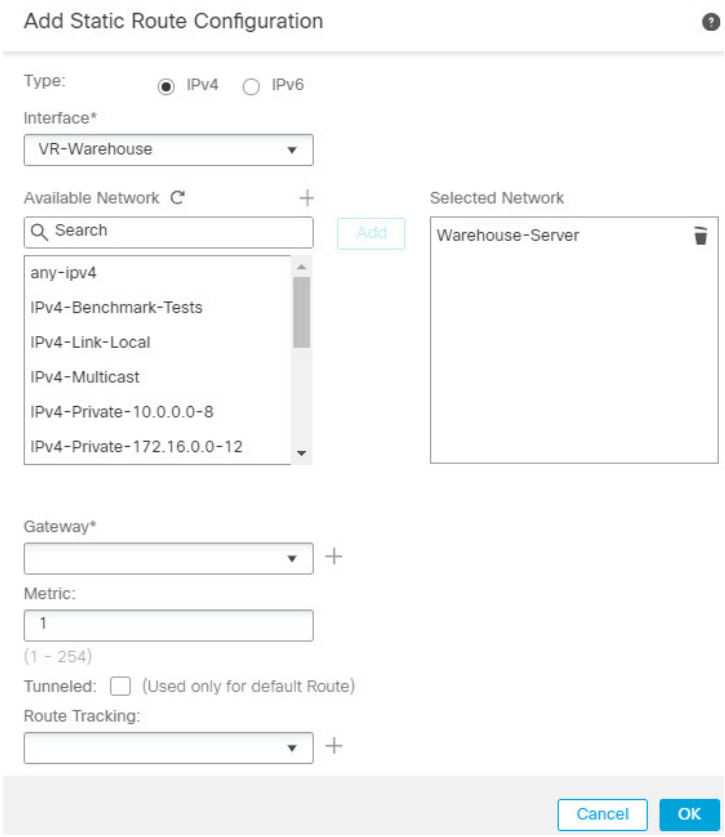
a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, click the device name, and click **Interfaces**.
b) Click **Edit** against VR-Warehouse interface. Specify the IP Address as 10.30.0.1/24. The system now allows you to configure with same IP address of VR-Sales, because the interfaces are seperately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 5 Create network objects for the warehouse server—10.50.0.0/24, and for the warehouse gateway— 10.40.0.2/30.

a) In the Cloud-Delivered Firewall Management Center, choose **Objects** > **Object Management**.
b) Choose **Add Network** > **Add Object**.
   - **Name**—For this example, Warehouse-Server.
   - **Network**—Click Network and enter 10.50.0.0/24.
c) Click **Save**.
d) Choose **Add Network** > **Add Object**.
   - **Name**—For this example, Warehouse-Gateway.
   - **Network**—Click Host and enter 10.40.0.2.

e) Click **Save**.

Step 6 Define the route leak in Sales that points to the VR-Warehouse interface.



a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Choose **Routing**.

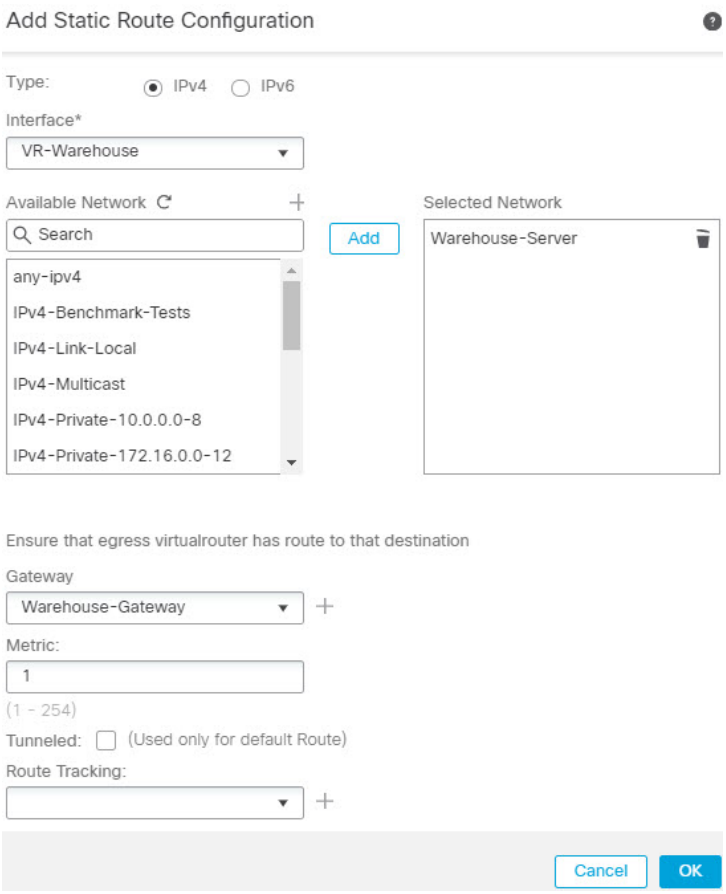
c) Choose Sales virtual router from the drop-down, and then click **Static Route**.

d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

e) Click **Ok**.

f) Click **Save**.



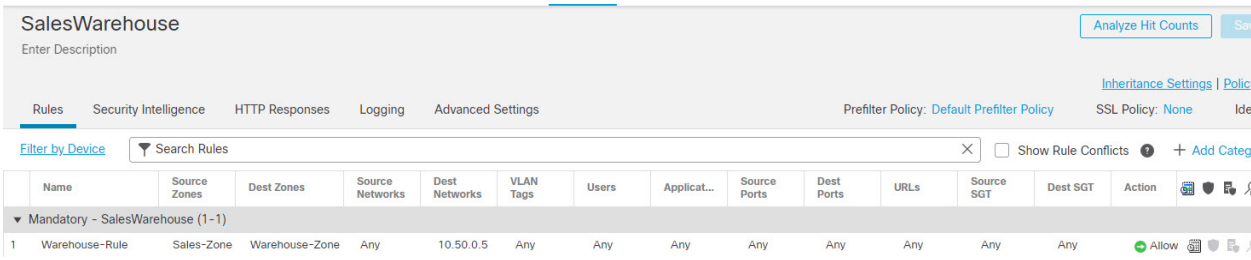
Step 7 In the Warehouse virtual router, define the route that points to the Warehouse Router 2 gateway.

a) In the Cloud-Delivered Firewall Management Center, choose Warehouse virtual router from the drop-down, and then click **Static Route**.

b) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.

- **Gateway**—Select the Warehouse-Gateway object.

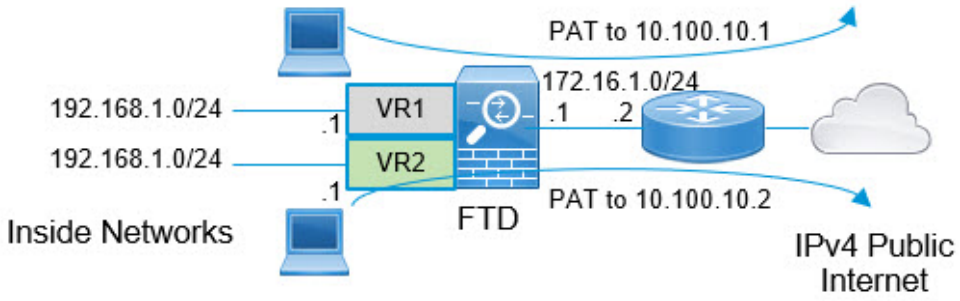


c) Click **Ok**.
d) Click **Save**.

Step 8 Configure access control rule that allows access to the warehouse server. For creating the access control rule, you need to create security zones. Use **Objects** > **Object Management** > **Interface**. Choose **Add** > **Security Zone** and create security zones for VR-Sales and VR-Warehouse; for Warehouse-Server network object, create a Warehouse-Server interface group (Choose **Add** > **Interface Group**).

Step 9 In the Cloud-Delivered Firewall Management Center, choose **Policies** > **Access Control heading** > **Access Control** and configure an access control rule to allow traffic from the source interfaces in the Sales virtual router to the destination interfaces in the Warehouse virtual router for the destination Warehouse-Server network object.

For example, if the interfaces in Sales are in the Sales-Zone security zone, and those in Warehouse are in the Warehouse-Zone security zone, the access control rule would look similar to this:



The route leak configuration enables traffic from the Sales virtual router to reach the warehouse server through the Warehouse virtual router. The access control rule allows the required traffic between the security zones.

How to Provide Internet Access with Overlapping Address Spaces

Ensure that endpoints using the same IP address space in different virtual routers can securely access the internet by implementing NAT/PAT policies

When using virtual routers, you can have the same network address for interfaces that reside in separate routers. However, because the IP addresses routed in these separate virtual routers are the same, apply NAT/PAT rules for each interface with separate NAT/PAT pools to ensure that return traffic goes to the correct destination. This example provides the procedure to configure the virtual routers and NAT/PAT rules to manage the overlapping address spaces.

For example, interfaces vr1-inside and vr2-inside on Firewall Threat Defense is defined to use the IP address 192.168.1.1/24, managing endpoints on their segment in the 192.168.1.0/24 network. To allow Internet access from two virtual routers that use the same address space, you need to apply NAT rules separately to the interfaces within each virtual router, ideally using separate NAT or PAT pools. You could use PAT to translate the source addresses in VR1 to 10.100.10.1, and for those in VR2, to 10.100.10.2. The following illustration shows this setup, where the Internet-facing outside interface is part of the global router. You must define the NAT/PAT rules with the source interface (vr1-inside and vr2-inside) explicitly selected—using “any” as the source interface makes it impossible for the system to identify the correct source because the same IP address could exist on two different interfaces.

Note Even if you have some interfaces within virtual routers that does not use overlapping address spaces, define the NAT rule with the source interface to make troubleshooting easier, and to ensure a cleaner separation between traffic from the virtual routers that is Internet-bound.

Procedure

Step 1 Configure the inside interface of the device for VR1:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, click the device name, and then click **Interfaces** .

b) Edit the interfaces that you want to assign to VR1:

- **Name**—For this example, vr1-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP** .
- **IP Address**—Enter 192.168.1.1/24.

c) Click **Ok** .

d) Click **Save** .

Step 2 Configure the inside interface of the device for VR2:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** , click the device name, and then click **Interfaces** .

b) Edit the interfaces that you want to assign to VR2:

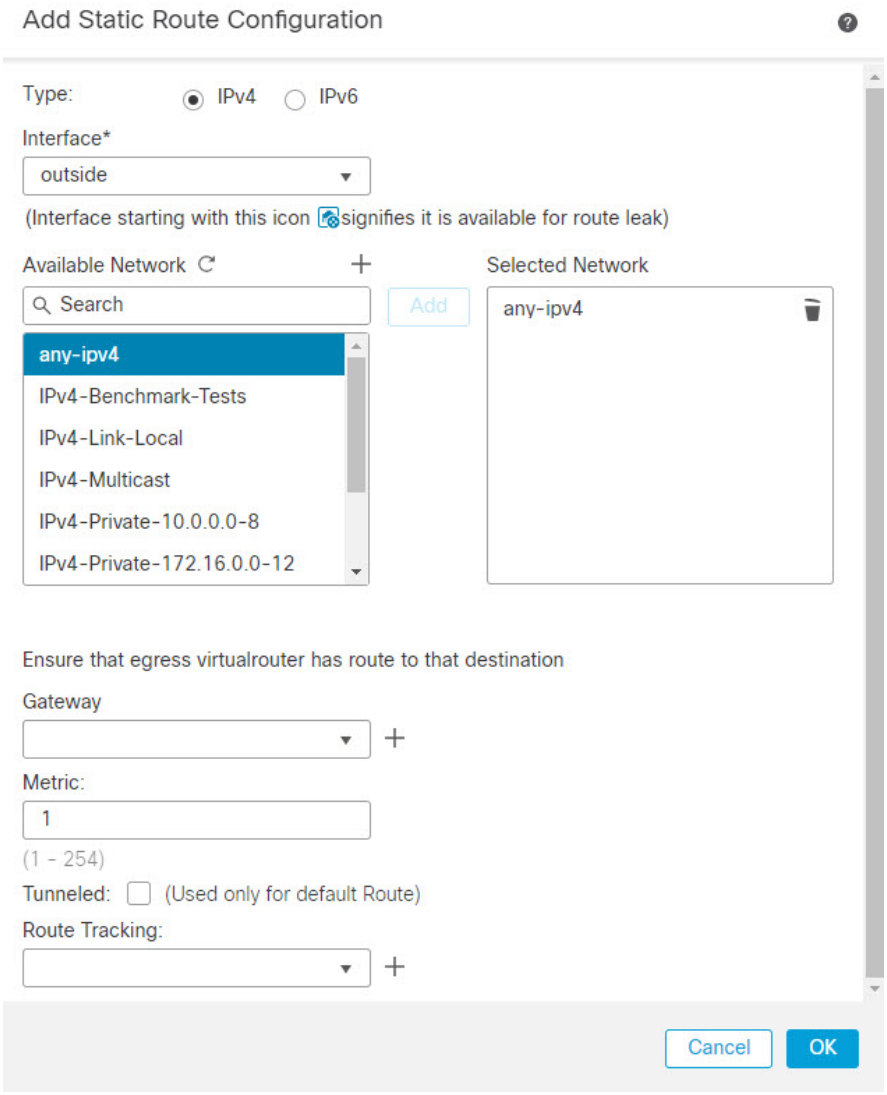
- **Name** —For this example, vr2-inside.
- Select the **Enabled** checkbox.
- In **IPV4** , for **IP Type** , choose **Use Static IP** .
- **IP Address** —Leave it blank. The system does not allow you to configure interfaces with same IP address, as you are yet to create user-defined virtual routers.

c) Click **Ok** .

d) Click **Save** .

Step 3 Configure VR1 and the static default route leak to the outside interface:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.



b) Choose **Routing** > **Manage Virtual Routers** . Click **Add Virtual Router** and create VR1.

c) For VR1, in **Virtual Router Properties** , assign vr1-inside and save.

d) Click **Static Route**.

e) Click **Add Route**. In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR1.
- **Gateway** —Leave it blank. When leaking a route into another virtual router, do not provide a Gateway.

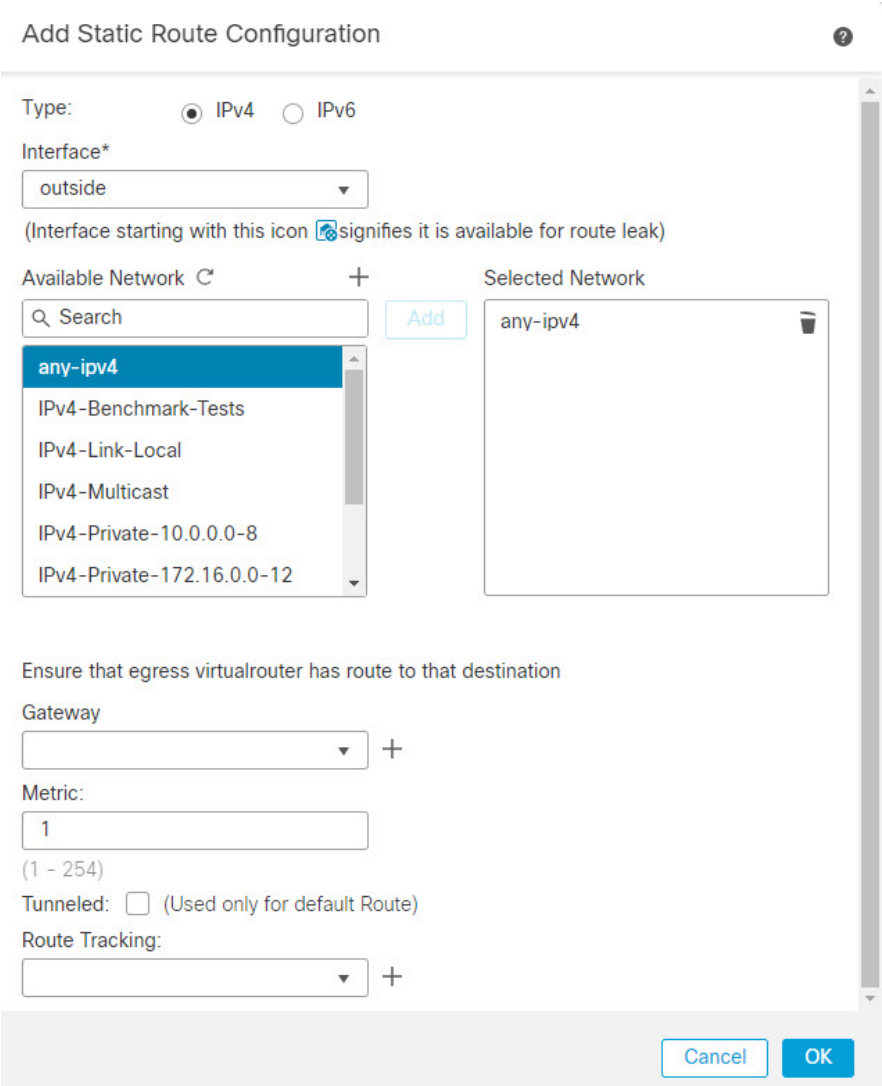
f) Click **Ok**.

g) Click **Save**.

Step 4 Configure VR2 and the static default route leak to the outside interface:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.

b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VR2.



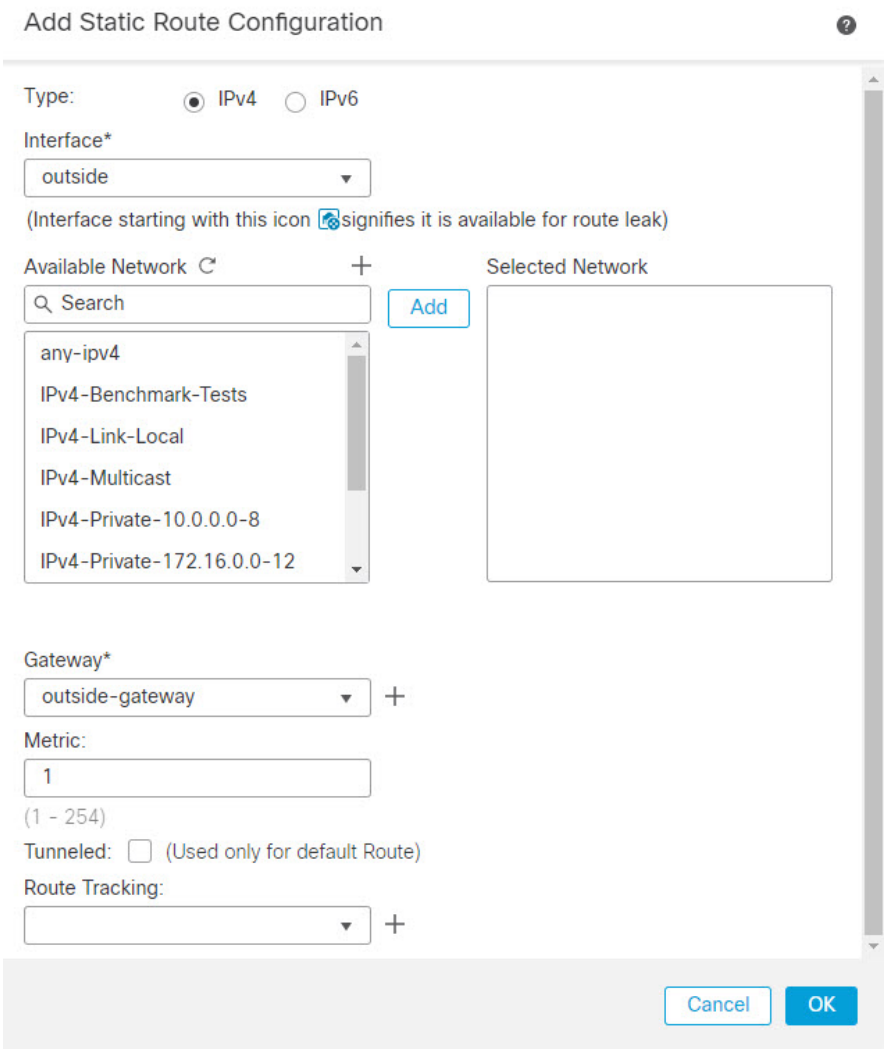
c) For VR2, in **Virtual Router Properties**, assign vr2-inside and save.

d) Click **Static Route**.

e) Click **Add Route**. In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR2.

- **Gateway** —Leave it blank. When leaking a route into another virtual router, do not select the Gateway.



f) Click **Ok**.
g) Click **Save**.

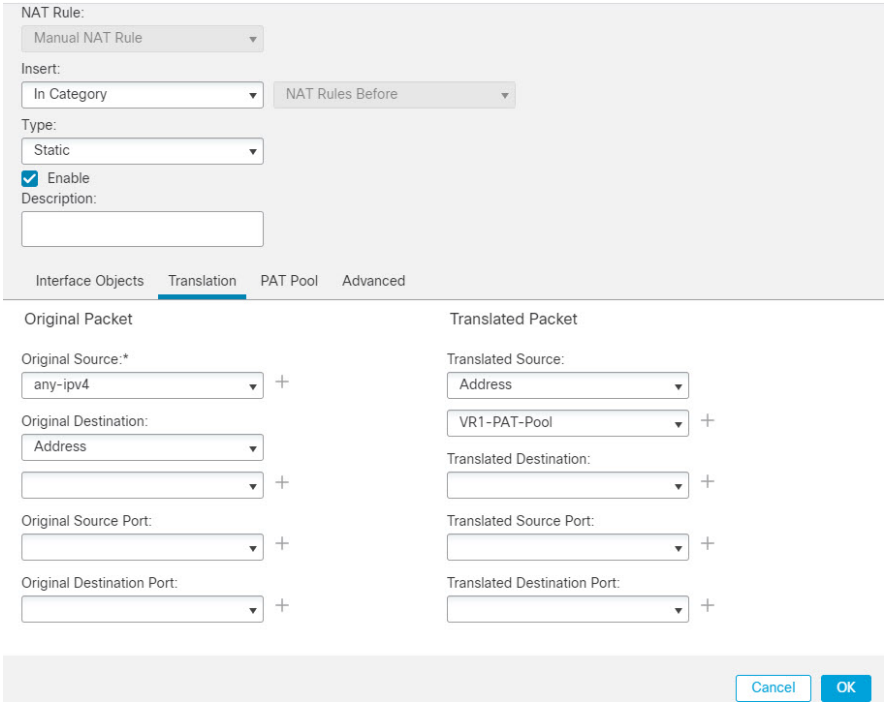
Step 5 Configure IPv4 static default route, namely 172.16.1.2 on the outside interface of the global router:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** , and edit the Firewall Threat Defense device.
b) Choose **Routing** and edit global router properties.
c) Click **Static Route** .
d) Click **Add Route** . In **Add Static Route Configuration** , specify the following:

- **Interface** —Select the outside interface of the global router.
- **Network** —Select the any-ipv4 object. This will be the default route for any IPv4 traffic.

- **Gateway** —If already created, select the host name from the drop-down. If the object is not yet created, click **Add** and define the host object for the IP address of the gateway at the other end of the network link on the outside interface, in this example, 172.16.1.2. After you create the object, select it in the Gateway field.

e) Click **Ok** .
f) Click **Save** .



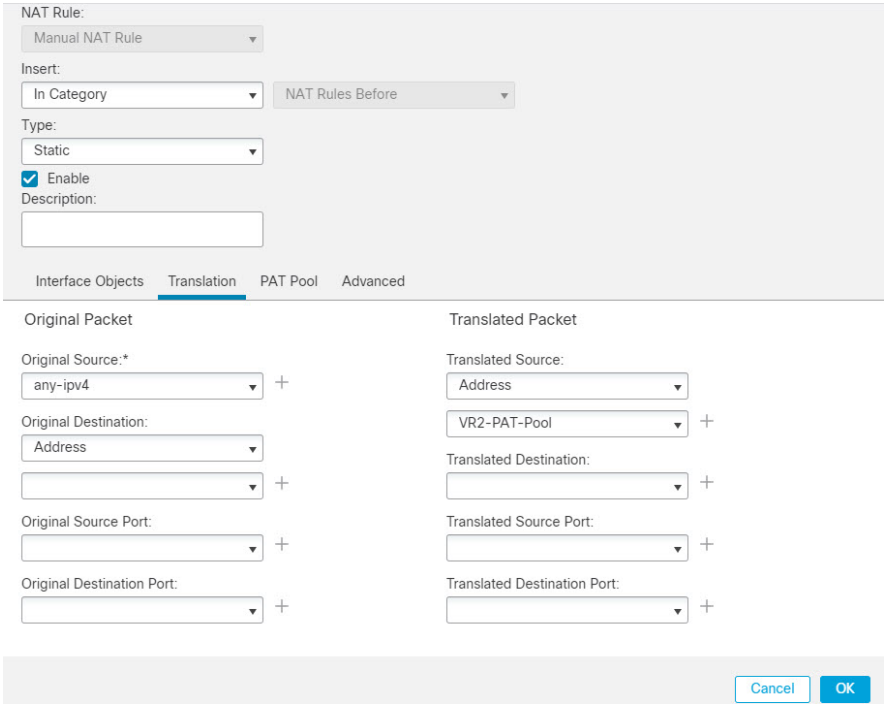
Step 6 Revisit the vr2-inside interface configuration:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** , click the device name, and then click **Interfaces** .
b) Click **Edit** against vr2-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with same IP address of vr1-inside, because the interfaces are separately assigned to two different virtual routers.
c) Click **Ok** .
d) Click **Save** .

Step 7 Create the NAT rule to PAT inside to outside traffic of VR1 to 10.100.10.1.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **NAT**.
b) Click **New Policy** > **Threat Defense NAT**.
c) Enter InsideOutsideNATRule as the NAT policy name, and select the Firewall Threat Defense device. Click **Save** .
d) In InsideOutsideNATRule page, click **Add Rule** and define the following:

- **NAT Rule** —Select Manual NAT Rule.
- **Type** —Select Dynamic.
- **Insert** —Above, if any dynamic NAT rule exists.
- Click **Enabled** .
- In **Interface Objects** , select vr1-interface object and click **Add to Source** (If the object is not available, create one in **Objects** > **Object Management** > **Interface**), and select outside as **Add to Destination** .
- In **Translation** , for **Original Source** , select any-ipv4. For **Translated Source** , click **Add** and define host object VR1-PAT-Pool with 10.100.10.1. Select VR1-PAT-Pool as shown in the figure below:

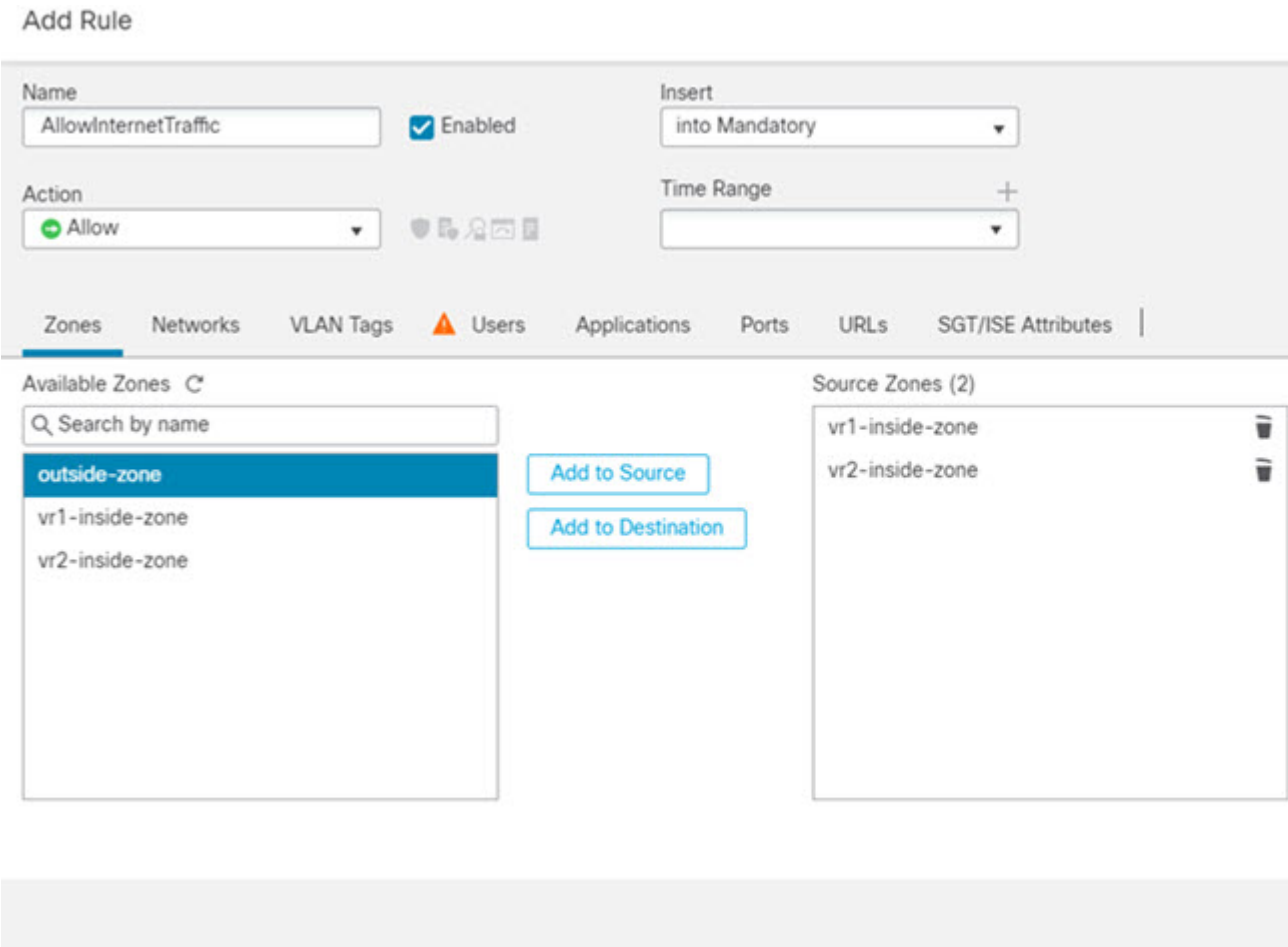


e) Click **Ok** .
f) Click **Save** .

Step 8 Add NAT rule to PAT inside to outside traffic of VR2 to 10.100.10.2.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **NAT** .
b) Edit InsideOutsideNATRule to define the VR2 NAT rule:

- **NAT Rule** —Select Manual NAT Rule.
- **Type** —Select Dynamic.

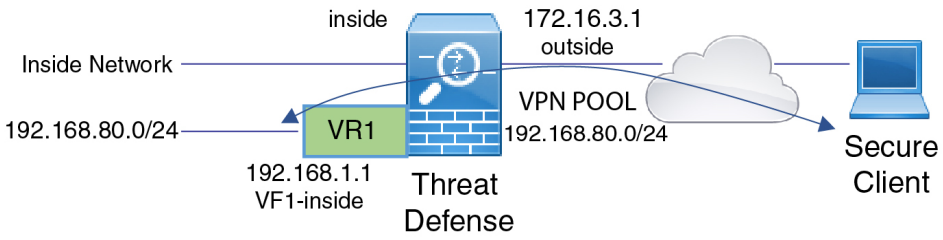


- **Insert** —Above, if any dynamic NAT rule exists.
- Click **Enabled** .
- In **Interface Objects** , select vr2-interface object and click **Add to Source** (If the object is not available, create one in **System** (⚙) > **Configuration** > **Management Interfaces**), and select outside as **Add to Destination** .
- In **Translation** , for **Original Source** , select any-ipv4. For **Translated Source** , click **Add** and define host object VR2-PAT-Pool with 10.100.10.2. Select VR2-PAT-Pool as shown in the figure below:

c) Click **Ok** .
d) Click **Save** .

Step 9 To configure the access control policy that allows traffic from the vr1-inside and vr2-inside interfaces to the outside interface, you need to create security zones. Use **Objects** > **Object Management** > **Interface** . Choose **Add** > **Security Zone** and create security zones for vr1-inside, vr2-inside, and outside interfaces. Choose **Policies** > **Access Control heading** > **Access Control** and configure an access control rule to allow traffic from vr1-inside-zone and vr2- inside-zone to outside-zone.

Assuming that you create zones named after the interfaces, a basic rule that allows all traffic to flow to the Internet will look like the following. You can apply other parameters to this access control policy:



Allow RA VPN access to internal networks in virtual routing

Allow Secure Client users to connect to user-defined virtual router networks by configuring route leaks between the global virtual router and user-defined virtual routers.

On virtual routing-enabled devices, RA VPN is supported only on global virtual router interfaces. This example provides the procedure that allows your Secure Client user to connect to user-defined virtual router networks.

In the following example, the RA VPN (Secure Client) user connects to the outside interface of Firewall Threat Defense at 172.16.3.1, and is given an IP address within the pool of 192.168.80.0/24. The user can access the inside network of only the global virtual router. To allow traffic flow through the network of the user-defined virtual router VR1, namely 192.168.1.0/24, leak the route by configuring the static routes on global and VR1.

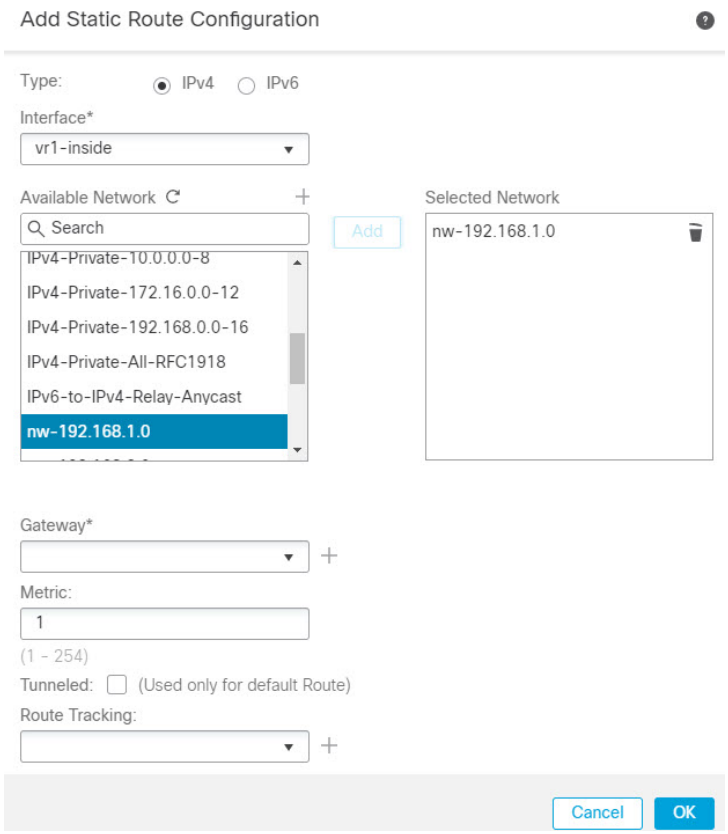
Before you begin

This example assumes that you have already configured the RA VPN, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

Follow these steps to allow RA VPN access to internal networks in virtual routing:

Procedure

Step 1 Configure route leak from Global virtual router to the user-defined VR1:



a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Click **Routing**. By default, the Global routing properties page appears.

c) Click **Static Route**.

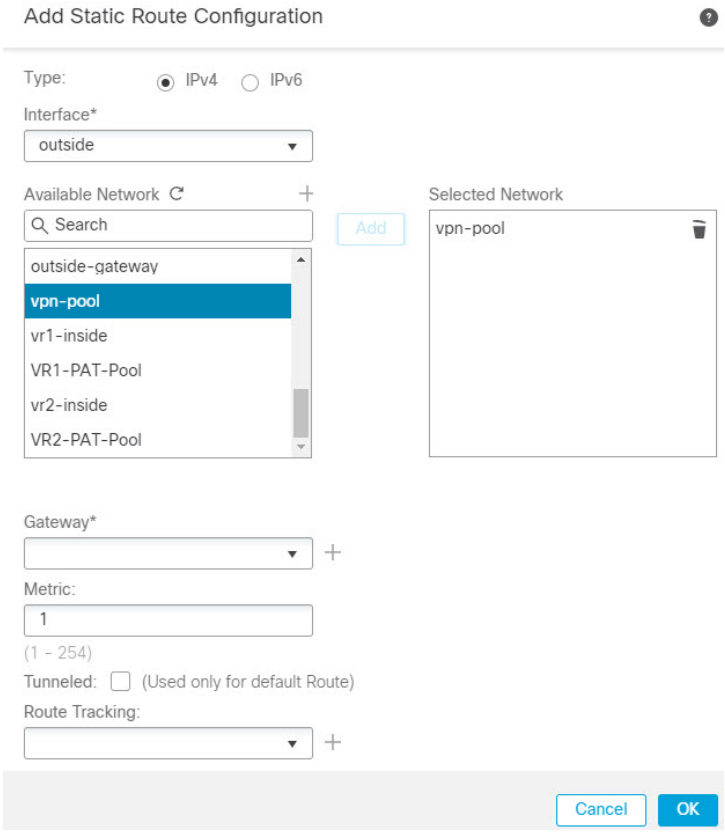
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

The route leak allows Secure Client assigned IP addresses in the VPN pool to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:



a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Click **Routing** and from the drop-down, select VR1.

c) Click **Static Route**.

d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

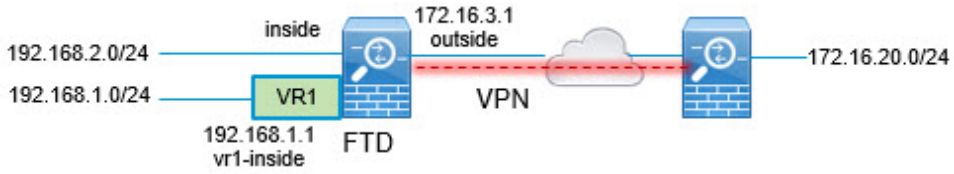
The configured static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections to Secure Client assigned IP addresses in the VPN pool.

e) Click **Ok**.

Secure Client users can now access networks in both the global virtual router and the user-defined VR1 virtual router through the configured route leaks.

What to do next

If RA VPN address pool and the IP addresses in the user-defined virtual router overlap, you must also use static NAT rules on the IP addresses to enable proper routing. Alternatively, you can change your RA VPN address pool so that there is no overlap.



Secure traffic from networks in multiple virtual routers over a site-to-site VPN

This task allows you to secure connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN by configuring route leaking between virtual routers and updating the VPN connection profile.

On virtual routing-enabled devices, Site-to-Site VPN is supported only on global virtual router interfaces. You cannot configure it on an interface that belongs to a user-defined virtual router. This procedure allows you to secure the connections from or to networks hosted within user-defined virtual routers over the site-to-site

VPN. You also need to update the site-to-site VPN connection to include the user-defined virtual routing networks.

Let us consider a scenario, where, a site-to-site VPN is configured between a branch office network to a company headquaters network; the Firewall Threat Defense in the branch office having virtual routers. In this case, the site-to-site VPN is defined on the outside interface of the branch office at 172.16.3.1. This VPN includes the inside network 192.168.2.0/24 without extra configuration, because the inside interface is also part of the global virtual router. But, to provide site-to-site VPN services to the 192.168.1.0/24 network, which is part of the VR1 virtual router, you must leak the route by configuring the static routes on global and VR1, and add the VR1 network to the site-to-site VPN configuration.

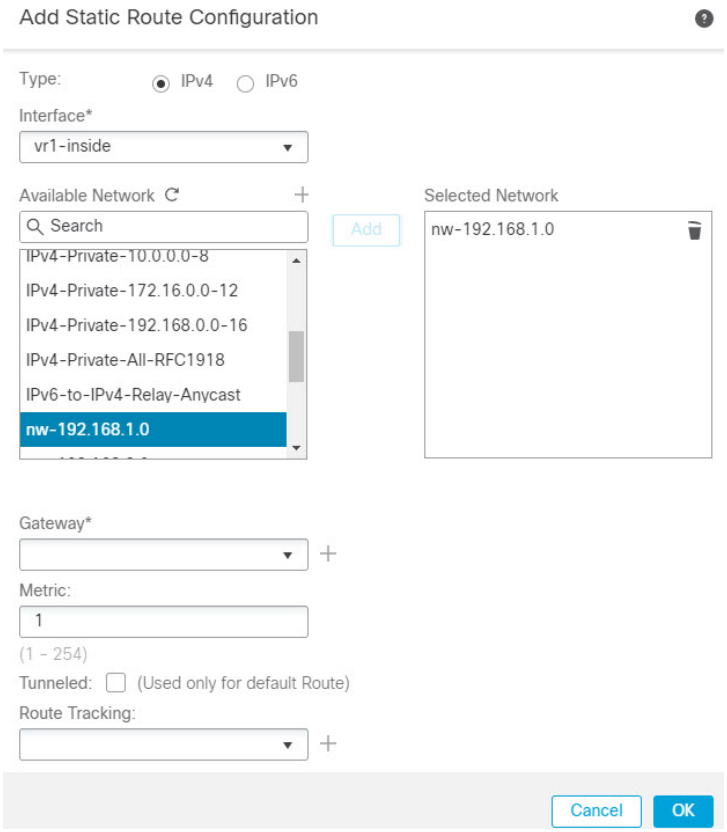
Before you begin

This example assumes that you have already configured the site-to-site VPN between the 192.168.2.0/24 local network and the 172.16.20.0/24 external network, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

Follow these steps to secure traffic from networks in multiple virtual routers over a site-to-site VPN:

Procedure

Step 1 Configure route leak from the Global virtual router to the user-defined VR1:



a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Click **Routing**. By default, the Global routing properties page appears.

c) Click **Static Route**.

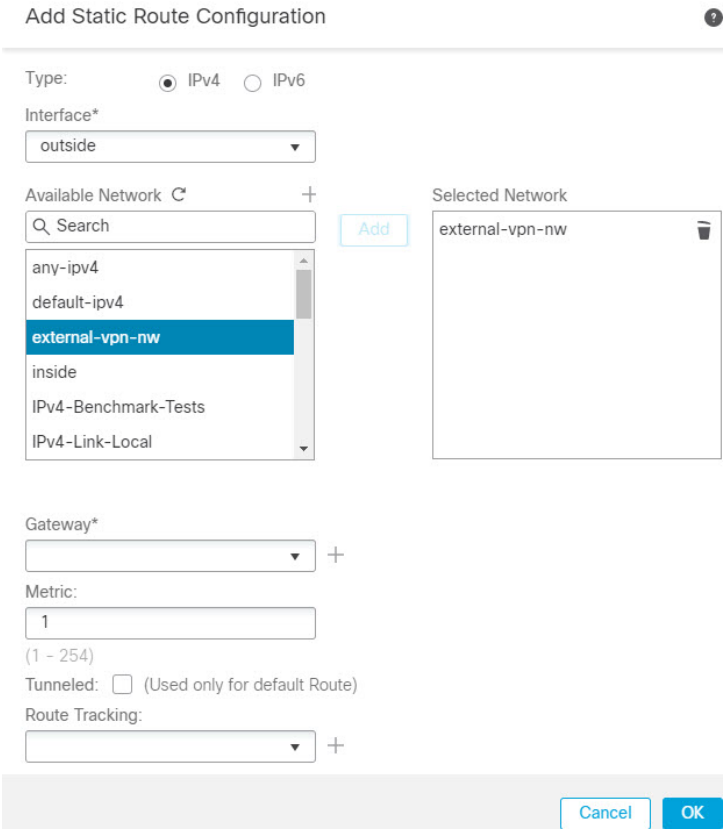
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

The route leak allows endpoints protected by the external (remote) end of the site-to-site VPN to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:



a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Click **Routing** and from the drop-down, select VR1.

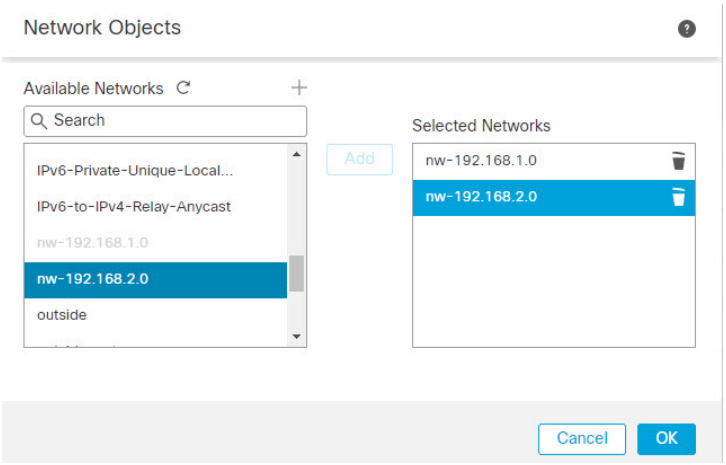
c) Click **Static Route**.

d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

This static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections that will traverse the site-to-site VPN tunnel. For this example, the remote endpoint that is protecting the 172.16.20.0/24 network.

e) Click **Ok**.



Step 3 Add the 192.168.1.0/24 network to the site-to-site VPN connection profile:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **VPN** > **Site to Site**, and edit the VPN Topology.

b) In **Endpoints**, edit Node A endpoint.

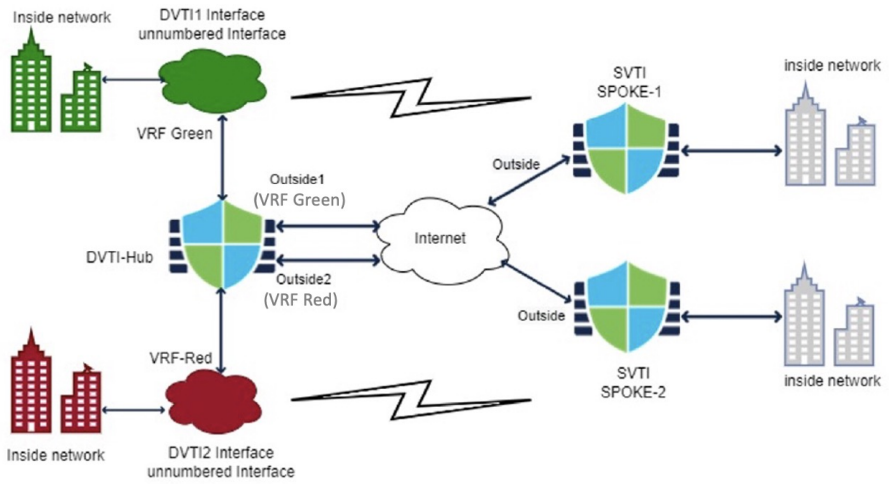
c) In **Edit Endpoint**, in the **Protected Networks** field, click **Add New Network Object**.

d) Add the VR1 network object with 192.168.1.0 network:

e) Click **Ok** and save the configuration.

The route leaking configuration allows traffic from networks in user-defined virtual routers to traverse the site-to-site VPN tunnel securely, enabling connectivity between the VR1 network and remote networks protected by the VPN.

Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI



This task enables ISPs to create virtual routers and associate dynamic VTIs with these virtual routers to extend the capabilities of dynamic VTIs in their network. You can associate dynamic VTIs either with global or user-defined virtual routers.

ISPs have different segmented networks for different customers. You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. A single threat defense device can act as a dynamic VTI hub with a global or one or more user-defined virtual routers. Each user-defined virtual router can be one customer network.

Let us consider an example where route-based site-to-site VPNs are configured between two company headquarter networks and their two branch office networks. The ISP's threat defense, a dynamic VTI hub, manages the two company headquarter networks with two user-defined virtual routers: VRF green and VRF red. The dynamic VTI hub establishes a site-to-site VPN between:

- Customer 1 (VRF green) and Branch 1 (SVTI spoke 1)
- Customer 2 (VRF red) and Branch 2 (SVT2 spoke 2)

Figure 327: Site-to-Site VPNs with multiple virtual routers and dynamic VTI

Procedure

Step 1 Configure a dynamic VTI interface on the hub.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and edit the threat defense device.
b) Choose **Add Interfaces > Virtual Tunnel Interface**.
c) Select the **Tunnel Type** as **Dynamic**.
d) Specify the interface name as DVTI1 and configure all the parameters for the dynamic VTI.
e) Click **Save**
f) Repeat steps 1a - e to configure the second dynamic VTI on the hub, DVTI2.

Step 2 Configure static VTI on spoke 1.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and edit the threat defense device.
b) Select **Add Interfaces > Virtual Tunnel Interface**.
c) Select the **Tunnel Type** as **Static**.
d) Specify the interface name as SVTI spoke-1 and configure all the parameters for the static VTI.
e) Click **Save**
f) Repeat steps 2a - e to configure the static VTI on spoke 2: SVTI spoke-2.

Step 3 Configure a route-based site-to-site VPN between hub and SVTI spoke 1.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **VPN** > **Site to Site** and click **+ Site To Site VPN**.
b) Enter a name for the VPN topology in the **Topology Name** field.
c) Choose **Route Based (VTI)** and select **Hub and Spoke** as the network topology.
d) Click the **Endpoints** tab.
e) Configure the hub and the spoke (DVTI1 and SVTI spoke-1) and their routing policies.
f) Configure the **IKE**, **IPsec**, and **Advanced** options for the VPN, if required.
g) Click **Save**.

h) Repeat steps 3a - g to configure the second route-based site-to-site VPN topology between hub (DVTI2) and SVTI spoke 2.

Step 4 Configure the two virtual routers.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and edit the threat defense device.
b) Click **Routing**.
c) Click **Manage Virtual Routers**.
d) Click **Add Virtual Router**.

Specify the name as VRF green and provide a description for the virtual router.

e) Repeat steps 4a - d to configure VRF red.

Step 5 Assign all the interfaces to the virtual routers.

a) From the drop-down list, select the virtual router.
b) In the **Virtual Router Properties** page, select the interfaces listed under the **Available Interfaces** box.

Assign the dynamic VTI interface along with the other interfaces.

c) Click **Add**.

Step 6 Repeat steps 5a - c for VRF red.

Step 7 Configure the routing policy for the virtual router.

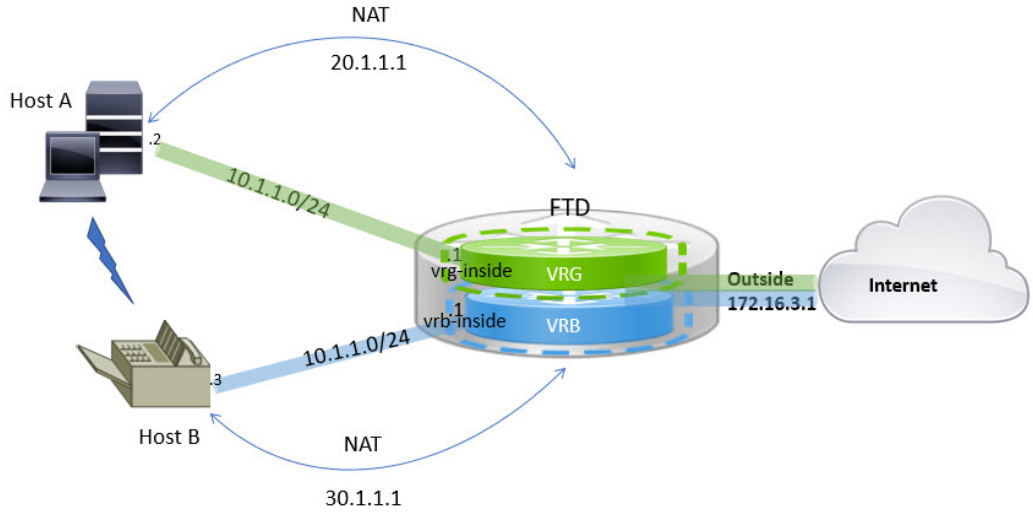
a) From the drop-down list, select the virtual router.
b) Click **Static Route** or one of the dynamic routing protocols.
c) Configure the routing parameters.
d) Click **Save**.

You have successfully configured networks with multiple virtual routers over a site-to-site VPN with dynamic VTI, enabling ISPs to manage different segmented networks for different customers through virtual routers.

What to do next

Select the hub and spoke devices and click **Deploy**. After the deployment, you can monitor the VPN tunnels in the Site-to site monitoring dashboard (**Overview** > **Dashboards** > **Site to Site VPN**).

You can also use the commands listed in Monitor virtual routers, on page 1390 to view and troubleshoot the virtual router.



Route traffic between two overlapping network hosts in virtual routing

Configure NAT rules to manage overlapping network hosts and enable communication between hosts on different virtual routers that have the same network address.

You can configure hosts on the virtual routers that have same network address. If the hosts want to communicate, you can configure twice NAT. This example provides the procedure to configure the NAT rules to manage the overlapping network host.

In the following example, two hosts Host A and Host B belong to different virtual routers: VRG (interface VRG-inside), VRB (interface VRB-inside) respectively with the same subnet 10.1.1.0/24. For both the hosts to communicate, create a NAT policy where, VRG-Host interface object would use a mapped NAT address

- 20.1.1.1, and VRB-Host interface object would use a mapped NAT address - 30.1.1.1. Thus, Host A uses 30.1.1.1 to communicate to Host B; Host B uses 20.1.1.1 to reach Host A.

Before you begin

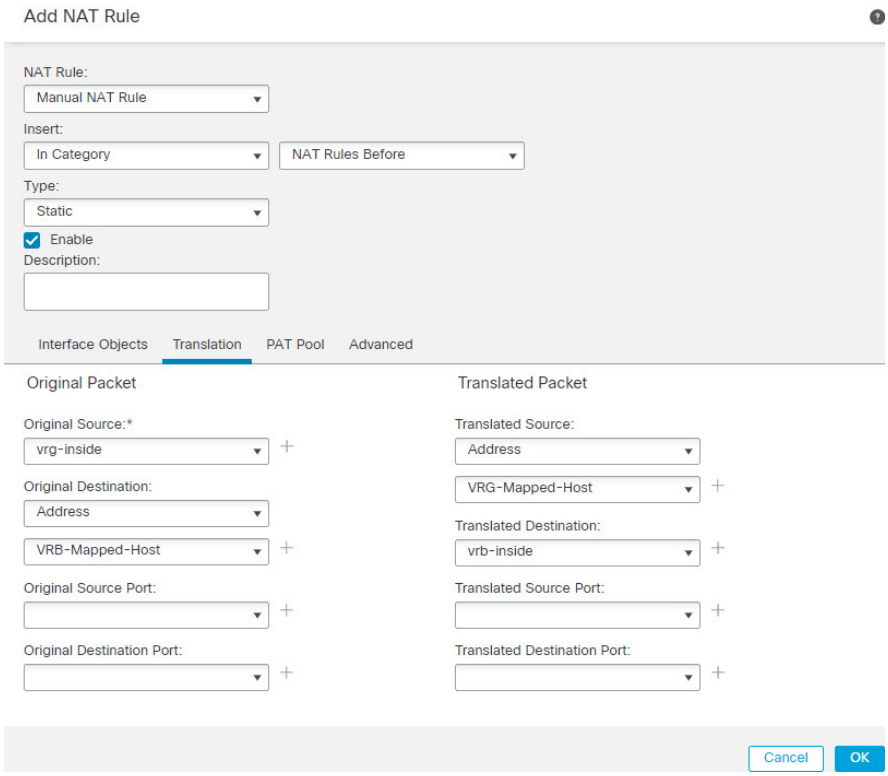
This example assumes that you have already configured:

- VRG-inside and VRB-inside interfaces are associated with virtual routers: VRG and VRB respectively and VRG-inside and VRB-inside interfaces configured with same subnet address (say, 10.1.1.0/24).
- Interfaces zones VRG-Inf, VRB-Inf created with VRG-inside and VRB-inside interfaces respectively.
- Host A in VRG with VRG-inside as default gateway; Host B in VRB with VRB-inside as default gateway.

Follow these steps to route traffic between two overlapping network hosts in virtual routing:

Procedure

Step 1 Create the NAT rule to handle traffic from Host A to Host B. In the Cloud-Delivered Firewall Management Center, choose **Devices** > **NAT**.



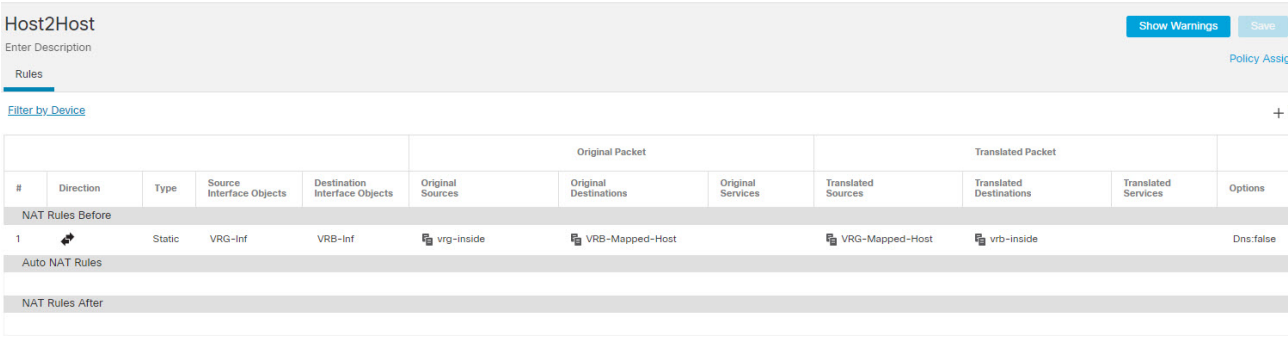
Step 2 Click **New Policy** > **Threat Defense NAT**.

Step 3 Enter a NAT policy name, and select the Firewall Threat Defense device. Click **Save**.

Step 4 In the NAT page, click **Add Rule** and define the following:

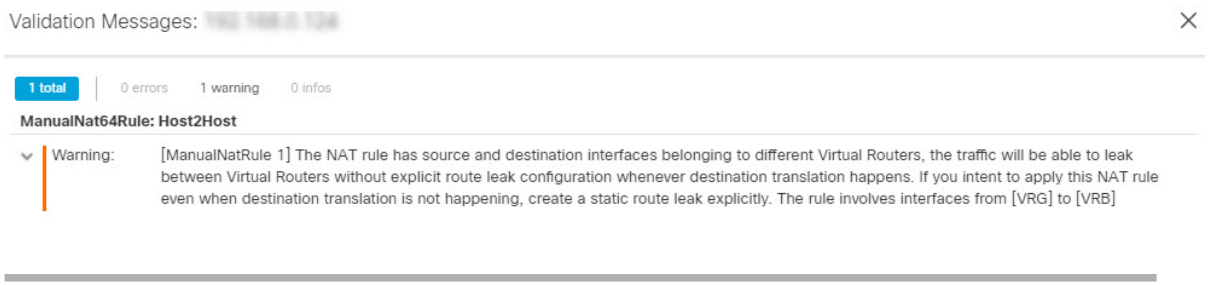
- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inf object and click **Add to Source** (If the object isn't available, create one in **Objects** > **Object Management** > **Interface**), and select VRB-Inf object and click **Add to Destination**.
- In **Translation**, select the following:

- **Original Source**, select VRG-inside.
- **Original Destination**, click **Add** and define object VRB-Mapped-Host with 30.1.1.1. Select VRB-Mapped-Host.
- **Translated Source**, click **Add** and define object, VRG-Mapped-Host with 20.1.1.1. Select VRG-Mapped-Host.
- **Translated Destination**, select VRB-inside as shown in the following figure:



When you run the **show NAT detail** command on the Firewall Threat Defense device, you will see an output similar to this:

```
firepower(config-service-object-group)# show nat detail
Manual NAT Policies (Section 1)
1 (2001) to (3001) source static vrg-inside VRG-MAPPED-HOST destination static VRB-MAPPED-HOST
 vrb-inside
translate_hits = 0, untranslate_hits = 0
Source - Origin: 10.1.1.1/24, Translated: 20.1.1.1/24
Destination - Origin: 30.1.1.1/24, Translated: 10.1.1.1/24
```

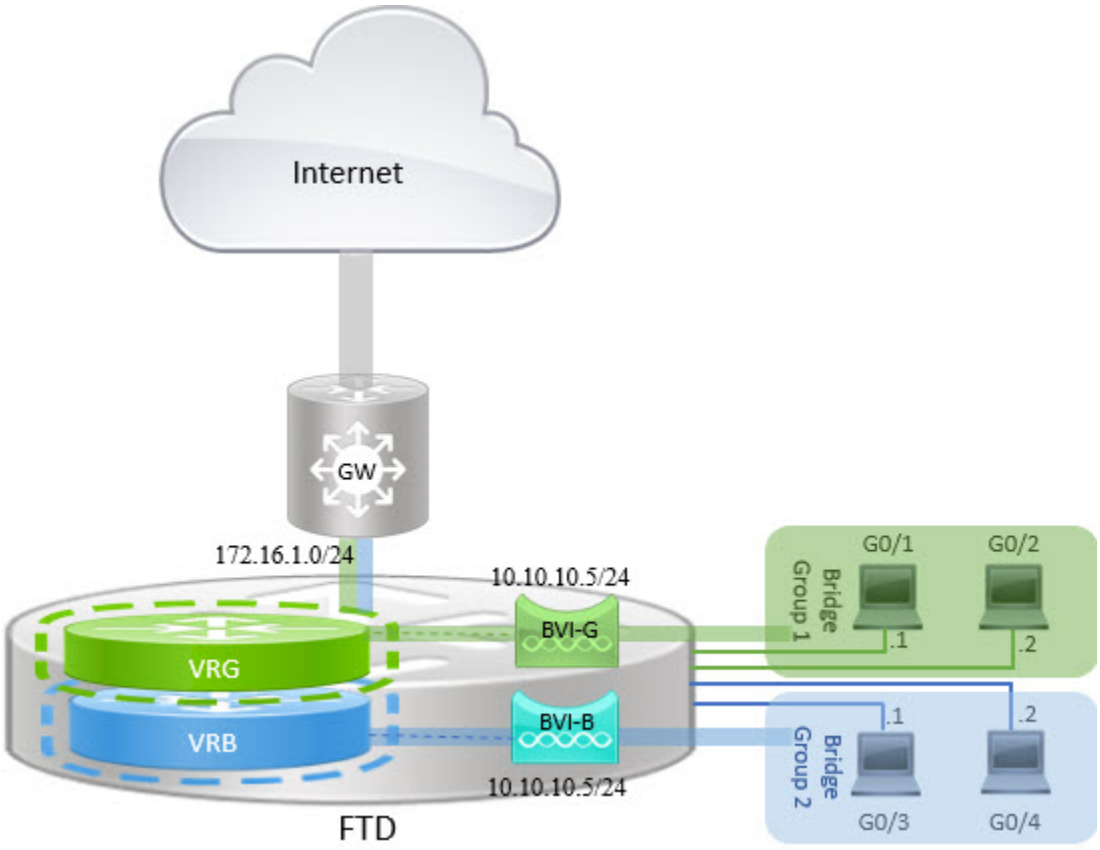


Step 5 Click **Ok**.

Step 6 Click **Save**.

The NAT rule looks like this:

When you deploy the configuration, a warning message appears:



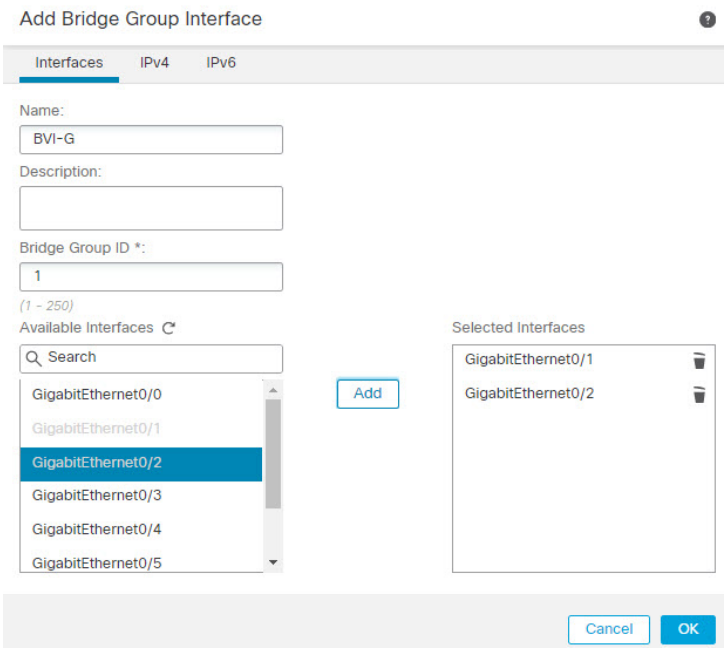
The NAT rule is configured to enable communication between Host A and Host B on overlapping network addresses. Host A uses 30.1.1.1 to communicate with Host B, and Host B uses 20.1.1.1 to reach Host A.

Manage overlapping segments in routed firewall mode with BVI interfaces

This task allows you to deploy single Firewall Threat Defense between multiple overlapping networks transparently and/or deploy the firewall between the hosts of same network by configuring BVI per virtual router.

BVI is a virtual interface within a router that acts like a normal routed interface. It does not support bridging, but represents the comparable bridge group to routed interfaces within the router. All the packets coming in or going out of these bridged interfaces, pass through the BVI interface. The interface number of the BVI is the number of the bridge group that the virtual interface represents.

In the following example, BVI-G is configured in VRG and Bridge Group 1 is the routed interface for interfaces G0/1 and G0/2. Similarly, BVI-B is configured in VRB and Bridge Group 2 is the routed interface for interfaces G0/3 and G0/4. Consider that both BVIs have the same IP subnet address, say 10.10.10.5/24. Because of virtual routers, the network is isolated on the shared resources.



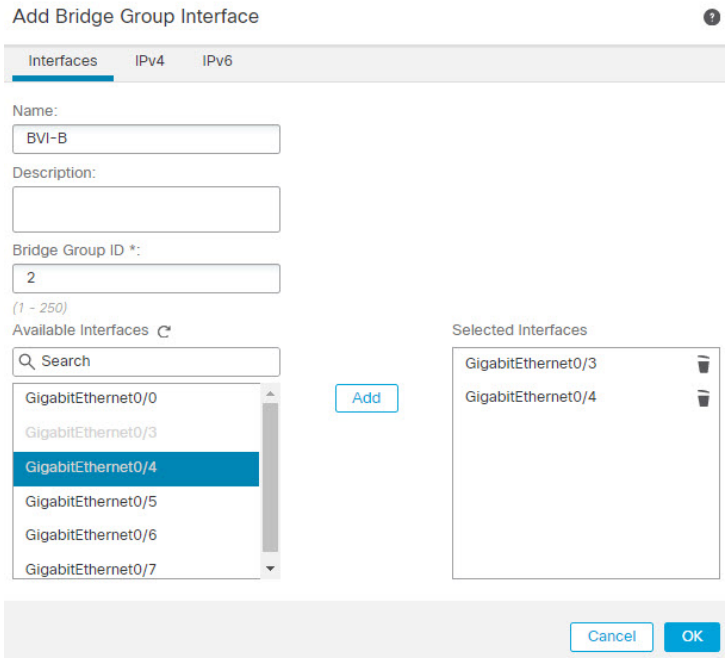
Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**. Edit the required device.

Step 2 In **Interfaces**, choose **Add Interfaces** > **Bridge Group Interface**.

a) Enter the following details for BVI-G:

- **Name**—For this example, BVI-G.
- **Bridge Group ID**—For this example, 1.
- **Available Interface**—Select the interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.10.10.5/24.



b) Click **Ok**.

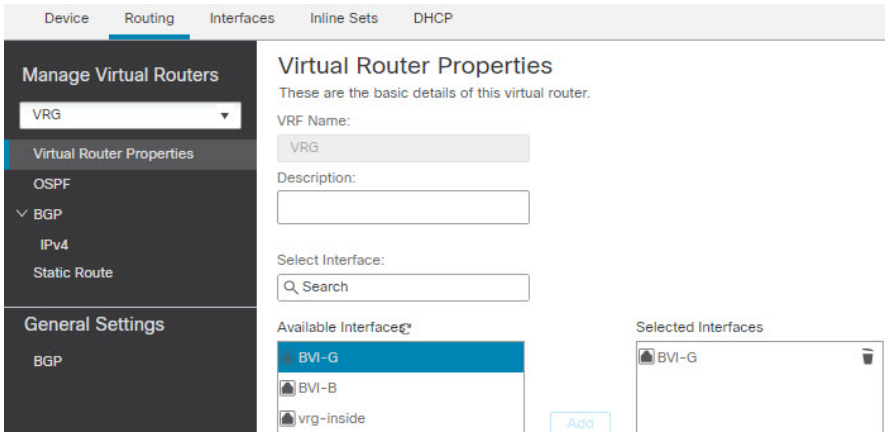
c) Click **Save**.

a) Enter the following details for BVI-B:

- **Name**—For this example, BVI-B.
- **Bridge Group ID**—For this example, 2.
- **Available Interface**—Select the sub interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave this field empty as the system does not allow two interfaces to have overlapping IP address. You can revisit the Bridge Group and provide the same IP address after aligning it under a virtual router.

b) Click **Ok**.

c) Click **Save**.



Step 3 Create virtual router, say VRG, and select BVI-G as its network:

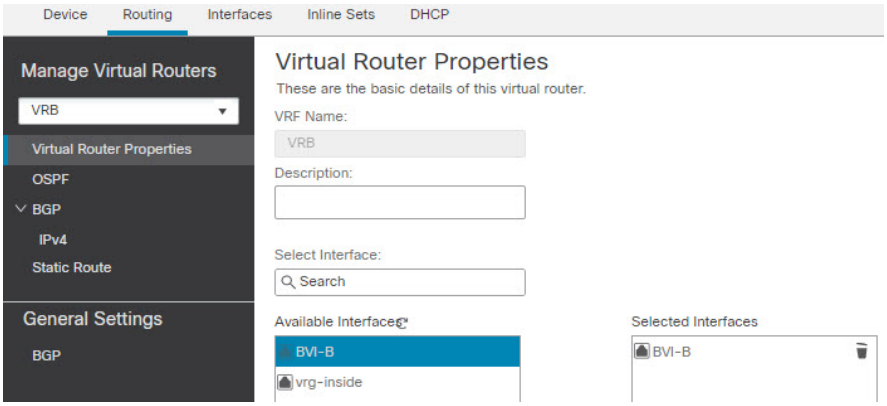
a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

d) In **Virtual Routing Properties**, select **BVI-G** and click **Add**.

e) Click **Save**.



Step 4 Create virtual router, say VRB, and select BVI-B as its network:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

d) In **Virtual Routing Properties**, select **BVI-B** and click **Add**.

e) Click **Save**.

Step 5 Revisit the BVI-B configuration:

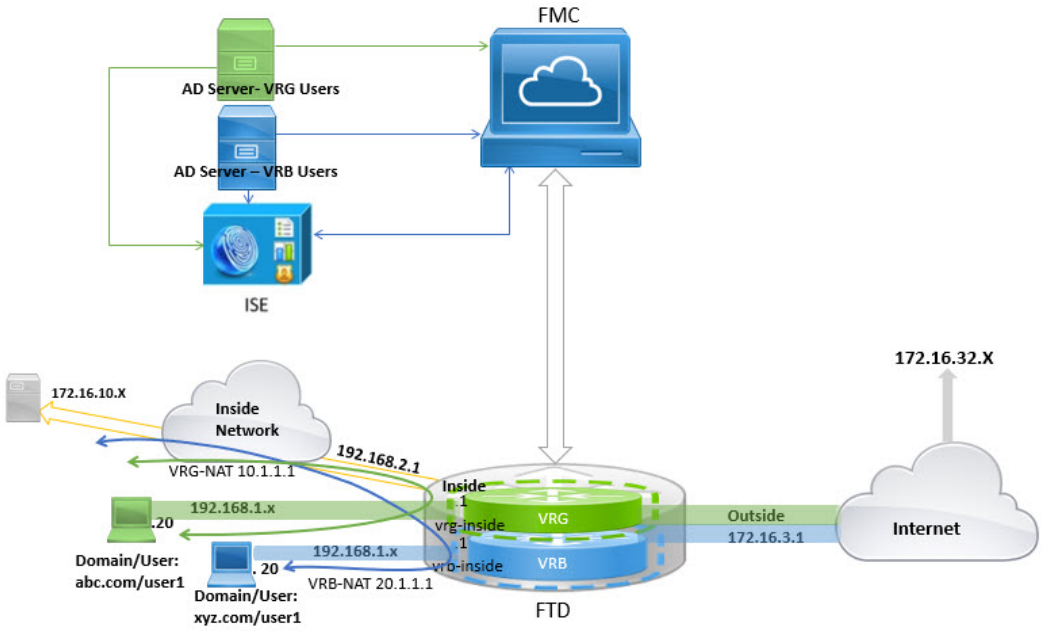
a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, edit the device and click **Interfaces**.

b) Click **Edit** against BVI-B interface. Specify the IP Address as 10.10.10.5/24. The system now allows you to configure with same IP address of BVI-G, because the interfaces are seperately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

If you want to enable inter-BVI communication, use an external router as default gateway. In overlapping BVI scenarios, as in this example, use twice NAT external router as gateway to establish inter-BVI traffic. When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself. When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify "any" as the interface.



You have successfully configured BVI interfaces per virtual router to manage overlapping segments in routed firewall mode. The virtual routers isolate the network on shared resources, allowing the use of same IP subnet addresses for both BVIs.

Configure user authentication with overlapping networks

This task enables you to configure user authentication in virtual routing environments where multiple virtual routers share overlapping IP addresses and user networks. The configuration allows users from different domains to access shared resources while maintaining proper access control.

In virtual routing, you can configure multiple virtual routers with overlapping IP and overlapping users. In the example, VRG, and VRB are the virtual routers with overlapping IP - 192.168.1.1/24. The users on two different domains are also on overlapping network IP 192.168.1.20. For VRG and VRB users to access the shared server 172.16.10.X, leak routes to the global virtual router. Use source NAT to handle the overlapping IP. For controlling the access from VRG and VRB users, you must set user authentication in Cloud-Delivered Firewall Management Center. Cloud-Delivered Firewall Management Center uses realms, Active Directories, Identity source, and Identity rules and policies for authenticating user identity. Because Firewall Threat Defense

does not have direct role in authenticating users, user access is managed only through the access control policy. For controlling traffic from the overlapping users, use Identity policy and rules to create access control policy.

Before you begin

This example assumes that you have:

- Two AD servers for the VRG and VRB users.
- ISE with the two AD servers added.

Follow these steps to configure user authentication with overlapping networks:

Procedure

Step 1 Configure the inside interface of the device for VRG:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, click the device name, and then click **Interfaces**.

b) Edit the interfaces that you want to assign to VRG:

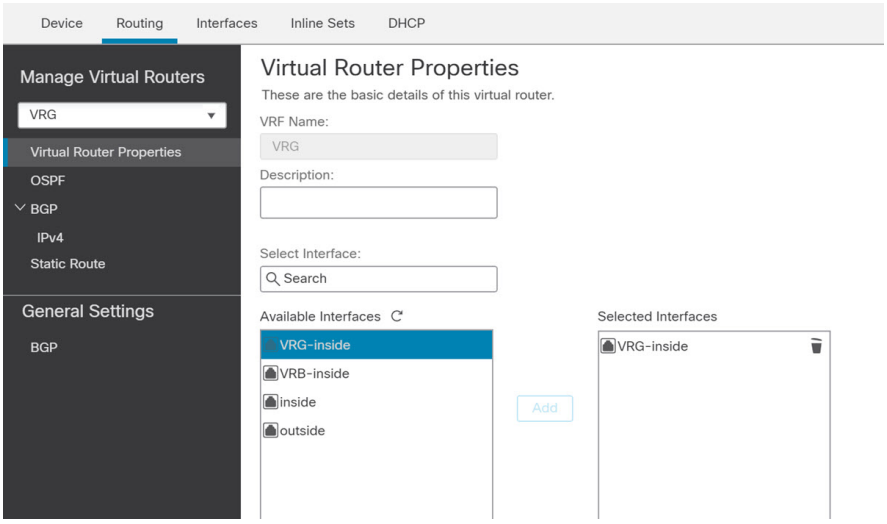
- **Name**—For this example, VRG-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 192.168.1.1/24.

c) Click **Ok**.

d) Click **Save**.

Step 2 Configure the inside interface of the device for VRB:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** > **Interfaces**.



b) Edit the interfaces that you want to assign to VRB:

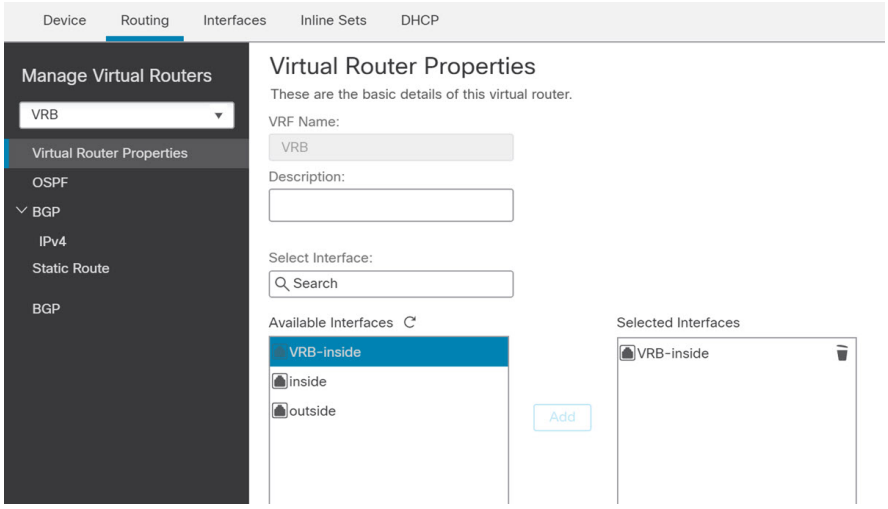
- **Name**—For this example, VRB-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system doesn't allow you to configure interfaces with same IP address, as you're yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Configure VRG and the static default route leak to the inside interface of the Global router for the VRG users to access the common server 172.16.10.1:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRG.
c) For VRG, in **Virtual Router Properties**, assign VRG-inside and save.

d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:



- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VRB and the static default route leak to the inside interface of the Global router for the VRB users to access the shared server 172.16.10.x:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRB.

c) For VRB, in **Virtual Router Properties**, assign VRB-inside and save.

d) Click **Static Route**.

e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.

g) Click **Save**.

Step 5 Revisit the VRB-inside interface configuration:

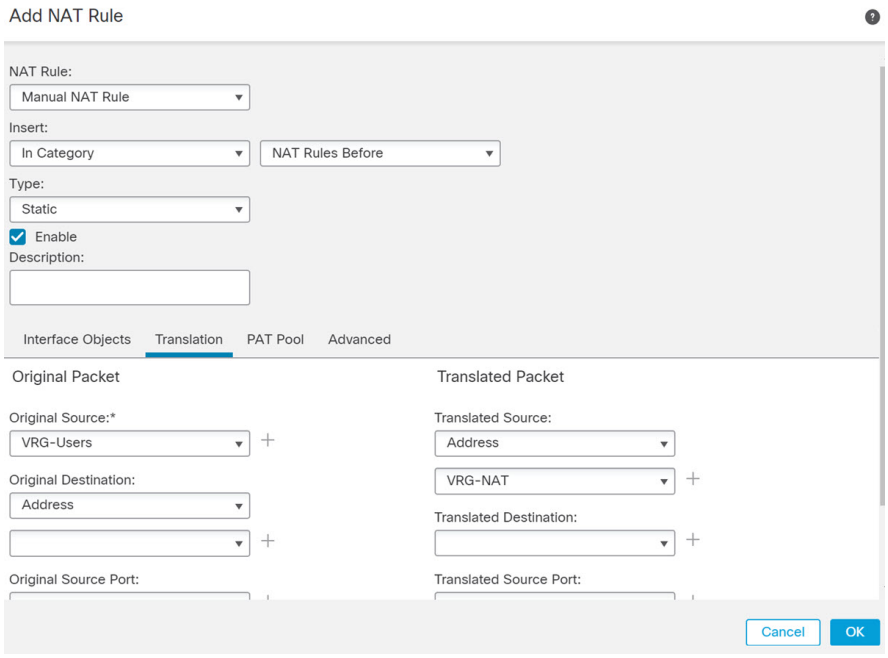
a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, click the device name, and then click **Interfaces**.

b) Click **Edit** against VRB-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with the same IP address as that of VRG-inside, because the interfaces are seperately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

Step 6 Add NAT rules for the source objects VRG and VRB. Click **Devices** > **NAT**.

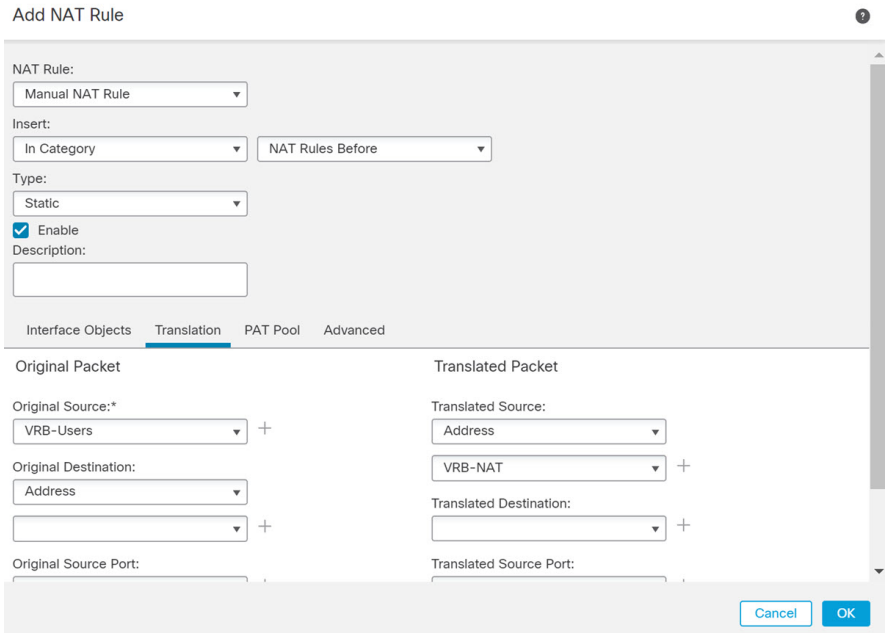


Step 7 Click **New Policy** > **Threat Defense NAT**.

Step 8 Enter a NAT policy name, and select the Firewall Threat Defense device. Click **Save**.

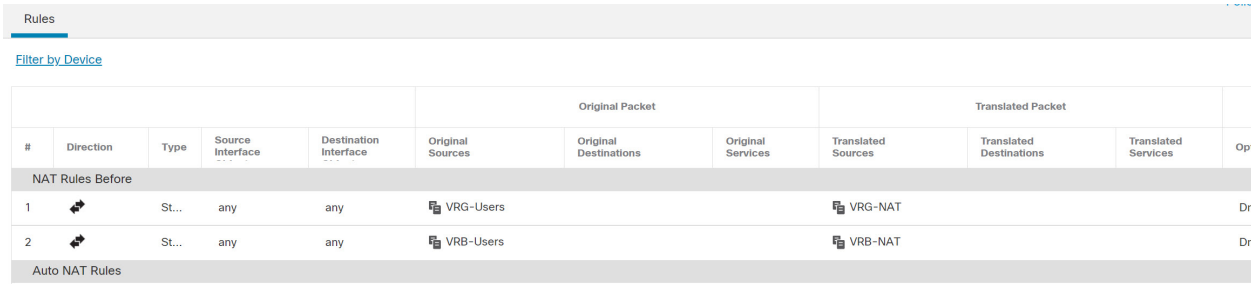
Step 9 In the NAT page, click **Add Rule** and define the following source NAT for VRG:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.



- In **Interface Objects**, select VRG-Inside object and click **Add to Source** (If the object is not available, create one in **Objects** > **Object Management** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRG-Users.
  - **Translated Source**, click **Add** and define object, VRG-NAT with 10.1.1.1. Select VRG-NAT as shown in the figure:

Step 10 Click **Ok**.



Step 11 In the NAT page, click **Add Rule** and define the following source NAT for VRB:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRB-Inside object and click **Add to Source** (If the object is not available, create one in **Objects** > **Object Management** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRB-Users.
  - **Translated Source**, click **Add** and define object, VRB-NAT with 20.1.1.1. Select VRB-NAT as shown in the figure:

Step 12 Click **Save**.

The NAT rule looks like this:

Step 13 Add the two unique AD servers in Cloud-Delivered Firewall Management Center one for each VRG and VRB users—choose **System** > **Integration** > **Realms**.

Step 14 Click **New Realm** and complete the fields. For detailed information on the fields, see Realm fields, on page 2281.

Step 15 For controlling the access from VRG and VRB users, define 2 Active Directories, see Realm directory and synchronize fields, on page 2285see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325

Step 16 Add ISE in Cloud-Delivered Firewall Management Center—choose **System** > **Integration** > **Identity Sources**.

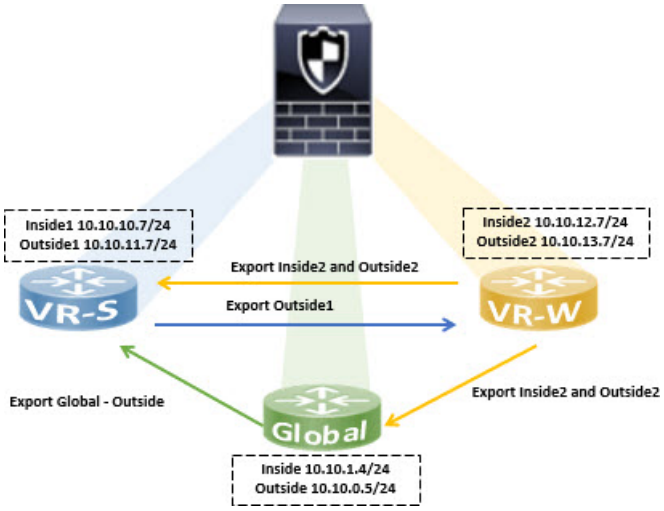
Step 17 Click **Identity Services Engine** and complete the fields. For detailed information on the fields, see Configure ISE/ISE-PIC for user control using a realm, on page 2380.

Step 18 Create Identity policy, rules, and then define access control policy for controlling access of overlapping users from VRG and VRB.

You have successfully configured user authentication for virtual routers with overlapping networks. VRG and VRB users can now access the shared server through proper NAT translation and authentication controls, with distinct identity policies managing access for each user group.

Interconnect virtual routers using BGP

This task enables you to configure BGP settings to leak routes among virtual routers (Global and user-defined virtual routers) by using route targets and route maps to share routes between different virtual routing instances.



You can now configure BGP settings on a device to leak the routes among virtual routers (Global and user-defined virtual routers). The route target of the source virtual router is exported to the BGP table, which, in turn is imported to the destination virtual router. The route map is used to share the Global virtual routes with the user-defined virtual routers and vice versa. Note that all import or export of the routes to the BGP table is configured at the user-defined virtual router, including the Global virtual routes.

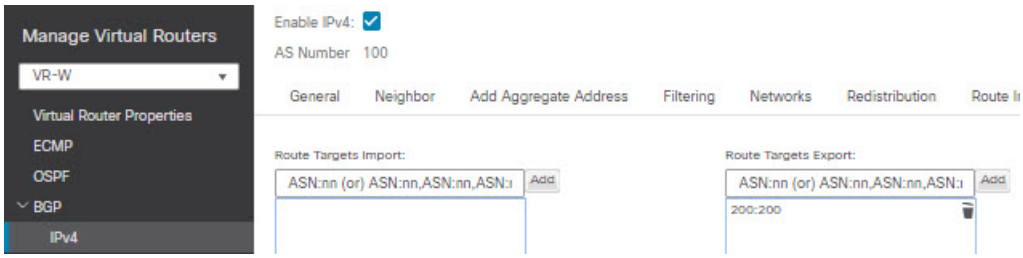
Consider the firewall device of a factory is configured with virtual routers and interfaces:

- Global virtual router is configured with Inside (10.10.1.4/24) and Outside (10.10.0.5/24)
- VR-S (Sales) virtual router is configured with Inside1 (10.10.10.7/24) and Outside1 (10.10.11.7/24)
- VR-W (Warehouse) virtual router is configured with Inside2 (10.10.12.7/24) and Outside2 (10.10.13.7/24)

Assume that you want the routes of warehouse (VR-W) to be leaked with sales (VR-S) and Global, and the outside interface routes of VR-S to VR-W. Similarly, you want the outside interface routes of the Global router to be leaked to sales (VR-S). This example demonstrates the BGP configuration procedure to achieve interconnecting the routers:

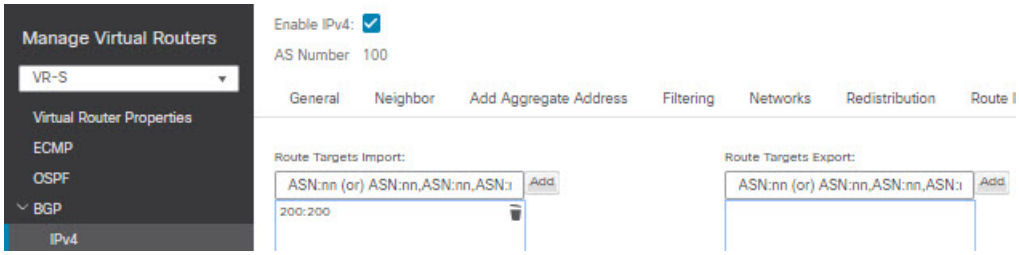
Figure 328: Interconnect virtual routers using BGP settings

Before you begin



- Create the virtual routers—VR-S and VR-W.
- Enable BGP and for each virtual router Configure BGP for redistribution of connected routes.

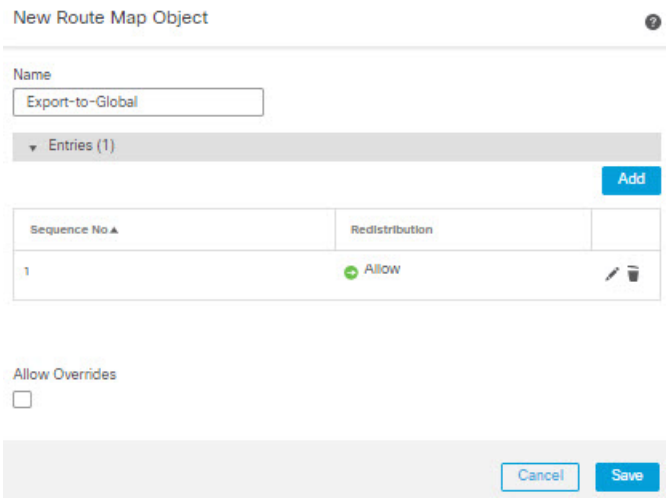
Follow these steps to interconnect virtual routers using BGP:



Procedure

Step 1 Configure VR-W to export its routes tagging them with a route target to VR-S:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, edit device, and then click the **Routing** tab.
b) From the virtual router drop-down, select VR-W. Then click **BGP** > **IPv4** > **Route Import/Export**.
c) To leak the VR-W routes to VR-S, tag the routes with a route target, so that the VR-W routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *200:200*. Click **Add**:

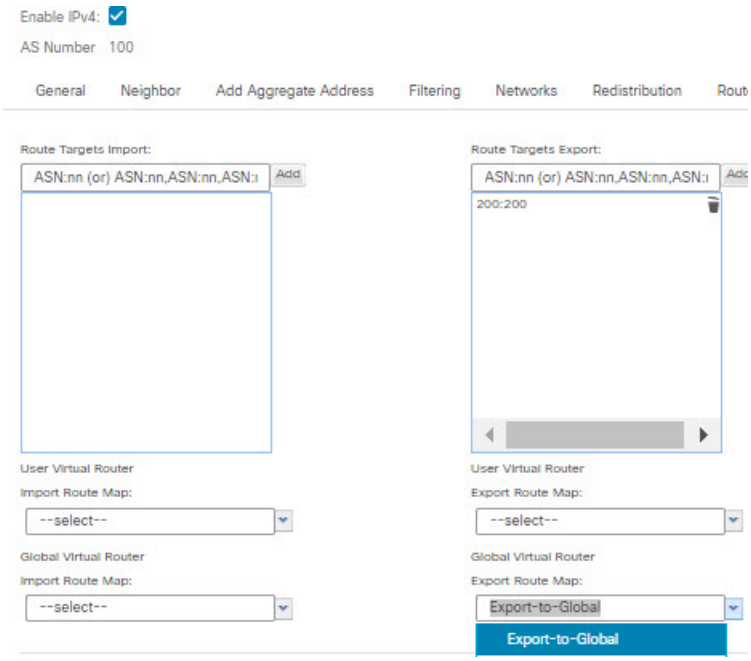


d) From the virtual router drop-down, select VR-S. Then click **BGP** > **IPv4** > **Route Import/Export**.
e) To receive the leaked routes from VR-W, configure the Import Route Target to import the VR-W routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the same route target value that you had configured for VR-W, *200:200*. Click **Add**.

Note
If you want to conditionalize routes to be leaked from VR-W, you can specify the match criteria in the route map object, and choose it in the **User Virtual Router Export Route Map**. Similarly, if you want to conditionalize the routes to be imported to VR-S from the BGP table, you can use the **User Virtual Router Import Route Map**. This procedure is explained in Step 3.

Step 2 Configure VR-W to export its routes to the Global virtual router:

a) You need to create a route map that would allow the VR-W routes to be exported to the Global routing table. In the Cloud-Delivered Firewall Management Center, choose **Objects** > **Object Management** > **Route Map**.
b) Click **Add Route Map**, give a name, say *Export-to-Global*, and then click **Add**.
c) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list:



d) Click **Save**.

In this example, all the VR-W routes are leaked to the Global routing table. Hence, no match criteria is configured for the route map.

e) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**.

f) From the **Global Virtual Router Export Route Map** drop-down list, choose Export-to-Global:

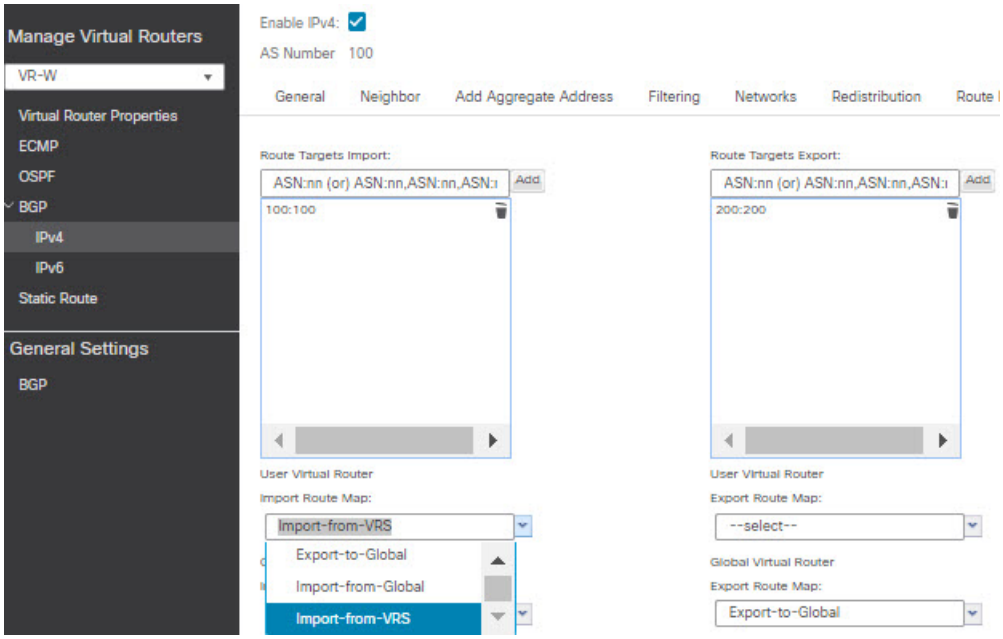
Step 3 To leak only the Outside1 routes of VR-S to VR-W:

a) From the virtual router drop-down, select VR-S and then click **BGP** > **IPv4** > **Route Import/Export**.

b) To leak the VR-S routes to VR-W, tag the routes with a route target, so that the VR-S routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *100:100*. Click **Add**.

c) From the virtual router drop-down, select VR-W, and choose **BGP** > **IPv4** > **Route Import/Export**. To receive the leaked routes from VR-S, configure the Import Route Target to import the VR-S routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the VR-S route target value, *100:100*. Click **Add**.

d) Now, you need to conditionalize that only the Outside1 routes of VR-S to be leaked to VR-W. Choose **Objects** > **Object Management** > **Prefix Lists** > **IPv4 Prefix List**. Click **Add IPv4 Prefix List**, give a name, say *VRS-Outside1-Only*, and then click **Add**.



e) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list. Enter the IP Address (first two octets) of the VR-S Outside1 interface and then click **Save**.

f) Create a route map with the match clause with the prefix list. Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-VRS*, and then click **Add**.

g) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

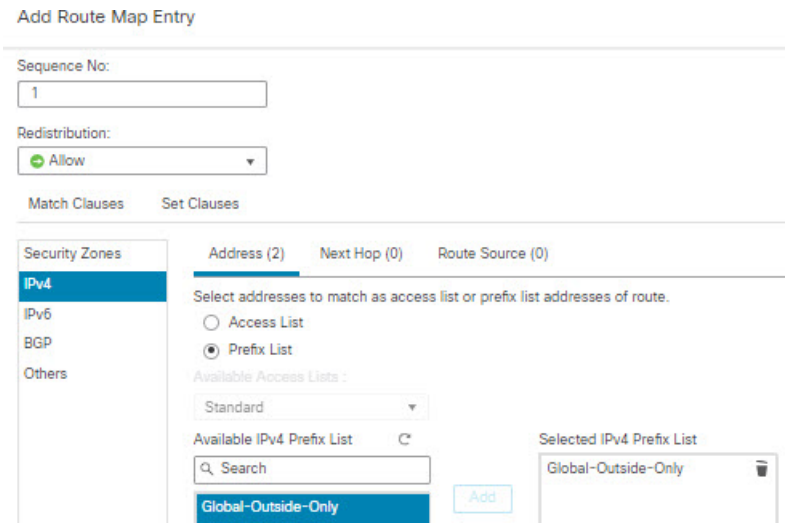
h) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**. Under **Available IPv4 Prefix List**, select VRS-Outside1-Only, and then click **Add**.

i) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**. From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-VRS:

Step 4 Configure VR-S to import the Outside routes of Global virtual router:

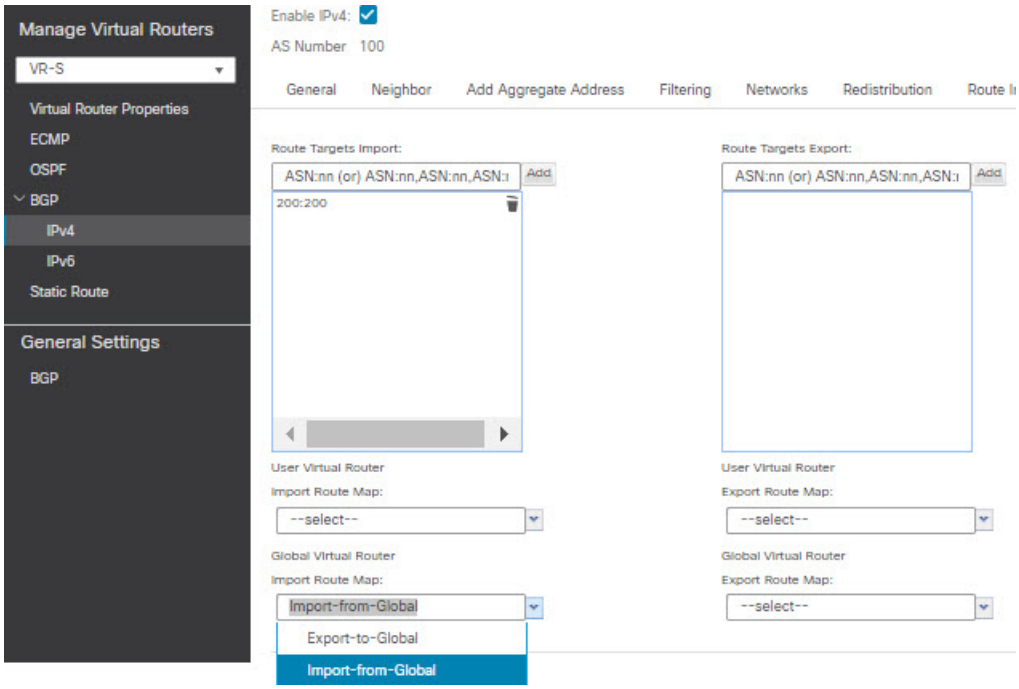
Note
To leak routes to or from a Global virtual router, you must configure the source or destination user defined virtual router respectively. Thus, in this example, VR-S is the destination router that imports the routes from Outside interface of the Global virtual router.

a) In the Cloud-Delivered Firewall Management Center, choose **Objects** > **Object Management** > **Prefix Lists** > **IPv4 Prefix List**.



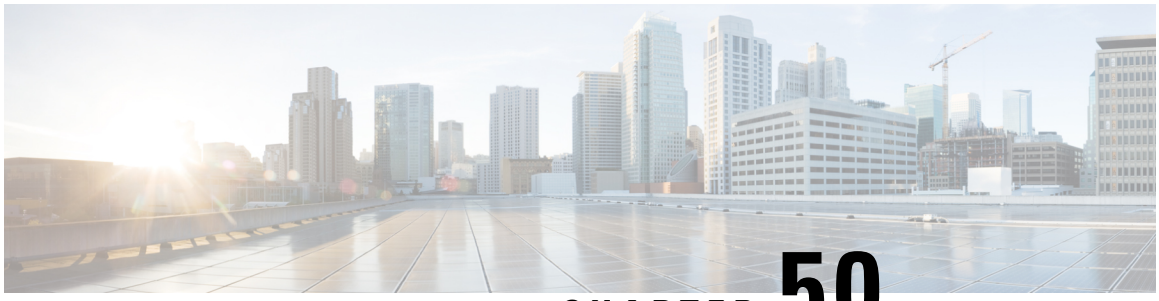
b) Click **Add IPv4 Prefix List**, give a name, say *Global-Outside-Only*, and then click **Add**. Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

c) Enter the IP Address (first two octets) of the Global Outside interface:



Then click **Save**.

d) Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-Global*, and then click **Add**.
e) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
f) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.
g) Under **Available IPv4 Prefix List**, select Global-Outside-Only, and then click **Add**:



Then click **Save**.

h) Navigate to the **Routing** tab of the device, and select VR-S. Click **BGP** > **IPv4** > **Route Import/Export**.
i) From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-Global:

Step 5 **Save** and **Deploy**.

The BGP configuration is complete and routes are now leaked among the virtual routers according to the configured route targets and route maps. VR-W routes are exported to VR-S and Global, VR-S Outside1 routes are exported to VR-W, and Global Outside routes are imported to VR-S.

CHAPTER 50

ECMP

Equal Cost Multi-Path (ECMP) is a routing strategy that allows a router to forward packets along multiple paths of equal cost to a destination.

- Enables load balancing across multiple network paths.
- Utilizes routing protocols to determine path cost.
- Increases total available bandwidth for traffic flows.

- ECMP routing methods, on page 1431
- Guidelines and limitations for ECMP, on page 1432
- Manage ECMP zones for virtual routers, on page 1433
- Create an ECMP zone, on page 1433
- Configure an equal cost static route, on page 1434
- Modify an ECMP zone, on page 1435
- Remove an ECMP zone, on page 1436
- Configure ECMP zones on your device, on page 1436

ECMP routing methods

ECMP is a routing method that

- enables traffic distribution across multiple equal-cost paths,
- supports up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone, and
- uses traffic zones per virtual router to contain a group of interfaces.

Multiple default routes configuration

This example shows multiple default routes configured across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2

route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2

route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Guidelines and limitations for ECMP

Follow these principles for effective ECMP zone configuration:

Firewall mode limitations

Use ECMP zones only in routed firewall mode.

Interface restrictions

Do not use dVTI or Loopback interfaces with ECMP zones.

ECMP zone configuration limits

Follow these limits when configuring ECMP zones:

- Devices can have a maximum of 256 ECMP zones.
- You can associate only 8 interfaces per ECMP zone.
- An interface can be a member of only one ECMP zone.

Interface management limitations

Do not remove interfaces or delete zones actively used for routing:

- You cannot remove an interface that is associated with an equal cost static route from the ECMP zone.
- You cannot delete an ECMP zone if its interface has equal cost static routes associated with it.

Supported interface types

Use only routed interfaces for ECMP zones. Do not associate these interface types with an ECMP zone:

- BVI interface.
- Member interfaces in an EtherChannel.
- Failover or state link interface.
- Management-only or management-access interfaces.
- Cluster control link interface.
- VNIs.
- VLAN interfaces.
- Interfaces in a remote access VPN configuration with SSL enabled.

Feature compatibility limitations

Consider these feature limitations when using ECMP zones:

- DHCP Relay is not supported on interfaces in an ECMP zone.
- Dual ISP/WAN Firewall Threat Defense Deployment—Create a single ECMP zone for the primary and secondary data interfaces, enabling static routes with identical metric values.

- The Firewall Threat Defense does not support ECMP with NAT in IPsec sessions—a standard IPsec virtual private network (VPN) tunnel does not work with NAT points in the delivery path of IPsec packets.

Manage ECMP zones for virtual routers

The ECMP page lets you manage existing ECMP zones linked with virtual routers. When you click **ECMP** on the **Routing** pane, the ECMP page displays the current ECMP zones, including the associated interfaces, for the selected virtual router. On this page, you can add new ECMP zones to the virtual router. You can also **Edit** ( ) and **Delete** ( ) ECMP zones.

You can perform these actions:

- Create an ECMP zone, on page 1433
- Configure an equal cost static route, on page 1434
- Modify an ECMP zone, on page 1435
- Remove an ECMP zone, on page 1436

Create an ECMP zone

Create an ECMP zone to enable load balancing across multiple equal-cost paths in a virtual router configuration.

ECMP zones are created per virtual router. Only interfaces that belong to the virtual router where the ECMP is being created can be associated with the ECMP zone.

Procedure

Step 1 Navigate to **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 From the virtual router drop-down, select the virtual router in which you want to create the ECMP zone.

You can create ECMP zones in the global virtual router and user-defined virtual routers. For information on creating virtual routers, refer to Create a virtual router, on page 1386.

Step 4 Click **ECMP**.

Step 5 Click **Add**.

Step 6 In the **Add ECMP** box, enter a name for the ECMP zone.

Note
The ECMP name must be unique on the routed device.

Step 7 Under the **Available Interfaces** box, select the interface and click **Add**.

- Only interfaces belonging to the virtual router where you are creating the ECMP can be associated with it. Interfaces must have a logical name to be displayed; edit the interface and save to set a logical name.

- From Version 10.0, ECMP is supported on dynamic VTIs (DVTIs) of hub devices in SD-WAN VPN topologies. When enabled on a DVTI, it is automatically added to a system-generated ECMP zone, so DVTIs do not appear under **Available Interfaces**.

Step 8 Click **OK**.

The ECMP page displays your newly created ECMP zone.

Step 9 Click **Save** and **Deploy** the configuration.

You can associate the ECMP zone interfaces with equal cost static route by defining them with same destination and metric value but with a different gateway.

What to do next

- Configure an equal cost static route, on page 1434
- Modify an ECMP zone, on page 1435
- Remove an ECMP zone, on page 1436

Configure an equal cost static route

Configure equal cost static routes to enable load balancing across multiple interfaces with the same destination and metric value within an ECMP zone.

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	N/A	Firewall Threat Defense and Firewall Threat Defense Virtual	Any	Admin/Network Admin/Security Approver

You can assign interfaces of a virtual router, both global and user-defined, to an ECMP zone for the device.

Before you begin

- To configure an equal cost static route for an interface, ensure that it is associated with an ECMP zone. For more information, refer to Create an ECMP zone, on page 1433.
- All routing configuration settings of a non-VRF-capable device are also available for a global virtual router.
- You cannot define a static route for interfaces with the same destination and metric without associating the interfaces with an ECMP zone.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the Firewall Threat Defense device. Click the **Routing** tab.

Step 2 From the drop-down list, select the virtual router whose interfaces are associated with an ECMP zone.

Step 3 To configure the equal cost static route for the interfaces, click **Static Route**.

Step 4 Either click **Add Route** to add a new route, or click **Edit** (✎) for an existing route.

Step 5 From the **Interface** drop-down, select the interface that belongs to the virtual router and is associated with an ECMP zone.

Step 6 Select the destination network from the **Available Networks** box and click **Add**.

Step 7 Enter a gateway for the network.

Step 8 Enter a metric value. It can be a number that ranges between 1 and 254.

Step 9 To save the settings, click **Save**.

To configure equal cost static routing, repeat these steps to configure the static route for another interface in the same ECMP zone with the same destination network and metric value. Remember to provide a different gateway.

The equal cost static routes are configured for the interfaces associated with the ECMP zone, enabling load balancing across multiple paths.

What to do next

- Modify an ECMP zone, on page 1435
- Remove an ECMP zone, on page 1436

Modify an ECMP zone

Use this procedure when you need to make changes to an existing ECMP zone configuration on your device.

Follow these steps to modify an ECMP zone:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **ECMP**.

ECMP zones with their associated interfaces appear.

Step 4 To modify an ECMP zone, click **Edit** (✎) next to the desired ECMP zone. In the **Edit ECMP** dialog box, you can make changes to the ECMP name or associated interfaces.

- ECMP Name: Ensure that the ECMP name you enter is unique.
- Interfaces: Add or remove one or more interfaces as needed.

Note
An interface must not belong to more than one ECMP zone, and it should not be linked to an equal-cost static route.

Step 5 Click **OK**.

Step 6 Click **Save**.

The ECMP zone shows your updated settings.

What to do next

- Configure an equal cost static route, on page 1434
- Remove an ECMP zone, on page 1436

Remove an ECMP zone

ECMP zones group interfaces for equal-cost multipath routing. You may need to remove an ECMP zone when reconfiguring your network topology or when the zone is no longer required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **ECMP**.

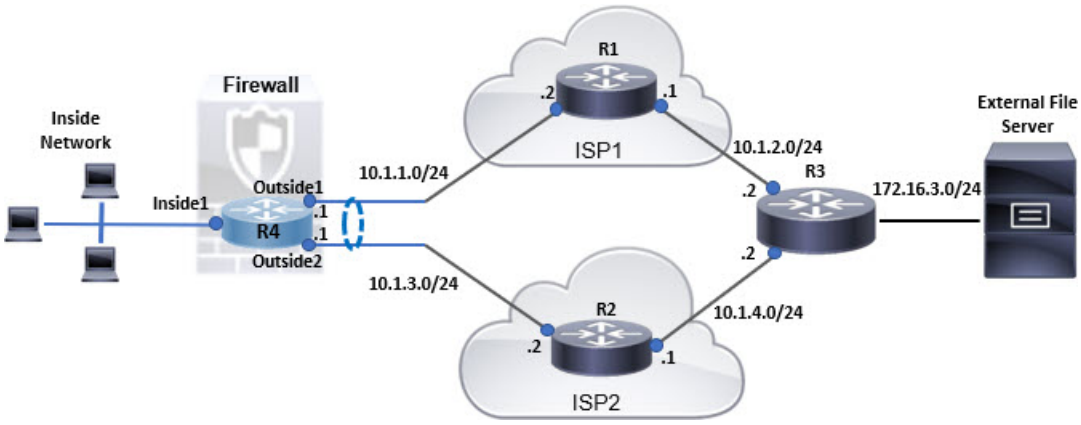
The ECMP zones with associated interfaces appear.

Step 4 To remove an ECMP zone, click **Delete** ( ) next to the ECMP zone.

Note
You cannot delete the ECMP zone if it has interfaces associated with equal-cost static routes.

Step 5 Click **Delete** in the confirmation message.

Step 6 Click **Save** to apply changes.



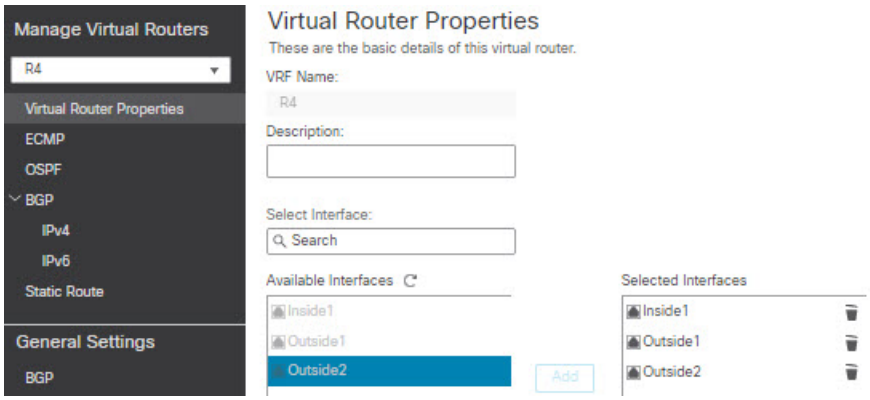
The ECMP zone is removed from the device configuration and is no longer available for routing operations.

Configure ECMP zones on your device

Configure Equal-Cost MultiPath (ECMP) to enable efficient traffic handling through the device with support for asymmetric routing, load balancing, and traffic rerouting when a path becomes unavailable.

This example demonstrates how to use Cloud-Delivered Firewall Management Center to configure ECMP zones on Firewall Threat Defense such that the traffic flowing through the device is handled efficiently. With ECMP configured, Firewall Threat Defense maintains the routing table on a per-zone basis, enabling efficient packet re-routing. Thus, ECMP supports asymmetric routing, load balancing, and traffic rerouting when a path becomes unavailable. In this example, R4 records the two paths to reach the external file server.

Figure 329: Configuration example for ECMP



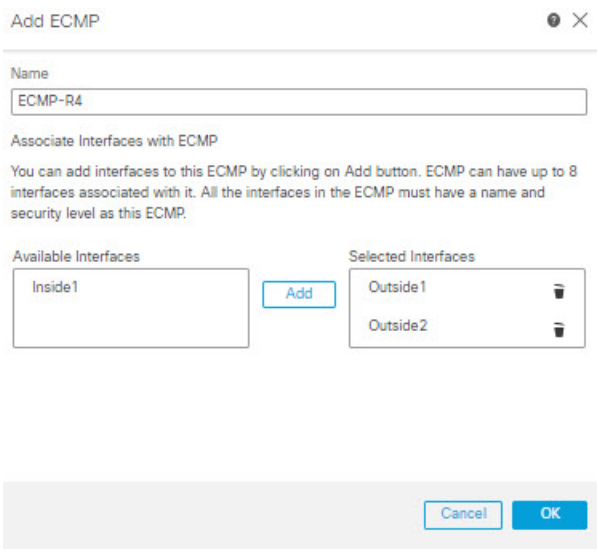
Follow these steps to configure ECMP on your device:

Procedure

Step 1 Create a virtual router.

Set up a new router on *R4* with interfaces: *Inside1*, *Outside1*, and *Outside2*. For more information, refer to Create virtual router.

Figure 330: Configuring R4 virtual router



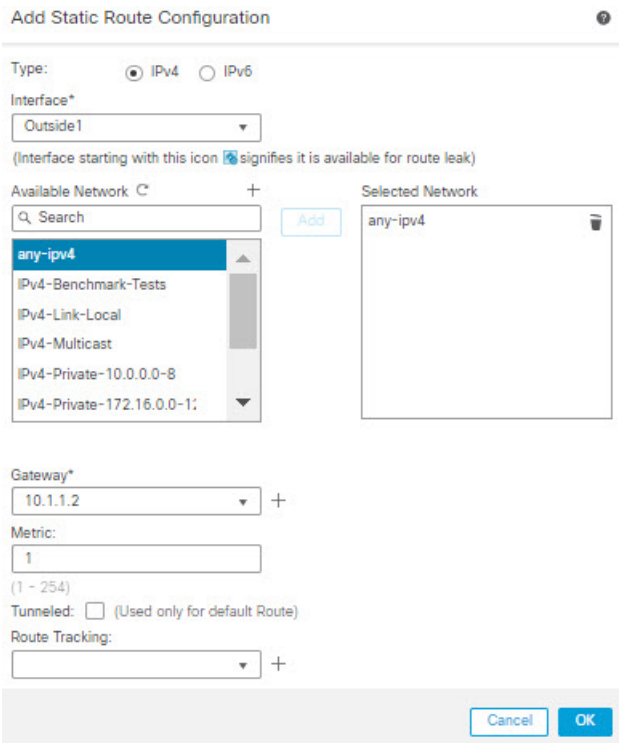
Step 2 Create ECMP zones:

a) In the **Routing** tab, choose R4 user-defined virtual router, and then click **ECMP**.

b) Click **Add**.

c) Enter an ECMP name and from the **Available Interfaces** list, choose *Outside1* and *Outside2*:

Figure 331: Creating ECMP zone



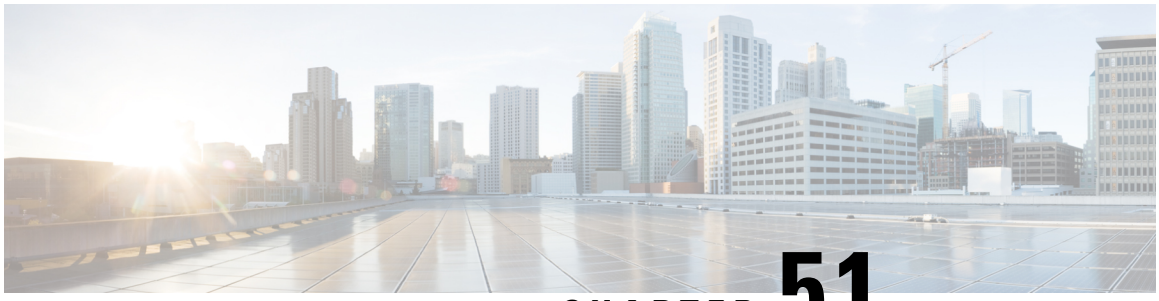
d) Click **OK**.
e) Click **Save**.

Step 3 Create static routes for the zone interfaces:

a) In the **Routing** tab, click **Static Route**.
b) From the **Interface** drop-down list, select Outside1.
c) Under **Available Network**, choose any-ipv4 and click **Add**.
d) Specify the next-hop address in the **Gateway** field, 10.1.1.2.

Figure 332: Configuring static route for Outside1

e) Configure the static route for Outside2 by repeating Step 3b through Step 3d.



Ensure that you specify the same metric but different gateways for the static routes:

Figure 333: Configured static routes of ECMP zone interfaces

Step 4 Save and deploy the changes to apply ECMP routing to your device.

Network packets will now utilize efficient routes to reach their destination R3, either through R4>R1>R3 or R4>R2>R3, according to the ECMP algorithm configuration. If the R1>R3 route becomes unavailable, traffic can be rerouted through R2, which helps reduce disruption during path failure. Additionally, return traffic from R3 can arrive on *Outside2* even if the original packet was sent through *Outside1*. When network traffic is heavy, R4 distributes the network load between two specified routes to maintain balanced traffic.

CHAPTER 51

Bidirectional Forwarding Detection Routing

This chapter describes how to configure Firewall Threat Defense to use the Bidirectional Forwarding Detection (BFD) routing protocol.

- BFD routing protocol, on page 1441
- Guidelines for BFD routing, on page 1442
- Configure BFD, on page 1443
- History for BFD routing, on page 1446

BFD routing protocol

A BFD routing protocol is a detection protocol that

- provides fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols
- operates in a unicast, point-to-point mode on top of any data protocol being forwarded between two systems, and
- carries packets in the payload of the encapsulating protocol appropriate for the media and the network.

Why BFD?

BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection.

Network administrators can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms. This makes network profiling and planning easier, and reconvergence time is consistent and predictable.

Note In Firewall Threat Defense, BFD is supported on BGP protocols only.

Guidelines for BFD routing

Context mode guidelines

BFD is supported on all Firewall Threat Defense platforms and is available in multi-instance mode.

Firewall mode guidelines

BFD is supported in routed firewall mode and not in transparent mode.

Failover and cluster guidelines

- BFD is not supported on failover interfaces.
- In clustering, BFD is supported only on the control node.

Routing and protocol guidelines

- OSPFv2, OSPFv3, BGP IPv4, and BGP IPv6 protocol are supported.

  IS-IS and EIGRP protocols are not supported.
- BFD for static routes is not supported. You can configure BFD on interfaces that belong only to virtual routers.
- Only named interfaces are supported.
- BFD on BVI, VTI, and loopback interfaces are not supported.

Single-hop guidelines

- Echo mode is disabled by default. You can enable echo mode on single-hop only.
- Echo mode is not supported for IPv6.
- Use only a single-hop template to configure a single-hop policy.
- Authentication of the single-hop template is optional.
- You cannot configure multiple BFDs on the same interface.

Multi-hop guidelines

- Do not configure the source IP address also as the destination IP address.
- Source and destination address should have same IP type—IPV4 or IPV6.
- Only network objects of host or network type are allowed.
- Use only a multi-hop template to configure a multi-hop policy.
- Authentication is mandatory for the multi-hop template.

Upgrade guidelines

When you upgrade to version 7.3 and the previous version has any FlexConfig BFD policies, the management center displays a warning message during deployment. However, it does not stop the deployment process. After post-upgrade deployment, to manage the BFD policies from the UI (**Device (Edit)** > **Routing** > **BFD**), you must configure BFD policies in the **Device (Edit)** > **Routing** > **BFD** page and remove the configuration from the FlexConfig policy for the device.

Configure BFD

This task enables and configures the Bidirectional Forwarding Detection (BFD) routing policy on your system to provide rapid detection of faults in the forwarding path.

Before you begin

Ensure you have access to the system where you want to configure BFD.

Follow these steps to configure BFD:

Procedure

Step 1 Create Configure a BFD template, on page 2956.

Step 2 Configure BFD policies, on page 1443.

Step 3 Configure BFD support in the BGP neighbor settings; see, Configure BGP Neighbor Settings.

BFD is enabled and configured on your system.

Configure BFD policies

BFD policies are used to provide rapid failure detection for interfaces associated with virtual routers. Configuring BFD templates allows you to monitor connectivity and quickly identify link failures.

- Enable fast failure detection for routing interfaces.
- Support both single-hop and multi-hop BFD configurations.

You can bind a BFD template to an interface belonging to a virtual router, or to a source and destination address pair.

Before you begin

- BFD policy is configurable only on interfaces that belong to virtual routers. See Configure interfaces to a virtual router.

To configure BFD policies, complete these steps.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, from the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.

Step 2 From the drop-down list, select the desired virtual router, and then click **BFD**.

Step 3 To configure a BFD on the interface, click the **Single-Hop** tab or **Multi-Hop** tab.

Note
For a single-hop policy, the BFD template is configured on an interface; for a multi-hop policy, the BFD template is configured on a source and destination address pair.

Step 4 Click **Add**. To modify the configured BFD policy, click **Edit** ( ).

Note
When you edit the interface mapping with BFD template to replace it with a new BFD template, the Cloud-Delivered Firewall Management Center uses a **no** command to remove the template mapping from interface and applies the new template to the interface which causes a BFD flap which may also lead to an OSPFv2, OSPFv3, or BGP flap. However, if the BFD intervals are higher, the BFD flap might not occur. Alternatively, to avoid the flapping, you can delete the existing BFD template mapping; deploy the interface, and then add the new BFD template to the interface and deploy the configuration.

- See Configure a single-hop BFD policy, on page 1444.
- See Configure a multi-hop BFD policy, on page 1445.

After completing this task, BFD policies are configured on the selected interfaces or address pairs.

Configure a single-hop BFD policy

You can configure a single-hop BFD policy only on an interface that belongs to a virtual router. This task is relevant when you need to apply BFD for rapid link failure detection on specific interfaces.

Before you begin

- Create single-hop BFD templates. You cannot configure single-hop BFD policy on interfaces that use a multi-hop template.

Follow these steps to configure a single-hop BFD policy:

Procedure

Step 1 In the **Single-Hop** tab, click **Add** or **Edit**.

Step 2 In the **Add BFD Single-Hop** dialog box, configure the following:

a) The **Interface** drop-down list displays interfaces belonging to virtual routers. Select the interface you want to configure with the BFD policy.

b) The **Template Name** drop-down list displays single-hop templates. Select the template that you want to apply.

If you have not created a single-hop template, use **Add** (+) and create a single-hop BFD template.

Step 3 Click **OK** and **Save** the configuration.

The single-hop BFD policy is applied to the selected interface. The interface will now use the specified BFD template for single-hop operations.

Configure a multi-hop BFD policy

Configure a multi-hop BFD policy to enable monitoring of connectivity between specific source and destination address pairs. This configuration helps to monitor links that traverse multiple hops in your network.

Before you begin

- Create multi-hop BFD templates. You cannot configure multi-hop BFD policy using a single-hop template.

Follow these steps to configure a multi-hop BFD policy:

Procedure

Step 1 In the **Add BFD Multi-Hop** dialog box, configure the following:

a) Click the BFD source address type:**IPv4** or **IPv6** radio button.

b) The **Source Address** drop-down list displays the network objects. Select the source address for the BFD policy; do not choose *any-ipv4* or *any-ipv6*.

If you have not created the required network object, use **Add** (+) and create a host/network object.

Note
The created network object's IP type should match with the selected source IP type.

c) The **Destination Address** drop-down list displays network objects. Select the destination address for the BFD; do not choose *any-ipv4* or *any-ipv6*.

If you have not created the required network object, use **Add** (+) and create a host/network object.

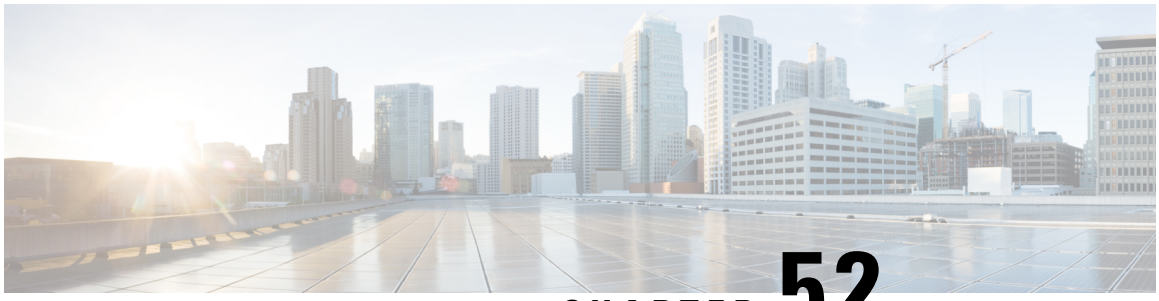
Note
The created network object's IP type should match with the selected source IP type.

Attention
Do not select the network object that has the same IP address as that of the source address.

d) The **Template Name** drop-down list displays multi-hop templates. Select the template to apply to the BFD policy.

If you have not created a multi-hop template, use **Add** (+) and create a multi-hop BFD template.

Step 2 Click **OK** and **Save** the configuration.



The multi-hop map (table view) is displayed on the **Multi-Hop** tab page.

History for BFD routing

The History table summarizes the introduction and evolution of the BFD routing in Cisco Cloud-Delivered Firewall Management Center across releases, enabling quick tracking of feature availability and changes.

Table 93: Feature history for BFD routing

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
BFD support for OSPF	7.4	7.4	You can enable BFD on interfaces that use OSPF version 2 and OSPF version 3. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**
BFD configuration	7.4	7.4	In the previous releases, BFD was configurable on threat defense only through FlexConfig. FlexConfig no longer supports BFD configuration. You can now configure BFD policies for threat defense in the management center UI. In threat defense, BFD is supported only on the BGP protocol. New/modified screens: **Devices** > **Device Management** > **Routing** > **BFD**.

CHAPTER 52

OSPF

This chapter describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

- OSPF, on page 1447
- Requirements and prerequisites for OSPF, on page 1451
- Guidelines for OSPF, on page 1451
- OSPFv2 configuration, on page 1454
- OSPFv3 configuration, on page 1467
- History for OSPF, on page 1477

OSPF

This chapter describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

OSPF routing

OSPF is an interior gateway routing protocol that

- uses link states rather than distance vectors for path selection,
- propagates link-state advertisements rather than routing table updates, and
- converges more quickly than RIP networks because only LSAs are exchanged instead of the entire routing tables.

OSPF characteristics and features

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include these characteristics:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, AS stale information is timed out.

- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The Firewall Threat Defense device calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The Firewall Threat Defense device can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The Firewall Threat Defense device supports these OSPF features:

- Intra-area, inter-area, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the Firewall Threat Defense device AS a designated router or a designated backup router. The Firewall Threat Defense device also can be set up AS an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports both MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such AS RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts AS a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting AS an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

Note Only Type 3 LSAs can be filtered. If you configure the Firewall Threat Defense device AS an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either AS default or Type 5 AS external LSAs. However, you need to configure

static routes for the private networks protected by the Firewall Threat Defense device. Also, you should not mix public and private networks on the same Firewall Threat Defense device interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the Firewall Threat Defense device at the same time.

OSPF support for fast hello packets

OSPF support for fast hello packets is a feature that

- provides a way to configure the sending of hello packets in intervals less than one second, and
- results in faster convergence in an Open Shortest Path First (OSPF) network.

OSPF fast hello packets configuration prerequisites

OSPF must be configured in the network already or configured at the same time as the OSPF Support for Fast Hello Packets feature.

OSPF hello interval and dead interval

OSPF hello interval and dead interval are configurable time parameters that

- maintain connectivity between OSPF neighbors through regular hello packet exchanges,
- detect neighbor failures when hello packets are not received within the specified timeframes, and
- must be consistent across all routers within the same network to ensure proper operation.

Hello interval and dead interval configuration details

OSPF hello packets are packets that an OSPF process sends to its OSPF neighbors to maintain connectivity with those neighbors. The hello packets are sent at a configurable interval (in seconds). The defaults are 10 seconds for an Ethernet link and 30 seconds for a non broadcast link.

Hello packets include a list of all neighbors for which a hello packet has been received within the dead interval. The dead interval is also a configurable interval (in seconds), and defaults to four times the value of the hello interval. The value of all hello intervals must be the same within a network. Likewise, the value of all dead intervals must be the same within a network.

These two intervals work together to maintain connectivity by indicating that the link is operational. If a router does not receive a hello packet from a neighbor within the dead interval, it will declare that neighbor to be down.

OSPF fast hello packets

OSPF fast hello packets are hello packets that

- are sent at intervals of less than 1 second,
- are achieved by using the OSPF dead-interval command with a dead interval set to 1 second, and
- use a hello-multiplier value set to the number of hello packets sent during that 1 second.

Fast hello packet behavior

When fast hello packets are configured on the interface, these behaviors occur:

- The hello interval advertised in the hello packets that are sent out this interface is set to 0.
- The hello interval in the hello packets received over this interface is ignored.

The dead interval must be consistent on a segment, whether it is set to 1 second (for fast hello packets) or set to any other value. The hello multiplier need not be the same for the entire segment as long as at least one hello packet is sent within the dead interval.

To understand fast hello packets, you should already understand the relationship between OSPF hello packets and the dead interval. See OSPF hello interval and dead interval, on page 1449.

Benefits of OSPF fast hello packets

A fast hello packet is an OSPF protocol feature that

- reduces network convergence time by enabling routers to detect changes in the network faster,
- allows rapid detection of lost neighbors within one second, and
- enhances reliability in LAN environments where neighbor loss may not be detected at the Open Systems Interconnection (OSI) physical or data-link layer.

The benefit of OSPF Fast Hello Packets is that your OSPF network can react swiftly to changes, minimizing downtime and improving overall network stability. This feature is particularly useful in scenarios where routers may not detect lost neighbors via traditional methods, allowing OSPF to maintain accurate routing tables.

If a router on a LAN segment is powered off or disconnected and the physical and data-link layers do not signal neighbor loss, OSPF fast hello packets will detect the neighbor's disappearance within one second.

OSPFv2 and OSPFv3 implementation differences

A protocol distinction is a protocol category that

- prevents backward compatibility between OSPFv2 and OSPFv3,
- requires both OSPF versions to run simultaneously for IPv4 and IPv6 routing, and
- allows OSPFv2 and OSPFv3 to coexist without interacting with each other.

OSPFv3 additional features

OSPFv3 provides additional features that include:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.

- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Requirements and prerequisites for OSPF

This reference provides the requirements and prerequisites that must be met before configuring OSPF on supported devices.

Network Admin

Guidelines for OSPF

Context mode guidelines

OSPFv2 supports single and multiple context mode.

- OSPFv2 instances cannot form adjacencies with each other across shared interfaces because, by default, inter-context exchange of multicast traffic is not supported across shared interfaces. However, you can use the static neighbor configuration under OSPFv2 process configuration under OSPFv2 process to bring up OSPFv2 neighbourship on a shared interface.
- Inter-context OSPFv2 on separate interfaces is supported.
- **(For point-to-point topology)** In a multiple context mode, you can configure static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. For a successful OSPF adjacency formation, when you remove and reconfigure OSPF on a shared interface, execute the commands in this order: Remove the OSPF configuration using **no router <OSPF name>**, and then remove the OSPF point-to-point non-broadcast configuration on the interface using **no OSPF network point-to-point non-broadcast**. When you reconfigure OSPF on the shared interface, configure the OSPF router using **router <OSPF name>**, and then configure the interface with **OSPF network point-to-point non-broadcast**.
- OSPFv3 supports single mode only.

Key chain authentication guidelines

OSPFv2 supports key chain authentication on both single and multiple mode, both in physical and virtual modes. However, in multiple mode, you can configure the key chain only in context mode.

- The rotating keys are applicable only for OSPFv2 protocol. OSPF area authentication with key chain is not supported.
- The existing MD5 authentication without time range in OSPFv2 is still supported along with new rotating keys.
- Though the platform supports SHA1 and MD5 cryptographic algorithms, only MD5 cryptographic algorithm is used for authentication.

Firewall mode guidelines

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

High availability Guidelines

OSPFv2 and OSPFv3 support Stateful High availability.

IPv6 guidelines

OSPFv2 does not support IPv6, while OSPFv3 provides IPv6 support with specific authentication and routing capabilities.

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The Firewall Threat Defense device installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.

OSPFv3 hello packets and GRE

Typically, OSPF traffic does not pass through GRE tunnel. When OSPFv3 on IPv6 is encapsulated inside GRE, the IPv6 header validation for security check such as Multicast Destination fails. The packet is dropped due to the implicit security check validation, as this packet has destination IPv6 multicast.

- You may define a pre-filter rule to bypass GRE traffic. However, with pre-filter rule, inner packets would not be interrogated by the inspection engine.

Clustering guidelines

OSPFv2 and OSPFv3 have specific limitations and behaviors in clustering environments.

- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In Spanned interface mode, dynamic routing is not supported on management-only interfaces.
- In Individual interface mode, make sure that you establish the control and data units as either OSPFv2 or OSPFv3 neighbors.

- In Individual interface mode, OSPFv2 adjacencies can only be established between two contexts on a shared interface on the control unit. Configuring static neighbors is supported only on point-to point-links; therefore, only one neighbor statement is allowed on an interface.
- When a control role change occurs in the cluster, specific behavior occurs based on interface mode. In spanned interface mode, the router process is active only on the control unit and is in a suspended state on the data units. Each cluster unit has the same router ID because the configuration has been synchronized from the control unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change. In individual interface mode, the router process is active on all the individual cluster units. Each cluster unit chooses its own distinct router ID from the configured cluster pool. A control role change in the cluster does not change the routing topology in any way.

Multiprotocol label switching (MPLS) and OSPF guidelines

When a MPLS-configured router sends Link State (LS) update packets containing opaque Type-10 link-state advertisements (LSAs) that include an MPLS header, authentication fails and the appliance silently drops the update packets, rather than acknowledging them. Eventually the peer router will terminate the neighbor relationship because it has not received any acknowledgments.

- Make sure that non-stop forwarding (NSF) is disabled on the appliance to ensure that the neighbor relationship remains stable. Navigate to the **Non Stop Forwarding** page in Cloud-Delivered Firewall Management Center (**Devices** > **Device Management (select the desired device)** > **Routing** > **OSPF** > **Advanced** > **Non Stop Forwarding**). Ensure the **Non Stop Forwarding Capability** boxes are not checked.

These guidelines apply to MPLS environments where opaque LSAs might cause authentication failures.

Note The Firepower 4100/9300 models may have high latency when using MPLS because they lack load balancing across multiple receiving queues.

Bidirectional and forwarding detection (BFD) and OSPF guidelines

You can enable BFD on specific interface types with OSPFv2 and OSPFv3.

- You can enable BFD on OSPFv2 and OSPFv3 interfaces (Physical Interfaces, Sub-Interfaces, and Port-Channels).
- BFD is not supported on VTI Tunnels, DVTI Tunnels, Loopback, Switchport, VNI, VTEP, and IRB interfaces.

Route redistribution guidelines

Route redistribution with prefix lists and between routing domains requires specific configuration considerations.

- Redistribution of route maps with IPv4 prefix list on OSPFv2 is supported. However, redistribution of route maps with IPv6 prefix list on OSPFv3 is not supported. Use an access list in the route map on OSPF for redistribution.
- When OSPF is configured on a device that is a part of EIGRP network or vice versa, ensure that OSPF-router is configured to tag the route (EIGRP does not support route tag yet). When redistributing OSPF into EIGRP and EIGRP into OSPF, a routing loop occurs when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from

one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Additional guidelines

OSPFv2 and OSPFv3 support various features and have specific limitations in different deployment scenarios.

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.
- OSPFv2 supports Cisco NSF Graceful Restart and IETF NSF Graceful Restart mechanisms as defined in RFCs 4811, 4812 & 3623 respectively.
- OSPFv3 supports Graceful Restart mechanism as defined in RFC 5187.
- There is a limit to the number of intra area (type 1) routes that can be distributed. For these routes, a single type-1 LSA contains all prefixes. Because the system has a limit of 35 KB for packet size, 3000 routes result in a packet that exceeds the limit. Consider 2900 type 1 routes to be the maximum number supported.
- For a device using virtual routing, you can configure OSPFv2 and OSPFv3 for a global virtual router. However, you can configure only OSPFv2 for a user-defined virtual router.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- OSPFv3 drops the LS update if the packet size exceeds 8190. As a result, the neighbourship is terminated. Hence, configure the switch with the "ospfv3 MTU-ignore" command to avoid neighbourship termination.

OSPFv2 configuration

This section describes the tasks involved in configuring an OSPFv2 routing process. For a device using virtual routing, you can configure OSPFv2 for global as well as for user-defined virtual routers.

Configure OSPF areas, ranges, and virtual links

Complete the configuration of OSPF by defining areas, assigning route summarization ranges, and creating virtual links to connect discontiguous OSPF areas.

You can configure several OSPF area parameters, which include setting authentication, defining stub areas, and assigning specific costs to the default summary route. You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

For a virtual-router-aware device, choose the virtual router from the virtual routers drop-down list.

Step 3 Click **OSPF** and configure the following on the **OSPF** page:

- Check the check box of **Process 1**. You can enable up to two OSPF process instances for each context /virtual router . You must choose an OSPF process to be able to configure the Area parameters.

  If the device is using virtual routing, the ID fields display the unique process IDs generated for the chosen virtual router.

- Choose the **OSPF Role** from the drop-down list, and enter a description for it in the next field. The options are Internal, ABR, ASBR, and ABR & ASBR. See OSPF routing, on page 1447 for a description of the OSPF roles.

Step 4 Select **Area** > **Add** .

You can click **Edit** ( ) , or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 5 Configure the following area options for each OSPF process:

- **OSPF Process** — Choose the process ID. For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID** —Designation of the area for which routes are to be summarized.
- **Area Type** —Choose one of the following:
  - **Normal** —(Default) Standard OSPF area.
  - **Stub** —A stub area does not have any routers or areas beyond it. Stub areas prevent Autonomous System (AS) External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Types 3 and 4) from being flooded into the area by not checking the **Summary Stub** check box.
  - **NSSA** —Makes the area a not-so-stubby area (NSSA). NSSAs accept Type 7 LSAs. You can disable route redistribution by not checking the **Redistribute** check box and checking the **Default Information Originate** check box. You can prevent summary LSAs from being flooded into the area by not checking the **Summary NSSA** check box.
- **Metric Value** —The metric used for generating the default route. The default value is 10. Valid metric values range from 0 through 16777214.
- **Metric Type** —The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Available Network** —Choose one of the available networks and click **Add** , or click **Add** ( ) to add a new network object. See Networks, on page 2982 for the procedure for adding networks.

- **Authentication** —Choose the OSPF authentication:
  - **None** —(Default) Disables OSPF area authentication.
  - **Password** —Provides a clear text password for area authentication, which is not recommended where security is a concern.
  - **MD5** —Allows MD5 authentication.
- **Default Cost** —The default cost for the OSPF area, which is used to determine the shortest paths to the destination. Valid values range from 0 through 65535. The default value is 1.
- Click **OK** to save the area configuration.

Step 6 Select **Range** > **Add** .

- Choose one of the available networks and whether to advertise, or,
- Click **Add** (+) to add a new network object. See Networks, on page 2982 for the procedure for adding networks.
- Click **OK** to save the range configuration.

Step 7 Select **Virtual Link** , click **Add** (+) , and configure the following options for each OSPF process:

- **Peer Router** —Choose the IP address of the peer router. To add a new peer router, click **Add** (+) . See Networks, on page 2982 for the procedure for adding networks.
- **Hello Interval** —The time in seconds between the hello packets sent on an interface. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. Valid values range from 1 through 65535. The default is 10.

  The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Transmit Delay** —The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 through 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval** —The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 through 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Dead Interval** —The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval is an unsigned integer. The default is four times the hello interval, or

40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 through 65535.

- **Authentication** —Choose the OSPF virtual link authentication from the following:
  - **None** —(Default) Disables virtual link area authentication.
  - **Area Authentication** —Enables area authentication using MD5. Click **Add** , and enter the key ID, key, confirm the key, and then click **OK** .
  - **Password** —Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5** —Allows MD5 authentication. Click **Add** , and enter the key ID, key, confirm the key, and then click **OK** .

    Note
    Ensure to enter only numbers as the MD5 key ID.
  - **Key Chain** —Allows key chain authentication. Click **Add** , and create the key chain, and then click **Save** . For detailed procedure, see Create a key chain object, on page 2981 . Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.
  - Click **OK** to save the virtual link configuration

Step 8 Click **Save** on the Routing page to save your changes.

OSPF is configured with designated areas, summarized ranges, and any necessary virtual links. Routing updates are generated based on your configuration.

What to do next

Continue with Configure OSPF Redistribution.

Configure OSPF redistribution

This task enables you to control the redistribution of routes between the OSPF routing processes on your Firewall Threat Defense device.

The Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Before you begin

Follow these steps to configure OSPF redistribution:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 From **OSPF Role** drop-down, choose role.

Step 6 Click **Redistribution** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 7 Configure the following redistribution options for each OSPF process:

- **OSPF Process**—Choose the process ID. For a device using virtual routing, this drop-down list displays the unique process IDs generated for the selected virtual router.
- **Route Type**—Choose one of the following types:
  - **Static**—Redistributes static routes to the OSPF routing process.
  - **Connected**—Redistributes connected routes (routes established automatically by virtue of having the IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed AS external to the device. You can select whether to use subnets under the Optional list.
  - **OSPF**—Redistributes routes from another OSPF routing process, for example, internal, external 1 and 2, NSSA external 1 and 2, or whether to use subnets. You can select these options under the Optional list.
  - **BGP**—Redistribute routes from the BGP routing process. Add the AS number and whether to use subnets.
  - **RIP**—Redistributes routes from the RIP routing process. You can select whether to use subnets under the Optional list.

    Note
    As a user-defined virtual router does not support RIP, you cannot redistribute routes from RIP.

  - **EIGRP**—Redistribute routes from the EIGRP routing process. Add the AS number and whether to use subnets.
- **Metric Value**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag Value**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **RouteMap**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified,

but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** (+). See Configure Route Map Entry to add a new route map.

Step 8 Click **OK** to save the redistribution configuration.

Step 9 Click **Save** on the Routing page to save your changes.

OSPF redistribution is now configured for the selected OSPF process with the specified route types and parameters.

What to do next

Continue with Configure OSPF Inter-Area filtering, on page 1459.

Configure OSPF Inter-Area filtering

Configure ABR type 3 LSA filtering to control which prefixes are sent between different OSPF areas and restrict other prefixes to their local OSPF area.

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.

Before you begin

Follow these steps to configure OSPF inter-area filtering:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **InterArea** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete inter-areas.

Step 6 Configure these inter-area filtering options for each OSPF process:

- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.

- **Area ID**—The area for which routes are to be summarized.
- **PrefixList**—The name of the prefix. To add a new prefix list object, see Step 5.
- **Traffic Direction**—Inbound or outbound. Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

Step 7 Click **Add** (+), and enter a name for the new prefix list, and whether to allow overrides.

You must configure a prefix list before you can configure a prefix rule.

Step 8 Click **Add** to configure prefix rules, and configure these parameters:

- **Action**—Select **Block** or **Allow** for the redistribution access.
- **Sequence No**—The routing sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
- **IP Address**—Specify the prefix number in the format of IP address/mask length.
- **Min Prefix Length**—(Optional) The minimum prefix length.
- **Max Prefix Length**—(Optional) The maximum prefix length.
- Click **OK** to save the inter-area filtering configuration.

Step 9 Click **Save** on the Routing page to save your changes.

The OSPF inter-area filtering configuration is saved and applied to control LSA distribution between the specified OSPF areas according to the configured prefix lists and traffic direction settings.

What to do next

Continue with Configure OSPF filter rules, on page 1460.

Configure OSPF filter rules

Configure OSPF filter rules to improve control of route distribution between OSPF areas by allowing only specified prefixes to be sent from one area to another area while restricting all other prefixes.

You can configure ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. You can apply this type of area filtering out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF area at the same time. OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Filter Rule** > **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete filter rules.

Step 6 Configure the following filter rule options for each OSPF process:

- **OSPF Process**— For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Access List**—The access list for this OSPF process. To add a new standard access list object, click **Add** ( ) and see Configure a standard ACL object, on page 2953.
- **Traffic Direction**—Choose In or Out for the traffic direction being filtered. Choose In to filter LSAs coming into an OSPF area, or Out to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.
- **Interface**—The interface for this filter rule.

Step 7 Click **OK** to save the filter rule configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF filter rules are configured and saved, enabling controlled route distribution between OSPF areas based on the specified access list and traffic direction settings.

What to do next

Continue with Configure OSPF summary addresses, on page 1461.

Configure OSPF summary addresses

Configure OSPF summary addresses to decrease the size of the OSPF link-state database by advertising a single route for all redistributed routes that are included for a specified network address and mask.

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the Firewall Threat Defense device to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database. Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Summary Address** > **Add**.

You can click **Edit** ( ) to edit, or use the right-click menu to cut, copy, past, insert, and delete summary addresses.

Step 6 Configure the following summary address options for each OSPF process:

- **OSPF Process**— For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Available Network**—The IP address of the summary address. Select one from the Available networks list and click **Add**, or to add a new network, click **Add** ( ). See Networks, on page 2982 for the procedure for adding networks.
- **Tag**—A 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.
- **Advertise—Advertises** the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Step 7 Click **OK** to save the summary address configuration.

Step 8 Click **Save** on the Routing page to save your changes.

The OSPF summary address configuration is saved and the device will advertise a single route for all redistributed routes that are included for the specified network address and mask.

What to do next

Continue with Configure OSPF interfaces and neighbors, on page 1462.

Configure OSPF interfaces and neighbors

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval, the dead interval, and the authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Interface** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 6 Configure the following Interface options for each OSPF process:

- **Interface**—The interface you are configuring.

  Note
  If the device is using virtual routing, this drop-down list displays only those interfaces that belong to the router.

- **Default Cost**—The cost of sending a packet through the interface. The default value is 10.
- **Priority**—The designated router for a network. Valid values range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router. This setting does not apply to interfaces that are configured as point-to-point interfaces.

- **MTU Ignore—OSPF** checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency is not established.
- **Database Filter**—Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.
- **Hello Interval**—Specifies the interval, in seconds, between hello packets sent on an interface. Valid values range 1–8192 seconds. The default value is 10 seconds.

  The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface.

- **Transmit Delay**—Estimated time in seconds to send an LSA packet on the interface. Valid values range 1–65535 seconds. The default is 1 second.

  LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

- **Retransmit Interval**—Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Dead Interval**—Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range 1–65535.
- **Hello Multiplier**—Specifies the number of Hello packets to be sent per second. Valid values are 3–20.
- **Point-to-Point**—Lets you transmit OSPF routes over VPN tunnels.
- **Authentication**—Choose the OSPF interface authentication from the following:
  - **None**—(Default) Disables interface authentication.
  - **Area Authentication**—Enables interface authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**—Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

    Note
    Enter only letters, numbers, and special characters for the MD5 key ID. Do not enter spaces; spaces are truncated in management center.

  - **Key Chain**—Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, see Create a key chain object, on page 2981. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.
- **Enable BFD**—Allows you to enable BFD on this interface.
- **Enter Password**—The password you configure if you choose Password as the type of authentication.
- **Confirm Password**—Confirm the password that you chose.

Step 7 Select **Neighbor** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 8 Configure the following parameters for each OSPF process:

- **OSPF Process**—Choose 1 or 2.
- **Neighbor**—Choose one of the neighbors in the drop-down list, or click **Add** () to add a new neighbor; enter the name, description, network, whether to allow overrides, and then click **Save**.
- **Interface**—Choose the interface associated with the neighbor.

Step 9 Click **OK** and click **Save** to save the changes.

OSPF interface and neighbor configuration is completed. The configured parameters are applied to the selected interfaces and neighbors, enabling OSPF routing functionality on the specified network segments.

Configure OSPF Advanced Properties

Enable advanced OSPF features for optimized routing behavior and enhanced protocol reliability.

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, an LSA timer, and graceful restarts.

Graceful Restarts

The Firewall Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv2 by using either using NSF Cisco (RFC 4811 and RFC 4812) or NSF IETF (RFC 3623).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing** .

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF** > **Advanced** .

Step 5 Select **General**, and configure the following: .

- **Router ID**: Choose Automatic or IP Address (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode) for the router ID.

If you choose IP address, enter the IP address in the adjacent field. If you choose Cluster Pool, choose the IPv4 cluster pool value in the adjacent drop-down field. For information on creating the cluster pool address, see Configure address pools, on page 2954 .

- **Ignore LSA MOSPF**: Suppresses syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
- **RFC 1583 Compatible**: Configures RFC 1583 compatibility as the method used to calculate summary route costs. Routing loops can occur with RFC 1583 compatibility enabled. Disable it to prevent routing loops. All OSPF routers in an OSPF routing domain should have RFC compatibility set identically.
- **Adjacency Changes**: Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

  - **Log Adjacency Changes**: Causes the Firewall Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
  - **Log Adjacency Change Details**: Causes the Firewall Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distance**: Allows you to modify the settings that were used to configure administrative route distances for **inter-area**, **intra-area**, and **external** IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **LSA Group Pacing**: Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Enable Default Information Originate**: Check the **Enable** check box to generate a default external route into an OSPF routing domain and configure the following options:
  - **Always advertise the default route**: Ensures that the default route is always advertised.
  - **Metric Value**: Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**: The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **RouteMap**: Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Configure Route Map Entry to add a new route map.

Step 6 Click **OK** to save the general configuration.

Step 7 Select **Non Stop Forwarding**, and configure Cisco NSF graceful restart for OSPFv2, for an NSF-capable or NSF-aware device.

Note
There are two graceful restart mechanisms for OSPFv2, Cisco NSF and IETF NSF. Only one of these graceful restart mechanisms can be configured at a time for an OSPF instance. An NSF-aware device can be configured as both Cisco NSF helper and IETF NSF helper but a NSF-capable device can be configured in either Cisco NSF or IETF NSF mode at a time for an OSPF instance.

a) Check the **Enable Cisco Non Stop Forwarding Capability** check box.
b) (Optional) Check the **Cancel NSF restart when non-NSF-aware neighboring networking devices are detected** check box if required.
c) (Optional) Make sure the **Enable Cisco Non Stop Forwarding Helper** mode check box is unchecked to disable the helper mode on an NSF-aware device.

Step 8 Configure IETF NSF Graceful Restart for OSPFv2, for an NSF-capable or NSF-aware device: .

a) Check the **Enable IETF Non Stop Forwarding Capability** check box.
b) In the **Length of graceful restart interval (seconds)** field, enter the restart interval in seconds. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.
c) (Optional) Make sure the **Enable IETF nonstop forwarding (NSF) for helper mode** check box is unchecked to disable the IETF NSF helper mode on an NSF-aware device.
d) **Enable Strict Link State advertisement checking**: When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.
e) **Enable IETF Non Stop Forwarding**: Enables non stop forwarding, which allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. OSPF uses extensions to the OSPF protocol to recover its state from neighboring OSPF devices. For the recovery to work, the neighbors must support the NSF protocol extensions and be willing to act as "helpers" to the device that is restarting. The neighbors must also continue forwarding data traffic to the device that is restarting while protocol state recovery takes place.

Advanced OSPF settings are applied. The device now uses customized OSPF general and graceful restart properties for improved routing behavior, syslog management, and protocol resilience.

OSPFv3 configuration

OSPFv3 configuration is a routing process setup that

- enables IPv6 routing functionality on network devices,
- involves multiple configuration tasks to establish the routing process, and
- supports configuration only for global virtual routers in virtual routing environments.

Virtual routing limitations

For a device using virtual routing, you can configure OSPFv3 only for its global virtual router and not for its user-defined virtual router.

Configure OSPFv3 Areas, Route Summaries, and Virtual Links

-

To enable OSPFv3, you need to create an OSPFv3 routing process, create an area for OSPFv3, enable an interface for OSPFv3, and then redistribute the route into the targeted OSPFv3 routing process.

Before you begin

-

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click the **Routing** tab. On the tab's left pane, click **OSPFv3** .

Step 3 By default **Enable Process 1** is selected. You can enable up to two OSPF process instances.

Step 4 Choose the OSPFv3 role from the drop-down list, and enter a description for it. The options are Internal, ABR, ASBR, and ABR and ASBR. See OSPF routing, on page 1447 for descriptions of the OSPFv3 roles.

Step 5 Select **Area** > **Add** .

You can click **Edit** ( ) , or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 6 Select **General** , and configure the following options for each OSPF process:

- **Area ID** —The area for which routes are to be summarized.
- **Cost** —The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
- **Type** —Specifies Normal, NSSA, or Stub. If you select Normal, there are no other parameters to configure. If you select Stub, you can choose to send summary LSAs in the area. If you select NSSA, you can configure the next three options:
  - **Allow Sending summary LSA into this area** —Allows the sending of summary LSAs into the area.
  - **Imports routes to normal and NSSA area** —Allows redistribution to import routes to normal and not to stubby areas.
  - **Defaults information originate** —Generates a default external route into an OSPFv3 routing domain.
- **Metric** —Metric used for generating the default route. The default value is 10. Valid metric values range from 0 to 16777214.
- **Metric Type** —The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

Step 7 Click **OK** to save the general configuration.

Step 8 (Not applicable for Internal OSPFv3 Role) Select **Route Summary** > **Add Route Summary** .

You can click **Edit** ( ) , or use the right-click menu to cut, copy, past, insert, and delete route summaries.

Step 9 Configure the following route summary options for each OSPF process:

- **IPv6 Prefix/Length** —The IPv6 prefix. To add a new network object, click **Add** ( ) . See Networks, on page 2982 for the procedure for adding networks.
- **Cost** —The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.

- **Advertise** —Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Step 10 Click **OK** to save the route summary configuration.

Step 11 (Not applicable for Internal OSPFv3 Role) Select **Virtual Link** , click **Add Virtual Link** , and configure the following options for each OSPF process:

- **Peer RouterID** —Choose the IP address of the peer router. To add a new network object, click **Add** (+) . See Networks, on page 2982 for the procedure for adding networks.
- **TTL Security** —Enables TTL security check. The value for the hop-count is a number from 1 to 254. The default is 1.

  OSPF sends outgoing packets with an IP header Time to Live (TTL) value of 255 and discards incoming packets that have TTL values less than a configurable threshold. Because each device that forwards an IP packet decrements the TTL, packets received via a direct (one-hop) connection have a value of 255. Packets that cross two hops have a value of 254, and so on. The receive threshold is configured in terms of the maximum number of hops that a packet may have traveled.
- **Dead Interval** —The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The default is four times the hello interval, or 40 seconds. Valid values range from 1 to 65535.

  The dead interval is an unsigned integer. The value must be the same for all routers and access servers that are attached to a common network.
- **Hello Interval** —The time in seconds between the hello packets sent on an interface. Valid values range from 1 to 65535. The default is 10.

  The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Retransmit Interval** —The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Transmit Delay** —The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 to 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

Step 12 Click **OK** to save the virtual link configuration.

Step 13 Click **Save** on the Router page to save your changes.

What to do next

Continue with Configure OSPFv3 Redistribution .

Configure OSPFv3 redistribution

Configure OSPFv3 redistribution to control how routes are redistributed between OSPF routing processes and other routing protocols on the Secure Firewall Threat Defense device.

The Secure Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Before you begin

Follow these steps to configure OSPFv3 redistribution:

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPF**.

Step 3 Select **Redistribution**, and click **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following redistribution options for each OSPF process:

- **Source Protocol**—The source protocol from which routes are being redistributed. The supported protocols are connected, OSPF, Static, EIGRP, and BGP. If you choose OSPF, you must enter the Process ID in the **Process ID** field. If you choose BGP, you must add the AS number in the **AS Number** field.
- **Metric**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **Route Map**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** ( ). See Configure a route map, on page 3017 for the procedure to add a new route map.

- **Process ID**—The OSPF process ID, either 1 or 2.

  Note
  The Process ID is enabled the OSPFv3 process is redistributing a route learned by another OSPFv3 process.

- **Match**—Enables OSPF routes to be redistributed into other routing domains:
  - **Internal** for routes that are internal to a specific autonomous system.
  - **External 1**for routes that are external to the autonomous system, but are imported into OSPFv3 AS Type 1 external routes.
  - **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 AS Type 2 external routes.
  - **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 AS Type 1 external routes.
  - **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 AS Type 2 external routes.

Step 5 Click **OK** to save the redistribution configuration.

Step 6 Click **Save** on the Routing page to save your changes.

The OSPFv3 redistribution configuration is saved and routes are redistributed according to the specified parameters.

What to do next

Continue with Configure OSPFv3 summary prefixes, on page 1471.

Configure OSPFv3 summary prefixes

Configure OSPFv3 summary prefixes to control route advertisement and suppression based on IPv6 prefix and mask pairs.

You can configure the Firewall Threat Defense device to advertise routes that match a specified IPv6 prefix and mask pair.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Summary Prefix** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete summary prefixes.

Step 4 Configure the following summary prefix options for each OSPF process:

- **IPv6 Prefix/Length**—The IPv6 prefix and prefix length label. Select one from the list or click **Add** (+) to add a new network object. See Networks, on page 2982 for the procedure for adding networks.
- **Advertise**— Advertises routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.
- (Optional) **Tag**—A value that you can use as a match value for controlling redistribution through route maps.

Step 5 Click **OK** to save the summary prefix configuration.

Step 6 Click **Save** on the Routing page to save your changes.

The OSPFv3 summary prefix configuration is saved and will control route advertisement based on your specified settings.

What to do next

Continue with Configure OSPFv3 interfaces, authentication, and neighbors, on page 1472.

Configure OSPFv3 interfaces, authentication, and neighbors

Set up OSPFv3 routing, authentication, and neighbor relationships to support IPv6 dynamic network routing.

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

For a successful implementation of OSPFv3 authentication with Nexus switches, ensure that you have the compatible version of the switch, for example, Nexus 3000, 7000, and 9000 series switches.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Interface** > **Add**.

You can click **Edit** to edit, or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following interface options for each OSPFv3 process:

- **Interface** —The interface you are configuring.
- **Enable OSPFv3** —Enables OSPFv3.
- **OSPF Process** —Choose 1 or 2.
- **Area** —The area ID for this process.

- **Instance** —Specifies the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

Step 5 Select **Properties** , and configuring the following options for each OSPFv3 process:

- **Filter Outgoing Link Status Advertisements** —Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Disable MTU mismatch detection** —Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.
- **Flood Reduction** —Changes normal LSAs into Do Not Age LSAs, so that they don't get flooded every 3600 seconds across areas.

  OSPF LSAs are refreshed every 3600 seconds. In large OSPF networks, this can lead to large amounts of unnecessary LSA flooding from area to area.
- **Point-to-Point Network** —Lets you transmit OSPF routes over VPN tunnels. When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:
  - You can define only one neighbor for the interface.
  - You need to manually configure the neighbor.
  - You need to define a static route pointing to the crypto endpoint.
  - If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
  - You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.
- **Broadcast** — Specifies that the interface is a broadcast interface. By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, nonbroadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.
- **Cost** —Specifies the cost of sending a packet on the interface. Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.
- **Priority** —Determines the designated router for a network. Valid values range from 0 to 255.
- **Dead Interval** —Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.
- **Hello Interval** — Time period in seconds between OSPF packets that the router will send before adjacency is established with a neighbor. Once the routing device detects an active neighbor, the hello packet interval

changes from the time specified in the poll interval to the time specified in the hello interval. Valid values range from 1 to 65535 seconds.

- **Retransmit Interval** —Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.
- **Transmit Delay** —Estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.
- **Enable BFD** —Allows you to enable BFD on this interface.

Step 6 Select **Authentication** , and configure the following options for each OSPFv3 process:

- **Type** —Type of authentication. The available options are Area, Interface, and None. The None option indicates that no authentication is used.
- **Security Parameters Index** — A number from 256 to 4294967295. Configure this if you chose Interface as the type.
- **Authentication** —Type of authentication algorithm. Supported values are SHA-1 and MD5. Configure this if you chose Interface as the type.
- **Authentication Key** — When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.
- **Encrypt Authentication Key** —Enables encryption of the authentication key.
- **Include Encryption** — Enables encryption.
- **Encryption Algorithm** —Type of encryption algorithm. Supported value is DES. The NULL entry indicates no encryption. Configure this if you chose **Include Encryption** .
- **Encryption Key** —Enter the encryption key. Configure this if you chose **Include Encryption** .
- **Encrypt Key** —Enables the key to be encrypted.

Step 7 Click **OK** to save the authentication configuration.

Step 8 Select **Neighbor** , click **Add** , and configure the following options for each OSPFv3 process:

- **Link Local Address** —The IPv6 address of the static neighbor.
- **Cost** —Enables cost. Enter the cost in the **Cost** field, and check the **Filter Outgoing Link State Advertisements** if you want to advertise.
- (Optional) **Poll Interval** —Enables the poll interval. Enter the **Priority** level and the **Poll Interval** in seconds.
- Click **Add** to add the neighbor.

Step 9 Click **OK** to save the Interface configuration.

OSPFv3 interface, authentication, and neighbor settings are configured on the device. OSPFv3 processes will operate according to the specified parameters.

Configure OSPFv3 Advanced Properties

Enable and fine-tune OSPFv3 advanced properties to optimize routing, ensure stability, and automate operations for your device

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, passive OSPFv3 routing, LSA timers, and graceful restarts.

Graceful Restarts

The Firewall Threat Defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv3 using graceful-restart (RFC 5187).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **OSPFv3** > **Advanced** .

Step 3 For **Router ID** , choose Automatic or IP Address (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode) . If you choose IP Address, enter the IPv6 address in the **IP Address** field. If you choose Cluster Pool, choose the IPv6 cluster pool value from the **Cluster Pool** down-down field. For information on creating the cluster pool address, see Configure address pools, on page 2954 .

Step 4 Check the **Ignore LSA MOSPF** check box if you want to suppress syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.

Step 5 Select **General** , and configure the following:

- **Adjacency Changes** —Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

- **Adjacency Changes** —Causes the Firewall Threat Defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
- **Include Details** —Causes the Firewall Threat Defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distances** —Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **Default Information Originate** —Check the **Enable** check box to generate a default external route into an OSPFv3 routing domain and configure the following options:
  - **Always Advertise** —Will always advertise the default route whether or not one exists.
  - **Metric** —Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type** —The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **Route Map** —Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Configure a route map, on page 3017 to add a new route map.

Step 6 Click **OK** to save the general configuration.

Step 7 Select **Passive Interface**, select the interfaces on which you want to enable passive OSPFv3 routing from the Available Interfaces list, and click **Add** to move them to the Selected Interfaces list.

Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface.

Step 8 Click **OK** to save the passive interface configuration.

Step 9 Select **Timer**, and configure the following LSA pacing and SPF calculation timers:

- **Arrival**—Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.
- **Flood Pacing**—Specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
- **Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Retransmission Pacing**—Specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
- **LSA Throttle** —Specifics the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 millisecond. The minimum specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds. The maximum specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.

Note
For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- **SPF Throttle** —Specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds. The minimum specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds. The maximum specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

  Note
  For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

Step 10 Click **OK** to save the LSA timer configuration.

Step 11 Select **Non Stop Forwarding** , and check the **Enable graceful-restart helper** check box. This is checked by default. Uncheck this to disable the graceful-restart helper mode on an NSF-aware device.

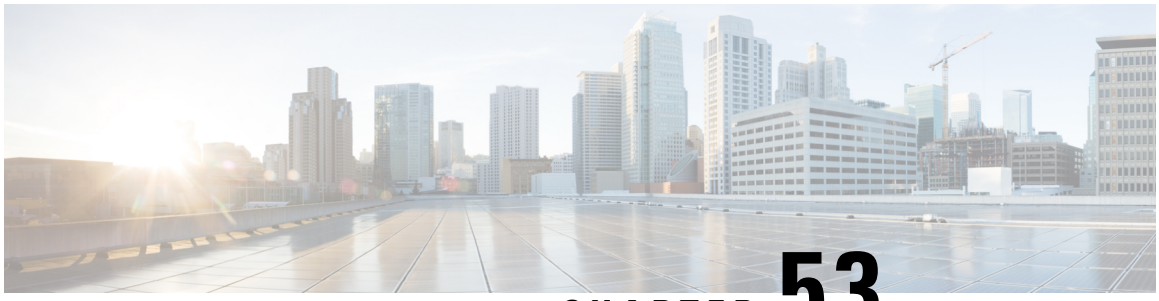
Step 12 Check the **Enable link state advertisement** check box to enable strict link state advertisement checking.

When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

Step 13 Check the **Enable graceful-restart (Use when Spanned Cluster or Failover Configured)** and enter the graceful-restart interval in seconds. The range is 1-1800. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.

Step 14 Click **OK** to save the graceful restart configuration.

Step 15 Click **Save** on the Routing page to save your changes.



The device is configured with your OSPFv3 advanced properties. All changes are applied, enhancing routing resilience, logging, and failover handling.

History for OSPF

This reference provides a summary of the key features introduced in OSPF and the versions in which they became available, along with details about their implementation.

Table 94: Feature history for OSPF

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
BFD Support for OSPF v2 and v3	7.4	7.4	You can enable BFD on OSPFv2 and OSPFv3 interfaces. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**

CHAPTER 53

EIGRP

EIGRP is a routing protocol that

- enables routers to efficiently exchange information,
- maintain network topology tables, and
- ensures secure data path selection and communication across networks.

EIGRP Operational Overview

This section covers the configuration of the Firewall Threat Defense to perform these routing tasks:

- Route data traffic
- Perform authentication
- Redistribute routing information

- EIGRP routing, on page 1479
- Requirements and prerequisites for EIGRP, on page 1480
- Guidelines and limitations for EIGRP routing, on page 1481
- Configure EIGRP routing on firewall devices, on page 1482

EIGRP routing

An Enhanced Interior Gateway Routing Protocol (EIGRP) is a routing protocol that

- sends updates only when network topology changes, not at regular intervals,
- offers rapid convergence and supports variable-length subnet masks, and
- supports partial updates and multiple network layer protocols.

EIGRP capabilities and operations

EIGRP stores all neighbor routing tables for quick adaptation to alternate routes. If a suitable route does not exist, EIGRP queries its neighbors to discover an alternate route. It propagates these queries through the network to locate a route. EIGRP's support for variable-length subnet masks allows routes to be automatically

summarized on a network boundary. Additionally, EIGRP can be configured to summarize any bit boundary at any interface.

EIGRP sends partial updates when route metrics change, limiting propagation to necessary routers, which minimizes bandwidth use compared to protocols that send periodic full updates.

To learn about routers on attached networks, EIGRP uses neighbor discovery through multicast hello packets to announce their presence on the network. When a new neighbor is detected through hello packets, a topology table exchange occurs.

EIGRP hello packets are normally sent as multicast messages and do not require explicit replies. For manually configured static neighbors, hello packets are sent as unicast messages to the specified neighbor.

Once this neighbor relationship is established, routing updates are exchanged only on topology changes. The relationship persists through regular multicast hello packets, with devices expected to respond within advertised hold times. Hold time is the time within which threat defense can expect to receive a hello packet from that neighbor. If the device does not receive a hello packet within the advertised hold time, it considers the neighbor unavailable.

EIGRP employs mechanisms like neighbor discovery/recovery, Reliable Transport Protocol (RTP), and Diffusing Update Algorithm (DUAL) for route computations. DUAL retains all routes to a destination, selecting the least-cost route for packet forwarding while retaining others in case of network changes. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router that is used for packet forwarding that has a least-cost path to a destination. DUAL utilizes a feasibility condition to ensure that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation takes place. During route recomputation, DUAL queries the EIGRP neighbors for a route. The query is propagated to successive neighbors. If a feasible successor is not found, an unreachable message is returned.

During route recomputation, DUAL marks the route as active. By default, threat defense waits for three minutes to receive a response from its neighbors. If the device does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasible successor are removed.

Requirements and prerequisites for EIGRP

This topic provides the necessary prerequisites and requirements for deploying EIGRP within a Cisco network environment.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Admin

Network Admin

Guidelines and limitations for EIGRP routing

Firewall mode guidelines

Use routed firewall mode only for EIGRP routing.

Device guidelines

Configure only one EIGRP process per device.

- EIGRP can be configured through management center UI on Firewall Threat Defense version 6.6 and later.

Interface guidelines

Use only routed interfaces with logical names and IP addresses for EIGRP routing processes.

- EIGRP can only incorporate interfaces from the global virtual router. EIGRP can learn, filter, and redistribute routes across routing protocols in the global virtual router.
- Supports physical, EtherChannel, redundant, and subinterfaces only. However, the members of EtherChannel interfaces are not supported.
-
- Passive interfaces cannot be configured as neighbor interfaces.

IP address and network objects support

Use only IPv4 addresses and standard access list objects for EIGRP configuration.

- Ranges, FQDNs, and wildcard masks are not supported.

Redistribution guidelines

Configure route tagging to prevent routing loops when redistributing between EIGRP and OSPF.

- BGP, OSPF, and RIP in the global virtual router can redistribute routes toward EIGRP.
- EIGRP can redistribute to BGP, OSPF, RIP, Static, and Connected in the global virtual router.
- When EIGRP is configured on a device that is a part of an OSPF network or vice versa, ensure that the OSPF router is configured to tag the route (EIGRP does not support route tag).

  When redistributing EIGRP into OSPF and OSPF into EIGRP, a routing loop can occur when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Deployment process guidelines

Disable and redeploy EIGRP when changing the AS number to prevent deployment failures.

To effectively change the AS number of an existing EIGRP setup, you should disable and redeploy EIGRP configurations to avoid repeated deployments and ensure error-free deployment processes.

Upgrade guidelines

Migrate FlexConfig EIGRP policies to UI management after upgrading to version 7.2 and later.

When you upgrade to version 7.2 and later, and if the previous version includes any FlexConfig EIGRP policies, the management center displays a warning message during deployment. It does not stop the deployment process; a warning message is displayed. After deployment, to manage the EIGRP policies from the UI (**Devices** > **Device Management**, click the **Edit** (✎) icon. Then, click **Routing>EIGRP**), you must redo the configuration in the **EIGRP** page and remove the configuration from FlexConfig. To automate policy creation in the UI, Cloud-Delivered Firewall Management Center provides an option to migrate the policies from FlexConfig to the UI. For more information, refer to Migrate FlexConfig policies, on page 1352.

Configure EIGRP routing on firewall devices

Enable EIGRP on a firewall device for efficient routing within an autonomous system.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click the **Routing** tab.

Step 3 Under Global, click **EIGRP**.

Step 4 Check the **Enable EIGRP** check box to enable the EIGRP routing process.

Step 5 In the **AS Number** field, enter the autonomous system (AS) number for the EIGRP process.

Valid values are from 1 to 65535. The AS number identifies the local EIGRP routing domain and must match on EIGRP neighbors.

Step 6 To configure other EIGRP properties, refer to these topics for detailed steps:

a. Configure EIGRP settings, on page 1483.

b. Configure EIGRP neighbors settings, on page 1483.

c. Configure EIGRP filter rules, on page 1484.

d. Configure EIGRP redistribution settings, on page 1485.

e. Configure EIGRP summary address settings, on page 1486.

f. Configure EIGRP interfaces settings, on page 1487.

g. Configure EIGRP advanced settings, on page 1488.

The firewall device is now configured with the base EIGRP process and the designated AS number. It can participate in EIGRP routing after the required interfaces, networks, and related settings are configured.

Configure EIGRP settings

Use this procedure when you need to set up EIGRP routing protocol parameters on your device. EIGRP configuration includes enabling automatic network summarization, selecting networks that participate in the routing process, and configuring passive interfaces that do not exchange routing updates.

Procedure

Step 1 On the **EIGRP** page, click the **Setup** tab.

Step 2 Check the **Auto Summary** check box to enable EIGRP to summarize at network boundaries.

Note
Enabling Auto Summary can cause routing problems if you have noncontiguous networks.

Step 3 In the **Available Networks/Hosts** box, select the networks or hosts that should participate in the EIGRP routing process, and then click **Add**. To add a new network object, click **Add** (+). For detailed instructions on adding networks, refer to Networks, on page 2982.

Step 4 To configure passive interfaces, check the **Passive Interface** check box. In EIGRP, a passive interface does not send or receive routing updates.

a) To specify selective interfaces as passive, click the **Selected Interface** radio button. In the **Available Interfaces** box, select the interfaces, and click **Add**.

b) To specify all interfaces as passive, click the **All Interfaces** radio button.

Step 5 Click **Save**.

The EIGRP settings are configured and saved. The routing protocol will operate according to the specified configuration, including automatic summarization behavior, network participation, and passive interface settings.

Configure EIGRP neighbors settings

Define static neighbors for the EIGRP process. This results in unicast hello packets being sent to that neighbor.

Procedure

Step 1 On the **EIGRP** page, click the **Neighbors** tab.

Step 2 Click +**Add**.

Step 3 Select the interface through which the neighbor is available from the **Interface** drop-down list.

Step 4 Select the IP address of the static neighbor from the **Neighbor** drop-down list.

Step 5 To add a new network object, click +. For instructions on adding network objects, refer to Networks, on page 2982.

Step 6 Click **OK**.

Step 7 Click **Save**.

The EIGRP static neighbor is configured, and hello packets are sent as unicast to the specified neighbor through the designated interface.

Configure EIGRP filter rules

Filter rules provide granular control over EIGRP route advertisements and acceptances, allowing you to manage network traffic flow and routing table contents based on specific criteria such as interface or protocol type.

To configure EIGRP filter rules, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Filter Rules** tab.

Step 2 Click **Add**.

Step 3 In the **Add Filter Rules** dialog box, select the direction for the rule from the **Filter Direction** drop-down list:

- **Inbound**: The rule filters routes received in incoming EIGRP updates.
- **Outbound**: The rule filters routes advertised in outgoing EIGRP updates.

Step 4 Under **Type**, choose one of these options:

- To select the interface to which the filtering rule applies, click **Interface**, and then select the interface from the **Select Interface** drop-down list. Select the access list from the **Access List** drop-down list. The list defines the networks that are to be received and suppressed in routing updates. To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2953. Click **OK**.

  Note
  You cannot apply EIGRP filtering rules on VTI interfaces.

- (This option is enabled only if you choose **Outbound** filter direction.) To select the protocol to which the filtering rule applies, click **Protocol** and then select BGP, RIP, Static, Connected, or OSPF from the **Select Protocol** drop-down list. You can specify the relevant **Process ID** for BGP and OSPF protocols. Select the access list from the **Access List** drop-down list. The list defines the networks that are to be received and suppressed in routing updates. To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2953. Click **OK**.

Step 5 Click **Save**.

The EIGRP filter rule is configured and applied to control route filtering based on the specified direction, interface, protocol, and access list criteria.

Configure EIGRP redistribution settings

Define rules to redistribute routes from other routing protocols to the EIGRP routing process to enable route sharing across different routing protocols.

To configure EIGRP redistribution settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Redistribution** tab.

Step 2 Click **Add**.

Step 3 In the **Add Redistribution** dialog box, from the **Protocol** drop-down list, select the source protocol from which the routes are being redistributed:

- **BGP**: Redistributes routes discovered by the BGP routing process to EIGRP. Specify the relevant **Process ID**.
- **RIP**: Redistributes routes discovered by the RIP routing process to EIGRP.
- **Static**: Redistributes static routes to the EIGRP routing process. Static routes within a network statement scope automatically redistribute to EIGRP, without additional rules. Specify the metric when redistributing static routes to VTI interfaces in EIGRP. You do not need to specify the metric for static routes pointing to other types of interfaces.
- **Connected**: Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed to EIGRP; you do not need to define a redistribution rule for them.
- **OSPF**: Redistributes routes discovered by the OSPF routing process to EIGRP. Specify the relevant **Process ID**. If you select this protocol, the Match options on this dialog box become available under **Optional OSPF Redistribution**:
  - **Internal**: Routes that are internal to a specific AS.
  - **External1**: Routes that are external to the AS and imported into OSPF as a Type 1 external route.
  - **External2**: Routes that are external to the AS and imported into the selected process as a Type 2 external route.
  - **Nsaa-External1**: Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
  - **Nsaa-External2**: (NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.

Note
These options are not available when redistributing static, connected, RIP, or BGP routes.

Step 4 Under **Optional Metrics**, enter the relevant values:

- **Bandwidth**: The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.

- **Delay Time**: The routing delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability**: The likelihood of successful packet transmission is expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**: The effective bandwidth of the route. Valid values range from 1 to 255. 255 indicates 100 percent loading.
- **MTU**: The smallest permissible value for the maximum transmission unit of the path. Valid values range from 1 to 65535.
- **Route Map**: Select the route map object to apply to the redistribution entry from the **Route Map** drop-down list. To create a new route map object, click +. For instructions on adding a new route map, refer to Configure Route Map Entry.

Step 5 Click **OK**.

Step 6 Click **Save**.

The EIGRP redistribution settings have been configured and saved. Routes from the selected source protocol will be redistributed to EIGRP according to the specified rules and metrics.

Configure EIGRP summary address settings

You can configure summary addresses for each interface. If you want to create summary addresses that do not occur at a network boundary, you should manually define them. Alternatively, you can use summary addresses with automatic route summarization disabled. If more specific routes are available in the routing table, EIGRP advertises the summary address with a metric equal to the minimum of all specific routes.

Procedure

Step 1 On the **EIGRP** page, click the **Summary Address** tab.

Step 2 Click +**Add**.

Step 3 From the **Interface** drop-down list, select the interface from which the summary address is advertised.

Step 4 From the **Network** drop-down list, select the network object with a specific IP address and network mask to be summarized. To add a new network, click +. For detailed instructions for adding networks, refer to Networks, on page 2982.

Step 5 In the **Administrative Distance** field, enter the administrative distance of the summary route. Valid values range from 1 to 255.

Step 6 Click **OK**.

Step 7 Click **Save**.

The EIGRP summary address settings are configured and saved. EIGRP will advertise the summary address from the specified interface with the configured administrative distance.

Configure EIGRP interfaces settings

Manage interface settings to optimize routing operations.

To configure EIGRP interface settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Interfaces** tab.

Step 2 Click **Add**.

Step 3 Select the appropriate interface from the **Interface** drop-down list.

Step 4 In the **Hello Interval** field, enter the hello interval in seconds for EIGRP packets on an interface. Valid values range from 1 to 65535. The default value is 5 seconds.

Step 5 In the **Hold Time** field, enter the hold time that is advertised by the device in EIGRP hello packets. Valid values range from 1 to 65535. The default value is 15 seconds.

To enable EIGRP split-horizon on the interface, check the **Split Horizon** check box.

Step 6 In the **Delay Time** field, enter the delay time in tens of microseconds. Valid values are from 1 to 16777215.

Note
This option is not supported in multi-context mode devices.

Step 7 Specify authentication properties:

- **Enable MD5 Authentication**: Check the check box to use the MD5 hash algorithm for authentication of EIGRP packets.
- **Key Type**: Select one key type from the drop-down list:
  - **None**: Indicates that no authentication is required.
  - **Unencrypted**: Indicates that the key string is a clear text password for authentication.
  - **Encrypted**: Indicates that the key string is an encrypted password for authentication.
  - **Auth Key**: Indicates that the key string is an EIGRP authentication key.
- **Key ID**: The ID of the key that is used to authenticate EIGRP updates. Enter a numerical key identifier. Valid values range from 0 to 255.
- **Key**: An alphanumeric character string up to 17 characters. For an encrypted authentication type, this field should have a minimum of 17 characters.
- **Confirm Key**: Re-enter the key.

Step 8 Click **OK**.

Step 9 Click **Save**.

The EIGRP interface settings that you configured are saved. The interface uses the specified hello interval, hold time, split-horizon setting, delay time, and authentication parameters for EIGRP routing operations.

Configure EIGRP advanced settings

Configure EIGRP advanced settings to optimize routing behavior and performance in your network.

To configure EIGRP advanced settings, perform these steps:

Procedure

Step 1 On the **EIGRP** page, click the **Advanced** tab.

Step 2 Under **Default Route Information**, specify the sending and receiving of default route information in EIGRP updates.

- (Appears for non-cluster and cluster in spanned etherchannel mode)**Router ID (IP Address)**: Enter the ID used to identify the originating router for external routes. If an external route is received with the local router ID, the route is discarded. Specify a global address for the router ID to prevent this issue. Each EIGRP router requires a unique value.
- (Appears only for a cluster in individual interface mode)**IPv4 Address Pool**: Select the relevant cluster pool value (IPv4 address pool object). To create the address pool, refer to Configure address pools, on page 2954.
- **Accept Default Route Info**: Check the check box to configure EIGRP to accept default route information.
  - **Access List**: From the **Access List** drop-down list, specify a standard access list that defines the networks that are allowed and the networks that are not when receiving default route information.

    To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2953.
- **Send Default Route Info**: Check the check box to configure EIGRP to advertise exterior default routing information.
  - **Access List**: From the **Access List** drop-down list, specify a standard access list that defines the networks that are allowed and the networks that are not when sending default route information.

    To add a new standard access list object, click +. For more information, refer to Configure a standard ACL object, on page 2953.

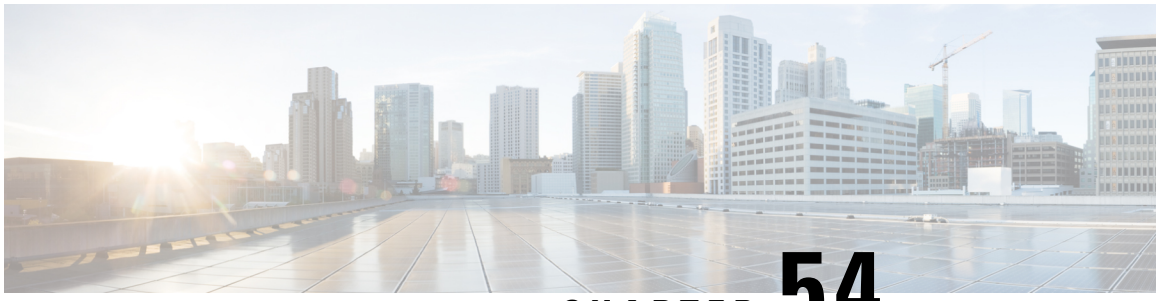
Step 3 Under **Administrative Distance**, specify:

- **Internal Distance**: Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system. Valid values range from 1 to 255. The default value is 90.
- **External Distance**: Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a neighbor external to the autonomous system. Valid values range from 1 to 255. The default value is 170.

Step 4 Under **Adjacency Changes**, specify:

- **Log Neighbor Changes**: Check the check box to enable the logging of EIGRP neighbor adjacency changes.

- **Log Neighbor Warnings**: Check the check box to enable the logging of EIGRP neighbor warning messages.
- (Optional) Enter the time interval (in seconds) between repeated neighbor warning messages. Valid values range from 1 to 65535. Repeated warnings are not logged if they occur during this interval.



Step 5 Under **Stub**, to enable the device as an EIGRP stub routing process, click one or more of the EIGRP stub routing processes check boxes:

- **Receive only**: Configures the EIGRP stub routing process to receive route information from the neighbor routers but not send route information to the neighbors. If this option is selected, you cannot select any of the other stub routing options.
- **Connected**: Advertises connected routes.
- **Redistributed**: Advertises redistributed routes.
- **Static**: Advertises static routes.
- **Summary**: Advertises summary routes.

Step 6 Under **Default Metrics**, define the default metrics for routes redistributed to the EIGRP routing process:

- **Bandwidth**: The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay Time**: The route delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability**: The likelihood of successful packet transmission expressed as a number from 0 to 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**: The effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loading.
- **MTU**: The smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.

EIGRP advanced settings are configured according to your specifications, optimizing routing behavior and performance.

CHAPTER 54

BGP

This section describes how to configure the Firewall Threat Defense to route data, perform authentication, and redistribute routing information using the Border Gateway Protocol (BGP).

- BGP, on page 1491
- Requirements and prerequisites for BGP, on page 1495
- Guidelines for BGP, on page 1495
- Configure BGP, on page 1496

BGP

Border Gateway Protocol (BGP) is an inter- and intra-autonomous system routing protocol that

- operates within and between autonomous systems (networks or groups of networks under common administration with common routing policies),
- exchanges routing information for the Internet, and
- serves as the protocol used between Internet service providers (ISPs).

Routing tables

A routing table is a network database that

- records paths to destination networks based on exchanged routing information
- updates dynamically as neighbors share new or modified routing routes, and
- determines the optimal path to a destination without requiring periodic updates.

BGP attributes for route selection

Routes learned via BGP have several attributes that determine the best path when multiple routes to a destination exist. The most important BGP attributes include:

- Weight: A Cisco-defined attribute that is local to a router. It is not advertised to neighboring routers. Among multiple routes to the same destination, the route with the highest weight is preferred.

- Local preference: This attribute selects an exit point from the local autonomous system (AS) and is shared throughout the local AS. If multiple exit points exist, the one with the highest local preference attribute is chosen for a specific route.
- Multi-exit discriminator: The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.
- Origin: The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  - IGP: The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  - EGP: The route is learned via the Exterior Border Gateway Protocol (EBGP).
  - Incomplete: The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.
- AS_PATH: When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS_PATH list is installed in the IP routing table.
- Next hop: The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS. However, when the next hop is in the same subnet the peering address of the EBGP peer, the next hop is not modified. This behavior is referred to as the third-party next hop.

  Use the **next-hop-self** command when redistributing VPN-advertised routes to IBGP as peers to ensure that the routes are redistributed with the correct next hop IP.
- Community: The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  - no-export: Do not advertise this route to EBGP peers.
  - no-advertise: Do not advertise this route to any peer.
  - internet: Advertise this route to the Internet community; all routers in the network belong to it.

Note As loop detection is done by scanning the full AS_PATH (as specified in the AS_PATH attribute), and checking that the AS number of the local system does not appear in the AS_PATH. By default, EBGP advertises the learned routes to the same peer to prevent additional CPU cycles on the device in performing loop checks and to avoid delays in the existing outgoing update tasks.

BGP usage scenarios

BGP usage scenarios are network configurations that

- enable ISPs to exchange customer and ISP routes between autonomous systems using External BGP (EBGP),
- allow service providers to exchange routes within an autonomous system using Interior BGP (IBGP), and
- support IPv6 prefix routing over IPv6 networks.

BGP implementation contexts

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

BGP can also be used for carrying routing information for IPv6 prefix over IPv6 networks.

BGP path selection

BGP path selection is a routing process that selects only one path as the best path when BGP receives multiple advertisements for the same route from different sources, puts the selected path in the IP routing table, and propagates the path to its neighbors using specific criteria in order of precedence.

BGP path selection criteria

BGP uses these criteria, in the order presented, to select a path for a destination:

1. If the path specifies a next hop that is inaccessible, drop the update. Otherwise, prefer the path with the largest weight.
2. If the weights are the same, prefer the path with the largest local preference. If the local preferences are the same, prefer the path that was originated by BGP running on this router.
3. If no route was originated, prefer the route that has the shortest AS_PATH. If all paths have the same AS_PATH length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
4. If the origin codes are the same, prefer the path with the lowest MED attribute. If the paths have the same MED, prefer the external path over the internal path.
5. If the paths are still the same, prefer the path through the closest IGP neighbor.
6. Determine if multiple paths require installation in the routing table for BGP multipath, on page 1493.
7. If both paths are external, prefer the path that was received first (the oldest one).
8. Prefer the path with the lowest IP address, as specified by the BGP router ID. If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
9. Prefer the path that comes from the lowest neighbor address.

BGP multipath

BGP multipath is a BGP feature that

- allows installation into the IP routing table of multiple equal-cost BGP paths to the same destination prefix,
- enables traffic to the destination prefix to be shared across all installed paths, and
- does not affect best path selection algorithm.

BGP multipath requirements

These paths are installed in the table together with the best path for load-sharing. BGP multipath does not affect best path selection. For example, a router still designates one of the paths as the best path, according to the algorithm, and advertises this best path to its BGP peers.

In order to be candidates for multipath, paths to the same destination need to have these characteristics equal to the best-path characteristics:

- Weight
- Local preference
- AS-PATH length
- Origin code
- Multi Exit Discriminator (MED)
- One of these:
  - Neighboring AS or sub-AS (before the addition of the BGP Multipaths)
  - AS-PATH (after the addition of the BGP multipaths)

Some BGP multipath features put additional requirements on multipath candidates:

- The path should be learned from an external or confederation-external neighbor (eBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric.

These are the additional requirements for internal BGP (iBGP) multipath candidates:

- The path should be learned from an internal neighbor (iBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric, unless the router is configured for unequal-cost iBGP multipath.

BGP inserts up to *n* most recently received paths from multipath candidates into the IP routing table, where *n* is the number of routes to install in the routing table, as specified when you configure BGP multipath. The default value, when multipath is disabled, is 1.

For unequal-cost load balancing, you can also use BGP Link Bandwidth.

Note The equivalent next-hop-self is performed on the best path that is selected among eBGP multipaths before it is forwarded to internal peers.

Requirements and prerequisites for BGP

This reference provides the requirements and prerequisites necessary for configuring BGP on supported devices.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Admin

Network Admin

Guidelines for BGP

Context mode guidelines

Consider these context mode requirements when implementing BGP.

- Supported in single and multiple context modes.
- Only one Autonomous System (AS) number is supported for all contexts.

Firewall mode guidelines

Does not support transparent firewall mode. BGP is supported only in routed mode.

IPv6 guidelines

Supports IPv6.

Additional guidelines

Consider these additional operational requirements and limitations.

- For BGP, the next hop IP address for the routes is the network IP address and not 0.0.0.0.
- The system does not add a route entry for the IP address received over PPPoE in the CP route table. BGP always looks into the CP route table for initiating the TCP session, hence BGP does not form TCP session.

  Thus, BGP over PPPoE is not supported.
- BGP is not supported on management-only or BVI interfaces.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.

- BGP with PATH MTU (PMTU) can cause adjacency flaps if MTU discovery fails, especially with ECMP routing. Hence, be cautious while using BGP, PMTU, and ECMP as packet drops can occur if MTU discovery fails due to any reason.
- The BGP table of the member unit is not synchronized with the control unit table. Only its routing table is synchronized with the control unit routing table.
- Enable the graceful timeout feature when you use BGP on Firewall Threat Defense devices that are configured in high availability mode. Enabling this feature reduces packet drops that occur due to issues related to BGP convergence.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the TTL hop count is greater than one if you use BGP as the routing protocol.
- On Firewall Threat Defense devices, changing a large number of BGP neighbors from iBGP to eBGP in a single deployment can fail. During deployment, Cloud-Delivered Firewall Management Center can remove and re-create the same peer in immediate succession, and the deployment can fail if the previous peer deletion is still in progress. To avoid this issue, split the changes across multiple deployments. Remove or modify a subset of neighbors, deploy the configuration, and then apply additional neighbor changes in subsequent deployments.

Configure BGP

Configure BGP routing protocol to establish peering relationships and control route advertisement between autonomous systems.

BGP configuration involves multiple components including basic settings, neighbor relationships, route filtering, and redistribution policies.

Procedure

Step 1 Configure basic BGP settings, on page 1497

Step 2 Configure BGP general settings, on page 1499

Step 3 Configure BGP Neighbor Settings, on page 1500

Step 4 Configure BGP aggregate address settings, on page 1504

Step 5 Configure BGPv4 filtering settings, on page 1505

Note
The Filtering section is applicable only to IPv4 settings

Step 6 Configure BGP network settings, on page 1506

Step 7 Configure BGP redistribution settings, on page 1507

Step 8 Configure BGP route injection settings, on page 1508

Step 9 Configure BGP route import and export, on page 1509

BGP is configured with all necessary settings, enabling dynamic routing and proper route exchange between autonomous systems.

Configure basic BGP settings

Enable and customize BGP settings to control routing behavior and improve network operations.

You can set many basic settings for BGP.

For a device using virtual routing, the basic settings described in this section must be configured in the **BGP** page under **General Settings**. For more information, refer to Modifications to the Cloud-Delivered Firewall Management Center web interface routing page.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** and do the following:

a) (For a virtual-router-aware device) Under **General Settings**, click **BGP**.

b) Check the **Enable BGP** check box to enable the BGP routing process.

c) In the **AS Number** field, enter the autonomous system (AS) number for the local BGP process. The AS number internally includes multiple autonomous numbers. Valid values are from 1 to 4294967295 or from 1.0 to 65535.65535 when a dot notation is used. The AS number is a uniquely assigned value that identifies each network on the Internet.

d) In the **Router Id** drop-down list, choose **Automatic** or **Manual** (appears for non-cluster and a cluster in spanned etherchannel mode) or **Cluster Pool** (appears for a cluster in individual interface mode). If you choose **Automatic**, the highest-level IP address on the Firewall Threat Defense device is used as the router ID. If you choose **Manual**, enter the IP address in the **IP Address** field. If you choose **Cluster Pool**, enter the cluster pool value in the **Cluster Pool** field. For more information on creating the cluster pool address, refer to Configure address pools, on page 2954..

e) To use a fixed router ID, choose **Manual** and enter an IPv4 address in the **IP Address** field. The default value is **Automatic**. For a virtual router-aware device, you can override the router ID settings in the **Virtual Routers** > **BGP** page.

Step 3 (Optional) Edit the various BGP settings, starting with **General**. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network. Click **Edit** ( ) to edit the settings in the group:

a) Enter a **Scanning Interval** for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.

b) In the **Number of AS numbers in AS_PATH attribute of received routes** field, enter the maximum number of AS numbers allowed in the AS_PATH attribute of received routes. An AS_PATH attribute is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Valid values are between 1 and 254. The default value is **None**.

c) Check the **Log Neighbor Changes** check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability. This is enabled by default.

d) Check the **Use TCP path MTU discovery** check box to use the Path MTU determining technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation. This is enabled by default.

e) Check the **Reset session upon failover** check box to reset the external BGP session immediately upon link failure. This is enabled by default.

f) Check the **Enforce the first AS is peer's AS for EBGP routes** check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH

attribute. This prevents a misconfigured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system. This is enabled by default.

g) Check the **Use dot notation for AS number** check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 1 to 65535 are represented as decimal numbers, and AS numbers greater than 65535 are represented using dot notation. This is disabled by default.

h) Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

i) Click **OK**.

Step 4 (Optional) Edit the **Best Path Selection** section:

a) Enter a value for **Default local preference** between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.

b) Check the **Allow comparing MED from different neighbors** check box to allow the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. This is disabled by default.

c) Check the **Compare Router ID for identical EBGP paths** check box to compare similar paths received from external BGP peers during the best path selection process and switch the best path to the route with the lowest router ID. This is disabled by default.

d) Check the **Pick the best-MED path among paths advertised by neighbor AS** check box to enable MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path. This is disabled by default.

e) Check the **Treat missing MED as the least preferred path** check box to consider the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred. This is disabled by default.

f) Click **OK**.

Step 5 (Optional) Edit the **Neighbor Timers** section:

a) Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message in the **Keepalive interval** field. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.

b) Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Hold time** field. The default value is 180 seconds. Specify a value from 0 to 65535.

c) (Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Min Hold time** field. Specify a value from 3 to 65535.

Note
A hold time of less than 20 seconds increases the possibility of peer flapping.

d) Click **OK**.

Step 6 In the **Next Hop** section, optionally check the **Address tracking** check box to enable BGP next hop address tracking and enter the **Delay Interval** between checks on updated next-hop routes installed in the routing table. Click **OK**.

Note
The **Next Hop** section is applicable only to IPv4 settings.

Step 7 (Optional) Edit the **Graceful Restart** section:

Note
This section is available only when the Firewall Threat Defense device is in failover or spanned cluster mode. This is done so that there is no drop in packets in the traffic flow, when one of the devices in the failover setup fails.

a) Check the **Enable Graceful Restart** check box to enable Firewall Threat Defense peers to avoid a routing flap following a switchover.
b) Specify the time duration that Firewall Threat Defense peers will wait to delete stale routes before a BGP open message is received in the **Restart Time** field. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.
c) Enter the time duration that the Firewall Threat Defense will wait before deleting stale routes after an end of record (EOR) message is received from the restarting Firewall Threat Defense in the **Stalepath Time** field. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.
d) Click **OK** and then click **Save**.

Step 8 To view the BGP basic settings, from the virtual routers drop-down, select the desired router, and then click **BGP**.

This page displays the basic settings that are configured in the **Settings** page. You can edit the router ID settings on this page.

Step 9 To edit the router ID settings, modify the IP address in the **IP Address** fields. The modified value overrides the router ID settings that were configured on the **BGP** page under **General Settings**.

The device is configured with basic BGP settings, enabling BGP routing, specifying the AS number, router ID, and any custom parameters you set.

Configure BGP general settings

Configure route maps, administrative route distances, synchronization, next-hop, and packet forwarding for BGP to optimize routing performance in your network.

The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, select the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 In the **General** tab, update the following sections:

a) In the **Setting** section, enter or select a **RouteMap** object and click **OK**.

Note
The **RouteMap** field is applicable only to IPv4 settings.

b) In the **Administrative Route Distances** section, update the following as required, and click **OK**:

- **External**: Enter the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
- **Internal**: Enter administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
- **Local**: Enter administrative distance for local BGP routes. Local routes are routes originated by the local BGP process, such as networks specified with the network router configuration command or routes redistributed into BGP from another routing process. The range of values for this argument is from 1 to 255. The default value is 200.

c) In the **Routes and Synchronization** section, update the following as required, and click **OK**:

- (Optional) **Generate default routes**: Check the check box of this option to configure default-information originate.
- (Optional) **Summarize subnet routes into network level routes**: Check the check box of this to configure automatic summarization of subnet routes into network-level routes. This check box is applicable only to IPv4 settings.
- (Optional) **Advertise inactive routes**: Check the check box of this to advertise routes that are not installed in the routing information base (RIB).
- (Optional) **Synchronize between BGP and IGP systems**: Check the check box of this to enable synchronization between BGP and your Interior Gateway Protocol (IGP) system. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems.
- (Optional) **Redistribute IBGP into IGP**: Check the check box of this to configure IBGP redistribution into an interior gateway protocol (IGP), such as OSPF.

d) In the **Forward Packets Over Multiple Paths** section, update the following as required and click **OK**:

- (Optional) **Number of Paths**: Enter the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.
- (Optional) **IBGP Number of Paths**: Enter the maximum number of parallel internal Border Gateway Protocol (IBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

Step 5 Click **Save**.

BGP general settings are configured with your specified route maps, administrative distances, synchronization options, and multi-path forwarding parameters.

Configure BGP Neighbor Settings

Define and customize BGP neighbor connections on your device for efficient routing and advanced peer management.

A BGP router must connect with each of its peers before exchanging updates. These peers are called BGP neighbors. Perform this procedure to define BGP IPv4 or IPv6 neighbors and neighbor settings.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

(For a virtual router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring BGP.

Step 2 Choose **BGP** > **IPv4** or **IPv6**. Click **Neighbor**.

Step 3 Click **Add** to define BGP neighbors and neighbor settings.

a) Enter the BGP neighbor **IP address**. This IP address is added to the BGP neighbor table. When you are configuring BGP IPv6 on static VTI, enter the virtual tunnel IP address of the neighbor. Choose the BGP neighbor **Interface**.

Note
The **Interface** field is only applicable to IPv6 settings.

b) Enter the autonomous system to which the BGP neighbor belongs, in the **Remote AS** field. Check the **Enabled address** check box to enable communication with this BGP neighbor. Further neighbor settings will be configured only if the **Enabled address** check box is selected.

c) (Use this option only when the routing does not result in a loop.) Check the **AS Override** check box to enable overriding of the AS number of the originating router with the AS number of the sending BGP router.

Note
Loop prevention in BGP is achieved by verifying the AS number in the AS path. BGP rejects route updates when the AS path attribute contains its own AS number. However, in circumstances where the same ASN is used by discontiguous network segments, to establish end-to-end reachability, you can opt to override the AS number with that of the sending BGP router.

d) (Optional) Check the **Shutdown administratively** check box to disable a neighbor or peer group.

e) (Optional) Check the **Configure graceful restart (failover / spanned mode)** check box to enable configuration of the BGP graceful restart capability for this neighbor. After selecting this option, you must check the **Enable graceful restart** check box to specify whether graceful restart should be enabled or disabled for this neighbor.

Note
- The graceful restart is enabled only when the device is in HA mode or when L2 cluster (all nodes from the same network) is configured.
- The graceful restart option for BGPv6 is enabled only on Firewall Threat Defense Version 7.3+.
- If you configure graceful restart only at General Settings and not at BGP IPv6, the global General Settings configuration persists.
- If you configure graceful restart at General Settings and also at BGP IPv6, the global General Settings configuration is overridden by the BGP IPv6 configuration settings.

f) (Optional) To enable configuration of the BFD support for BGP, from the **BFD Fallover** drop-down list, choose the BFD type—single-hop, multi-hop, or auto-detect-hop. This selection registers the BGP neighbor

to receive forwarding path detection failure messages from BFD. Choose None if you do not want to have BFD support.

g) (Optional) Enter a **Description** for the BGP neighbor.

h) (Optional) From the **Update Source** drop-down list, choose an interface to source the BGP packets.

You can choose a loopback address as this interface to overcome path failures. You can also choose any physical, port-channel, or a sub-interface.

Step 4 (Optional) In **Filtering Routes**, use access lists, route maps, prefix lists and AS path filters as required, to distribute BGP Neighbor information. Update the following sections:

a) Choose or select the appropriate incoming or outgoing **Access List** to distribute BGP neighbor information.

Note
Access lists are only applicable to IPv4 settings.

b) Choose or select the appropriate incoming or outgoing **Route Maps** to apply a route map to incoming or outgoing routes.

c) Choose or select the appropriate incoming or outgoing **Prefix List** to distribute BGP neighbor information.

d) Choose or select the appropriate incoming or outgoing **AS path filter** to distribute BGP neighbor information.

e) Check the check box of **Limit the number of prefixes allowed from the neighbor** to control the number of prefixes that can be received from a neighbor.

- Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
- Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.

f) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following:

- Check the **Terminate peering when prefix limit is exceeded** check box to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the **Restart interval** field.
- Check the **Give only warning message when prefix limit is exceeded** check box to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

g) Click **OK**.

Step 5 (Optional) In **Routes**, specify miscellaneous Neighbor route parameter. Proceed to update the following:

a) Enter the minimum interval (in seconds) between the sending of BGP routing updates in the **Advertisement Interval** field. Valid values are between 1 and 600.

b) Check the **Remove private AS numbers from outbound routing updates** check box to exclude the private AS numbers from being advertised on outbound routes.

c) Check the **Generate default routes** check box to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the **Route map** field.

d) To add conditionally advertised routes, click Add Row +. In the Add Advertised Route dialog box, do the following:

1. Add or choose a route map in the **Advertise Map** field, that will be advertised if the conditions of the exist map or the non-exist map are met.
2. Click **Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
3. Click **Non-Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
4. Click **OK**.

Step 6 In **Timers**, check the **Set timers for the BGP peer** check box to set the keepalive frequency, hold time, and minimum hold time.

- **Keepalive interval**: Enter the frequency (in seconds) with which Firewall Threat Defense sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
- **Hold time**: Enter the interval (in seconds) after not receiving a keepalive message that Firewall Threat Defense declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
- **Min hold time**: (Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that Firewall Threat Defense declares a peer dead. Valid values are between 3 and 65535. The default value is 3 seconds.

  Note
  A hold time of less than 20 seconds increases the possibility of peer flapping.

Step 7 In **Advanced**, update the following:

a) (Optional) Check the **Enable Authentication** check box to enable MD5 authentication on a TCP connection between two BGP peers.

1. Choose an encryption type from the **Enable Encryption** drop-down list.
2. Enter a password in the **Password** field. Reenter the password in the **Confirm Password** field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The string can contain any alphanumeric characters, including spaces.

   Note
   You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.

b) (Optional) Select the **Send Community attribute to this neighbor** check box to specify that community attributes should be sent to the BGP neighbor

c) (Optional) Select the **Use FTD as next hop for this neighbor** check box to configure the router as the next-hop for a BGP speaking neighbor or peer group.

d) Select the **Disable Connection Verification** check box to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly

connected to same network segment, connection verification will prevent the peering session from being established.

e) Select **Allow connections with neighbor that is not directly connected** to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the **TTL hops** field. Valid values are between 1 and 255. However, for eBGP multi-hop neighborship configuration, you must enter the **TTL hops** value. Alternatively, select **Limited number of TTL hops to neighbor**, to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the **TTL hops** field. Valid values are between 1 and 254.

f) (Optional) Select the **Use TCP MTU path discovery** check box to enable a TCP transport session for a BGP session.

g) Choose the TCP connection mode from the **TCP Transport Mode** drop-down list. Options are Default, Active, or Passive.

h) (Optional) Enter a **Weight** for the BGP neighbor connection.

i) Select the **BGP Version** that Firewall Threat Defense will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.

Step 8 Update **Migration**, only if AS migration is considered.

Note
The AS migration customization should be removed after transition has been completed.

a) (Optional) Check the **Customize the AS number for routes received from the neighbor** check box to customize the AS_PATH attribute for routes received from an eBGP neighbor.

b) Enter the local autonomous system number in the **Local AS number** field. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.

c) (Optional) Check the **Do not prepend local AS number to routes received from neighbor** check box to prevent the local AS number from being prepended to any routes received from eBGP peer.

d) (Optional) Check the **Replace real AS number with local AS number in routes received from neighbor** check box to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.

e) (Optional) Check the **Accept either real AS number or local AS number in routes received from neighbor** check box to configure the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Step 9 Click **OK**, and then click **Save**.

The BGP neighbor and its associated advanced settings are configured. The device can now establish and manage BGP sessions as specified, ensuring effective routing and network reachability.

Configure BGP aggregate address settings

Route aggregation combines the attributes of several different routes so that only a single route is advertised, reducing the number of routes that need to be advertised.

BGP neighbors store and exchange routing information and the amount of routing information increases as more BGP speakers are configured. Route aggregation is the process of combining the attributes of several different routes so that only a single route is advertised. Aggregate prefixes use the classless interdomain routing (CIDR) principle to combine contiguous networks into one classless SET of IP addresses that can be

summarized in routing tables. As a result fewer routes need to be advertised. Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

Procedure

Step 1 When editing the Firewall Threat Defense device, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Add Aggregate Address**.

Step 5 Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

Step 6 Click (+)**Add** and update the **Add Aggregate Address** dialog box:

a) **Network**: Enter an IPv4 address or select the desired network/hosts objects.
b) **Attribute Map**: (Optional) Enter or select the route map used to SET the attribute of the aggregate route.
c) **Advertise Map**: (Optional) Enter or select the route map used to select the routes to create AS_SET origin communities.
d) **Suppress Map**: (Optional) Enter or select the route map used to select the routes to be suppressed.
e) **Generate AS SET path Information**: (Optional) Check the check box to enable generation of autonomous system SET path information.
f) **Filter all routes from updates**: (Optional) Check the check box to filter all more-specific routes from updates.
g) Click **OK**.

The BGP aggregate address settings are configured and fewer routes need to be advertised due to route aggregation.

What to do next

- For BGPv4 settings, proceed to Configure BGPv4 filtering settings, on page 1505.
- For BGPv6 settings, proceed to Configure BGP network settings, on page 1506.

Configure BGPv4 filtering settings

Configure filtering settings to filter routes or networks received in incoming BGP updates and restrict routing information that the router learns or advertises.

Filtering settings are used to filter routes or networks received in incoming BGP updates. Filtering is used to restrict routing information that the router learns or advertises.

Before you begin

Filtering is only applicable for a BGP IPv4 routing policy.

Follow these steps to configure BGPv4 filtering settings:

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4**.

Step 4 Click **Filtering**.

Note
The **Filtering** field is applicable only to IPv4 settings.

Step 5 Click (+)**Add** and update the **Add Filter** dialog box:

a) **Access List**: Choose an access control list that defines which networks are to be received and which are to be suppressed in routing updates.

b) **Direction**: (Optional) Choose a direction that specifies if the filter should be applied to inbound updates or outbound updates.

c) **Protocol**: (Optional) Choose the routing process for which you want to filter: None, BGP, Connected, OSPF, RIP, or Static.

d) **Process ID**: (Optional) Enter the process ID for the OSPF routing protocol.

e) Click **OK**.

Step 6 Click **Save**.

BGPv4 filtering settings are configured to filter routes or networks based on the specified access control list and filtering criteria.

Configure BGP network settings

Configure BGP network settings to control which networks are advertised by the BGP routing process and to apply route map filters for network advertisement.

Network settings are used to add networks that will be advertised by the BGP routing process and route maps that will be examined to filter the networks to be advertised.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Networks**.

Step 5 Click **Add** and update the **Add Networks** dialog box:

a) **Network**: Choose the network to be advertised by the BGP routing processes.

Note
For a network prefix to be advertised, a route to the device must exist on the routing table.

To add a new network object, refer to Create a network object, on page 2985.

b) (Optional) **Route Map**: Enter or choose a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed. To add a new route map object, refer to Configure a route map, on page 3017.

c) Click **OK**.

Step 6 Click **Save**.

The BGP network settings are configured with the specified networks and route maps for advertisement filtering.

Configure BGP redistribution settings

Configure redistribution settings to define the conditions for redistributing routes from another routing domain into BGP.

Redistribution settings allow you to define the conditions for redistributing routes from another routing domain into BGP.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Redistribution**.

Step 5 Click **Add** and update the **Add Redistribution** dialog:

a) **Source Protocol**: Select the protocol from which you want to redistribute routes into the BGP domain from the Source Protocol drop-down list.

Note
User-defined virtual routers do not support redistributing routes from RIP.

b) **Process ID**: Enter the identifier for the selected source protocol. Applies to the OSPF protocol. For devices using virtual routing, this drop-down lists the process ID assigned for the virtual router for which you are configuring the BGP settings.

c) **Metric**: (Optional) Enter a metric for the redistributed route.

d) **Route Map**: Enter or select a route map that should be examined to filter the networks to be redistributed.

If not specified, all networks are redistributed. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Configure Route Map Entry.

e) **Match**: The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more conditions. These options are enabled only when OSPF is chosen as the Source Protocol.

- Internal
- External 1
- External 2
- NSSA External 1
- NSSA External 2

f) Click **OK**.

The BGP redistribution settings are configured and routes from the specified source protocol are redistributed into the BGP domain according to the defined conditions.

Configure BGP route injection settings

Configure BGP route injection settings to control which routes are conditionally injected into the BGP routing table based on defined criteria.

Route injection settings allow you to define the routes to be conditionally injected into the BGP routing table.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Route Injection**.

Step 5 Click **Add** and update the **Add Route Injection** dialog box:

a) **Inject Map**: Enter or select the route map that specifies the prefixes to inject into the local BGP routing table. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Configure Route Map Entry.

b) **Exist Map**: Enter or select the route map containing the prefixes that the BGP speaker will track.

c) **Injected routes will inherit the attributes of the aggregate route**: Check this box to configure the injected route to inherit attributes of the aggregate route.

d) Click **OK**.

Step 6 Click **Save**.

The BGP route injection settings are configured and the specified routes will be conditionally injected into the BGP routing table according to the defined route maps.

Configure BGP route import and export

This task enables you to implement inter-virtual-router route leaking in BGP by importing or exporting routes using route target extended communities, allowing controlled sharing of routes between virtual routers.

In BGP, you can implement an inter-virtual-router route leak by importing or exporting routes using the route target extended community of the destination and source virtual routers respectively. You can use a route map to filter the desired route targets instead of leaking the entire routing table. You can also leak the routes of global virtual router to user-defined virtual routers and vice versa.

- You can configure BGP to leak routes between two user-defined virtual routers using the route target extended communities:
  - Tag the routes with the route targets from the source virtual router using route target export.
  - Import the routes that are matching the route targets into the destination virtual router using route target import.
  - Optionally, you can filter routes from source virtual router or to destination virtual router using export or import route maps respectively. You can configure route map with match extended community list for filtering the routes. Similarly, you can configure route map with set extended community route targets to tag the routes with the route target extended community.
- To import routes from the global virtual router to a user-defined virtual router, specify the IPv4/IPv6 route map in Global Virtual Router Import Route Map to import to the user-defined virtual router.
- To export routes from a user-defined virtual router to the global virtual router, in addition to exporting the route targets, you can also specify the Global Virtual Router Export Route Map to export from the user-defined virtual router.

The BGP inter-virtual-router route leaking supports both IPv4 and IPv6 prefixes.

Before you begin

- Create virtual routers.
- Enable BGP on the virtual router.
- Configure BGP, on page 1496.

Follow these steps to configure BGP route import/export settings:

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 (Supported for virtual routers only) Click **Route Import/Export**.

Step 5 In the **Route Targets Import** field, enter the route target extended community that you want to match for the routes to be imported. On deployment, the routes of the destination virtual router that match this value are imported to the source virtual router's BGP table.

Note

- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma-separated values.
- This value can range from 0:1 to 65534:65535.

Step 6 In the **Route Targets Export** field, enter the route target extended community to tag the source virtual router's routes with the route target value. On deployment, the routes of the source virtual router are tagged with this value.

Note

- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma separated values.
- This value can range from 0:1 to 65534:65535.

Step 7 Route maps help you to narrow down the routes to be shared instead of leaking the entire routing table. Route map filtering is applied on the list of routes that are obtained with the specified route target values:

a) (Optional) Under **User Virtual Router**, choose the route map from the **Import Route Map** drop-down list to filter the routes at the destination virtual router.

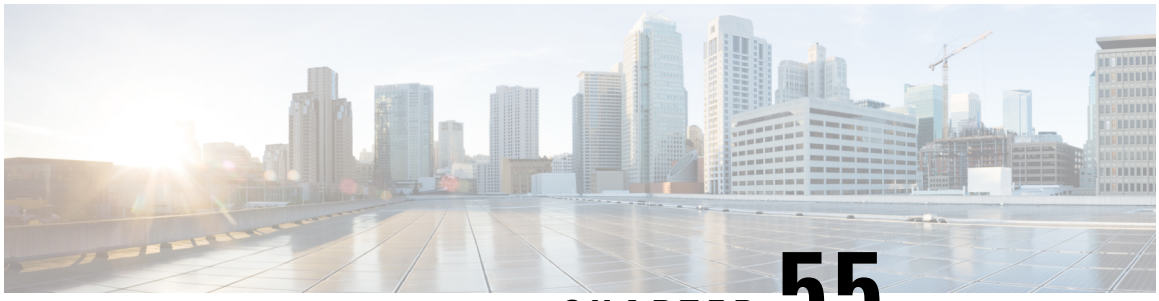
Note
The user virtual router import route map is effective only when the route targets import is configured.

b) (Optional) Under **User Virtual Router**, choose the route map from the **Export Route Map** drop-down list to filter the routes at the source virtual router before the routes are exported to other virtual routers.

Note
You can use the match and set clauses in the route map with the route target extended community lists for filtering based on other criteria or tagging the routes with the route target community values. For more information, refer to Configure a route map, on page 3017.

Step 8 To share the routes between a user-defined virtual router and global virtual router, specify the route map under the **Global Virtual Router**:

a) To leak the global virtual router routes to the user-defined virtual router, select the route map from the **Import Route Map** drop-down list. The IPv4 or IPv6 route map is imported to the user-defined virtual router.



b) To leak the user-defined virtual router routes to the global virtual router, select the route map from the **Export Route Map** drop-down list. The IPv4 or IPv6 route map is exported to the global virtual router.

Note
You must specify the route targets for export apart from specifying the route map.

Note
You can use the match clause of the route map object to filter the routes for leaking. For more information, refer to Configure a route map, on page 3017.

Step 9 Follow the procedure (Step 3 to Step 8) to configure relevant BGP route import and export settings for other virtual routers as well. Click **Save**, then **Deploy** to apply your import/export settings.

When the packets flow into the ingress virtual router, BGP imports the routes from the destination virtual routers that have the matching route target value and if a route map is also configured, the routes are further filtered and used to identify the best path routes for routing the packets.

CHAPTER 55

RIP

The Routing Information Protocol (RIP) is a distance-vector routing protocol that

- enables devices to exchange routing information,
- supports authentication mechanisms, and
- facilitates redistribution of routing information.

RIP Configuration Constraints

There are constraints when deploying RIP on the Firewall Threat Defense:

- RIP configuration is restricted to the global virtual router and is not supported for user-defined virtual routers.

- RIP, on page 1513
- Requirements and prerequisites for RIP, on page 1516
- Guidelines for RIP, on page 1516
- Configure RIP, on page 1517

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that

- uses hop count as the metric for path selection,
- exchanges RIP broadcasts with neighboring devices to dynamically learn and advertise routes, and
- includes four basic components: routing update process, RIP routing metrics, routing stability, and routing timers.

RIP characteristics and versions

RIP is a widely used routing protocol. It sends routing updates at regular intervals and when the network topology changes. These updates provide information about network reachability and the number of hops to each destination..

You can configure RIP with less effort than OSPF, but it generates more network traffic. RIP supports both Version 1 and Version 2.

Secure Firewall Threat Defense device supports both RIP Version 1 and Version 2. RIP Version 1 does not send subnet masks with its updates; Version 2 supports variable-length subnet masks and neighbor authentication to ensure trusted routing information exchanges.

RIP offers simple configuration and adapts to topology changes. In contrast, static routes require manual updates for each change. RIP, however, incurs higher network and processing overhead compared to static routing.

How RIP routing updates work

Summary

Key components in the RIP routing update process include:

- RIP routers: Send and receive routing update messages to maintain network topology information
- Routing tables: Store the best routes to destinations with associated metric values
- Routing update messages: Contain network topology changes and route information
- Metric values: Determine the best path, with routers maintaining only the lowest metric route

Workflow

The process involves these stages:

1. RIP routers send routing-update messages at regular intervals and when the network topology changes.
2. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop.
3. RIP routers maintain only the best route to a destination, which is the route with the lowest metric value.
4. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates occur independently from regularly scheduled RIP router updates.

RIP routing metric

A RIP routing metric is a network measurement that

- calculates the distance between a source and a destination network,
- assigns a hop count value, typically 1, to each hop in a network path from the source to the destination, and
- updates the routing table when new routing data is received, using the sender's IP address as the next hop.

RIP stability features

RIP stability features are routing mechanisms that

- prevent routing loops by setting a limit on the number of hops in a path from source to destination,
- provide stability despite potentially rapid changes in network topology, and
- include split horizon and hold-down mechanisms to prevent incorrect routing information propagation.

Additional stability mechanisms

The maximum number of hops allowed in a path is 15. If a routing update shows a new or changed entry, the system increases the metric value to infinity (16), which makes the network destination unreachable. This stability mechanism limits the maximum diameter of a RIP network to fewer than 16 hops.

RIP timers

RIP timers are network protocol mechanisms that

- regulate RIP performance through timed intervals for routing updates and route management,
- control when routes are marked invalid, placed in holddown, or flushed from the routing table, and
- help prevent network congestion by managing the timing of routing updates across devices.

RIP timer stages

RIP uses numerous timers to regulate its performance. These are the timer stages for RIP:

- Update: The routing-update timer is the interval between periodic routing updates. This is how often the device sends routing updates. Generally, set to 30 seconds, a small random delay added to prevent simultaneous route updates.
- Invalid: Each routing table entry has a route-timeout timer for the last valid update. The route is marked invalid and moves to holddown once the timer expires. The default is 180 seconds (3 minutes).
- Holddown: The period the system waits before accepting any new updates for invalid routes. The default is 180 seconds (3 minutes).
- Flush: The route-flush timer marks the period from when the system receives the last valid update until the route is discarded and removed from the routing table. The default is 240 seconds (4 minutes).

RIP timer sequence when adjacent router interface goes down

When an adjacent router goes down, routing updates stop, and the Invalid and Flush timers start increasing. In the first 180 seconds, nothing will happen. After 180 seconds, the Invalid timer expires, marks the route invalid, and the Holddown timer begins, holding the route for 60 seconds.

If there is no routing update for the adjacent router's status (that is, it is still down), the route enters into the Flush state. In total, the system has waited for 240 seconds from the last update (180 seconds for the Invalid timer and 60 seconds for Holddown timer), and then the system flushes the route. Even if the adjacent router's interface comes up immediately, the system waits for the Holddown timer to complete the 120-second period before accepting updates.

Requirements and prerequisites for RIP

These requirements and prerequisites must be met for configuring RIP on supported firewall models.

Model support

Firewall Threat Defense

Firewall Threat Defense Virtual

Supported domains

Any

User roles

Admin

Network Admin

Guidelines for RIP

IPv6 guidelines

RIP does not support IPv6.

RIP version 2 guidelines

Consider these guidelines for RIP Version 2 configuration:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the Secure Firewall Threat Defense device transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

RIP limitations

These are the limitations of RIP:

- The Secure Firewall Threat Defense device cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.
- You can only enable a single RIP process on the Secure Firewall Threat Defense device.

Configure RIP

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection.

Use this procedure to define networks, manage redistribution, and apply interface-specific filtering or broadcast parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **Routing** and select **RIP** from the table of contents.

Check the **Enable RIP** check box to configure the RIP settings.

Choose the RIP versions for sending and receiving RIP updates from the **RIP Version** drop-down list:

- **Receive Version 1 & 2, Send Version 1**
- **Send & Receive Version 1**
- **Send & Receive Version 2**

Step 3 (Optional) Check the **Generate Default Route** check box to generate a default route for distribution, based on the route map that you specify.

a) Specify a route map name to use for generating default routes, in the **Route Map** field.

Generate the default route 0.0.0.0/0 for distribution when a route map is specified in the **Route Map** field.

Step 4 When you choose Send and Receive Version 2, the **Enable Auto Summary** option is available. When the **Enable Auto Summary** check box is checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.

Note
RIP Version 1 always uses automatic summarization—you cannot disable it.

Step 5 Click **Networks**. Define one or more networks for RIP routing. Enter IP address(es), or enter or select the desired Network/Hosts objects. There is no limit to the number of networks you can add to the security appliance configuration. Interfaces belonging to the defined network will participate in the RIP routing. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.

Note
RIP only supports IPv4 objects.

Step 6 (Optional) Click **Passive Interface**. Use this option to specify passive interfaces on the appliance, and by extension the active interfaces. The device receives RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive receive and send updates.

Step 7 Click **Redistribution** to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process.

a) Click **Add** to specify redistribution routes.
b) Choose the routing protocol to redistribute into the RIP routing process, in the **Protocol** drop-down list. Available options are **Static**, **Connected**, **OSPF**, **BGP**, and **EIGRP**.

Note
For OSPF, specify the process ID in the **Process ID** field. For BGP, specify the AS number in the **AS Number** field. When you choose the Connected option in the **Protocol** drop-down list, you can redistribute directly connected networks into the RIP routing process.

c) (Optional) If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute in the **Match** drop-down list. Ctrl-click to select multiple types:

- **Internal**: Routes internal to the autonomous system (AS) are redistributed.
- **External 1**: Type 1 routes external to the AS are redistributed.
- **External 2**: Type 2 routes external to the AS are redistributed.
- **NSSA External 1**: Type 1 routes external to a not-so-stubby area (NSSA) are redistributed.
- **NSSA External 2**: Type 2 routes external to an NSSA are redistributed.

Note
The default is match Internal, External 1, and External 2.

d) Select the RIP metric type to apply to the redistributed routes in the **Metric** drop-down list. The three choices are:

- **Transparent**: Use the current route metric.
- **Specified Value**: Assign a specific metric value from 0 to 16 in the **Metric Value** field.
- **None**: No metric is specified. Do not use any metric value, to apply to redistributed routes.

Note
None option is applicable only for **Static** and **Connected** protocols.

e) (Optional) Enter the name of a route map that must be satisfied, in the **Route Map** field before the route can be redistributed into the RIP routing process. Routes are redistributed only if IP address matches an allow statement in the route map address list. To create a new route map object, click **Add** (+). See Configure Route Map Entry for the procedure to add a new route map.
f) Click **OK**.

Step 8 (Optional) Click **Filtering** to manage filters for the RIP policy. In this section, filters are used to prevent routing updates through an interface, control the advertising of routes in routing updates, control the processing of routing updates and filtering sources of routing updates.

a) Click **Add** to add RIP filters.
b) Select the type of traffic to be filtered - Inbound or Outbound in the **Traffic Direction** field.

Note
If traffic direction is inbound, you can only define an Interface filter.

c) Specify whether the filter is based on an Interface or a Route, by selecting appropriate option in the **Filter On** field. If you click **Interface**, you can enter or choose the name of the interface on which routing updates are to be filtered. If you click **Route**, you can choose the route type:

- **Static**: Only static routes are filtered.
- **Connected**: Only connected routes are filtered.
- **OSPF**: Only OSPFv2 routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
- **BGP**: Only BGPv4 routes discovered by the specified BGP process are filtered. Enter the value in the **Process ID** field.
- **EIGRP**: Only EIGRP routes are filtered.

d) In the **Access List** field, enter or choose the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements. To add a new standard access list object, click **Add** (+) and see Configure a standard ACL object, on page 2953.

e) Click **OK**.

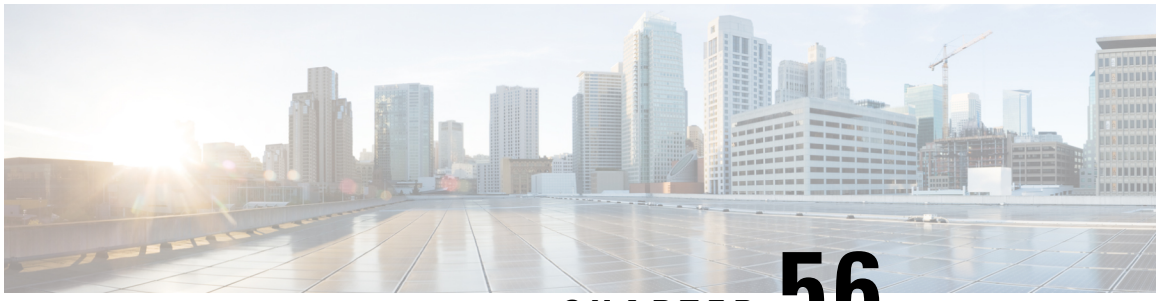
Step 9 (Optional) Click **Broadcast** to add or edit interface configurations. Using Broadcast, you can override the global RIP versions to send or receive per interface. You can also define the authentication parameters per interface if you want to implement authentication to ensure valid RIP updates.

a) Click **Add** to add interface configurations.

b) Enter or choose an interface defined on this appliance in the **Interface** field.

c) In the Send option, select the appropriate boxes to specify sending updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Send versions specified.

d) In the Receive option, select the appropriate boxes to specify accepting updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Receive versions specified.



e) Select the **Authentication** used on this interface for RIP broadcasts.

- **None**: No authentication
- **MD5**: Employ MD5
- **Clear Text**: Employ clear-text authentication

If you choose MD5 or Clear Text, you must also provide the following authentication parameters.

- **Key ID**: The ID of the authentication key; valid values are from 0 to 255.
- **Key**: The key used by the chosen authentication method; can contain up to 16 characters.
- **Confirm**: Enter the authentication key again to confirm.

f) Click **OK**.

CHAPTER 56

Multicast

This chapter describes how to configure the Secure Firewall Threat Defense device to use the multicast routing protocol.

- Multicast routing, on page 1521
- Prerequisites for Multicast Routing, on page 1526
- Guidelines for multicast routing, on page 1526
- Configure IGMP features, on page 1527
- Configure PIM features, on page 1532
- Configure multicast routes, on page 1538
- Configure multicast boundary filters, on page 1539

Multicast routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications include videoconferencing, corporate communications, distance learning, and distributing software, stock quotes, and news.

Multicast routing applications and protocols

Multicast routing protocols send source traffic to multiple receivers efficiently, without adding extra load on the source or receivers, and use less network bandwidth than other technologies. Multicast packets are replicated in the network by Firewall Threat Defense device enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols, which results in the most efficient delivery of data to multiple receivers possible.

The Firewall Threat Defense device supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single Firewall Threat Defense device.

Note The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.

IGMP Protocol

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

Note When you enable multicast routing on the Firewall Threat Defense device, IGMP Version 2 is automatically enabled on all interfaces.

Query Messages to Multicast Groups

The Firewall Threat Defense device sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the Firewall Threat Defense device. If the Firewall Threat Defense device discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packets for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the Firewall Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

Stub multicast routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing.

When configured for stub multicast routing, the Firewall Threat Defense device acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the Firewall Threat Defense device forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the Firewall Threat Defense device cannot be configured for PIM sparse or bidirectional mode. Enable PIM on the interfaces that participate in IGMP stub multicast routing.

The Firewall Threat Defense device supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees, each rooted at a single Rendezvous Point (RP) per multicast group. Optionally, it creates shortest-path trees for each multicast source.

PIM multicast routing

Bidirectional PIM is a variant of PIM-SM that builds bidirectional shared trees connecting multicast sources and receivers.

DF election process

Bidirectional trees are built using a Designated Forwarder (DF) election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point (RP) and then along the shared tree to receivers. This process does not require source-specific state. The DF election takes place during RP discovery and provides a default route to the RP.

Note If the Firewall Threat Defense device is the PIM RP, use the untranslated outside address of the Firewall Threat Defense device as the RP address.

PIM sparse mode

PIM Sparse Mode (PIM-SM) is a PIM mode that forwards traffic only when specifically requested by receivers. It uses a central Rendezvous Point (RP) to coordinate the multicast traffic forwarding between the multicast source and the destination. RP is a router that serves as the meeting point for the source and the receivers. Multicast sources register with the RP through their first hop router. They send a copy of the multicast traffic to the receivers through the RP.

PIM source specific multicast support

Firewall Threat Defense device can forward source specific multicast traffic (e.g., for groups in the 232.x.x.x range) even though they do not support PIM-SSM configuration or Internet Group Management Protocol version 3 (IGMPv3).

SSM is classified as a data delivery mechanism for one-to-many applications such as IPTV. The SSM model uses a concept of "channels" denoted by an (S,G) pair, where S is a source address and G is an SSM destination address. Subscribing to a channel is achieved by using a group management protocol such as IGMPv3. SSM enables a receiving client, once it has learned about a particular multicast source, to receive multicast streams directly from the source rather than receiving it from a shared Rendezvous Point (RP). Access control mechanisms are introduced within SSM, providing a security enhancement that is not available with current sparse or sparse-dense mode implementations.

Limitation:

- Firewall Threat Defense device cannot act as the last-hop router for SSM multicast because it does not support IGMPv3 (which receivers use to join SSM groups).

  If the Firewall Threat Defense device is the last-hop, it will ignore IGMPv3 join messages from receivers for SSM groups, and SSM forwarding will not work.

- Static multicast routes on Firewall Threat Defense device do not work for SSM range (232.x.x.x).

Workaround:

For Cisco Firewall Threat Defense device firewall to forward SSM-related multicast traffic, you must add a multicast-capable layer 3 device (such as a router or switch) that supports PIM and IGMPv3 on the same network segment as the receivers.

How it Works:

- Receivers register their SSM group joins (IGMPv3) with this layer 3 device.
- This layer 3 device sends PIM join messages towards the Firewall Threat Defense device.
- The Firewall Threat Defense device receives these PIM messages and dynamically learns multicast routes.
- SSM multicast traffic is then properly forwarded by the Firewall Threat Defense device, since it is no longer the last-hop device.

Multicast Bidirectional PIM

Multicast bidirectional PIM is useful for networks that have many sources and receivers talking to each other simultaneously and where each participant can become both the source and receiver of multicast traffic, such as in videoconferencing, Webex meetings, and group chat. When PIM bidirectional mode is used, the RP only creates the (*,G) entry for the shared tree. There is no (S,G) entry. This conserves resources on the RP because state tables for each (S,G) entry are not maintained.

In PIM sparse mode, traffic only flows down the shared tree. In PIM bidirectional mode, traffic flows up and down the shared tree.

PIM bidirectional mode also does not use the PIM register/register-stop mechanism to register sources to the RP. Each source can begin sending to the source at any time. When the multicast packets arrive at the RP, they are forwarded down the shared tree (if there are receivers) or dropped (when there are no receivers). However, there is no way for the RP to tell the source to stop sending multicast traffic.

Design-wise you must think about where to place the RP in your network because it should be somewhere in the middle between the sources and receivers in the network.

PIM bidirectional mode has no Reverse Path Forwarding (RPF) check. Instead it uses the concept of a Designated Forwarder (DF) to prevent loops. This DF is the only router on the segment that is allowed to send multicast traffic to the RP. If there is only one router per segment that forwards multicast traffic, there will be no loops. The DF is chosen using the following mechanism:

- The router with the lowest metric to the RP is the DF.
- If the metric is equal, then the router with the highest IP address becomes the DF.

PIM bootstrap router (BSR)

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for RP function and for relaying the RP information for a group.

The RP function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree through BSR messages that travel from PIM router to PIM router on a per-hop basis.

This feature allows networks to learn RPs dynamically. Dynamic RP discovery is essential in large, complex networks where an RP may occasionally go down and come up.

PIM bootstrap router (BSR) terminology

This reference provides definitions for key terminology used in PIM Bootstrap Router (BSR) configurations to help understand the roles and functions of different components in the BSR election and RP advertisement process.

These terms are frequently referenced in the PIM BSR configuration:

- Bootstrap Router (BSR) — A BSR advertises Rendezvous Point (RP) information to other routers with PIM on a hop-by-hop basis. Among multiple Candidate-BSRs, a single BSR is chosen after an election process. The primary purpose of this Bootstrap router is to collect all Candidate-RP (C-RP) announcements in to a database called the RP-set and to periodically send this out to all other routers in the network as BSR messages (every 60 seconds).
- Bootstrap Router (BSR) messages — BSR messages are multicast to the All-PIM-Routers group with a TTL of 1. All PIM neighbors that receive these messages retransmit them (again with a TTL of 1) out of all interfaces except the one in which the messages were received. BSR messages contain the RP-set and the IP address of the currently active BSR. This is how C-RPs know where to unicast their C-RP messages.
- Candidate Bootstrap Router (C-BSR) — A device that is configured as a candidate-BSR participates in the BSR election mechanism. A C-BSR with highest priority is elected as the BSR. The highest IP address of the C-BSR is used as a tiebreaker. The BSR election process is preemptive, for example if a new C-BSR with a higher priority comes up, it triggers a new election process.
- Candidate Rendezvous Point (C-RP) — An RP acts as a meeting place for sources and receivers of multicast data. A device that is configured as a C-RP periodically advertises the multicast group mapping information directly to the elected BSR through unicast. These messages contain the Group-range, C-RP address, and a hold time. The IP address of the current BSR is learned from the periodic BSR messages that are received by all routers in the network. In this way, the BSR learns about possible RPs that are currently up and reachable.

Note The Firewall Threat Defense device does not act as a C-RP, even though the C-RP is a mandatory requirement for BSR traffic. Only routers can act as a C-RP. So, for BSR testing functionality, you must add routers to the topology.

- BSR Election Mechanism — Each C-BSR originates Bootstrap messages (BSMs) that contain a BSR Priority field. Routers within the domain flood the BSMs throughout the domain. A C-BSR that hears about a higher-priority C-BSR than itself suppresses its sending of further BSMs for some period of time. The single remaining C-BSR becomes the elected BSR, and its BSMs inform all the other routers in the domain that it is the elected BSR.

Multicast group concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries. Hosts can be

located anywhere on the Internet. Hosts that want to receive data sent to a group must join the group using IGMP.

Group membership requirements

Hosts must be a member of the group to receive the data stream.

Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

Clustering

Multicast routing supports clustering. In Spanned EtherChannel clustering, the control unit sends all multicast routing packets and data packets until fast-path forwarding is established.

After fast-path forwarding is established, data units may forward multicast data packets. All data flows are full flows. Stub forwarding flows are also supported. Because only one unit receives multicast packets in Spanned EtherChannel clustering, redirection to the control unit is common.

Guidelines for multicast routing

Table 95: System requirements

Item	Description
Context mode	Supported in single context mode.
Firewall mode	Supported only in routed firewall mode. Transparent firewall mode is not supported.

Item	Description
IPv6	IPv6 is not supported.
Multicast group	The range of addresses from 224.0.0.0 to 224.0.0.255 is reserved for routing protocols and other topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Internet multicast routing from the 224.0.0/24 address range is not supported. When multicast routing is enabled for reserved addresses, an IGMP group is not created.
Clustering	In clustering, for IGMP and PIM, this feature is only supported on the primary unit.

Access control configuration

You must configure an access control or prefilter rule on the inbound security zone to allow traffic to the multicast host, such as 224.1.2.3. However, you cannot specify a destination security zone for the rule, or it cannot be applied to multicast connections during initial connection validation.

Interface and protocol management

Ensure proper configuration management when working with PIM-enabled interfaces and multicast routing protocols.

- You cannot disable an interface with PIM configured on it. If you have configured PIM on the interface (see Configure PIM protocol, on page 1533), disabling the multicast routing and PIM does not remove the PIM configuration. You must remove (delete) the PIM configuration to disable the interface.
- Multicast routing is not supported in ECMP.
- Do not configure Firewall Threat Defense to simultaneously be a Rendezvous Point (RP) and a First Hop Router.
- The HSRP standby IP address does not participate in PIM neighborship. If the RP router IP is routed through the HSRP standby IP address, multicast routing does not work in Firewall Threat Defense. To ensure multicast traffic passes through successfully, configure the route for the RP address to use an interface IP address rather than the HSRP standby IP address.
- For a device using virtual routing, you can configure multicast only for its global virtual router and not for its user-defined virtual router.

Configure IGMP features

Configure IGMP features to enable dynamic registration of individual hosts in multicast groups on a particular LAN and to manage multicast traffic efficiently.

IP hosts use IGMP to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IP hosts use IGMP to report their group memberships to directly connected multicast routers. IGMP dynamically registers individual hosts in a multicast group on a specific LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

This section describes how to configure optional IGMP settings on a per-interface basis.

Procedure

Step 1 Enable multicast routing, on page 1528.

Step 2 Configure IGMP protocol, on page 1529.

Step 3 Configure IGMP access groups, on page 1530.

Step 4 Configure IGMP static groups, on page 1531.

Step 5 Configure IGMP join groups, on page 1531.

Enable multicast routing

Enable multicast routing to allow the device to forward multicast traffic using Internet Group Management Protocol (IGMP) and Protocol Independent Multicast (PIM) protocols on all interfaces.

Enabling multicast routing on the Firewall Threat Defense device, enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

Note Only the UDP transport layer is supported for multicast routing.

These are the maximum number of entries for specific multicast tables. Any new entries are discarded when these limits are reached.

- Multicast Forwarding Information Base (MFIB): 30,000
- IGMP Groups: 30,000
- PIM Routes: 72,000

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 Check the **Enable Multicast Routing** check box.

Checking this check box enables IP multicast routing on the device. Unchecking it disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces.

You can disable multicast on a per-interface basis. This is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the Firewall Threat Defense device from sending host query messages on that interface.

Configure IGMP protocol

Use this task to configures IGMP parameters per-interface. These settings help manage multicast group membership on a Firewall Threat Defense device.

You can configure IGMP parameters per interface, such as the forward interface, query messages, and time intervals.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 Click the **Protocol** tab and click **Add**, or edit an interface.

In the **Add IGMP parameters** dialog box, configure new IGMP parameters to the Firewall Threat Defense device. Use the **Edit IGMP parameters** dialog box to modify the existing parameters.

Step 4 Configure these parameters:

- **Interface**: From the drop-down list, choose the interface for which you want to configure IGMP protocol.
- **Enable IGMP**: Check the check box to enable IGMP.

  Note
  Disabling IGMP on specific interfaces is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the device from sending host query messages on that interface.

- **Forward Interface**: From the drop-down list, choose the specific interface from which you want to forward IGMP messages.

  This configures the Secure Firewall Threat Defense device to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface.

- **Version**: Choose IGMP Version 1 or 2.

  By default, the Firewall Threat Defense device runs IGMP Version 2, which enables several additional features.

  Note
  All multicast routers on a subnet must support the same version of IGMP. The Firewall Threat Defense device does not automatically detect Version 1 routers and switch to Version 1. However, you can have a mix of IGMP Version 1 and 2 hosts on the subnet; the Firewall Threat Defense device running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

- **Query Interval**: The interval in seconds at which the designated router sends IGMP host-query messages. The range is 1 to 3600. The default is 125.

Note
If the Firewall Threat Defense device does not hear a query message on an interface for the specified timeout value, then the device becomes the designated router and starts sending the query messages.

- **Response Time**: The interval in seconds before the Firewall Threat Defense device deletes the group. The range is 1 to 25. The default is 10.

  If the Firewall Threat Defense device does not receive a response to a host query within this amount of time, it deletes the group.

- **Group Limit**: Maximum number of hosts that can join on an interface. The range is 1 to 500. The default is 500.

  You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports that exceed the configured limits are not entered in the IGMP cache, and their traffic is not forwarded.

- **Query Timeout**: The period of time in seconds before which the Firewall Threat Defense device takes over as the requester for the interface after the previous requester has stopped. The range is 60 to 300. The default is 255.

Step 5 Click **OK** to save the IGMP protocol configuration.

Configure IGMP access groups

You can control access to multicast groups by using access control lists.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Access Group**.

Step 3 On **Access Group**, click **Add** or **Edit**.

Use the **Add IGMP Access Group parameters** dialog box to add new IGMP access groups to the Access Group table. Use the **Edit IGMP Access Group parameters** dialog box to change the parameters of an existing access group.

Step 4 Configure the access group options:

a) From the **Interface** drop-down list, choose the interface associated with the access group. You cannot change the associated interface when you are editing an existing access group.

b) Click one of the following:

- **Standard Access List**: From the **Standard Access List** drop-down list, choose the standard ACL or click **Add** (+) to create a new standard ACL. For more information, refer to Configure a standard ACL object, on page 2953.
- **Extended Access List**: From the **Extended Access List** drop-down list, choose the extended ACL or click **Add** (+) to create a new extended ACL. For more information, refer to Configure an extended ACL object, on page 2949.

Step 5 Click **OK** to save the access group configuration.

Configure IGMP static groups

Configure a statically joined IGMP group to enable multicast traffic for that group to be sent to a network segment even when group members cannot report membership or no members exist on the segment.

Sometimes a group member cannot report its membership in the group or there may be no members of a group on the network segment, but you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group. With this method, the Firewall Threat Defense device does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Static Group**, click **Add** or **Edit**.

Use the **Add IGMP Static Group parameters** dialog box to statically assign a multicast group to an interface. Use the **Edit IGMP Static Group parameters** dialog box to change existing static group assignments.

Note
The IGMP Static Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to statically assign a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Multicast Groups** drop-down list, choose the multicast group to which you want to assign the interface, or click **Add** (+) to create a new multicast group. Refer to Creating Network Objects for the procedure.

Step 5 Click **OK** to save the static group configuration.

Configure IGMP join groups

You can configure an interface to be a member of a multicast group.

Configuring the Firewall Threat Defense device to join a multicast group, upstream routers maintain multicast routing table information for that group and keep the group's paths active.

Note Refer to Configure IGMP static groups, on page 1531 if you want to forward multicast packets for a specific group to an interface without the Firewall Threat Defense device accepting those packets as part of the group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Join Group**, click **Add** or **Edit**.

Use the **Add IGMP Join Group parameters** dialog box to configure the Firewall Threat Defense device to be a member of a multicast group. Use the **Edit IGMP Join Group parameters** dialog box to change existing parameters.

Note
The IGMP Join Group enables PIM to send *Join* requests to sources or to the Rendezvous Point (RP) if the firewall with this command is the PIM Designated Router (DR) on that interface.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface you want to be a member of a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Join Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Plus** to create a new multicast group. Refer to Creating Network Objects for the procedure.

Configure PIM features

This section describes how to configure optional PIM settings.

Routers use PIM to maintain forwarding tables to use for forwarding multicast diagrams. Enable multicast routing on the Secure Firewall Threat Defense device, to automatically enable IGMP and PIM on all interfaces.

Note PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

Procedure

Step 1 Configure PIM protocol, on page 1533.

Step 2 Configure PIM neighbor filters, on page 1534.

Step 3 Configure PIM bidirectional neighbor filters, on page 1534.

Step 4 Configure PIM rendezvous points, on page 1535.

Step 5 Configure PIM route trees, on page 1536.

Step 6 Configure PIM request filters, on page 1537.

Step 7 Configure multicast boundary filters, on page 1539.

Configure PIM protocol

You can enable or disable PIM on a specific interface.

You can also configure the Designated Router (DR) priority. The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, the DR is chosen based on DR priority. If multiple devices share the same DR priority, the device with the highest IP address becomes the DR. By default, the Firewall Threat Defense device has a DR priority of 1.

Router query messages are used to choose the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the Firewall Threat Defense device sends PIM join or prune messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 Click the **Protocol** tab and click **Add**, or edit an interface.

In the **Add PIM parameters** dialog box, add new PIM parameters for the interface. Use the **Edit PIM parameters** dialog box to change existing parameters.

Step 4 Configure these options:

- **Interface**: From the drop-down list, select the interface for which you want to configure PIM protocol.
- **Enable PIM**: Check the check box to enable PIM.
- **DR Priority**: Set the DR priority value for the selected interface. The router with the highest DR priority on the subnet becomes the designated router.
- **Hello Interval**: The interval in seconds at which the interface sends PIM hello messages. The range is 1 to 3600. The default is 30.
- **Join Prune Interval**: The interval in seconds at which the interface sends PIM join and prune advertisements. The range is 10 to 600. The default is 60.

Step 5 Click **OK** to save the PIM protocol configuration.

Configure PIM neighbor filters

You can define and filter the routers that become Protocol Independent Multicast (PIM) neighbors.

PIM neighbor filters allow you to define and filter the routers that become Protocol Independent Multicast (PIM) neighbors to:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 Click the **Neighbor Filter** tab and click **Add**, or edit an interface.

In the **Add PIM Neighbor Filter** dialog box, add new PIM neighbor filters to the interface. Use the **Edit PIM Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure these options:

- From the **Interface** drop-down list, choose the interface to which you want to add a PIM neighbor filter.
- From the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2953 for the procedure.

  Note
  Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the multicast group advertisements pass through the interface. Choosing **Block** prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

Step 5 Click **OK** to save the PIM neighbor filter configuration.

Configure PIM bidirectional neighbor filters

Configure PIM bidirectional neighbor filters to control which neighbor devices participate in the Designated Forwarder (DF) election for bidirectional multicast routing. This helps ensure proper multicast traffic forwarding in the network.

A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the Designated Forwarder (DF) election. If you do not configure a PIM bidirectional neighbor filter for an interface, there are no restrictions. If you configure a PIM bidirectional neighbor filter, only neighbors permitted by the ACL can participate in the DF election process.

Bidirectional PIM allows multicast routers to keep reduced state information. All multicast routers in a segment must be bidirectionally enabled to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

- If a permitted neighbor does not support bidirectional mode, the DF election does not occur.
- If a denied neighbor supports bidirectional mode, the DF election does not occur.
- If a denied neighbor does not support bidirectional mode, the DF election can occur.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Multicast Routing** > **PIM**.

Step 3 On **Bidirectional Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Bidirectional Neighbor Filter** dialog box to create ACL entries for the PIM bidirectional neighbor filter ACL. Use the **Edit PIM Bidirectional Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure these options:

- In the **Interface** drop-down list, select the interface for which you want to configure the PIM bidirectional neighbor filter ACL entry.
- From the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2953 for the procedure.

  Note
  Choosing **Allow** in the **Add Standard Access List Entry** dialog box lets the specified devices participate in the DR election process. Choosing **Block** prevents the specified devices from participating in the DR election process.

Step 5 Click **OK** to save the PIM bidirectional neighbor filter configuration.

Configure PIM rendezvous points

You can configure the Firewall Threat Defense device to serve as a RP to more than one group.

The group range specified in the ACL determines the PIM RP group mapping. If an ACL is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4). Refer to Multicast Bidirectional PIM, on page 1524 for more information about bidirectional PIM.

These restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify **All Groups** for more than one RP.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Rendezvous Points**, click **Add** or **Edit**.

Use the **Add Rendezvous Point** dialog box to create a new entry in the Rendezvous Point table. Use the **Edit Rendezvous Point** dialog box to modify existing parameters.

Step 4 Configure these options:

- From the **Rendezvous Point IP address** drop-down list, choose the IP address that you want to add as an RP or click **Add** (+) to create a new network object. Refer to Creating Network Objects for the procedure.
- Check the **Use bi-directional forwarding** check box to enable bidirectional mode for the specified multicast groups. In this mode, if the Firewall Threat Defense device receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.
- Click **Use this RP for all Multicast Groups** to use the specified RP for all multicast groups on the interface.
- Click **Use this RP for all Multicast Groups as specified below** to designate the multicast groups to use with the specified RP and then from the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2953 for the procedure.

Step 5 Click **OK** to save the rendezvous point configuration.

Configure PIM route trees

Configure PIM route trees to control whether the Firewall Threat Defense device joins the shortest-path tree or uses the shared tree for multicast traffic routing.

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the Firewall Threat Defense device should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

The shortest-path tree is used for any group that is not specified in the Multicast Groups table. The Multicast Groups table displays the multicast groups to use with the shared tree. The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.

Note This behavior is known as Shortest Path Switchover (SPT). We recommend that you always use the Shared Tree option.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Route Tree**, select the path for the route tree:

- Click **Shortest Path** to use the shortest-path tree for all multicast groups.
- Click **Shared Tree** to use the shared tree for all multicast groups.
- Click **Shared tree for below mentioned group** to designate the groups specified in the Multicast Groups table, and then from the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2953 for the procedure.

Step 4 Click **OK** to save the route tree configuration.

Configure PIM request filters

When the Firewall Threat Defense device is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. You can define the multicast sources from which the Firewall Threat Defense device will accept PIM register messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Request Filter**, define the multicast sources that are allowed to register with the Firewall Threat Defense device when it acts as an RP:

- From the **Filter PIM register messages using:** drop-down list select **None**, **Access List**, or **Route Map**.
- If you choose **Access List** from the drop-down list, select an extended ACL or click **Add** (+) to create a new extended ACL. Refer to Configure an extended ACL object, on page 2949 for the procedure.

  Note
  In the **Add Extended Access List Entry** dialog box, select **Allow** from the drop-down list to create a rule that allows the specified source of the specified multicast traffic to register with the Firewall Threat Defense device, or select **Block** to create a rule that prevents the specified source of the specified multicast traffic from registering with the device.

- If you choose **Route Map**, select a route map from the **Route Map** drop-down list, or click **Add** (+) to create a new route map. Refer to Creating Network Objects for the procedure.

Step 4 Click **OK** to save the request filter configuration.

Configure the Firewall Threat Defense device as a candidate bootstrap router

You can configure the Firewall Threat Defense device as a candidate BSR.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Bootstrap Router**, check the **Configure this FTD as a Candidate Bootstrap Router (C-BSR)** check box to perform the C-BSR setup.

a) From the **Interface** drop-down list, select the interface in the Firewall Threat Defense device from which the BSR address is derived to make it a candidate.

This interface must be enabled with PIM.

b) In the **Hash mask length** field, enter the length of a mask (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This allows you to configure one RP for multiple groups. The range is 0 to 32.

c) In the **Priority** field, enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR. The range is 0 to 255. The default value is 0.

Step 4 (Optional) Click **Add** (+) to select an interface on which no PIM BSR messages will be sent or received in the **Configure this FTD as a Border Bootstrap Router (BSR)** section.

- From the **Interface** drop-down list, select the interface on which no PIM BSR messages will be sent or received.

  RP or BSR advertisements are filtered effectively isolating two domains of RP information exchange.

- Check the **Enable Border BSR** check box to enable BSR.

Step 5 Click **OK** to save the bootstrap router configuration.

Configure multicast routes

Configure static multicast routes to separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the Firewall Threat Defense device expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Routes** > **Add or Edit**.

Use the **Add Multicast Route Configuration** dialog box to add a new multicast route to the Firewall Threat Defense device. Use the **Edit Multicast Route Configuration** dialog box to change an existing multicast route.

Step 3 Choose an existing network from the **Source Network** drop-down, or click **Add** (+) to add a new network.

Refer to Creating Network Objects for the procedure.

Step 4 To configure an interface to forward the route, click **Interface** and configure the following options:

- From the **Source Interface** drop-down list, choose the incoming interface for the multicast route.
- From the **Output Interface/Dense** drop-down list, choose the destination interface that the route is forwarded through.
- In the **Distance** field, enter the distance of the multicast route. The range is 0 to 255.

Step 5 To configure an RPF address to forward the route, click **Address** and configure the following options:

- In the **RPF Address** field, enter the IP address for the multicast route.
- Enter the multicast route distance in the **Distance** field. The value must be between 0 and 255.

Step 6 Click **OK** to save the multicast routes configuration.

Configure multicast boundary filters

Address scoping defines domain boundary filters so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary filter on an interface for multicast group addresses. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. The addresses are considered local and are not globally unique.

A standard ACL defines the range of affected addresses. When a boundary filter is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary filter allows the same multicast group address to be reused in different administrative domains.

You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary filter only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

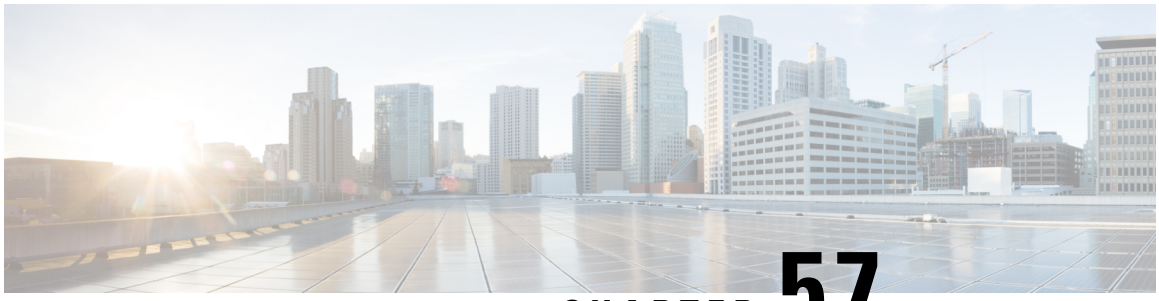
Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Boundary Filter**, and then click **Add** or **Edit**.

Use the **Add Multicast Boundary Filter** dialog box to add new multicast boundary filters to the device. Use the **Edit Multicast Boundary Filter** dialog box to change existing parameters.

You can configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.



Step 3 From the **Interface** drop-down list, choose the interface for which you are configuring the multicast boundary filter ACL.

Step 4 From the **Standard Access List** drop-down list, choose the standard ACL you want to use, or click **Add** (+) to create a new standard ACL. Refer to Configure a standard ACL object, on page 2953 for the procedure.

Step 5 Check the **Remove any Auto-RP group range announcement from the Auto-RP packets that are denied by the boundary** check box to filter Auto-RP messages from sources denied by the boundary ACL. If this check box is not checked, all Auto-RP messages are passed.

Step 6 Click **OK** to save the multicast boundary filter configuration.

The multicast boundary filter is configured on the selected interface with the specified standard ACL, restricting multicast traffic according to the filter rules and enabling address reuse across administrative domains.

CHAPTER 57

Policy-Based Routing

This chapter describes how to configure Firewall Threat Defense to support policy-based routing (PBR) through Cloud-Delivered Firewall Management Center's policy-based routing page. The following sections describe policy based routing, guidelines for PBR, and configuration for PBR.

- About policy-based routing, on page 1541
- Licenses for policy-based routing, on page 1543
- Best practices for policy-based routing, on page 1543
- Path monitoring metrics for best path route determination, on page 1545
- Configure policy-based routing policy, on page 1548
- Configure policy-based routing, on page 1551
- Configure PBR with path monitoring, on page 1556
- Useful CLIs for monitoring PBR, on page 1558
- Troubleshoot PBR, on page 1560

About policy-based routing

Policy-based routing (PBR) extends traditional routing protocols to provide greater control over traffic flow. It enables routing decisions based on criteria beyond destination IP, such as source and destination ports, protocols, and applications. Furthermore, PBR facilitates secure, application-specific traffic breakout in large-scale network deployments.

Policy-based routing characteristics

In traditional routing, packets are routed based on the destination IP address. Changing the routing of specific traffic in a destination-based routing system is difficult. PBR extends and complements the mechanisms provided by routing protocols.

PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link. With PBR, you can define routing that is based on criteria other than destination network such as source port, destination address, destination port, protocol, applications, or a combination of these objects.

You can use PBR to classify the network traffic based on applications, username, group membership, and security group association. This routing method applies to scenarios involving numerous devices accessing applications and data in large network deployment. In large deployments, network traffic is typically backhauled to a hub as encrypted traffic in a route-based VPN. These topologies often result in issues such as packet

latency, reduced bandwidth, and packet drop. Resolving these issues requires costly, complex deployments and management.

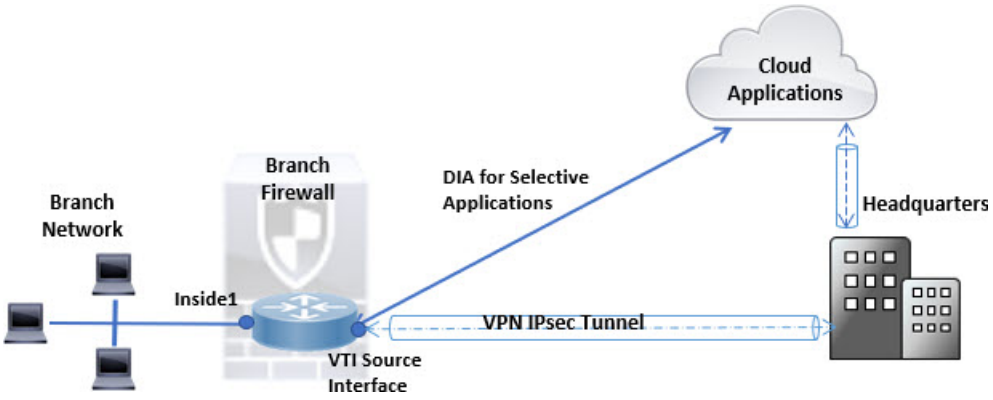
PBR policy enables you to securely break out traffic for specified applications. You can configure PBR policy in the Cloud-Delivered Firewall Management Center user interface to allow the applications to be directly accessed.

Consider a company that has two links between locations: one a high-bandwidth, low-delay expensive link, and the other a low-bandwidth, higher-delay, less-expensive link. While using traditional routing protocols, the higher-bandwidth link gets most, if not all, of the traffic sent across it based on the metric savings obtained by the bandwidth, delay, or both (using EIGRP or OSPF) characteristics of the link. With PBR, you can route higher priority traffic over the high-bandwidth/low-delay link, while sending all other traffic over the low-bandwidth/high-delay link.

These scenarios demonstrate policy-based routing applications:

- **Direct internet access**: In this topology, application traffic from the branch office can be routed directly to the internet instead of through the VPN tunnel connecting to the headquarters. The branch Firewall Threat Defense is configured with an internet exit point. The PBR policy is applied on the ingress interface (*Inside 1*) to identify the traffic based on the applications, user identity (username and group membership), and Security Group Tag (security group association) defined in the ACL. Correspondingly, the traffic is forwarded through the egress interfaces directly to the internet or to the IPsec VPN tunnel.
- **Equal-access and source-sensitive routing**: In this topology, traffic from the HR and Mgmt networks can be configured to go through ISP1 and traffic from Eng network can be configured to go through ISP2. Thus, policy-based routing enables the network administrators to provide equal-access and source-sensitive routing, in this example.
- **Load sharing**: In addition to the dynamic load-sharing capabilities offered by ECMP load balancing, network administrators can now implement policies to distribute traffic among multiple paths based on the traffic characteristics. As an example, in the topology depicted in the Equal-Access Source Sensitive Routing scenario, an administrator can configure policy-based routing to route the traffic from HR network through ISP1 and traffic from Eng network through ISP2 and thus share the load.

Figure 334: Direct internet access scenario



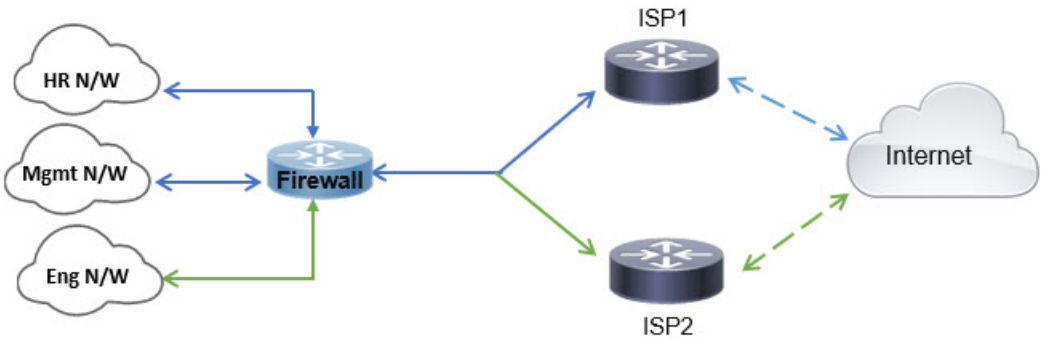


Figure 335: Equal access scenario

Licenses for policy-based routing

Policy-based routing (PBR) has specific licensing requirements depending on the features and services used in your configuration.

- All PBR policy features are supported with the Essentials Firewall Threat Defense smart license.
- Secure Client licensing is required if you are configuring PBR for routing traffic through RA VPN tunnel interface.
- Cisco ISE license is required for ISE usage in PBR policy.

Best practices for policy-based routing

Device guidelines

Ensure proper version compatibility and device-specific configurations when implementing PBR.

- On cluster devices, do not configure application, user identity, and Security Group Tag (SGT) based PBR policies, because they are not supported on cluster devices.

Interface guidelines

Configure appropriate interface types and settings for PBR policies.

- Configure only routed-mode interfaces and non management-only interfaces in the Global virtual router as ingress or egress interfaces for the PBR policy. You cannot configure user-defined virtual router interfaces for the policy.
- The interfaces that you want to define in the policy must have a logical name.
- Configure Static VTIs only as egress interfaces.
- Do not choose Dynamic VTIs for configuring the PBR egress interfaces.

You can apply PBR for managing both IPv4 and IPv6 traffic.

Application-based PBR and DNS configuration

Ensure proper DNS configuration for application-based PBR functionality.

- Application-based PBR uses DNS snooping for application detection. Application detection succeeds only if the DNS requests pass through Firewall Threat Defense in a clear-text format; the DNS traffic is not encrypted.
- You must configure trusted DNS servers for the application detection to succeed.

For more information on configuring DNS servers, refer to Configure DNS server settings, on page 1246.

PBR policies not applied for output route look-up

PBR is an ingress-only feature; The system applies PBR only to the first packet of a new incoming connection, at which time the egress interface for the forward leg of the connection is selected. Note that PBR will not be triggered if the incoming packet belongs to an existing connection, or if NAT is applied and NAT chooses the egress interface.

PBR policies not applied for embryonic traffic

An embryonic connection is where the necessary handshake between source and destination has not been made. When a new internal interface is added and a new VPN policy is created using a unique address pool, PBR is applied to the outside interface matches the source of the new client pool. Thus, PBR sends traffic from the client to the next hop on the new interface. However, PBR does not process return traffic from a host until the new internal interface establishes a connection with the client. Thus, the return traffic from the host to the VPN client, specifically, the VPN client response is dropped as there is no valid route. To prevent the response from being dropped, configure a weighted static route with a higher metric on the internal interface.

HTTP-based path monitoring guidelines

Configure HTTP-based path monitoring with appropriate interface types and version considerations.

- Configure HTTP-based path monitoring only on physical, port-channel, subinterfaces, and static tunnel interfaces. Do not configure it on cluster devices.
- HTTP uses only IPv4 to ping applications. IPv4 metrics are applied for routing and forwarding both IPv4 and IPv6 traffic.
- HTTP-based application monitoring is enabled by default in Cloud-Delivered Firewall Management Center.

Additional guidelines

Follow these additional configuration considerations for effective PBR implementation.

- All existing configuration restrictions and route map limitations remain in effect.
- When you define the ACL for the policy match criteria, you can select multiple predefined applications from a list to form an Access Control Entry (ACE). In Firewall Threat Defense, the predefined applications are stored as Network Service objects and the group of applications as Network Service Groups (NSG). You can create a maximum of 1024 such NSGs. The application or network service group is detected through first-packet classification. Currently, you cannot add to or modify the predefined applications list.
- Unicast Reverse Path Forwarding (uRPF) validates the source IP address of packets received on an interface against the routing table and not against the PBR route map. When uRPF is enabled, packets received on an interface through PBR are dropped as they are without the specific route entry. Therefore, when using PBR, ensure you disable uRPF.

Path monitoring metrics for best path route determination

Path monitoring metrics for best path route determination is a dynamic routing method that uses various monitoring approaches, such as ICMP and HTTP, to collect performance metrics and determine the best path.

Path monitoring methods and operation

PBR uses either static cost or path monitoring (dynamic metrics) to route its traffic.

Path monitoring, when configured on interfaces, derive metrics such as round trip time (RTT), jitter, mean opinion score (MOS), and packet loss per interface. These metrics are used to determine the best path for routing PBR traffic.

ICMP-based path monitoring method

The metrics on the interfaces are collected dynamically using ICMP probe messages to the interface's default gateway or a specified remote peer.

HTTP-based path monitoring method

Path monitoring calculates dynamic metrics for each remote peer associated with an interface. HTTP is preferred over ICMP when monitoring multiple applications and determining the best path through a policy on a branch firewall, because:

- HTTP-ping can derive the performance metrics of the path up to the application layer of the server, where the application is hosted.
- Because the application domain is tracked instead of the IP address, you do not need to change the firewall configuration when the application server IP address changes.

Note You can configure both ICMP and HTTP on the same interface. If the destination in the policy matches to any of the domain IP, the corresponding metrics are used. If the destination does not match to any of the configured domains, the metrics from the ICMP are used by PBR to select the outgoing interface.

Default monitoring timers for metric collection

For metric collection and monitoring, the following timers are used:

- The interface monitor average interval is 30 seconds. This interval indicates the frequency to which the probes average.
- The interface monitor update interval is 30 seconds. This interval indicates the frequency at which the average of the collected values are calculated and made available for PBR to determine the best routing path.
- The interface monitor probe interval by ICMP is one second. This interval indicates the frequency at which an ICMP ping is sent.
- The application monitor probe interval by HTTP is 10 seconds. This interval indicates the frequency at which an HTTP ping is sent. Path monitoring uses the last 30 samples of HTTP ping for calculating the average metrics.

Note You cannot configure or modify the interval for any of these timers.

PBR and path monitoring integration

PBR uses IP-based path monitoring to collect the performance metrics (RTT, jitter, packet-lost, and MOS) of the egress interfaces. PBR uses the metrics to determine the best path (egress interface) for forwarding the traffic. Path monitoring periodically notifies PBR about the monitored interface whose metric got changed. PBR retrieves the latest metric values for the monitored interfaces from the path monitoring database and updates the data path.

Path monitoring functions only with dynamic metrics, and only if the RTT, jitter, packet-lost, or MOS variables are set on the interfaces. Path monitoring does not function with static metrics—interface cost (cost set in interface).

You must enable path monitoring for the interface and configure the monitoring type. The PBR policy page allows you to specify the desired metric for path determination. See Configure policy-based routing policy, on page 1548.

PBR and HTTP-based path monitoring

PBR can be configured to use HTTP-based path monitoring to collect the performance metrics of the application domains and not just one destination IP address. Path monitoring begins only after a DNS entry for a domain is detected; it does not start immediately when HTTP-based application monitoring is configured. After obtaining the resolved IP address for the domain, path monitoring sends an HTTP request and receives a response. If DNS resolves multiple IP addresses for a domain, path monitoring probes and monitors the application using the first resolved IP address. Path monitoring continues until the IP address changes or until HTTP-based monitoring is disabled.

Based on the HTTP request and response durations, path monitoring computes the performance metrics for the application. Path monitoring sends collected metrics to PBR at regular intervals so that PBR can make routing and forwarding decisions for traffic from the configured ingress interface. If traffic arrives before path monitoring sends metrics to PBR, the routing table determines the traffic flow. Once metrics are available, PBR uses them to make routing decisions for subsequent traffic.

Note Based on the Network Service Groups in the match ACL of the policy, you can apply PBR for multiple domains having multiple IP addresses.

The management center associates applications and NSGs with the egress interface only when the PBR configuration meets these criteria:

- The match ACL contains the monitored applications.
- The PBR policy is configured with any one of the interface ordering values (metric type):
  - Minimal Jitter
  - Maximum Mean Opinion Score
  - Minimal Round-Trip Time
  - Minimal Packet Loss

Configure path monitoring settings

Configure path monitoring to collect metrics such as RTT, jitter, MOS, and packet loss on specified interfaces for effective traffic management and routing optimization.

The PBR policy relies on flexible metrics, such as round-trip time (RTT), jitter, mean opinion score (MOS), and packet loss of the interfaces to identify the best routing path for its traffic. Path monitoring collects these metrics on the specified interfaces. On the **Interfaces** page, you can configure path monitoring settings on interfaces to send ICMP probes or HTTP pings to collect metrics.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Path Monitoring** tab.

Step 4 To configure ICMP based monitoring of the interface, click the **Enable IP based Monitoring** check box.

Step 5 From the **Monitoring Type** drop-down list, select the relevant option:

- **Auto**—Sends ICMP probes to the IPv4 default gateway of the interface. If the IPv4 gateway does not exist, path monitoring sends the probes to the IPv6 default gateway of the interface.
- **Peer IPv4**—Sends ICMP probes to the specified peer IPv4 address (next-hop IP) for monitoring. If you select this option, enter the IPv4 address in the **Peer IP To Monitor** field.
- **Peer IPv6**—Sends ICMP probes to the specified peer IPv6 address (next-hop IP) for monitoring. If you select this option, enter the IPv6 address in the **Peer IP To Monitor** field.
- **Auto IPv4**—Sends ICMP probes to the default IPv4 gateway of the interface.
- **Auto IPv6**—Send ICMP probes to the default IPv6 gateway of the interface.

Note

- The Auto options are not available for VTI interfaces. You must specify the peer address.
- Only one next-hop is monitored to a destination. That is, you cannot specify more than one peer address to monitor for an interface.

Step 6 By default, the **Enable HTTP based Application Monitoring** check box is selected. All applications selected for path monitoring in the match ACL of the PBR policy are listed, provided this interface is configured as the egress interface in the policy. To disable the HTTP-based monitoring of the interface, clear the check box.

Step 7 Click **Ok**.

Step 8 To save the settings, click **Save**.

Path monitoring is configured on the interface with the specified settings. The system will collect metrics using ICMP probes or HTTP pings based on your configuration to optimize routing paths.

Add path monitoring dashboard

Add the Path Monitoring Dashboard to enable viewing path monitoring metrics with customizable display options through predefined correlations and widget management.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **System** (⚙) > **Health** > **Monitor**.

Step 2 Select the device, and click **Add new dashboard** (+).

Step 3 Enter a name for the custom dashboard.

Step 4 In the **Metrics** area, click the **Add from predefined correlations** button.

Step 5 From the list, click **Interface - Path metrics**.

By default, all four metrics and an additional metric field are selected to display as widgets in the dashboard.

To exclude any, click **Delete** ( ).

Step 6 Click **Add dashboard**.

Configure policy-based routing policy

This task enables you to configure Policy-Based Routing (PBR) to control traffic routing based on specific criteria rather than relying solely on the routing table.

You can configure the PBR policy on the Policy Based Routing page by specifying the ingress interfaces, match criteria (Extended Access Control List), and egress interfaces.

Before you begin

To use the path monitoring metrics for configuring the traffic forwarding priority over egress interfaces, you must configure the path monitoring settings for the interfaces. See Configure path monitoring settings, on page 1547.

Follow these steps to configure policy-based routing policy:

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Click **Routing**.

Step 3 Click **Policy Based Routing**.

On the Policy Based Routing page, you can view the configured policy. The grid shows ingress interfaces and the combination of the policy-based route access list and egress interfaces.

Step 4 To configure the policy, click **Add**.

Step 5 In the **Add Policy Based Route** dialog box, select the **Ingress Interface** from the drop-down list.

Note
You can only select interfaces with logical names that belong to a global virtual router from the drop-down list. You cannot configure a VLAN interface with a logical name as the source (ingress) interface.

Step 6 To specify the match criteria and the forward action in the policy, click **Add**.

Step 7 In the **Add Forwarding Actions** dialog box, do the following:

a) From the **Match ACL** drop-down, choose the extended access control list object. You can predefine the ACL object (see Configure an extended ACL object, on page 2949) or click the **Add** (+) icon to create the object. In the **New Extended Access List Object** box, enter a name, click **Add** to open the **Add Extended Access List Entry** dialog box, where you can define the network, port, user identity, SGT, or application match criteria for the PBR policy.

Note
You can either have destination address or application/user identity/SGT defined in an ACE.

To selectively apply PBR on the incoming interface, you can define *Block* criteria in the ACE. When the traffic matches the block rule of the ACE, the traffic is forwarded to the egress interface based on the routing table.

b) From the **Send To** drop-down list:

- To select the configured interfaces, choose **Egress Interfaces**.
- To specify the IPv4/IPv6 next hop addresses, choose **IP Address**. Proceed to Step 7.e, on page 1550

c) If you have selected **Egress Interfaces**, from the **Interface Ordering** drop-down, choose the relevant option:

- By **Interface Priority**—The traffic is forwarded based on the priority of the interfaces. Traffic is routed to the interface with the least priority value first. When the interface is not available, the traffic is then forwarded to the interface with the next lowest priority value. For example, let us assume that interface1, interface2, and interface3 are configured with priority values *0*,*1*, and *2*, respectively. The traffic is forwarded to interface1. If interface1 becomes unavailable, the traffic is then forwarded to interface2.

  Note
  To configure the priority for the interfaces, click **Configure Interface Priority** on the Policy Based Routing page. In the dialog box, provide the priority number against the interfaces, and then click **Save**. You can also configure the priority for an interface in the Interface Settings.

  When the priority value is the same for all the interfaces, the traffic is balanced among the interfaces. By default, the interface priority for PBR is set to 0. Interfaces with the lowest priority value are preferred for traffic forwarding.

- By **Order**—The traffic is forwarded based on the sequence of the interfaces specified here. For example, let us assume that interface1, interface2, and interface3 are selected in this order, interface2, interface3, interface1. The traffic is forwarded first to interface2, then to interface3, regardless of their priority values.
- By **Minimal Jitter**—The traffic is forwarded to the interface that has the lowest jitter value. You need to enable Path Monitoring on the interfaces for PBR to obtain the jitter values.

- By **Maximum Mean Opinion Score**—The traffic is forwarded to the interface that has the maximum mean opinion score (MOS). You need to enable Path Monitoring on the interfaces for PBR to obtain the MOS values.
- By **Minimal Round Trip Time**—The traffic is forwarded to the interface that has the minimal round trip time (RTT). You need to enable Path Monitoring on the interfaces for PBR to obtain the RTT values.
- By **Minimal Packet Loss**—The traffic is forwarded to the interface that has the minimal packet loss. You need to enable Path Monitoring on the interfaces for PBR to obtain the packet loss values.

d) In the **Available Interfaces** box, all the interfaces with their priority values are listed. From the list of interfaces, click the **Add** (+) button to add to the selected egress interfaces. Proceed to Step 8.

Note
The selected interface route must be present in the routing table.

e) If you have selected **IP Address**, enter the IP addresses separated by commas in the **IPv4 Addresses** or **IPv6 Addresses** fields.

Note
When multiple next-hop IP addresses are provided, the traffic is forwarded as per the sequence of the specified IP addresses until a valid routable next-hop IP address is found. The configured next-hops should be directly connected.

f) From the **Don't Fragment** drop-down list, select Yes, No, or None. If the DF (Don't Fragment) flag is set to *Yes*, the intermediate routers never perform fragmentation of a packet.To specify the current interface as the default for forwarding, check the **Default Interface** check box.

g) The **IPv4 Settings** and **IPv6 Settings** tabs enable you to specify the recursive and default settings:

Note
For a route-map, you can only specify either IPv4 or IPv6 next-hop settings.

- **Recursive**—The route map configuration is applied only when the specified next-hop address and the default next-hop address are found on a directly connected subnet. However, you could use the recursive option, where the next-hop address need not be directly connected. Here, a recursive lookup is performed on the next-hop address, and matching traffic is forwarded to the next-hop used by that route entry according to the current routing path of the router.
- **Default**—If the normal route lookup fails to match traffic, the traffic is forwarded to this specified next-hop IP address.

h) Check the **Peer Address** check box to use the next-hop address as the peer address.

Note
You cannot configure a route map with both default next-hop address and peer address.

i) For IPv4 settings, you can check whether the next IPv4 hops of a route map are available under **Verify Availability**—click the **Add** (+) button and add the next-hop IP address entries:

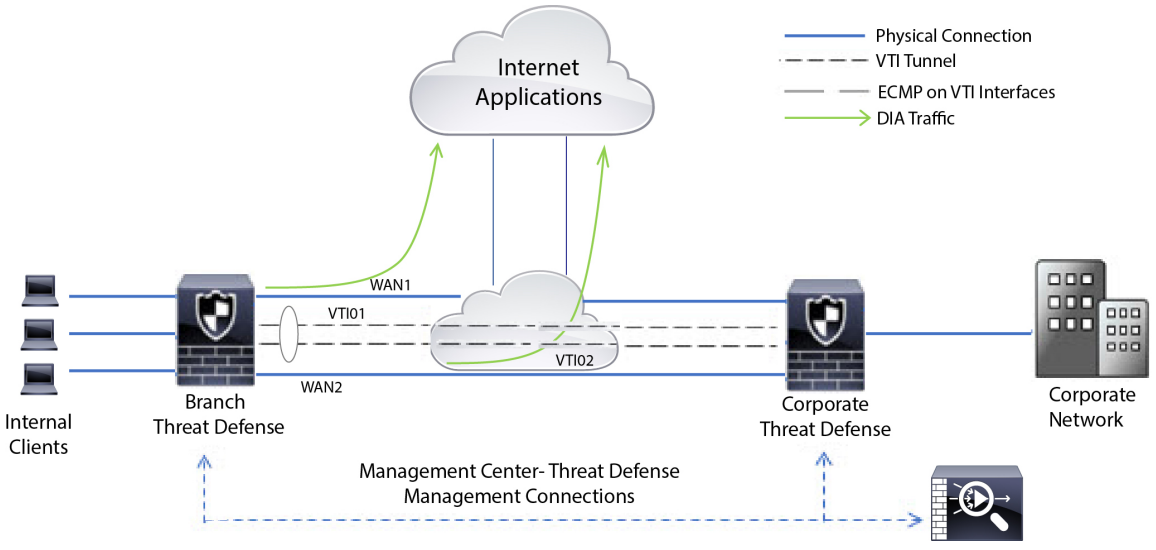
- **IP Address**—Enter the next hop IP address.
- **Sequence**—Entries are assessed in order using the sequence number. Ensure that no duplicate sequence numbers are entered. The valid range is 1 to 65535.

- **Track**—Enter a valid ID. The valid range is 1 to 255.

Step 8 To save the policy, click **Save** and **Deploy**.

The Firewall Threat Defense uses ACLs to match traffic and perform routing actions on the traffic. Typically, you configure a route map that specifies an ACL against which traffic is matched, and then you specify one or more actions for that traffic. With the use of path monitoring, PBR can now select the best egress interface for routing the traffic. Finally, you associate the route map with an interface on which you want to apply PBR on all incoming traffic.

Configure policy-based routing



Configure PBR to enable direct internet access for specific web-based applications, optimize traffic flow, and achieve load balancing between WAN and VTI interfaces.

Consider a typical corporate network scenario where all the branch network traffic passes through a route-based VPN of the corporate network and diverges to the extranet, when required. Accessing web-based applications through the corporate network to support daily operations may increase network size and maintenance costs. This example illustrates how to configure PBR for direct internet access.

The following figure depicts the topology of a corporate network. The branch network is connected to the corporate network through a route-based VPN. Traditionally, the corporate Firewall Threat Defense is configured to handle both the internal and external traffic of the branch office. With the PBR policy, the branch Firewall Threat Defense is configured with a policy that routes specific traffic to the WAN network instead of the virtual tunnels. The rest of the traffic flows through the route-based VPN, as usual.

This example also illustrates how to configure the WAN and VTI interfaces with ECMP zones to achieve load balancing.

Figure 336: Configuring policy-based routing on Branch Firewall Threat Defense in Cloud-Delivered Firewall Management Center

Before you begin

This example assumes that you have already configured WAN and VTI interfaces for the branch Firewall Threat Defense in Cloud-Delivered Firewall Management Center.

Procedure

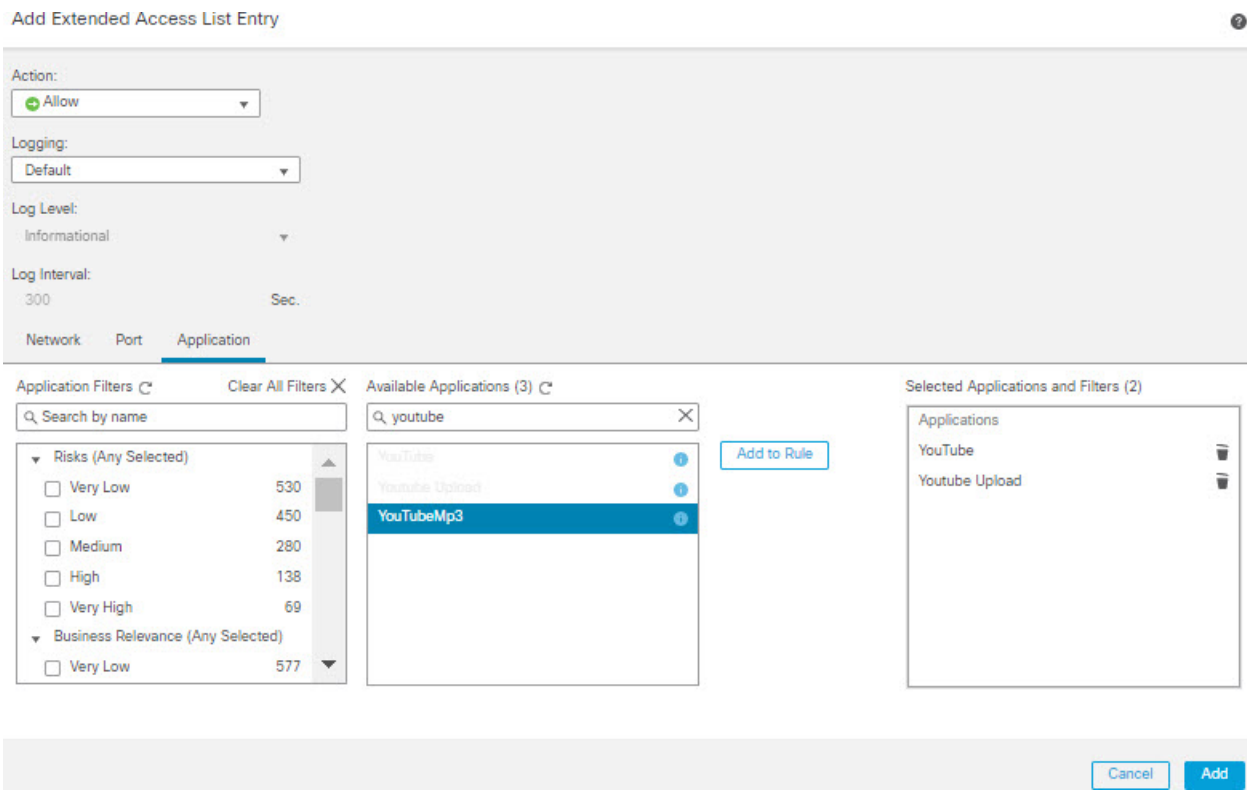
Step 1 Configure policy-based routing for the branch Firewall Threat Defense, select the ingress interfaces:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.

c) In the **Add Policy Based Route** dialog box, select the interfaces (say, *Inside 1*, and *Inside 2*) from the **Ingress Interface** drop-down list.

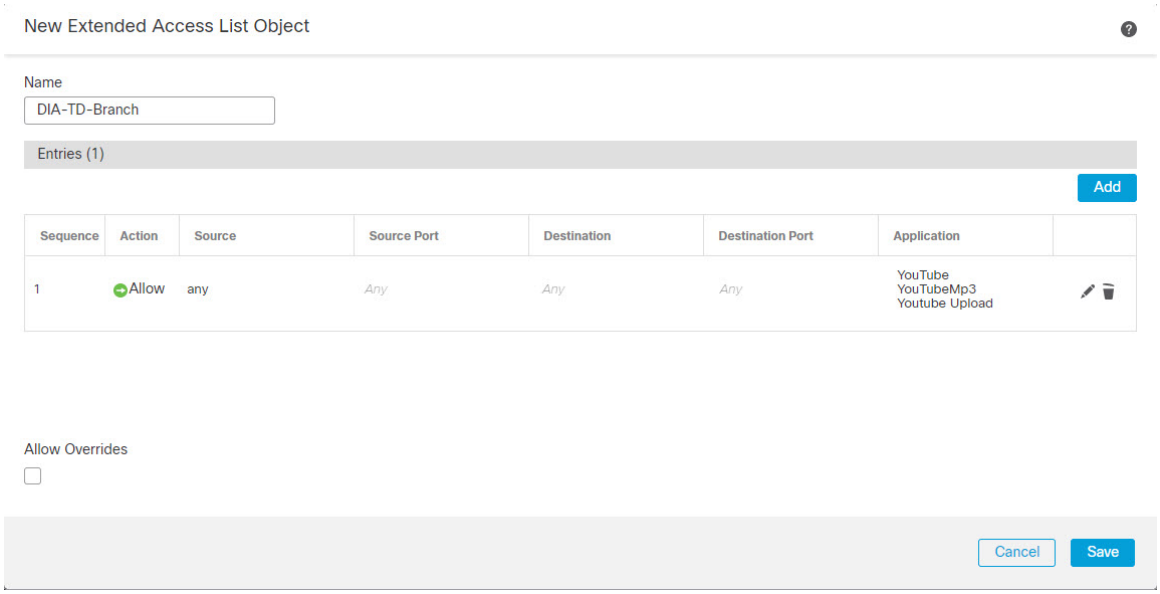
Step 2 Specify the match criteria:



a) Click **Add**.

b) To define the match criteria, click the **Add** (+) button.

c) In **New Extended Access List Object**, enter the name for the ACL (say, *DIA-FTD-Branch*), and click **Add**.



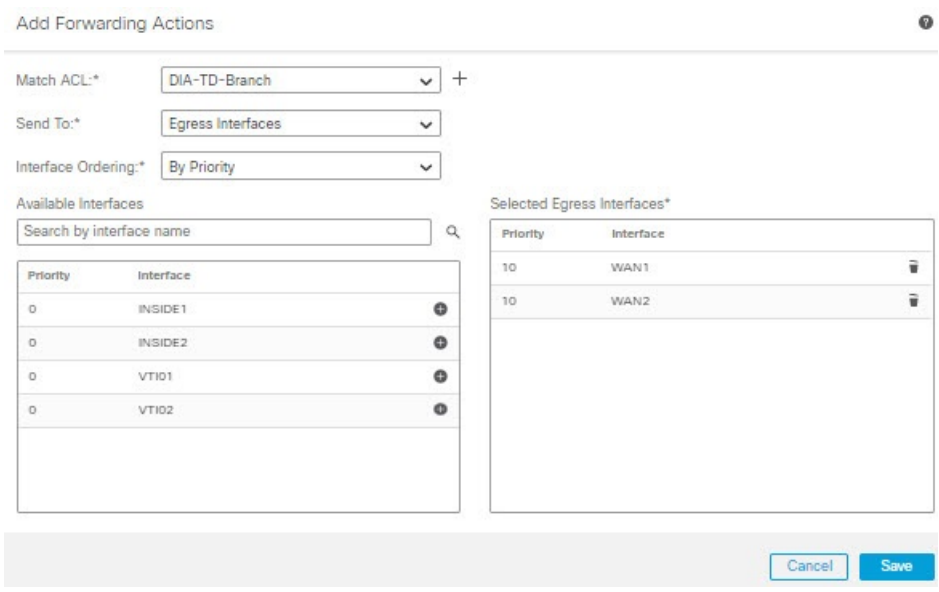
d) In the **Add Extended Access List Entry** dialog box, choose the required web-based applications from the **Application** tab:

Figure 337: Applications tab

On the Firewall Threat Defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

Figure 338: Extended ACL

e) Click **Save**.



f) Select *DIA-FTD-Branch* from the **Match ACL** drop-down list.

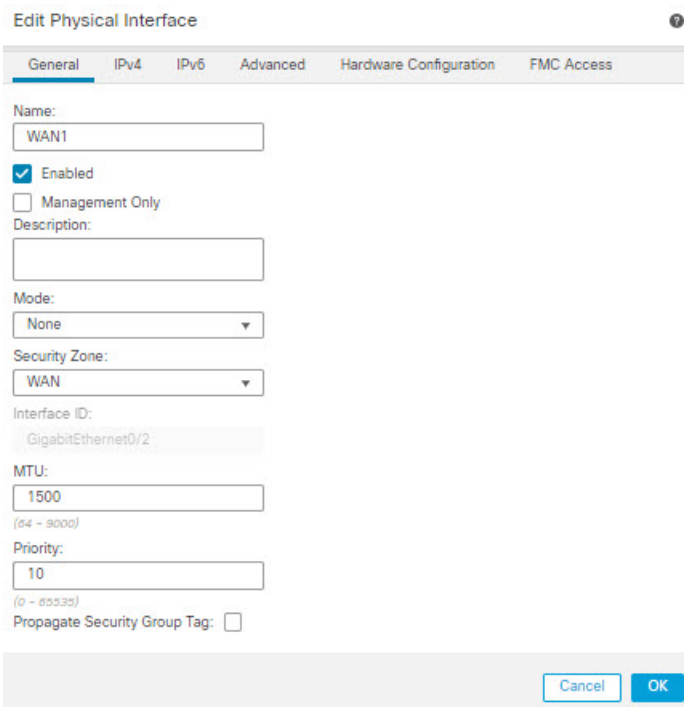
Step 3 Specify the egress interfaces:

a) From the **Send To** and **Interface Ordering** drop-down lists, choose Egress Interfaces, and Interface Priority respectively.

b) Under **Available Interfaces**, click the ⊕ button against the respective interface names to add *WAN1* and *WAN2*:

Figure 339: Configuring policy-based routing

c) Click **Save**.



Step 4 Configure interface priority:

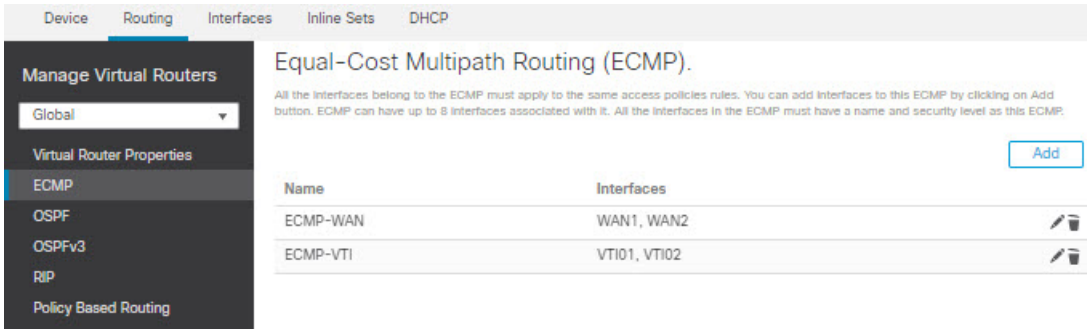
You can set the priority value for the interfaces either in the **Edit Physical Interface** page, or in the **Policy Based Routing** page (**Configure Interface Priority**). In this example, the Edit Physical Interface method is described.

a) Choose **Devices** > **Device Management**, and edit the branch Firewall Threat Defense.

b) Set the priority for the interfaces. Click **Edit** against the interface and enter the priority value:

Figure 340: Setting interface priority

c) Click **Ok** and **Save**.



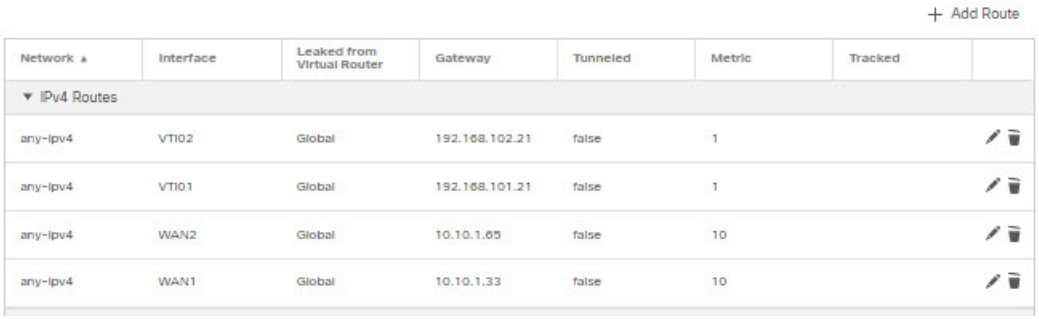
Step 5 Create ECMP zones for load balancing:

a) In the **Routing** page, click **ECMP**.

b) To associate interfaces to the ECMP zone, click **Add**.

c) Select *WAN1* and *WAN 2* and create an ECMP zone—*ECMP-WAN*. Similarly, add *VTI01* and *VTI02* and create an ECMP zone—*ECMP-VTI*:

Figure 341: Associating interfaces with ECMP zone



Step 6 Configure static routes for the zone interfaces for load balancing:

a) In the **Routing** page, click **Static Route**.

b) Click **Add** and specify the static routes for *WAN1*, *WAN2*, *VTI01*, and *VTI02*. Ensure that you specify the same metric value for the interfaces belonging to the same ECMP zones (Step 5):

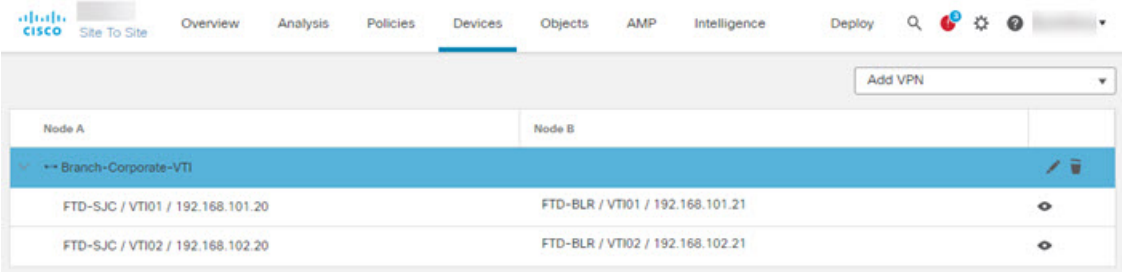
Figure 342: Configuring static routes for ECMP zone interfaces

Note
Ensure that the zone interfaces have the same destination address and metric, but different gateway addresses.

Step 7 Configure trusted DNS on the WAN objects of the branch Firewall Threat Defense to ensure secure flow of traffic to the internet:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Platform Settings**, and create a DNS policy on the branch Firewall Threat Defense.

b) To specify the trusted DNS, edit the policy and click **DNS**.



c) To specify the DNS servers for the DNS resolution to be used by WAN objects, in the **DNS Settings** tab, provide the DNS server group details and select WAN from the interface objects.

d) Use the **Trusted DNS Servers** tab to provide specific DNS servers that you trust for the DNS resolution.

Step 8 Click **Save**, and then click **Deploy**.

Any *YouTube* related access requests from the branch inside network *INSIDE1* or *INSIDE2* are routed to *WAN1* or *WAN2* as they would match the *DIA-FTD-Branch* ACL. Any other request, say *google.com*, are routed through *VTI01* or *VTI02* as configured in the Site to Site VPN Settings.

Figure 343: Site to site VPN settings

With the ECMP configured, the network traffic is seamlessly balanced.

Configure PBR with path monitoring

Configure PBR with path monitoring to optimize application traffic routing by dynamically selecting the best egress interface based on performance metrics such as jitter, round-trip time, and packet loss.

This example describes how to configure PBR with path monitoring for the following applications with flexible metrics:

- Audio or video sensitive applications (example, WebEx Meetings) with Jitter.
- Cloud-based application (example, Office365) with RTT.
- Network-based access control (with a specific source and destination) with packet loss.

Before you begin

1. This example assumes that you are aware of the basic configuration steps for PBR.
2. You have configured ingress and egress interfaces with logical names. In this example, the ingress interface is named *Inside1*, and egress interfaces are named *ISP01*, *ISP02*, and *ISP03*.

Follow these steps to configure PBR with path monitoring:

Procedure

Step 1 Path monitoring configuration on interfaces *ISP01*, *ISP02*, and *ISP03*:

For the metrics collection on the egress interfaces, you must enable and configure path monitoring on them.

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit Firewall Threat Defense.
b) Under the **Interfaces** tab, edit the interface (in our example, *ISP01*)
c) Click the **Path Monitoring** tab, select the **Enable Path Monitoring** check box, and then specify the monitoring type (see Configure path monitoring settings, on page 1547).
d) Click **Ok** and **Save**.
e) Repeat these steps to configure the path monitoring settings for *ISP02* and *ISP03*.

Step 2 Configure policy-based routing for a branch in an organization Firewall Threat Defense, select the ingress interfaces:

a) In the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.
b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.
c) In the **Add Policy Based Route** dialog box, select *Inside 1* from the **Ingress Interface** drop-down list.

Step 3 Specify the match criteria:

a) Click **Add**.
b) To define the match criteria, click the **Add** (+) button.
c) In **New Extended Access List Object**, enter the name for the ACL (example, *PBR-WebEx*), and click **Add**.
d) In the **Add Extended Access List Entry** dialog box, choose the necessary web-based applications, such as WebEx Meetings) from the **Application** tab.

Remember
On Firewall Threat Defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

e) Click **Save**.
f) Select *PBR-WebEx* from the **Match ACL** drop-down list.

Step 4 Specify the egress interfaces:

a) From the **Send To** drop-down list, choose Egress Interfaces.
b) From the **Interface Ordering** drop-down list, choose By Minimal Jitter.
c) Under **Available Interfaces**, click the **Right Arrow** (>)button against the respective interface names to add *ISP01*, *ISP02*, and *ISP03*.
d) Click **Save**.

Step 5 Repeat Step 2 and Step 3 to create PBRs for the *Inside1* interface to route Office365 and network-based access control traffic:

a) Create a match criteria object, example *PBR-Office365*, and select the Office365 application from the **Application** tab.
b) From the **Interface Ordering** drop-down list, choose By Minimal Round Trip Time.
c) Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.
d) Now, create a match criteria object, example *PBR-networks*, and specify the source and destination interface in the **Network** tab.
e) From the **Interface Ordering** drop-down list, choose By Minimal Packet Loss.
f) Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.

Step 6 Click **Save**, and then click **Deploy**.

Step 7 To view path monitoring metrics, in the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management**, and from **More** (⋮) click **Health Monitor**. To view the metric details for the interfaces of the device, you must add the path metrics dashboard. For details, see Add path monitoring dashboard, on page 1548.

The WebEx, Office365, and networks-based ACL traffic are forwarded through the best route derived from the metrics value collected on *ISP01*, *ISP02*, and *ISP03*.

Useful CLIs for monitoring PBR

Run the monitoring commands described in this topic from the Firewall Threat Defense device CLI.

Interface configurations

To view the interface configurations of the device, run the `show run interface` command:

```
> show run interface
!
interface Ethernetl/l
 description Outside ispl handoff
 nameif outside1
 security-level 0
 zone-member ECMP-WAN
 ip address dhcp setroute
 policy-route cost 10
 policy-route path-monitoring 8.8.8.8
 policy-route path-monitoring object-group network-service FMC_NSG_4295470581 policy-route
 path-monitoring object-group network-service FMC_NSG_4295470600
!
interface Ethernet1/2
 description Outside isp2 handoff
 nameif outside2
 security-level 0
 zone-member ECMP-WAN
 ip address 192.133.243.240 255.255.255.192
 policy-route cost 20
 policy-route path-monitoring 8.8.8.8
 policy-route path-monitoring object-group network-service FMC_NSG_4295470581 policy-route
 path-monitoring object-group network-service FMC_NSG_4295470600
!
```

DNS configurations

Application-based routing only uses trusted DNS servers to resolve domains. To view the DNS configurations of the device, run the `show run DNS` command:

```
> show run dns
DNS server-group DefaultDNS
dns trusted-source 10.100.0.5
dns trusted-source 10.200.0.5
```

Route map configurations

When you configure PBR on the device, the Management Center auto-generates the route-map and applies it to the specified ingress interface. To view the route maps of the device, run the `show run route-map` command:

```
> show run route-map
!
route-map FMC_VPN_CONNECTED_DIST_RMAP_1000 permit 10
 match interface inside-employee
 set community 1000
!
route-map FMC GENERATED PBR 1729024850865 permit 5
 match ip address Cloud-storage-apps-acl
  set adaptive-intertace cost outside1 outside2
```

```
!
route-map FMC_GENERATED_PBR_1729024850865 permit 10
match ip address Social-media-apps-acl
set adaptive-interface rtt outside1 outside2

!
route-map FMC_GENERATED_PBR_1729024850865 permit 15
match ip address Conferencing-apps-acl
set adaptive-interface jitter outside1 outside2

!
route-map FMC_GENERATED_PBR_1729024850865 permit 20
match ip address Corp-internal-apps-acl
set adaptive-interface cost outside1_static_vti_1 outside2_static_vti_4
```

Access lists and network service groups configurations

The route-map applied to the ingress interface can reference an extended access control list. To view the details of an access list for PBR, run the `show run access list <access list_name>` command:

```
> show run access-list Cloud-storage-apps-acl
access-list Cloud-storage-apps-acl extended permit ip any object-group-network-service
FMC_NSG_4295470562
```

The network-service objects and object-groups are configured in extended access control lists and referenced in policy-based routing route maps and access control groups. To view the NSG configurations, run the `show object-group network-service <network-service-groups-name>` command. The *network-service-groups-name* is derived from the above show command for an access list.

```
> show object-group network-service FMC_NSG_4295470562
 object-group network-servire FMC_NSG_4295470562 (id=@xfdff0000)
 network-service-member "Box" dynamic
 description File storage and transfer site.

    Last updated: 12 second(s) ago
```

Troubleshoot PBR

This task helps you debug PBR configuration when packets get dropped by verifying routes, monitoring metrics, and validating interface selection.

When PBR is not working as intended, you need to systematically verify the configuration components including route maps, path monitoring, and interface selection to identify the root cause of packet drops.

Before you begin

Follow these steps to troubleshoot PBR configuration when packets get dropped:

Procedure

Step 1 Check that all essential routes for recursive resolution are present by using the show route or show ipv6 route commands in the appropriate tables.

Unless the route map for the interfaces participating in PBR is updated with correct routes, PBR will not work as intended.

Step 2 Display the remote address that path-monitoring uses to monitor metrics by using the **show running-config interface** command.

Example:

```
interface GigabitEthernet0/0
nameif outside_0
security-level 0
zone-member ecmp-zone
ip address 20.0.0.3 255.255.255.0 -> This is egress interface "show running-config" output,
 the monitored address and cost metric value is determined in this output.
policy-route cost 1
policy-route path-monitoring
20.0.0.4
!
int GigabitEthernet 0/3
!
interface GigabitEthernet0/3
nameif outside_3
security-level 0
ip address 11.1.1.2 255.255.255.0 -> This is ingress interface "show running-config" output,
 the specific route-map will be used by PBR to determine the next route.
policy-route route-map rtt-tes
```

This command shows the monitored address and cost metric values for path monitoring by sending ICMP packets or HTTP pings.

Step 3 Examine the **show path-monitoring** and **show run route-map** outputs for packet loss.

Example:

```
ciscoasa(config)# show path-monitoring
Interface: outside_0  -> The remote address used for ICMP monitoring
Remote peer: 20.0.0.4
Version: 6223
Remote peer reachable: Yes -> If this value turns "No", then the ICMPv4/v6 packet is not
reaching the required remote address.
RTT average: 1920 microsecond(s)
Jitter: 394 microsecond(s)
Packet loss: 0%
MOS: 4.40
Last updated: 17 second(s) ago -> The data should be updated by path monitoring after every
 30 seconds. The 'show route-map' would show the
updated metric values.
Interface: outside_2
Remote peer: 40.0.0.4
Version: 6223
Remote peer reachable: Yes
RTT average: 1935 microsecond(s)
Jitter: 433 microsecond(s)
Packet loss: 0%
MOS: 4.40
Last updated: 17 second(s) ago
```

Example:

```
ciscoasa(config)# show route-map
route-map rtt-test, permit, sequence 10
Match clauses:
Set clauses:
adaptive-interface rtt outside_0 (1920) outside_2 (1935) outside_1 (1971) -> Displays the
metric type (rtt) that is used by the policy route to select the adequate interface to send
 the packet. The interface list where cost of each interface is given. As the metric type
is "rtt" and considering the minimum rtt value, the "outside_0" interface route will be
selected by PBR.
route-map mos-test, permit, sequence 10
Match clauses:
Set clauses:
adaptive-interface mos outside_0 (378) outside_1 (390) outside_2 (440) - > As the metric
type is "mos", considering the maximum value of mos, the "outside_2" interface will be
selected by PBR.
```

The metric types (lost, rtt, jitter, cost) should select the interface with the minimum metric value for routing.

The metric type "mos" should select the interface with the maximum metric value for routing.

Step 4 Use **packet-tracer** command to validate the interface selection based on the metric type defined in the PBR.

Example:

```
packet-tracer input <interface> icmp <src ip address> 8 0 <dst ip
address> detailed
Phase: 3
Type: PBR-LOOKUP
Subtype: policy-route
Result: ALLOW
Elapsed time: 60656 ns
Config:
route-map rtt-test permit 10
match ip address allow_101_1_1_2
set adaptive-interface rtt outside_0 outside_2
Additional Information:
Matched route-map rtt-test, sequence 10, permit
Found next-hop 40.0.0.4 using egress ifc outside_2 -> PBR selects the adequate interface
from adaptiveinterface list given in "rtt-test" route-map.
```

Step 5 Use the **packet-tracer** command similar to the **debug policy-route** command.

When PBR successfully selects the route, the packet tracer output looks like this:

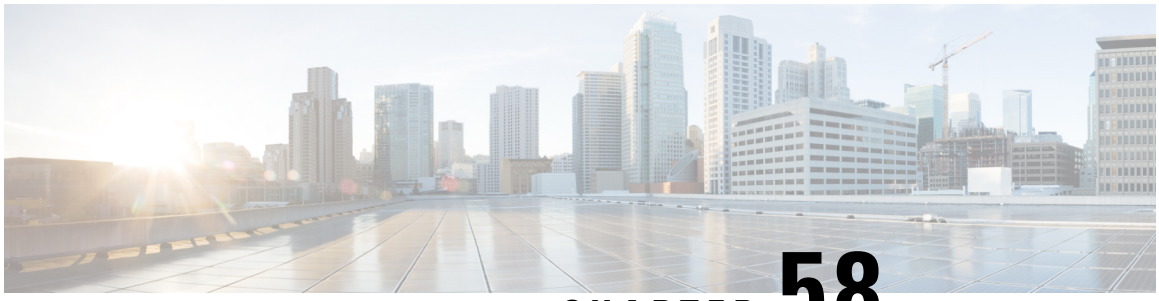
```
pbr: policy based route lookup called for 101.1.1.1/0 to 101.1.1.2/0 proto 1 sub_proto 8
received on
interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map rtt-test, sequence 10, permit; proceed with policy routing
pbr: policy based routing applied; egress_ifc = outside_2 : next_hop = 20.0.0.4
```

When PBR is not able to find the adequate route, it falls back to normal route lookup, and the packet tracer output looks like this:

```
pbr: policy based route lookup called for 100.1.1.1/0 to 100.1.1.2/0 proto 1 sub_proto 8
received on interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map mos-test, sequence 10, permit; proceed with policy routing
pbr: no route to 100.1.1.2 on adaptive-interface outside_2
pbr: no route to 100.1.1.2 on adaptive-interface outside_1
pbr: no route to 100.1.1.2 on adaptive-interface outside_0
pbr: policy based routing could not be applied; proceeding with normal route lookup
```

When a monitored remote address goes down, and path monitoring marks **Remote peer reachable** as **No** for that address, the PBR displays the a log that excludes the interface from adaptive-interface list.

```
pbr: policy based route lookup called for 100.1.1.1/0 to 101.1.1.2/0 proto 1 sub_proto 8
received on
interface outside_3, NSGs, nsg_id=none
pbr: First matching rule from ACL(-1)
pbr: route map rtt-test, sequence 10, permit; proceed with policy routing
pbr: Path Monitoring Ifc Down : adaptive-interface outside_1 Excluded from PBR routing
pbr: policy based routing applied; egress_ifc = outside_2 : next_hop = 40.0.0.4
```



Note
The interface becomes eligible for adaptive PBR routing when the interface is reported as reachable in the path monitoring module.

PART XIV

Network Policies

- Network Address Translation, on page 1567
- Quality of Service, on page 1693

CHAPTER 58

Network Address Translation

The following topics explain Network Address Translation (NAT) and how to configure it on Firewall Threat Defense devices.

- NAT functions, on page 1567
- NAT basics, on page 1568
- Requirements and prerequisites for NAT policies, on page 1577
- Guidelines for NAT, on page 1577
- Manage NAT policies, on page 1583
- Configure NAT for threat defense, on page 1585
- Translating IPv6 networks, on page 1627
- Monitoring NAT, on page 1640
- Examples for NAT, on page 1641

NAT functions

NAT enables private IP networks to connect to the Internet by replacing private IP addresses with public IP addresses. It conserves public addresses by advertising at minimum only one public address for the entire network to the outside world.

Private IP address ranges

Most devices within an IP network are assigned private IP addresses, which are not routable outside the company network due to the shortage of public IPv4 addresses. RFC 1918 defines the private IP address ranges that should not be advertised externally:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the primary functions of NAT is to enable private IP networks to access the Internet by translating private IP addresses into legal, routable public addresses. This approach conserves public IP addresses since NAT can be configured to advertise only a single public address for the entire network.

Other functions of NAT include:

- Security: Hides internal IP addresses, discouraging direct attacks.

- IP routing solutions: Handles overlapping IP addresses without conflict.
- Flexibility: Allows internal IP addressing schemes to change without affecting externally visible public addresses.
- Translating between IPv4 and IPv6 (Routed mode only): Supports translating between IPv4 and IPv6, enabling interoperability between different network types.

Note NAT is optional. If NAT is not configured for specific traffic, that traffic will not be translated but will still be subject to normal security policies.

NAT basics

The following topics explain some of the basics of NAT.

NAT terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the "real" network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, "real" can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the "mapped" network.

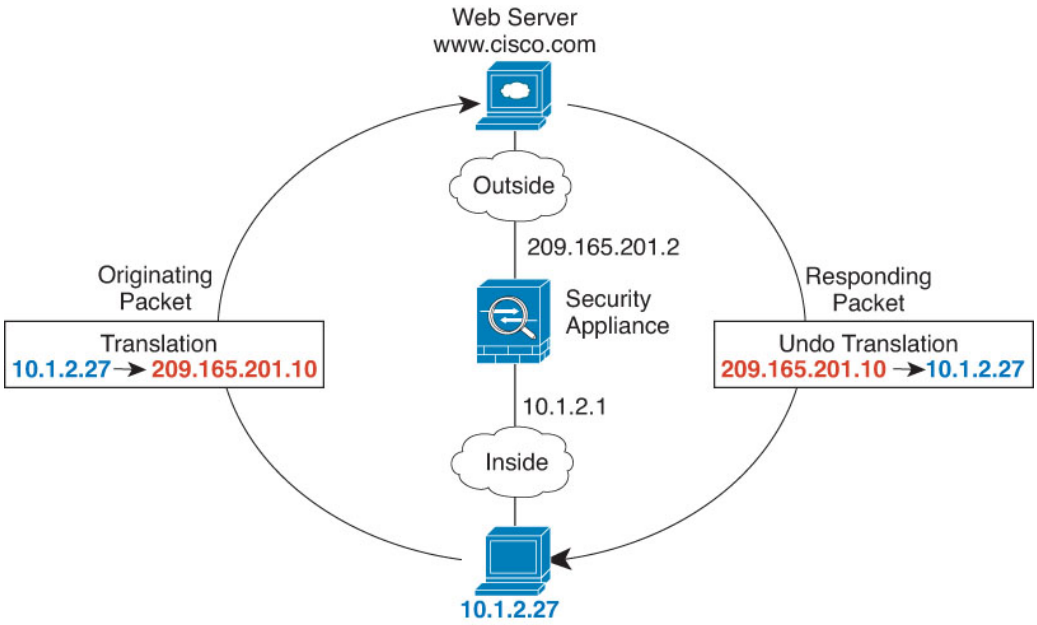
Note During address translation, IP addresses configured for the device interfaces are not translated.

- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that "source" and "destination" are used in commands and descriptions throughout this guide even though a given connection might originate at the "destination" address.

NAT types

You can implement NAT using the following methods:

- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See Dynamic NAT, on page 1593.
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See Dynamic PAT, on page 1598.
- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See Static NAT, on page 1608.
- Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See Identity NAT, on page 1617.



NAT in routed and transparent mode

You can configure NAT in both routed and transparent firewall mode. You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. The following sections describe typical usage for each firewall mode.

NAT in routed mode

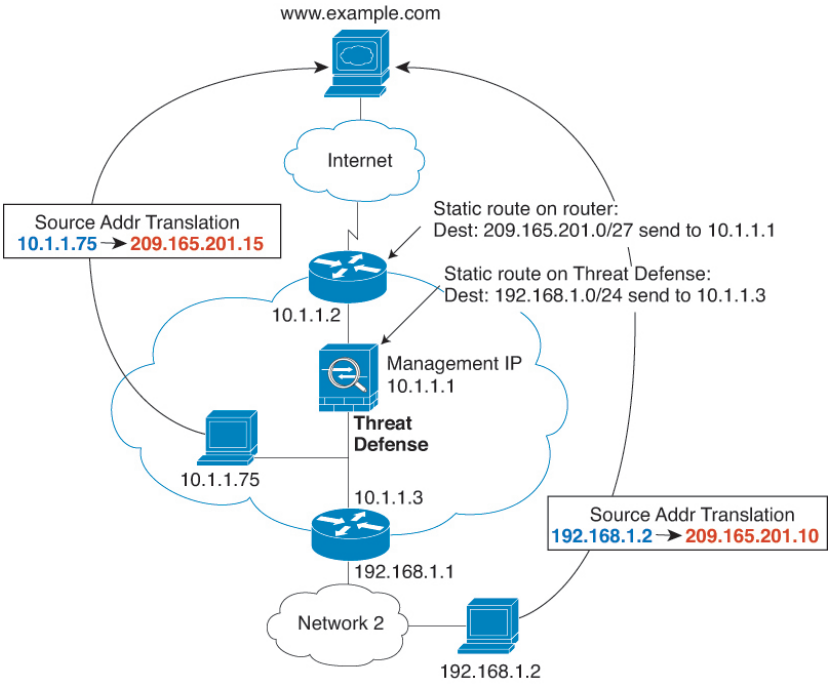
The following figure shows a typical NAT example in routed mode, with a private network on the inside.

Figure 344: NAT Example: Routed Mode

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the Firewall Threat Defense receives the packet because the Firewall Threat Defense performs proxy ARP to claim the packet.

3. The Firewall Threat Defense then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

NAT in transparent mode or within a bridge group



Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. It can perform a similar function within a bridge group in routed mode.

NAT in transparent mode, or in routed mode between members of the same bridge group, has the following requirements and limitations:

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the Firewall Threat Defense sends an ARP request to a host on the other side of the Firewall Threat Defense, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

The following figure shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

Figure 345: NAT Example: Transparent Mode

1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.

2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the Firewall Threat Defense receives the packet because the upstream router includes this mapped network in a static route directed to the Firewall Threat Defense management IP address.
3. The Firewall Threat Defense then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the Firewall Threat Defense sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except for returning traffic, the Firewall Threat Defense looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the Firewall Threat Defense static route for 192.168.1.0/24.

Auto NAT and Manual NAT

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)

Auto NAT

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

Manual NAT

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

Note For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Comparing Auto NAT and Manual NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that manual NAT is more scalable.
- How source and destination NAT is implemented.
  - Auto NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.
- Order of NAT Rules.
  - Auto NAT—Automatically ordered in the NAT table.
  - Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

NAT rule order

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.

Note There is also a Section 0, which contains any NAT rules that the system creates for its own use. These rules have priority over all others. The system automatically creates these rules and clears xlates as needed. You cannot add, edit, or modify rules in Section 0.

Table 96: NAT Rule Table

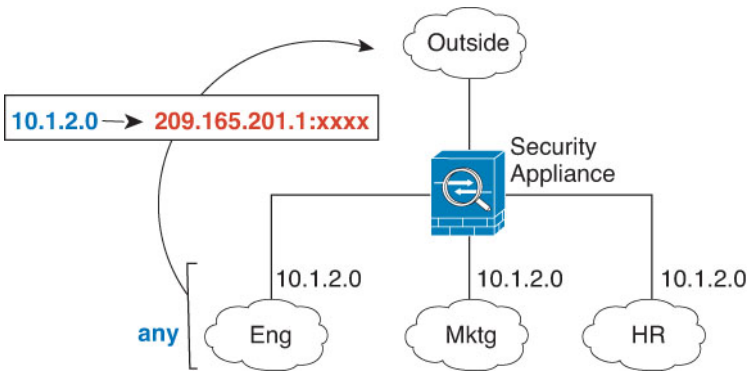
Table Section	Rule Type	Order of Rules within the Section
Section 1	Manual NAT	Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1. By "specific rules first," we mean: • Static rules should come before dynamic rules. • Rules that include destination translation should come before rules with source translation only. If you cannot eliminate overlapping rules, where more than one rule might apply based on the source or destination address, be especially careful to follow these recommendations. If you do not follow the above recommendation, ensure that accurate routes are configured for the mapped addresses to match the correct NAT rule.
Section 2	Auto NAT	If a match in section 1 is not found, section 2 rules are applied in the following order: **1.** Static rules. **2.** Dynamic rules. **Within each rule type, the following ordering guidelines are used:** **1.** Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses. **2.** For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0. **3.** If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.
Section 3	Manual NAT	If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply.

For section 2 rules, for example, you have the following IP addresses defined within network objects:

- 192.168.1.0/24 (static)

- 192.168.1.0/24 (dynamic)
- 10.1.1.0/24 (static)
- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:



- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

NAT interfaces

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

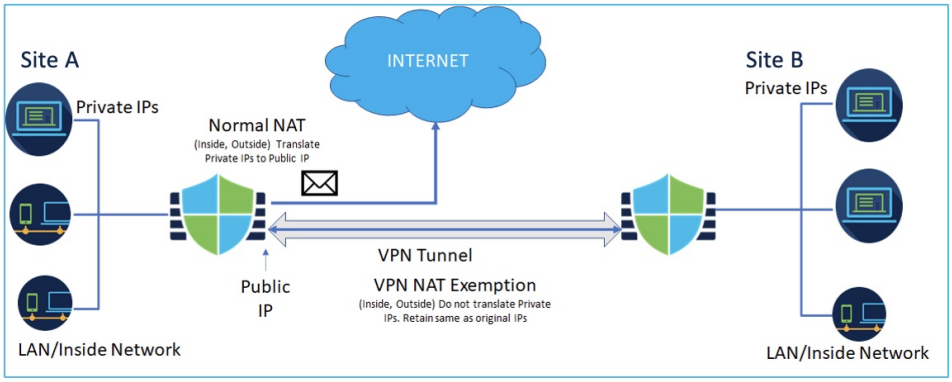
For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.

Figure 346: Specifying Any Interface

However, the concept of "any" interface does not apply to bridge group member interfaces. When you specify "any" interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. When specifying interfaces, you do so indirectly by selecting the interface object that contains the interface.

NAT exemption



When internet edge devices have a site-to-site VPN configured on an interface and also have NAT rules for that interface, you must exempt the VPN traffic from the NAT rules. If you do not exempt the VPN traffic from NAT translation, the traffic gets dropped or is not routed through the VPN tunnel to the remote peer.

NAT exemption allows you to exclude traffic from being translated by NAT rules. When you create a policy-based site-to-site VPN using the Cloud-Delivered Firewall Management Center VPN wizard, you can select the **NAT Exempt** option to create the rules automatically (**Devices** > **VPN** > **Site to Site**). By default, this option is enabled. You can view the NAT exemptions for a device in the NAT policy page (**Devices** > **NAT**, and then click **NAT Exemptions**).

The Cloud-Delivered Firewall Management Center supports NAT exemption for all policy-based site-to-site VPN topology types. For more information, see Configure a policy-based site-to-site VPN, on page 1731.

Consider the following example, which shows a site-to-site VPN tunnel connecting Site A and Site B. For traffic that must go to the Internet, NAT translates the private IPs to a public IP address to access the Internet. For traffic that must go over the VPN tunnel, you must configure NAT exemption for the device in the VPN wizard.

Figure 347: Site-to-site VPN Topology with NAT Exemption

Note that when you upgrade from versions earlier than 7.4, if you have enabled NAT exemption, Cloud-Delivered Firewall Management Center will disable this option. You must enable this option in the policy-based site-to-site VPN wizard.

Configuring routing for NAT

The Firewall Threat Defense device needs to be the destination for any packets sent to the translated (mapped) address.

When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

Addresses on the same network as the mapped interface

If you use addresses on the same network as the destination (mapped) interface, the Firewall Threat Defense uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the Firewall Threat Defense does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

Note If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address. Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur. Configure the ARP table in the ingress interface's **Advanced** settings.

Addresses on a unique network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the Firewall Threat Defense.

Alternatively for routed mode, you can configure a static route on the Firewall Threat Defense for the mapped addresses using any IP address on the destination network as the gateway, and then redistribute the route using your routing protocol. For example, if you use NAT for the inside network (10.1.1.0/24) and use the mapped IP address 209.165.201.5, then you can configure a static route for 209.165.201.5 255.255.255.255 (host address) to the 10.1.1.99 gateway that can be redistributed.

For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the Firewall Threat Defense: specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

The same address as the real address (identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The Firewall Threat Defense will then proxy ARP for the address, even though the packet is not actually destined for the Firewall Threat Defense. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the

Firewall Threat Defense ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the Firewall Threat Defense.

Requirements and prerequisites for NAT policies

Ensure you meet these requirements for configuring NAT policies:

User roles

You must have one of these user privileges to configure and use NAT policies:

- Admin
- Access Admin
- Network Admin

Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

Firewall mode guidelines for NAT

NAT is supported in routed and transparent firewall mode.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Group Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.
- When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.
- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported. However, you can do NAT64/46 between members of different bridge groups, or between a bridge group member (source) and standard routed interface (destination).

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes.

IPv6 NAT guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.
- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.
- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

IPv6 NAT best practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-to-net, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.
- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

NAT support for inspected protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

- Pinhole creation—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.

- NAT rewrite— Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.
- Protocol enforcement—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.

The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.

Note NAT rewrite is supported on the listed ports only. For some of these protocols, you can extend inspection to other ports using Network Analysis Policies, but NAT rewrite is not extended to those ports. This includes DCERPC, DNS, FTP, and Sun RPC inspection. If you use these protocols on non-standard ports, do not use NAT on the connections.

Table 97: NAT Supported Application Inspection

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
DCERPC	TCP/135	No NAT64.	Yes
DNS over UDP	UDP/53	No NAT support is available for name resolution through WINS.	No
ESMTP	TCP/25	No NAT64.	No
FTP	TCP/21	(Clustering) No static PAT.	Yes
H.323 H.225 (Call signaling) H.323 RAS	TCP/1720 UDP/1718 For RAS, UDP/1718-1719	(Clustering) No static PAT. No extended PAT. No NAT64.	Yes
ICMP ICMP Error	ICMP (ICMP traffic directed to a device interface is never inspected.)	No limitations.	No
IP Options	RSVP	No NAT64.	No
NetBIOS Name Server over IP	UDP/137, 138 (Source ports)	No extended PAT. No NAT64.	No
RSH	TCP/514	No PAT. No NAT64. (Clustering) No static PAT.	Yes

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
RTSP	TCP/554 (No handling for HTTP cloaking.)	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
SIP	TCP/5060 UDP/5060	No extended PAT. No NAT64 or NAT46. (Clustering) No static PAT.	Yes
Skinny (SCCP)	TCP/2000	No extended PAT. No NAT64, NAT46, or NAT66. (Clustering) No static PAT.	Yes
SQL*Net (versions 1, 2)	TCP/1521	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
Sun RPC	TCP/111 UDP/111	No extended PAT. No NAT64.	Yes
TFTP	UDP/69	No NAT64. (Clustering) No static PAT. Payload IP addresses are not translated.	Yes
XDMCP	UDP/177	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes

FQDN destination guidelines

You can specify the translated (mapped) destination in a manual NAT rule using a fully-qualified domain name (FQDN) network object instead of an IP address. For example, you can create a rule based on traffic that is destined for the www.example.com web server.

When using an FQDN, the system obtains the DNS resolution and writes the NAT rule based on the returned address. If you are using multiple DNS server groups, the filter domains are honored and the address is requested from the appropriate group based on the filters. If more than one address is obtained from the DNS server, the address used is based on the following:

- If there is an address on the same subnet as the specified interface, that address is used. If there isn't one on the same subnet, the first address returned is used.
- The IP type for the translated source and translated destination must match. For example, if the translated source address is IPv6, the FQDN object must specify IPv6 as the address type. If the translated source is IPv4, the FQDN object can specify IPv4 or both IPv4 and IPv6. In this case, an IPv4 address is selected.

You cannot include an FQDN object in a network group that is used for manual NAT destination. In NAT, an FQDN object must be used alone, as only a single destination host makes sense for this type of NAT rule.

If the FQDN cannot be resolved to an IP address, the rule is not functional until a DNS resolution is obtained.

Additional guidelines for NAT

- NAT rules apply to through the device traffic only, they do not apply to traffic initiated by the device, such as a RADIUS authentication.
- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.
- You cannot write NAT rules for a Virtual Tunnel Interface (VTI), which are used in site-to-site VPN. Writing rules for the VTI's source interface will not apply NAT to the VPN tunnel. To write NAT rules that will apply to VPN traffic tunneled on a VTI, you must use "any" as the interface; you cannot explicitly specify interface names.
- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.
- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.
- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the **clear xlate** command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

  If you create a new NAT rule that should apply to an existing connection (such as a VPN tunnel), you need to use **clear conn** to end the connection. Then, the attempt to re-establish the connection should hit the NAT rule and the connection should be NAT'ed correctly.

Note If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** or **clear conn** commands. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- A network object used in NAT cannot include more than 131,838 IP addresses, either explicitly or implied in a range of addresses or a subnet. Break up the address space into smaller ranges and write separate rules for the smaller objects.

- (Manual NAT only.) When using **any** as the source address in a NAT rule, the definition of “any” traffic (IPv4 vs. IPv6) depends on the rule. Before the Firewall Threat Defense performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the Firewall Threat Defense can determine the value of **any** in a NAT rule. For example, if you configure a rule from “any” to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means “any IPv6 traffic.” If you configure a rule from “any” to “any,” and you map the source to the interface IPv4 address, then **any** means “any IPv4 traffic” because the mapped interface address implies that the destination is also IPv4.
- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify “any” interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  - The failover interface IP address.
  - (Transparent mode.) The management IP address.
  - (Dynamic NAT.) The standby interface IP address when VPN is enabled.
- Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.
- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.
- If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.
- If you use PAT on Sun RPC traffic, which is used to connect to NFS servers, be aware that the NFS server might reject connections if the PAT'ed port is above 1024. The default configuration of NFS servers is to reject connections from ports higher than 1024. The error is typically "Permission Denied." Mapping ports above 1024 happens if you do not select the option to include the reserved ports (1-1023) in the port range of a PAT pool. You can avoid this problem by changing the NFS server configuration to allow all port numbers.
- NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.
- Do not name a network object or group pat-pool, using any combination of upper- or lower-case letters.
- The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.
- You cannot use NAT on the internal payload of Protocol Independent Multicast (PIM) registers.
- (Manual NAT) When writing NAT rules for a dual ISP interface setup (primary and backup interfaces using service level agreements in the routing configuration), do not specify destination criteria in the rule. Ensure the rule for the primary interface comes before the rule for the backup interface. This allows the device to choose the correct NAT destination interface based on the current routing state when the primary ISP is unavailable. If you specify destination objects, the NAT rule will always select the primary interface for the otherwise duplicate rules.

- If you get the ASP drop reason nat-no-xlate-to-pat-pool for traffic that should not match the NAT rules defined for the interface, configure identity NAT rules for the affected traffic so the traffic can pass untranslated.
- If you configure NAT for GRE tunnel endpoints, you must disable keepalives on the endpoints or the tunnel cannot be established. The endpoints send keepalives to the original addresses.
- DHCP and BOOTP share ports UDP/67-68. Because BOOTP is obsolete, writing NAT rules for the bootps port can cause port allocation problems when also running DHCP. Consider using DHCP relay instead for transmitting DHCP requests between network segments.
- (Secure Firewall 200) If you use PAT with SIP sessions, and you send thousands of SIP connections through the device, reduce the SIP invite timeout to the minimum of 1 minute. This can avoid problems with free memory consumption by xlates related to the SIP sessions. Configure the timeout on the **Timeout** page in the Platform Settings policy.
- In rare cases, return traffic (server to client) with an existing translation (xlate) might be logged as a new flow in Connection Events. This can occur when the client has already terminated the connection and the server sends another packet that reaches the device during the brief interval between connection closure and xlate removal, often due to application behavior or TCP stack cleanup. Because the device removes the xlate only after deleting the connection, a server packet can arrive while the xlate still exists. If no valid connection entry is found, the device logs a separate connection event based on the matched Access Control Policy rule.

Manage NAT policies

NAT converts the IP address of an incoming packet to a different address in the outgoing packet. One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into routable addresses that can be used on the public Internet. NAT keeps track of the translations, also known as xlates, to ensure that return traffic is directed to the correct untranslated host address.

Procedure

Step 1 Choose **Devices** > **NAT**.

Step 2 Manage your NAT policies:

- Create—Click **New Policy** and select **Threat Defense NAT**. Refer to Create NAT policies, on page 1584.
- Copy—Click **Copy** ( ) next to the policy you want to copy. You are prompted to give the copy a new, unique name. The copy includes all policy rules and configurations, but does not include device assignments.
- Report—Click **Report** ( ) for the policy. You are prompted to save the PDF report, which includes policy attributes, device assignments, rules, and object usage information.
- Edit—Click **Edit** ( ) next to the policy you want to edit. Refer to Configure NAT for threat defense, on page 1585.

- Delete—Click **Delete** ( ) next to the policy you want to delete, then click **OK**. When prompted whether to continue, you are also informed if another user has unsaved changes in the policy.

  Caution
  After you have deployed a NAT policy to a managed device, you cannot delete the policy from the device. Instead, you must deploy a NAT policy with no rules to remove the NAT rules already present on the managed device. You also cannot delete a policy that is the last deployed policy on any of its target devices, even if it is out of date. Before you can delete the policy completely, you must deploy a different policy to those targets.

Create NAT policies

Create a NAT policy to define how network addresses are translated between different network segments.

When you create a new NAT policy you must, at minimum, give it a unique name. Although you are not required to identify policy targets at policy creation time, you must perform this step before you can deploy the policy. If you apply a NAT policy with no rules to a device, the system removes all NAT rules from that device.

Procedure

Step 1 Choose **Devices** > **NAT**.

Step 2 Click **New Policy** and from the drop-down list, choose **Threat Defense NAT** for Firewall Threat Defense devices.

Firepower NAT is for older devices that are not covered in this document.

Step 3 Enter a unique **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Choose the devices where you want to deploy the policy:

- Choose a device in the **Available Devices** list, and then click **Add to Policy**.

  Alternatively, click and drag a device from the **Available Devices** list to the **Selected Devices** list.

- Remove a device from the **Selected Devices** list by clicking **Delete** ( ) next to the device.

Step 6 Click **Save**.

Configure NAT policy targets

Identify the managed devices that you want to target with your policy while creating or editing a policy and assign NAT policies to identified devices to control NAT behavior. You can search a list of available devices and high-availability pairs, and add them to a list of selected devices.

Procedure

Step 1 Choose **Devices** > **NAT**.

Step 2 Click **Edit** ( ) next to the NAT policy you want to modify.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Policy Assignments**.

Step 4 Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add to Policy**. Alternatively, you can also drag and drop selected devices.
- To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

Step 5 Click **OK**.

Configure NAT for threat defense

The NAT policy is a shared policy. Assign it to devices that need similar NAT rules.

Each rule applies to a device if its interface objects (security zones or interface groups) include an interface for that device. When the interface objects include one or more interface for the device, the rule is deployed to the device. You can target subsets of devices within a shared policy by designing interface objects accordingly. Rules using the "any" interface object apply to all devices.

If you change an interface type to one not valid for NAT on an assigned device, the policy marks the interface as deleted. Click **Save** in the NAT policy to automatically remove the interface from the policy.

You can configure multiple NAT policies if groups of your devices require significantly different rules.

Procedure

Step 1 Navigate from Security Cloud Control to Cloud-Delivered Firewall Management Center, on page 3094

Step 2 Select **Devices** > **NAT**.

- Click **New Policy** > **Threat Defense NAT** to create a new policy. Give the policy a name, optionally assign devices to it, and click **Save**.

  You can change device assignments later by editing the policy and clicking **Policy Assignments**.

- Click **Edit** ( ) to edit an existing threat defense NAT policy. Note that the page also shows Firepower NAT policies, which are not used by Firewall Threat Defense devices.

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Decide what kinds of rules you need.

You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, refer to NAT types, on page 1568.

Step 4 Decide which rules should be implemented as manual or auto NAT.

For a comparison of these two implementation options, refer to Auto NAT and Manual NAT, on page 1571.

Step 5 Decide which rules should be custom per device.

Because you can assign a NAT policy to multiple devices, you can configure a single rule on many devices. However, you might have rules that should be interpreted differently by each device, or some rules that should apply to a subset of devices only.

Use interface objects to control on which devices a rule is configured. Then, use object overrides on network objects to customize the addresses used per device.

For detailed information, refer to Customize NAT rules for multiple devices, on page 1587.

Step 6 Create the rules as explained in these sections.

- Dynamic NAT, on page 1593
- Dynamic PAT, on page 1598
- Static NAT, on page 1608
- Identity NAT, on page 1617

Step 7 Do these to manage your NAT policy:

- To edit the policy name or description, click in those fields, type in your changes, and click outside the fields.
- To view only those rules that apply to a specific device, click **Filter by Device** and select the desired device. A rule applies to a device if it uses an interface object that includes an interface on the device.
- To view any warnings or errors in the policy, click **Show Warnings**, then choose a **Device**. Warnings and errors mark configurations that could adversely affect traffic flow or prevent the policy from deploying.
- To change the devices to which the policy is assigned, click the **Policy Assignments** link and modify the selected devices list as desired.
- To change the number of rules displayed on the page, use the **Rows Per Page** drop-down list.

Step 8 Do these to manage your NAT rules:

- To add a rule, click the **Add Rule** button.
- To edit a rule, click the **Edit** ( ) icon next to the rule.
- To delete a rule, click the **Delete** ( ) icon next to the rule.
- To enable or disable a rule, right-click the rule and choose **Enable** or **Disable** from the **State** menu. You can temporarily disable a rule without deleting it using these controls.
- To select more than one rule to enable, disable, or delete, click the checkbox for the rules, or the checkbox in the header, then perform the action.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customize NAT rules for multiple devices

Because the NAT policy is shared, you can assign a given policy to more than one device. However, you can configure at most one auto NAT rule for a given object. Thus, if you want to configure different translations for an object based on the specific device doing the translation, you need to carefully configure the interface objects (security zones or interface groups) and define network object overrides for the translated address. The interface objects determine on which devices a rule gets configured. The network object overrides determine what IP addresses are used by a given device for that object.

Consider the following scenario:

- FTD-A and FTD-B have inside networks 192.168.1.0/24 attached to the interface named “inside.”
- On FTD-A, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.100.10.10 - 10.100.10.200 range when going to the “outside” interface.
- On FTD-B, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.200.10.10 - 10.200.10.200 range when going to the “outside” interface.

Do these steps to accomplish the above scenario. Although this example rule is for dynamic auto NAT, you can generalize the technique for any type of NAT rule.

Procedure

Step 1 Create the security zones for the inside and outside interfaces.

a) Choose **Objects** > **Object Management**.
b) Select **Interface** from the table of contents and click **Add** > **Security Zone**.

You can use interface groups instead of zones.

c) Configure the inside zone properties.

- **Name**—Enter a name, for example, **inside-zone**.
- **Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
- **Selected Interfaces**—Add the FTD-A/inside and FTD-B/inside interfaces to the selected list.

d) Click **Save**.
e) Click **Add** > **Security Zone** and define the outside zone properties.

- **Name**—Enter a name, for example, **outside-zone**.
- **Interface Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
- **Selected Interfaces**—Add the FTD-A/outside and FTD-B/outside interfaces to the selected list.

f) Click **Save**.

Step 2 Create the network object for the original inside network on the Object Management page.

a) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

b) Configure the inside network properties.

- **Name**—Enter a name, for example, **inside-network**.
- **Network**—Enter the network address, for example, **192.168.1.0/24**.

c) Click **Save**.

Step 3 Create the network object for the translated NAT pool and define overrides.

a) Click **Add Network** > **Add Object**.

b) Configure the NAT pool properties for FTD-A.

- **Name**—Enter a name, for example, **NAT-pool**.
- **Network**—Enter the range of addresses to include in the pool for FTD-A, for example, **10.100.10.10-10.100.10.200**.

c) Select **Allow Overrides**.

d) Click the **Overrides** heading to open the list of object overrides.

e) Click **Add** to open the Add Object Override dialog box.

f) Select FTD-B and **Add** it to the **Selected Devices** list.

g) Click **Override** and change **Network** to **10.200.10.10-10.200.10.200**.

h) Click **Add** to add the override to the device.

By defining an override for FTD-B, whenever the system configures this object on FTD-B, it will use the override value instead of the value defined in the original object.

i) Click **Save**.

Step 4 Configure the NAT rule.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-zone.
- **Destination Interface Objects** = outside-zone.

Note
The interface objects control on which devices the rule is configured. Because in this example the zones contain interfaces for FTD-A and FTD-B only, even if the NAT policy were assigned to additional devices, the rule would be deployed to those 2 devices only.

e) On **Translation**, configure the following:

- **Original Source** = inside-network object.
- **Translated Source** > **Address**= NAT-pool object.

f) Click **Save**.

You now have a single rule that will be interpreted differently for FTD-A and FTD-B, providing unique translations for the inside networks protected by each firewall.

Search and filter the NAT rule table

You can search and filter the NAT rule table to help you find rules that you need to modify or view. When you filter the table, only matching rules are shown. Note that although the rule numbers change to be sequentially 1, 2, and so forth, filtering does not change the actual rule number or the rule's location in the table relative to hidden rules. Filtering simply changes what you can see to help you locate rules that interest you.

When editing the NAT policy, you can use the fields above the table to do these types of search or filter:

- **Filter by Device**—Click **Filter by Device**, then select the devices whose rules you want to see and click **OK**. Whether a rule applies to a device is determined by the rule's interface constraints. If you specify a security zone or interface group for either the source or destination interface, the rule applies to a device if at least one interface for the device is in the zone or group. If a NAT rule applies to any source and any destination interface, then it applies to all devices.

  If you also do a text or multiple-attribute search, the results are constrained to the selected devices.

  To remove this filter, click **Filter by Device** and deselect the devices, or select **All**, and click **OK**.

- **Simple Text Search**—In the **Filter** box, type a string and press Enter. The string is compared to all values in the rules. For example, if you enter "network-object-1," which is the name of a network object, you would get rules that use the object in source, destination, and PAT pool attributes.

  For network and port objects, the string is also compared to the contents of the objects used in the rule. For example, if a PAT pool object includes the range 10.100.10.3-10.100.10.100, searching on either 10.100.10.3 or 10.100.10.100 (or a partial 10.100.10) will include rules that use that PAT pool object. However, the match must be exact: searching on 10.100.10.5 will not match this PAT pool object, even though the IP address is within the object's IP address range.

  To remove the filter, click the **x** on the right side of the Filter box.

- **Multiple-Attribute Search**—If a simple text search gives you too many hits, you can configure multiple values for the search. Click in the **Filter** box to open the list of attributes, then select or enter strings for the attributes you intend to search and click the **Filter** button. These attributes are the same as the ones you would configure within a NAT rule. The attributes are and'ed, so filtered results include only those rules that match all attributes you configured.

  - For binary attributes, such as the rule state (enabled/disabled), whether a PAT pool is configured (enabled/disabled), the direction of the rule (uni/bi), or rule type (static/dynamic), simply check or uncheck the boxes as appropriate. Select both boxes if you do not care about the attribute value. If you deselect both boxes, no rules will match the filter.

- For string attributes, type a full or partial string relevant to that attribute. These will be object names, either for security zones/interface groups, network objects, or port objects. It can also be the network or port object contents, which are matched the same way they are for simple text searches.

To remove the filter, click the **x** on the right side of the Filter box, or click in the Filter box to open the drop-down list, and click the Clear button.

Enable, disable, or delete multiple rules

You can enable or disable manual NAT rules, or delete any NAT rule, one by one. You can also select multiple rules and apply changes to all of them at once. Because enable/disable applies to manual NAT only, if you select a mix of rule types, you can delete them only. Note that when you enable or disable rules, it does not matter if you select some rules that were already enabled or disabled. For example, enabling an already enabled rule simply leaves the rule enabled.

Procedure

Step 1 Select **Devices** > **NAT**, and edit a threat defense NAT policy.

Step 2 (Optional) Filter the NAT rules to locate the ones you want to change.

Filtering is especially useful if you have a large NAT policy. For example, you could search on disabled rules to find ones that need to be enabled.

Step 3 Select the rules you want to change.

- Click the checkbox in the left column of the rule to select (or deselect) individual rules.
- Click the checkbox in the table header to select all the rules on the currently displayed page.

Your selection is preserved as you go from page to page. However, in practice, it makes most sense to perform your actions on the rules selected on a page before going to the next page.

Step 4 Perform the desired action. When selecting multiple rules, you are asked to confirm the action.

Note that these actions are also available on the right-click menu.

- To enable all rules, click **Select Bulk Action** > **Enable**.
- To disable all rules, click **Select Bulk Action** > **Disable**.
- To delete all rules, click **Select Bulk Action** > **Delete**.

NAT templates

A NAT template is a predefined configuration tool that simplifies complex NAT setups by offering predefined recommended configurations. It streamlines the NAT setup process, making it accessible and efficient.

NAT template use cases

NAT templates are designed to address specific scenarios. The available templates cover these use cases:

- Allow internal hosts to access the Internet.
- Allow external hosts to access internal resources.

These templates simplify the configuration process by providing predefined NAT flows tailored to these typical requirements.

After you enter the required information for each template, a visual representation of the NAT rule appears at the bottom of the page. This feature provides a clear view of the NAT rule during addition or modification, enhancing the user interface experience.

Create a NAT rule for internal hosts

When internal hosts need to access resources across the Internet, you can use this template. This template creates a dynamic Auto NAT rule that translates the source to the destination interface IP.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, you can create objects while defining the NAT rule.

Configure an **Original Source**. This must be a network object (not a group), and can be a host, range, or subnet.

Procedure

Step 1 Select **Policies** > **Network Policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Click the **Add** drop-down button to create a new rule.

Step 3 Under **Use templates**, choose the **Allow internal hosts to access internet** option.

Step 4 On the page that appears, select the Source interface, Destination Interface and Original source.

- Source interface is the interface group or zone from which the internal hosts are connected or closest.
- Destination interface is the exit interface group or zone, which is connected to or closest to Internet.
- Original Source is the internal network or IP addresses from which need to reach the Internet.

Note

- The **Create** button in the original source drop-down can be used to create a network object for the original source.
- The **Create** button in the Source interface or Destination interface drop-down can be used to create interface group or zone object to be used.

Step 5 Click **Add Rule** to save the rule.

Note

- The **Preset network configuration** drop-down shows the configurations preset for this template. You cannot change these configurations.

- The **Preview configuration** panel lets you view a visual representation of the rule during configuration.

Create a NAT rule for external hosts

When external hosts need to access internal resources, this template creates a static auto NAT rule that translates the source to the destination interface IP. Use this configuration when you need to allow external access to internal servers or services.

Before you begin

Select **Objects** and create the network objects or groups needed in the rule. Alternatively, create objects while you define a NAT rule.

Configure an **Original Source**. This must be a network object (not a group), and can be a host, range, or subnet.

Procedure

Step 1 Select **Policies** > **Network Policies** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Click the **Add** drop-down button to create a new rule.

Step 3 Under **Use templates** select the **Allow external hosts to access internal resources** option.

Step 4 On the page that appears, select the **Source interface**, **Destination interface**, and **Original source**.

- Source interface is the interface group or zone on which the internal server is connected or closest.
- Destination interface is the exit interface group or zone which is connected or closest to Internet.
- Original source is the internal network or IP addresses of the internal server.

Note

- The **Create** button in the original source drop-down can be used to create a network object for the original source.
- The **Create** button in the Source interface or Destination interface drop-down can be used to create interface group or zone.

Step 5 Select the **Port type** as TCP or UDP.

Step 6 Configure the original and translated ports.

- **Original source port** is the port on which the internal server is listening.
- **Translated source** port is the port that will be used to connect to the internal server.

Step 7 Click on **Add Rule** to save the rule.

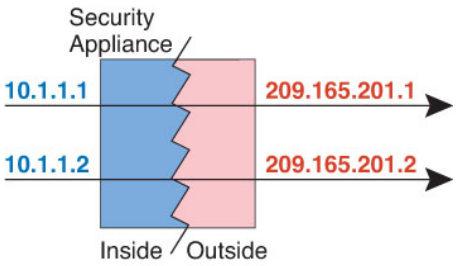
Note

- The **Preset network configuration** drop-down shows the configurations preset for this template. You cannot change these configurations.

- The **Preview configuration** panel lets you view a visual representation of the rule during configuration.

Dynamic NAT

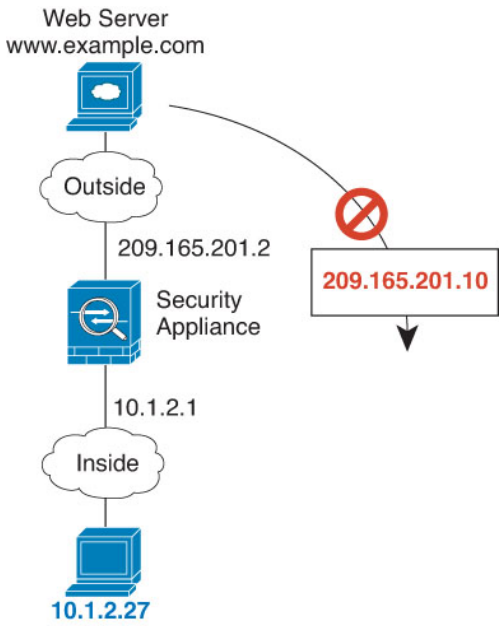
The following topics explain dynamic NAT and how to configure it.



About dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule. A successful connection from a remote host can reset the idle timer for the connection.



The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

Figure 348: Dynamic NAT

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.

Figure 349: Remote Host Attempts to Initiate a Connection to a Mapped Address

Dynamic NAT disadvantages and advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

Configure dynamic auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The network object or group that contains the mapped addresses.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1677.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure dynamic manual NAT

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—This can be a network object or group, but it cannot include a subnet. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

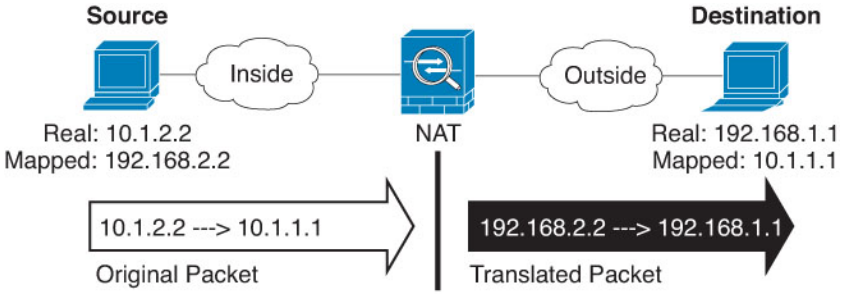
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule and select the **Manual NAT rule** option in the drop-down.
- Click **Edit** () to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The network object or group that contains the mapped addresses.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 (Optional.) On **Advanced**, select the desired options:

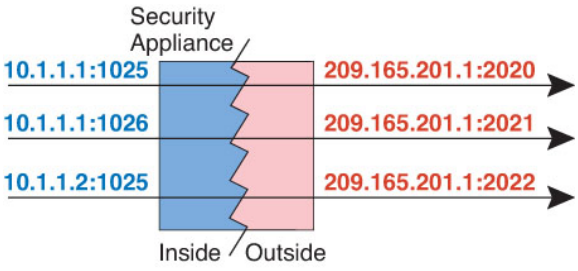
- (For source translation only.) **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1677.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

Dynamic PAT

The following topics describe dynamic PAT.



About dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

Figure 350: Dynamic PAT

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

Note We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.

Dynamic PAT disadvantages and advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the Firewall Threat Defense interface IP address as the PAT address.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see NAT support for inspected protocols, on page 1578.

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

PAT pool object guidelines

When creating network objects for a PAT pool, follow these guidelines.

For a PAT pool

- Ports are mapped to an available port in the 1024 to 65535 range. You can optionally include the reserved ports, those below 1024, to make the entire port range available for translations.

  When operating in a cluster, blocks of 512 ports per address are allocated to the members of the cluster, and mappings are made within these port blocks. If you also enable block allocation, the ports are distributed according to the block allocation size, whose default is also 512. If you change the cluster unit limit (the size of the cluster), ensure that you clear xlates or reboot the devices so that PAT pools can be appropriately reallocated to the cluster units.

- If you enable block allocation for a PAT pool, port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host.

- If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT, then the other rule must also specify extended PAT.

- If a host has an existing connection, then subsequent connections from that host use the same PAT IP address. If no ports are available, this can prevent the connection. Use the round robin option to avoid this problem.

- For best performance, limit the number of IP addresses within a PAT pool to 10,000.

For extended PAT for a PAT pool

- Many application inspections do not support extended PAT.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.
- You cannot use extended PAT on units in a cluster.
- Extended PAT increases memory usage on the device.

For round robin for a PAT pool

- If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. However, this “stickiness” does not survive a failover. If the device fails over, then subsequent connections from a host might not use the initial IP address.
- IP address “stickiness” is also impacted if you mix PAT pool/round robin rules with interface PAT rules on the same interface. For any given interface, choose either a PAT pool or interface PAT; do not create competing PAT rules.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

Configure dynamic auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** drop-down button to create a new rule and select the **Auto NAT rule** option in the drop-down.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Do not select the destination interface IP or a single address as the **Translated Source**.

Step 6 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 7 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address or PAT pool.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 8 Click **Save** to add the rule.

Step 9 Click **Save** on the NAT page to save your changes.

Configure dynamic manual PAT

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

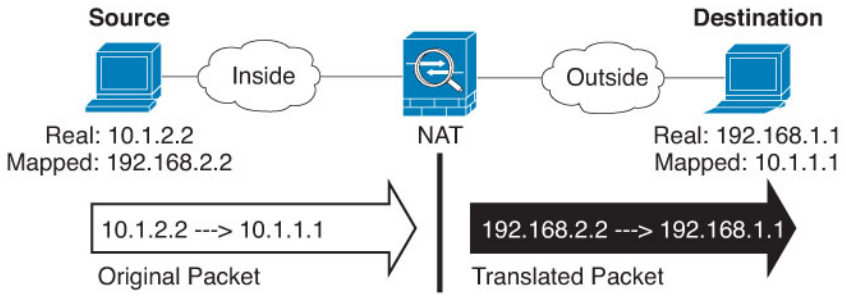
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule and select the **Manual NAT rule** option in the drop-down.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Do not select the destination interface IP or a single address as the **Translated Source**.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 9 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 10 Click **Save** to add the rule.

Step 11 Click **Save** on the NAT page to save your changes.

Configure PAT with port block allocation

For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). If you allocate a block of ports, subsequent connections from the host use new randomly-selected ports within the block. If necessary, additional blocks are allocated

if the host has active connections for all ports in the original block. Blocks are freed when the last xlate that uses a port in the block is removed.

The main reason for allocating port blocks is reduced logging. The port block allocation is logged, connections are logged, but xlates created within the port block are not logged. On the other hand, this makes log analysis more difficult.

Port blocks are allocated in the 1024-65535 range only. There are separate blocks for TCP, UDP, and ICMP connections, and these blocks can overlap. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host. You can create a separate NAT rule that does not use block allocation for applications that use low port numbers; for twice NAT, ensure the rule comes before the block allocation rule.

Before you begin

Usage notes for NAT rules:

- You can include the **Use Round Robin Allocation** option, but you cannot include the options for extending PAT uniqueness, using a flat range, including the reserved ports, or falling through to interface PAT. Other source/destination address and port information is also allowed.
- As with all NAT changes, if you replace an existing rule, you must clear xlates related to the replaced rule to have the new rule take effect. You can clear them explicitly or simply wait for them to time out. However, when operating in a cluster, you must reload the cluster so that the units can distribute blocks correctly.

Note If you are switching between a regular PAT and block allocation PAT rule, for object NAT, you must first delete the rule, then clear xlates. You can then create the new object NAT rule. Otherwise, you will see pat-port-block-state-mismatch drops in the **show asp drop** output.

- When you form a cluster while the device that will become the control node has an existing NAT policy that uses PAT pools, PAT port block distribution might not initialize correctly. The control node does not own or distribute the port blocks, and the **show nat pool cluster summary** command might show all port blocks as *RESERVED* on every cluster node.
  - Before forming a cluster, remove any existing NAT policy that uses PAT pools from the device that will become the control node. After cluster formation is complete, reconfigure and deploy the NAT policy.
  - If the cluster is already formed and all port blocks appear as *RESERVED*, delete the affected NAT policy and deploy the change. Then re-create and deploy the policy. Use the **show nat pool cluster summary** command to verify that the port blocks are distributed correctly across the cluster nodes.
- For a given PAT pool, you must specify (or not specify) block allocation for all rules that use the pool. You cannot allocate blocks in one rule and not in another. PAT pools that overlap also cannot mix block allocation settings. You also cannot overlap static NAT with port translation rules with the pool.

Procedure

Step 1 (Optional.) Configure global PAT port block allocation settings.

There are a few global settings that control port block allocation. If you want to change the defaults for these options, you must configure a FlexConfig object and add it to your FlexConfig policy.

a) Select **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object** and create a new object.

b) Configure the block allocation size, which is the number of ports in each block.

xlate block-allocation size *value*

The range is 32-4096. The default is 512. Use the "no" form to return to the default.

If you do not use the default, ensure that the size you choose divides evenly into 64,512 (the number of ports in the 1024-65535 range). Otherwise, there will be ports that cannot be used. For example, if you specify 100, there will be 12 unused ports.

Using the default block-allocation size, a single PAT IP can serve 126 unique, simultaneous users (number of ports 64,512 divided by 512).

c) Configure the maximum blocks that can be allocated per host.

xlate block-allocation maximum-per-host *number*

The limit is per protocol, so a limit of 4 means at most 4 UDP blocks, 4 TCP blocks, and 4 ICMP blocks per host. The range is 1-8, the default is 4. Use the "no" form to return to the default.

d) (Optional.) Enable interim syslog generation.

xlate block-allocation pba-interim-logging *seconds*

By default, the system generates syslog messages during port block creation and deletion. If you enable interim logging, the system generates the following message at the interval you specify. The messages report all active port blocks allocated at that time, including the protocol (ICMP, TCP, UDP) and source and destination interface and IP address, and the port block. You can specify an interval from 21600-604800 seconds (6 hours to 7 days).

%ASA-6-305017: Pba-interim-logging: Active *protocol* block of ports for translation from *real_interface*:*real_host_ip* to *mapped_interface*:*mapped_ip_address*/*start_port_num*-*end_port_num*

Example:

The following example sets the block allocation size to 64, the per-host maximum to 8, and enables interim logging every 6 hours.

```
xlate block-allocation size 64
xlate block-allocation maximum-per-host 8
xlate block-allocation pba-interim-logging 21600
```

e) Select the following options in the FlexConfig object:

- **Deployment** = **Everytime**
- **Type** = **Append**

f) Click **Save** to create the FlexConfig object.

g) Select **Devices** > **FlexConfig**, and create or edit the FlexConfig policy that is assigned to the devices that need to have these settings adjusted.
h) Select your object in the available objects list and click > to move it to the selected objects list.
i) Click **Save**.

You can click **Preview Config**, select one of the target devices, and verify that the xlate commands appear correctly.

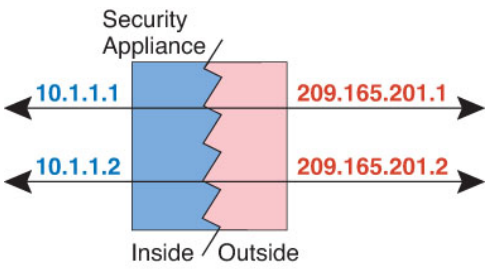
Step 2 Add NAT rules that use PAT pool port block allocation.

a) Select **Devices** > **NAT** and add or edit the threat defense NAT policy.
b) Add or edit a NAT rule and configure at least the following options.

- **Type** = **Dynamic**
- In **Translation** > **Original Source**, select the object that defines the source address.
- On **PAT Pool**, configure the following options:
  - Select **Enable PAT Pool**
  - In **PAT** > **Address**, select a network object or group that defines the pat pool.
  - Select the **Block Allocation** option.

c) Save your changes to the rule and to the NAT policy.

Static NAT



The following topics explain static NAT and how to implement it.

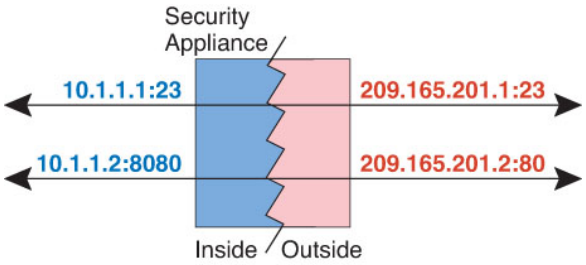
About static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

Figure 351: Static NAT

Note You can disable bidirectionality if desired.



Static NAT with port translation

Static NAT with port translation lets you specify a real and mapped protocol and port.

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 352: Typical Static NAT with Port Translation Scenario

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.

Note For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

Static NAT with Identity Port Translation

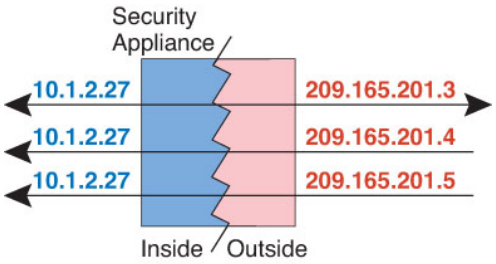
You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect

to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

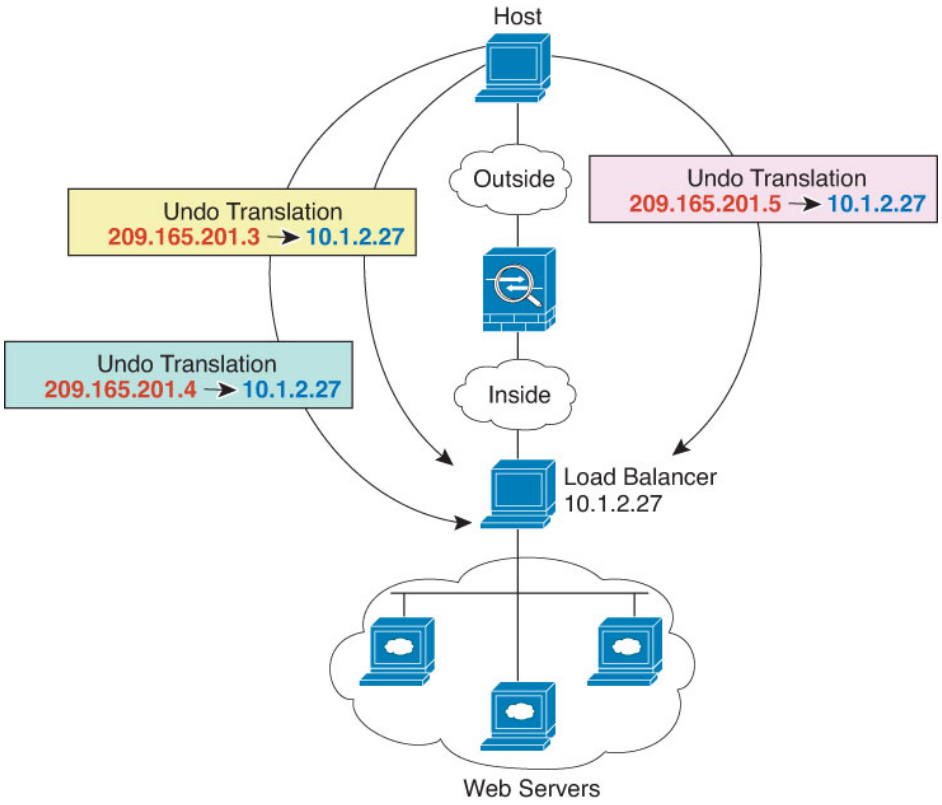
Static Interface NAT with Port Translation



You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

One-to-many static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

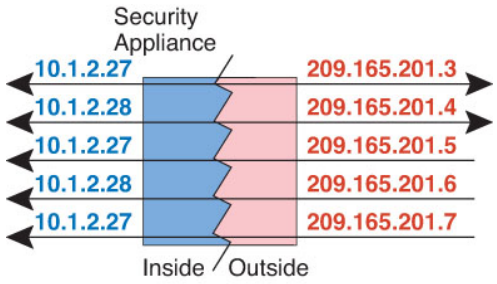


The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

Figure 353: One-to-Many Static NAT

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 354: One-to-Many Static NAT Example



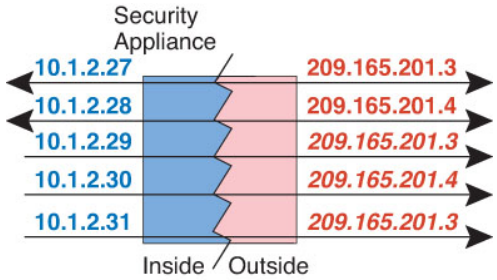
Other mapping scenarios (not recommended)

NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated *to* the real host, but all traffic *from* the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.

Figure 355: Few-to-Many Static NAT



For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

Note Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

Figure 356: Many-to-Few Static NAT

Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

Configure static auto NAT

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, ranges, or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** drop-down button to create a new rule and select the **Auto NAT rule** option in the drop-down.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

- (Optional.) **Original Port**, **Translated Port**—If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1677. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure static manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

- **Address**—Create a network object or group containing hosts, range, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

Procedure

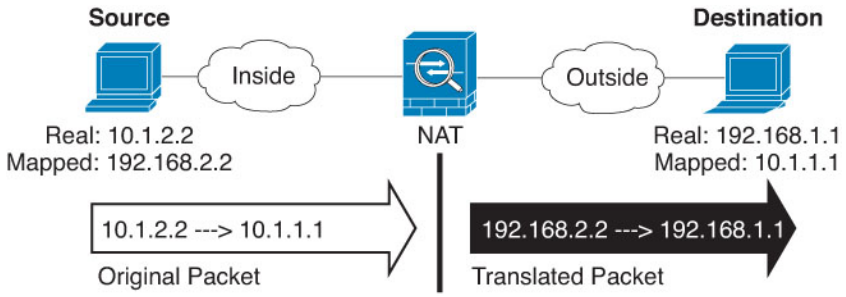
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule and select the **Manual NAT rule** option in the drop-down.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

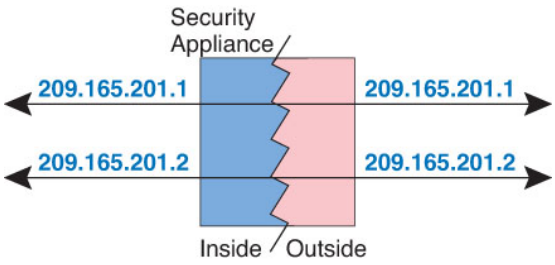
NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1677. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.



Step 10 Click **Save** on the NAT page to save your changes.

Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate that network to itself.

The following figure shows a typical identity NAT scenario.

Figure 357: Identity NAT

The following topics explain how to configure identity NAT.

Configure identity auto NAT

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—A network object or group with the exact same contents as the original source object. You can use the same object.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** drop-down button to create a new rule and select the **Auto NAT rule** option in the drop-down.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Do not configure the **Original Port** and **Translated Port** options for identity NAT.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Do not configure this option for identity NAT.
- **Net to Net Mapping**—Do not configure this option for identity NAT.

- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure identity manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.

Procedure

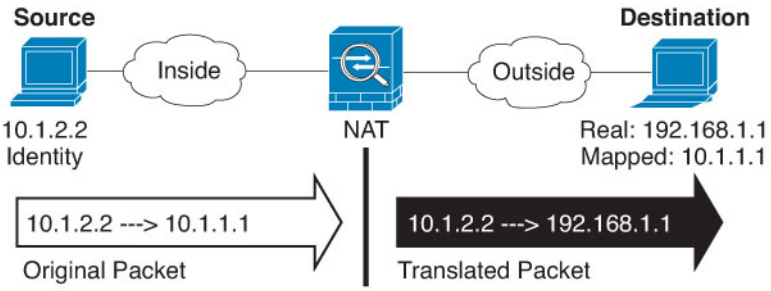
Step 1 Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule and select the **Manual NAT rule** option in the drop-down.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Interface Object** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

NAT rule properties for Firewall Threat Defense

Use network address translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publicly routable addresses. The translation can be from one address to another, or you can use port address translation (PAT) to translate many addresses to one or a few addresses, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

NAT Type

Whether you want to configure a **Manual NAT Rule** or an **Auto NAT Rule**. Auto NAT translates the source address only, and you cannot make different translations based on the destination address. Because auto NAT is more simple to configure, use it unless you need the added features of manual NAT. For more information on the differences, see Auto NAT and Manual NAT, on page 1571.

Type

Whether the translation rule is **Dynamic** or **Static**. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

Enable (Manual NAT only.)

Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page. You cannot disable auto NAT rules.

Insert (Manual NAT only.)

Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Description (Optional. Manual NAT only.)

A description of the purpose of the rule.

The following topics describe the tabs for the NAT rules properties.

Interface objects NAT properties

Interface objects (security zones or interface groups) define the interfaces to which a NAT rule applies. In routed mode, you can use the default "any" for both source and destination to apply to all interfaces of all assigned devices. However, you typically want to select specific source and destination interfaces.

Notes

- The concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. You cannot configure NAT for the bridge virtual interface (BVI) itself, you can configure NAT for member interfaces only.

  If you select interface objects, a NAT rule will be configured on an assigned device only if the device has interfaces included in all selected objects. For example, if you select both source and destination security zones, both zones must contain one or more interface for a given device.

- If more than one interface in an interface object exists on a given device, identical rules are created for each interface. This can become an issue for static NAT rules that include destination translation. Because NAT rules are applied based on first hit rule, only the rule created for the first interface configured for the object matches traffic. When configuring static NAT with destination translation, use interface objects that include at most one interface per device assigned to the NAT policy to ensure you are getting the desired results.

Source Interface Objects, Destination Interface Objects

(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped

interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Translation properties for auto NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

Original Source (Always required.)

The network object that contains the addresses you are translating. This must be a network object (not a group), and it can be a host, range, or subnet.

You cannot create auto NAT rules for the system-defined any-ipv4 or any-ipv6 objects.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary. Do not configure these options for identity NAT.

Translation properties for manual NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

Original Source (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can specify **Any** in the rule.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback. If the object contains one host address only, it is used for PAT.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Destination

The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Translated Destination

The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

You can use a network object that specifies a fully-qualified domain name as the translated destination; for more information, see FQDN destination guidelines, on page 1580.

Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port

The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

- (Dynamic NAT or PAT.) You cannot do translation on the **Original Source Port** and **Translated Source Port**. You can do translation on the destination port only.
- NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

PAT pool NAT properties

When you configure dynamic NAT, you can define a pool of addresses to use for port address translation using the properties on the **PAT Pool** tab.

Enable PAT Pool

Select this option to configure a pool of addresses for PAT.

PAT

The addresses to use for the PAT pool, one of the following:

- **Address**—The object that defines the PAT pool addresses, either a network object that includes a range, or a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.
- **Destination Interface IP**—Indicates that you want to use the destination interface as the PAT address. For this option, you must select a specific **Destination Interface Object**; you cannot use **Any** as the destination interface. This is another way to implement interface PAT.

Round Robin

To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one

address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

Extended PAT Table

To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

Flat Port Range; Include Reserved Ports

To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the Firewall Threat Defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

Block Allocation

To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Advanced NAT properties

When you configure NAT, you can configure properties that provide specialized services in the **Advanced** options. All of these properties are optional: configure them only if you need the service.

Translate DNS replies that match this rule

Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see DNS query and response rewriting using NAT, on page 1677. This option is not available if you are doing port translation in a static NAT rule.

Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address. You also cannot select the option if you configure a PAT pool.

IPv6

Whether to use the IPv6 address of the destination interface for interface PAT.

Net to Net Mapping (Static NAT only.)

For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.

Do not proxy ARP on Destination Interface (Static NAT only.)

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Unidirectional (Manual NAT only, static NAT only.)

Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Translating IPv6 networks

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:

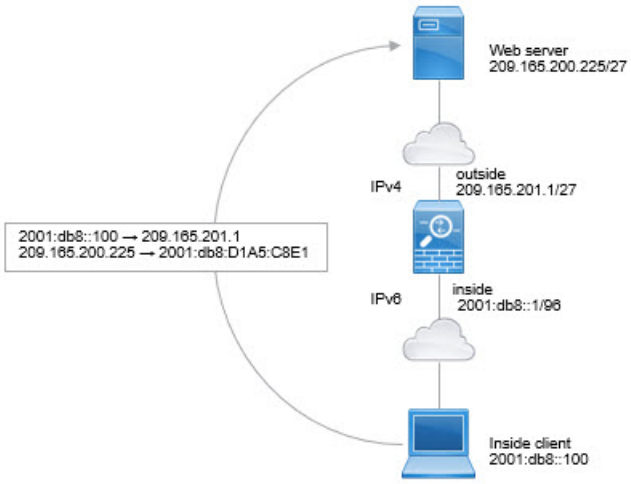
- NAT64, NAT46—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

Note NAT46 supports static mappings only.

- NAT66—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Note NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

NAT64/46: translating IPv6 addresses to IPv4



When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.

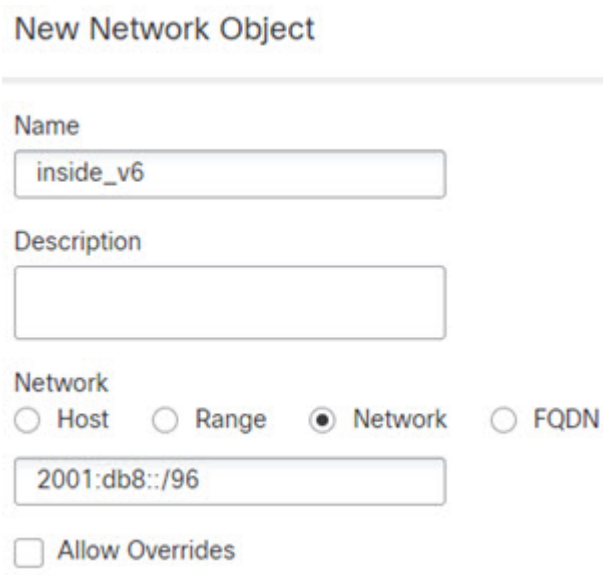
- The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.
- The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

NAT64/46 example: inside IPv6 network with outside IPv4 internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.



Procedure

Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

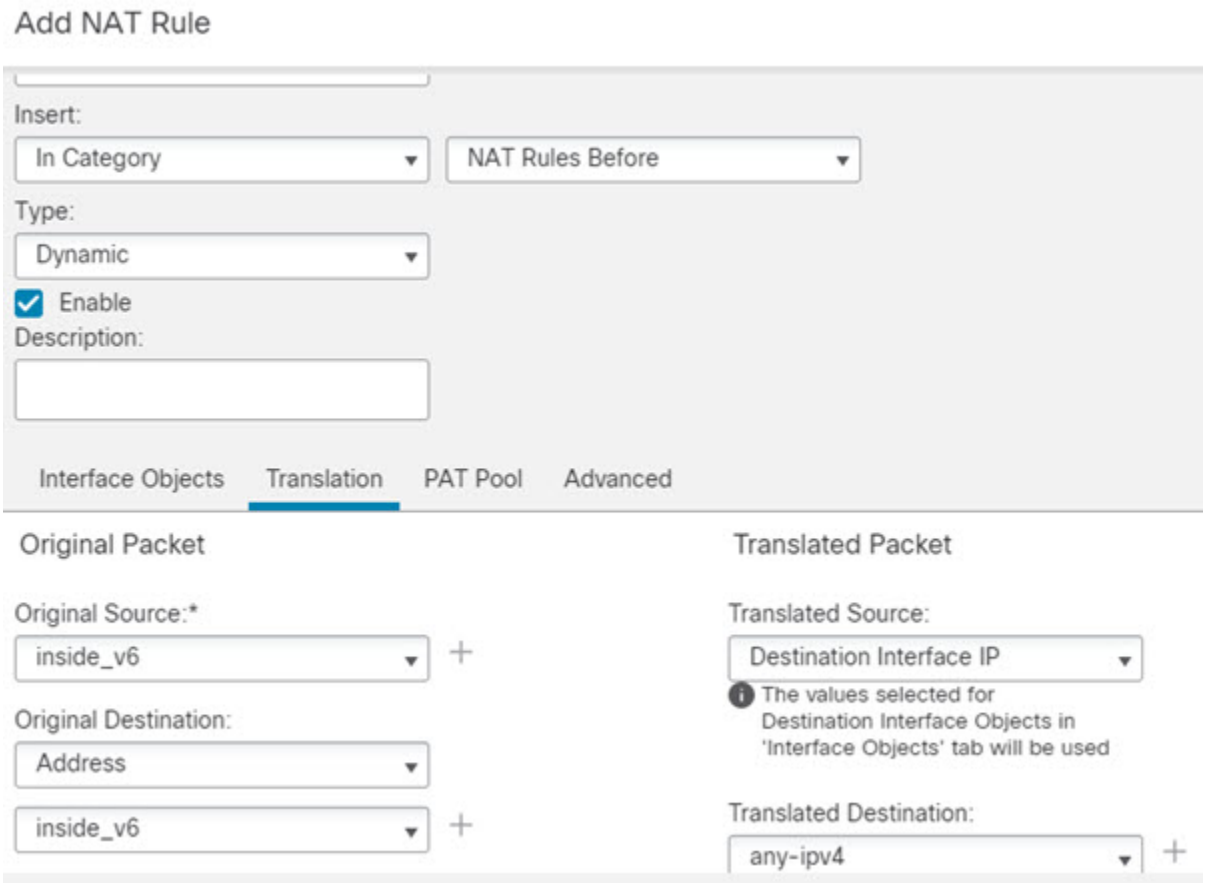
c) Click **Save**.

Step 2 Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



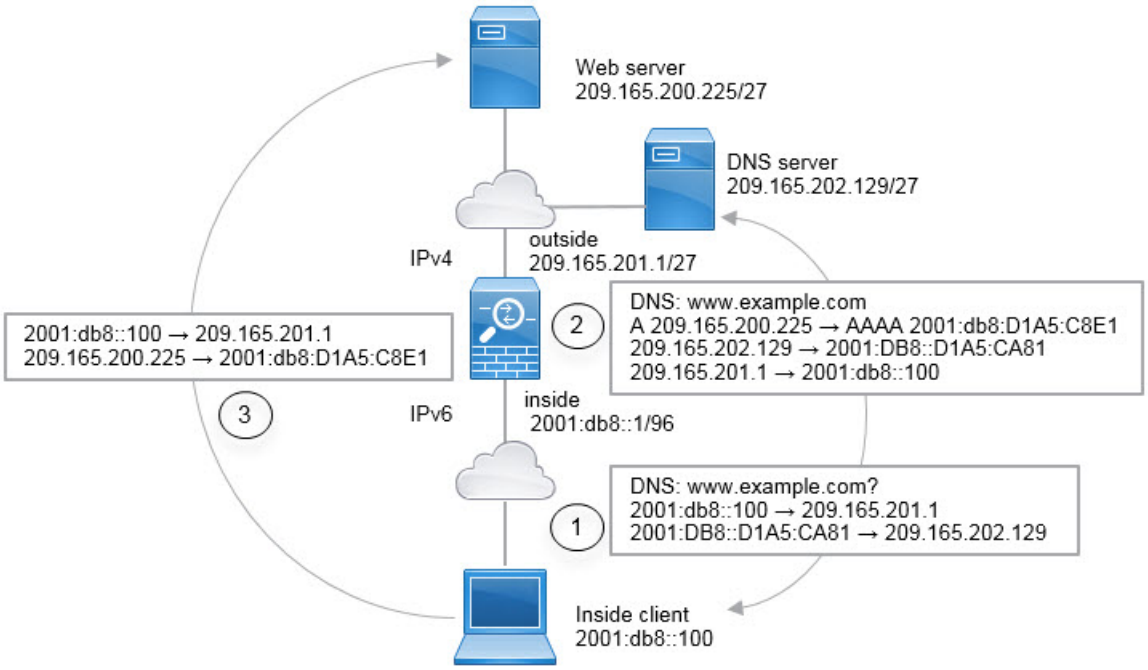
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.
- **Original Destination** = inside_v6 network object.
- **Translated Destination** = any-ipv4 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

g) Click **Save** on the NAT rules page.

NAT64/46 example: inside IPv6 network with outside IPv4 internet and DNS translation

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

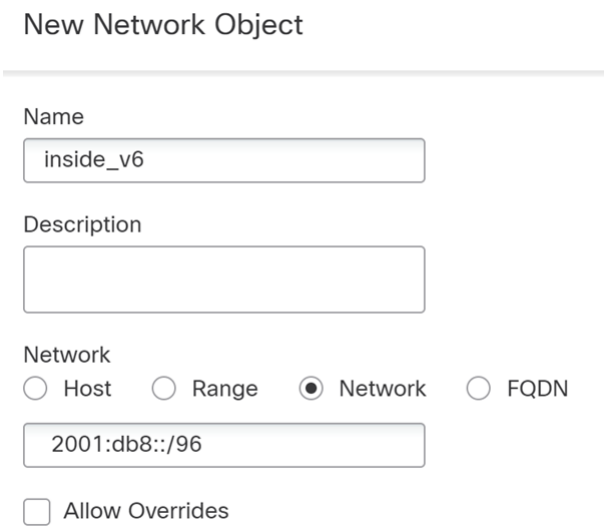
Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

1. The client's computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
   - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
   - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)
2. The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
   - 209.165.202.129 to 2001:DB8::D1A5:CA81
   - 209.165.201.1 to 2001:db8::100
3. The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
   - 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
   - 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)

The following procedure explains how to configure this example.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

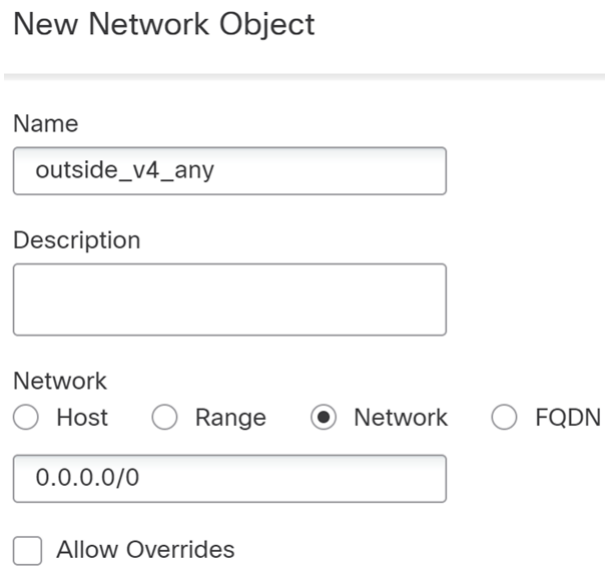


Procedure

Step 1 Create the network objects that define the inside IPv6 and outside IPv4 networks.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the outside IPv4 network.

Name the network object (for example, outside_v4_any) and enter the network address 0.0.0.0/0.

e) Click **Save**.

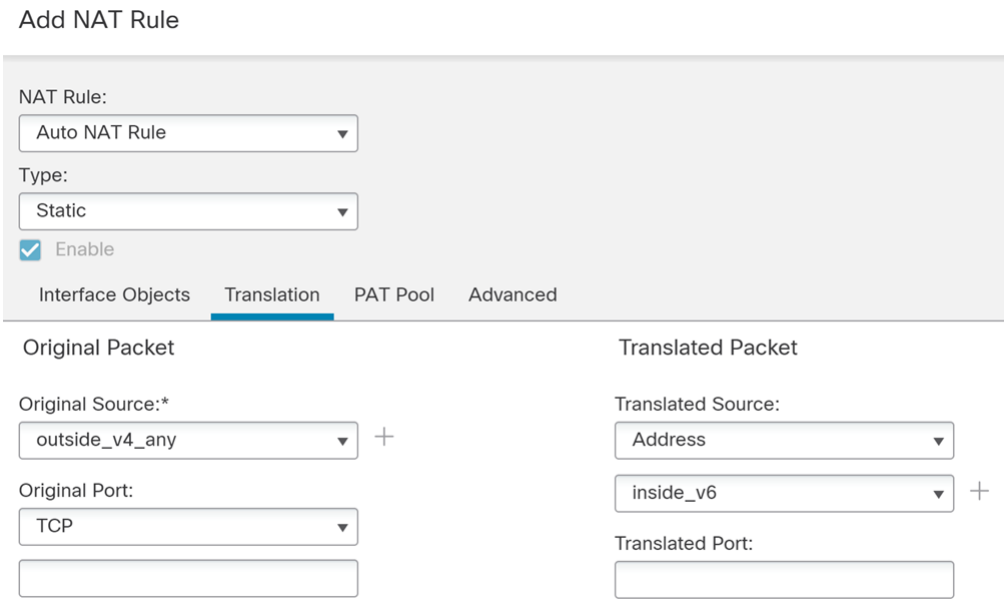
Step 2 Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

Step 3 Configure the static NAT46 rule for the outside IPv4 network.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

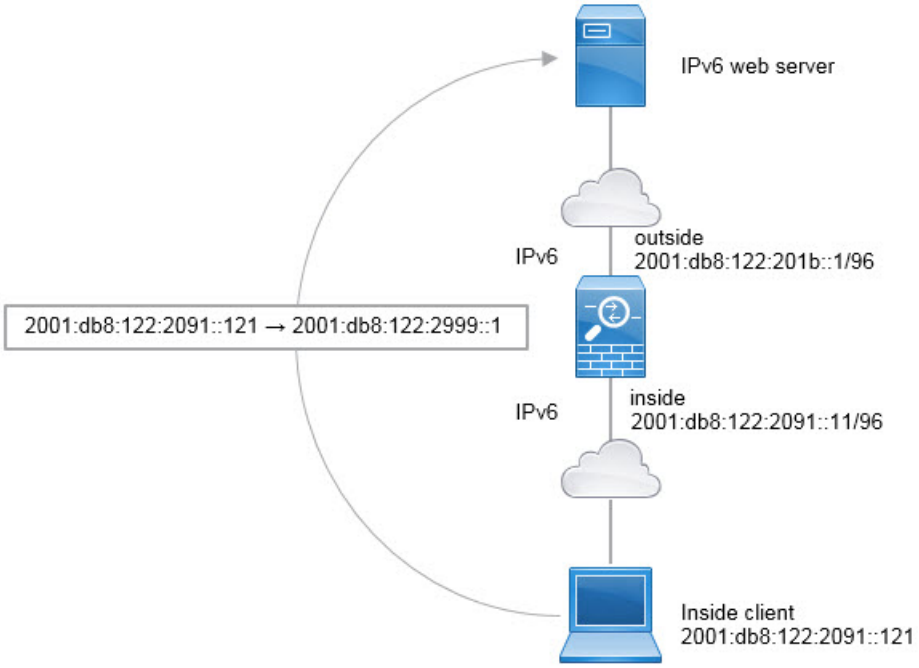
d) On **Translation**, configure the following:

- **Original Source** = outside_v4_any network object.
- **Translated Source** > **Address** = inside_v6 network object.

e) On **Advanced**, select **Translate DNS replies that match this rule**.

f) Click **OK**.

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.



NAT66: translating IPv6 addresses to different IPv6 addresses

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

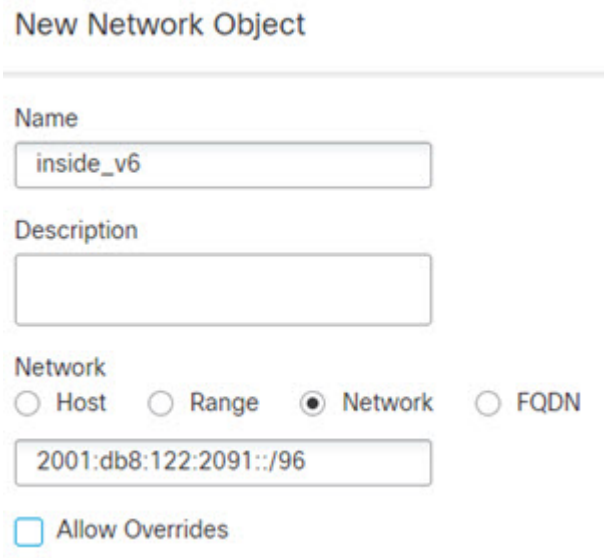
Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

NAT66 example, static translation between networks

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

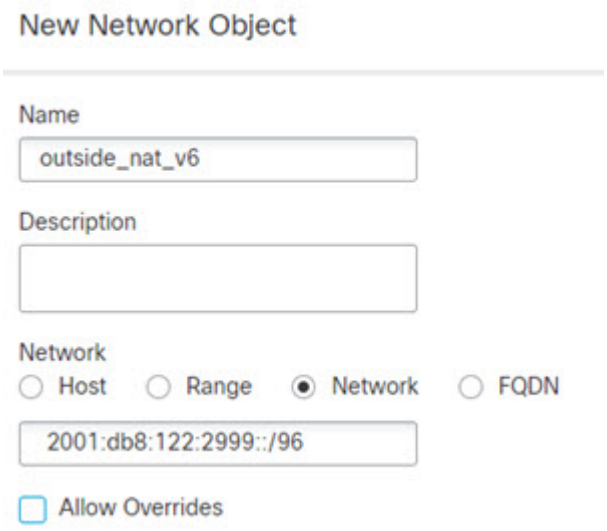


Procedure

Step 1 Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the outside IPv6 NAT network.

Name the network object (for example, outside_nat_v6) and enter the network address 2001:db8:122:2999::/96.

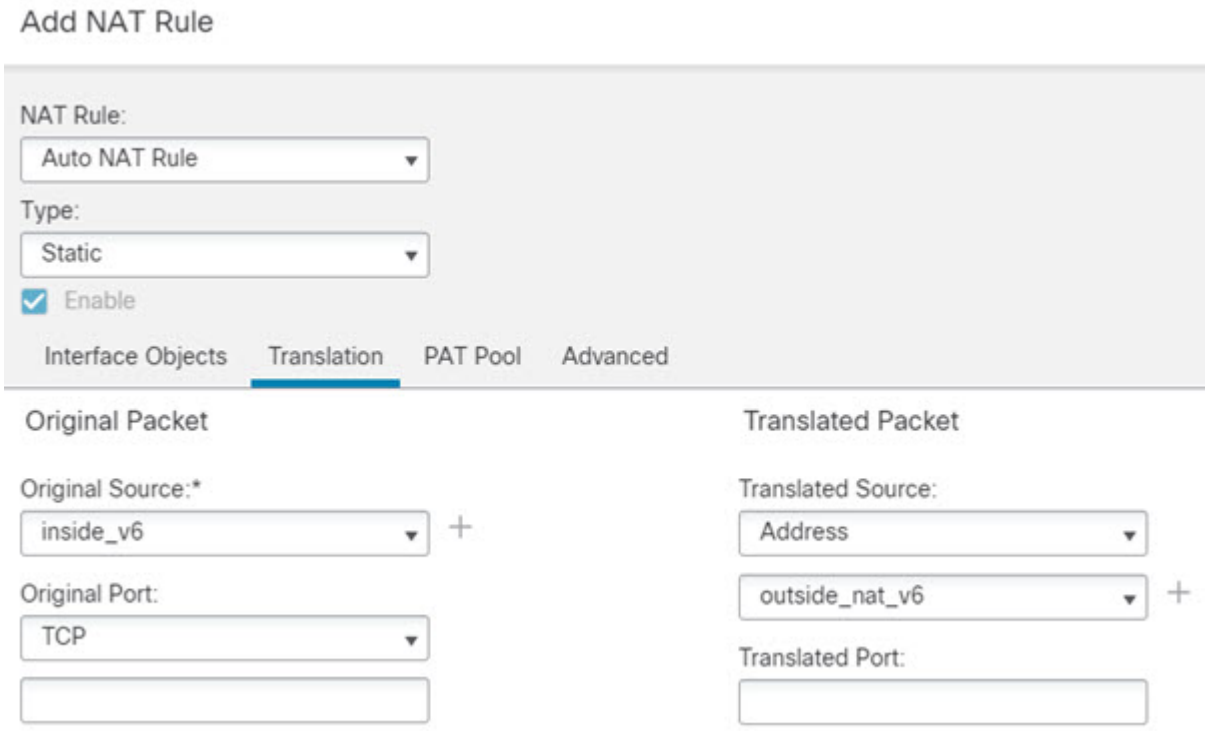
e) Click **Save**.

Step 2 Configure the static NAT rule for the inside IPv6 network.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



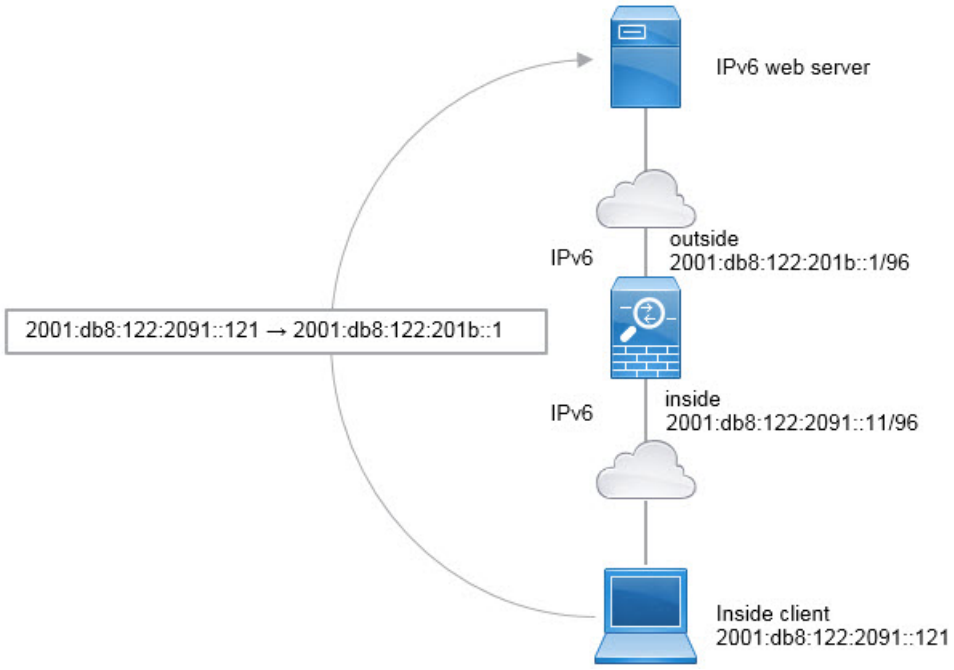
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = outside_nat_v6 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

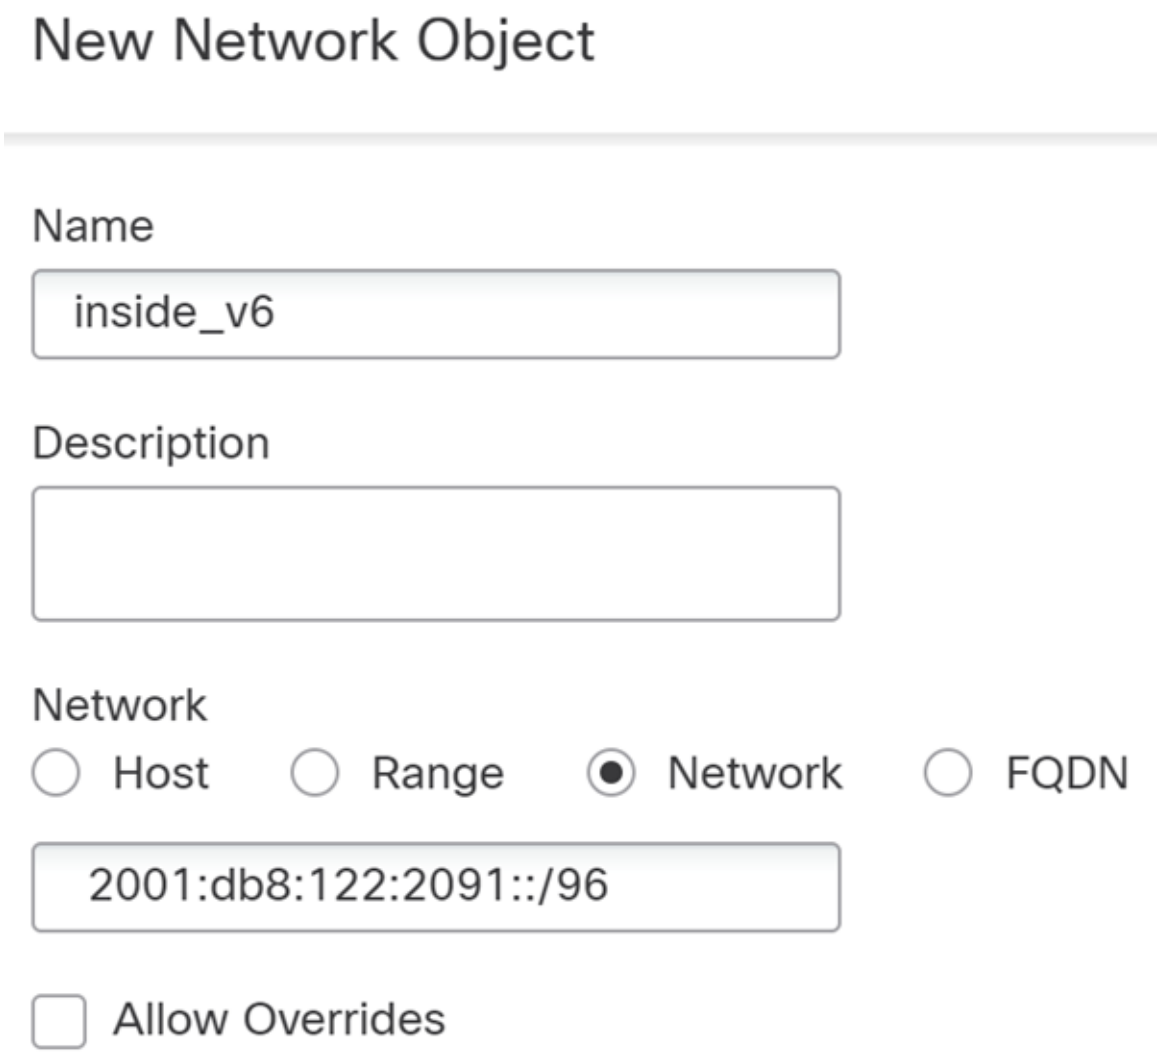
NAT66 example, simple IPv6 interface PAT

A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

When you configure an interface PAT rule for NAT66, all the global addresses that are configured on that interface are used for PAT mapping. Link-local or site-local addresses for the interface are not used for PAT.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.



Procedure

Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the inside IPv6 network.

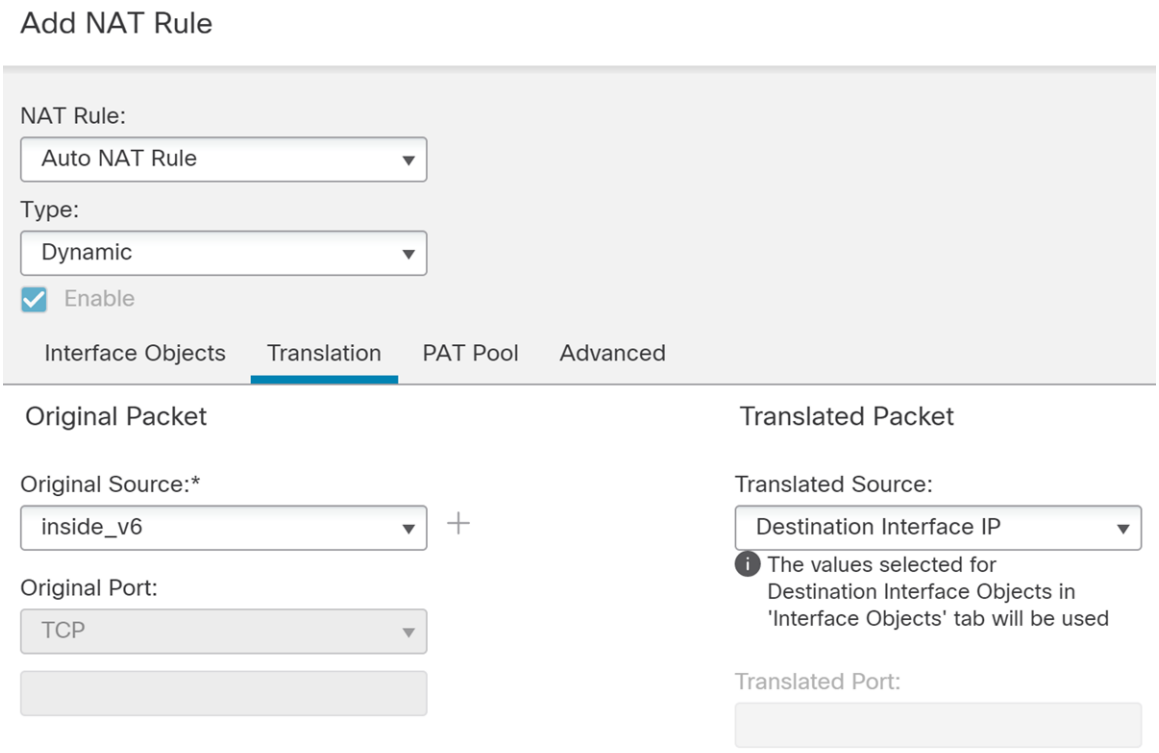
Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

c) Click **Save**.

Step 2 Configure the dynamic PAT rule for the inside IPv6 network.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.

f) On **Advanced**, select **IPv6**, which indicates that the IPv6 address of the destination interface should be used.

g) Click **OK**.

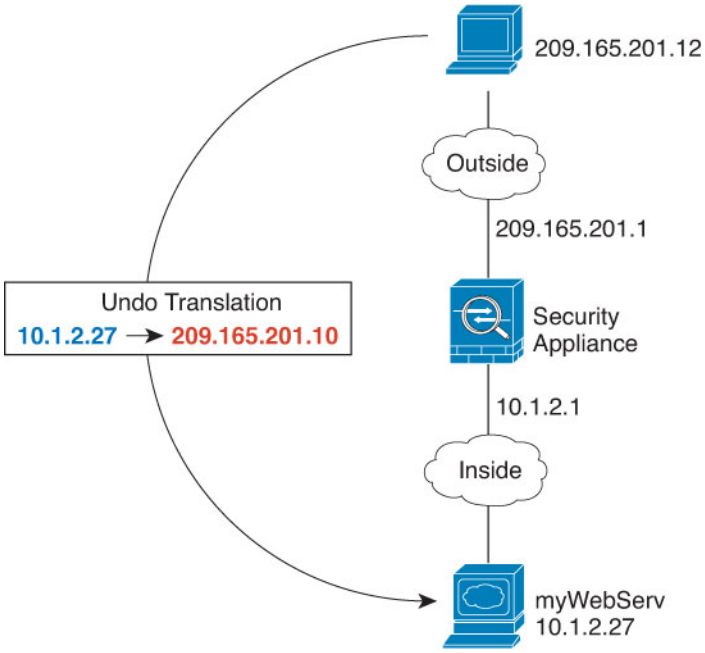
With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a NAT66 PAT translation to one of the IPv6 global addresses configured for the outside interface.

Monitoring NAT

To monitor and troubleshoot NAT connections, log into the device CLI and use the following commands.

- **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.
- **show xlate** displays the actual NAT translations that are currently active.
- **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the

connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules.



Examples for NAT

The following topics provide examples for configuring NAT.

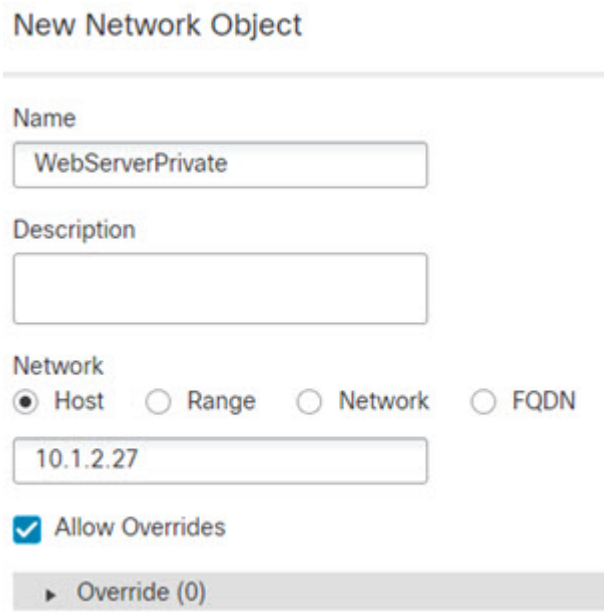
Providing access to an inside web server (static auto NAT)

This example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

Figure 358: Static NAT for an inside web server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

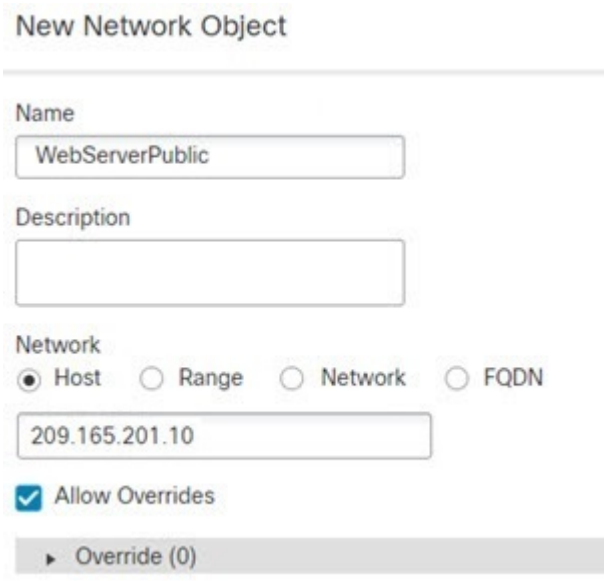


Procedure

Step 1 Create the network objects that define the server's private and public host addresses.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the web server's private address.



Name the network object (for example, WebServerPrivate) and enter the real host IP address, 10.1.2.27.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the public address.

Name the network object (for example, WebServerPublic) and enter the host address 209.165.201.10.

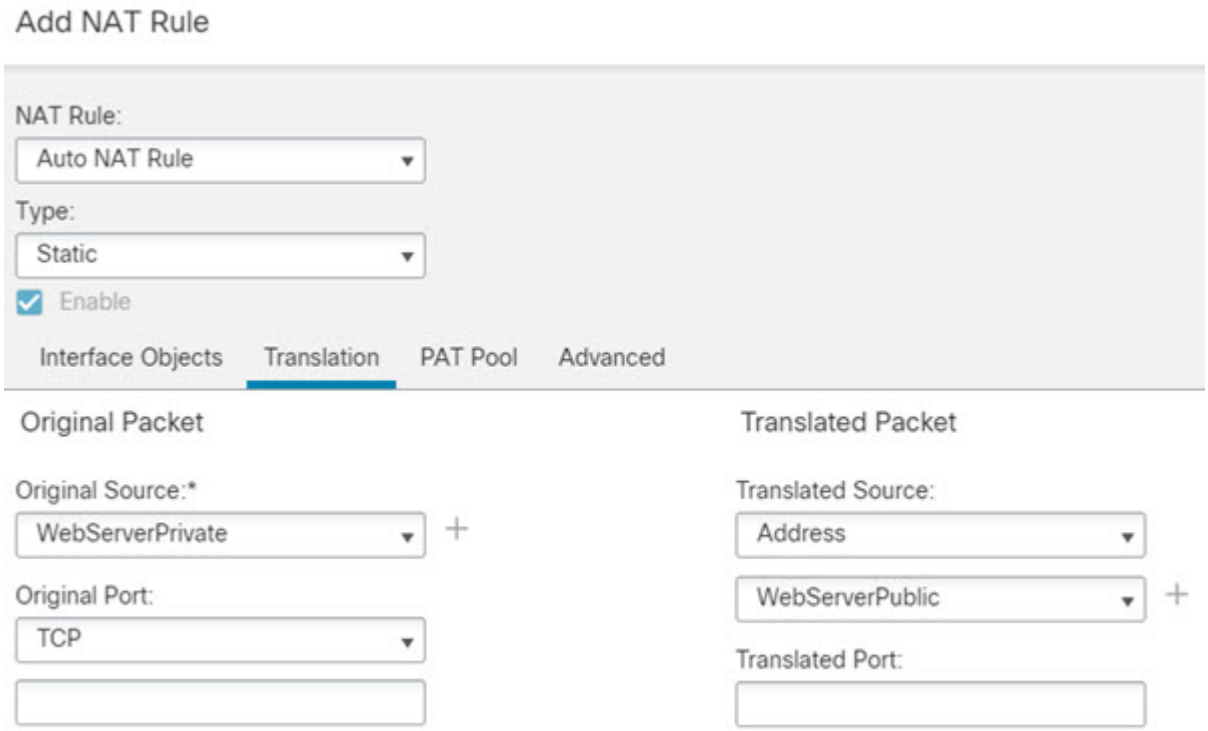
e) Click **Save**.

Step 2 Configure static NAT for the object.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



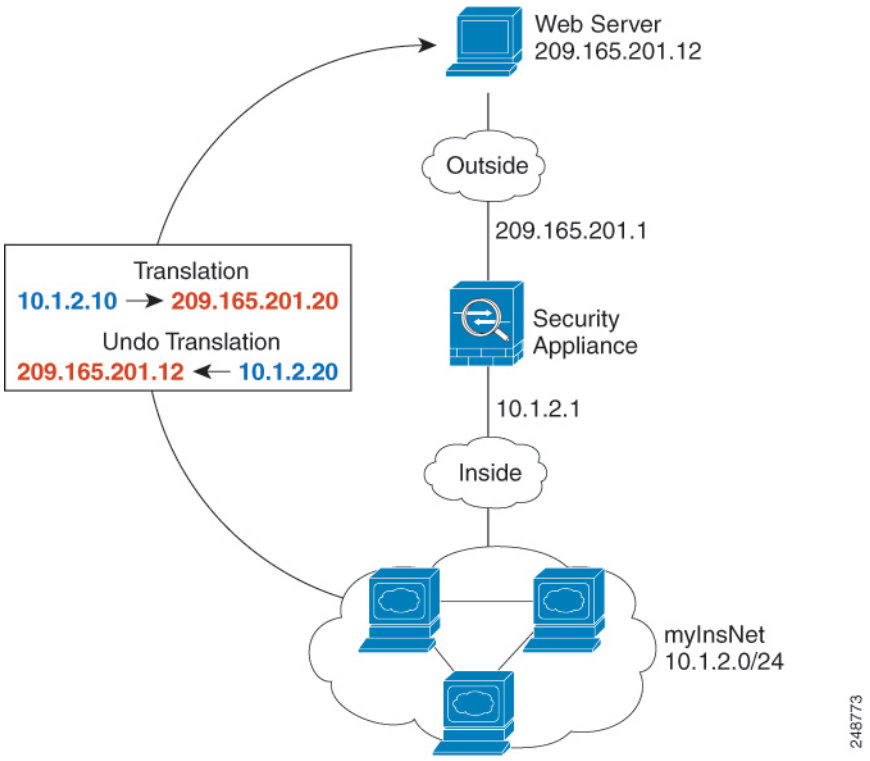
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = WebServerPrivate network object.
- **Translated Source** > **Address** = WebServerPublic network object.



f) Click **Save**.

Step 3 Click **Save** on the NAT rule page.

Dynamic auto NAT for inside hosts and static NAT for an outside web server

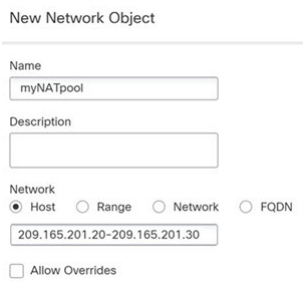
The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network.

Figure 359: Dynamic NAT for Inside, Static NAT for Outside Web Server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select and click **Add Network** > **Add ObjectObjects** > **Object Management** > **Interface**.

Procedure



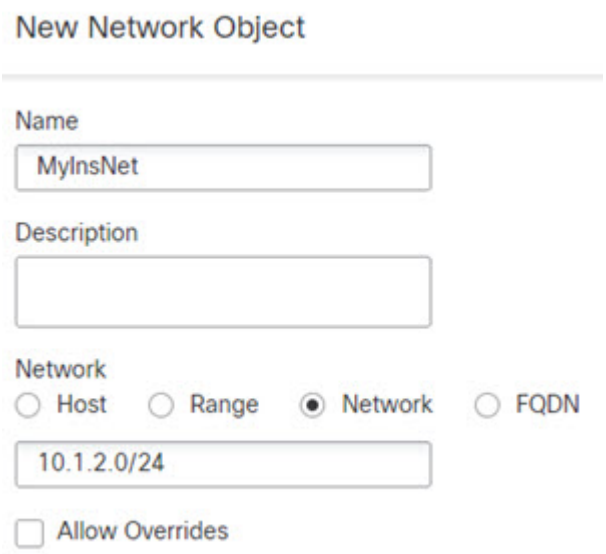
Step 1 Create a network object for the dynamic NAT pool to which you want to translate the inside addresses.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the dynamic NAT pool.

Name the network object (for example, myNATpool) and enter the network range 209.165.201.20-209.165.201.30.

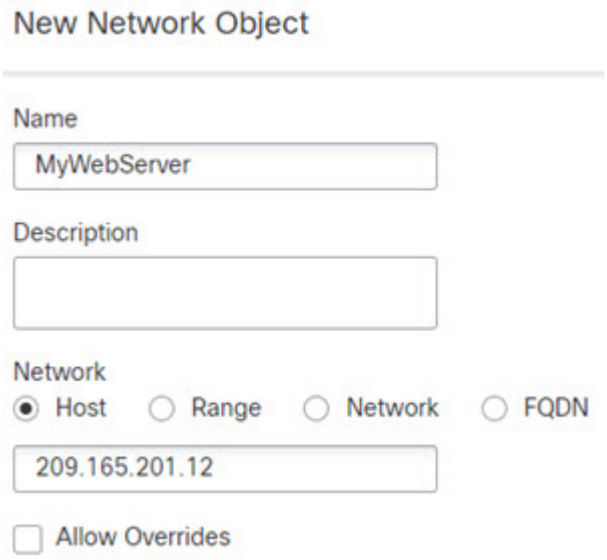


d) Click **Save**.

Step 2 Create a network object for the inside network.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyInsNet) and enter the network address 10.1.2.0/24.

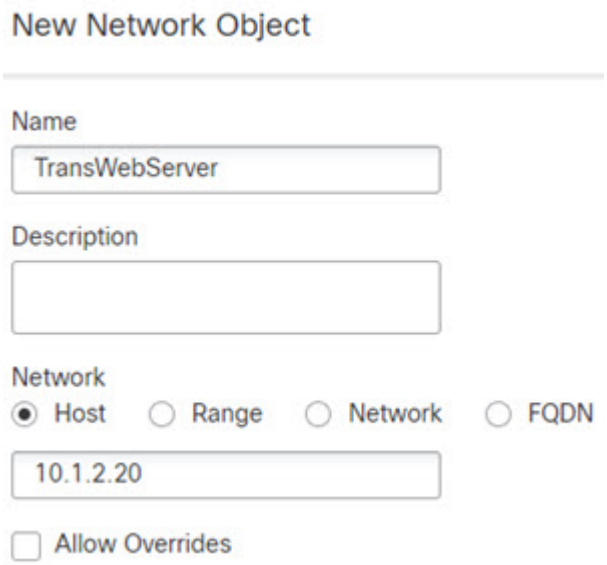


c) Click **Save**.

Step 3 Create a network object for the outside web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyWebServer) and enter the host address 209.165.201.12.



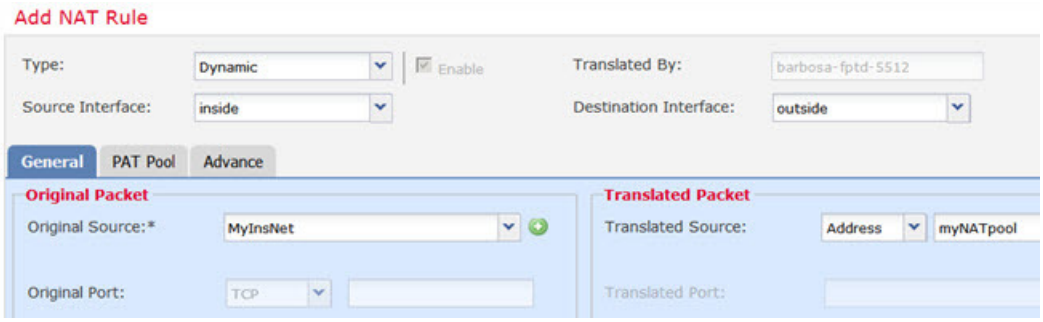
c) Click **Save**.

Step 4 Create a network object for the translated web server address.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TransWebServer) and enter the host address 10.1.2.20.

c) Click **Save**.



Step 5 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

b) Click **Add NAT Rule** > **Add Auto NAT**.

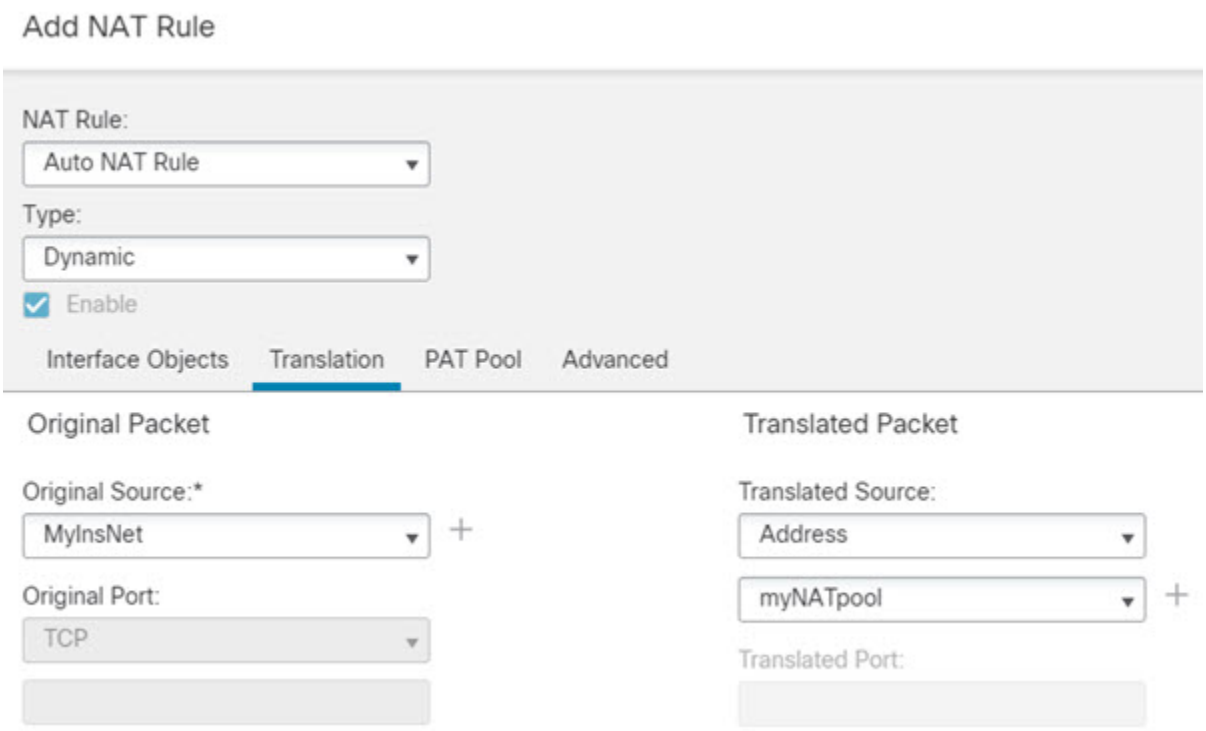
c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

d) Click **Save**.

Step 6 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:



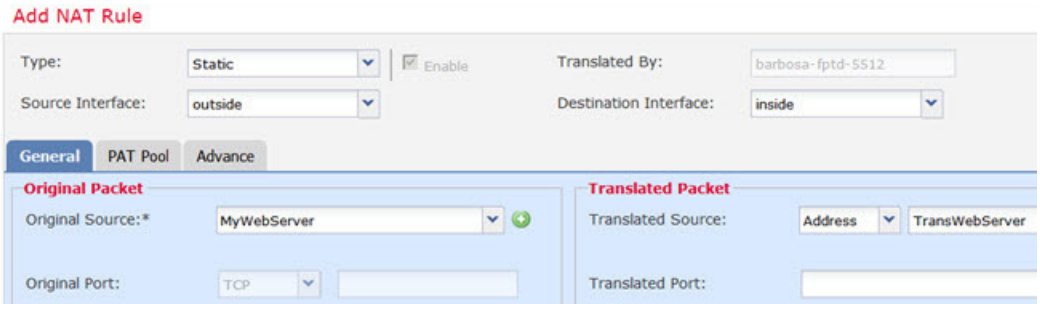
- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

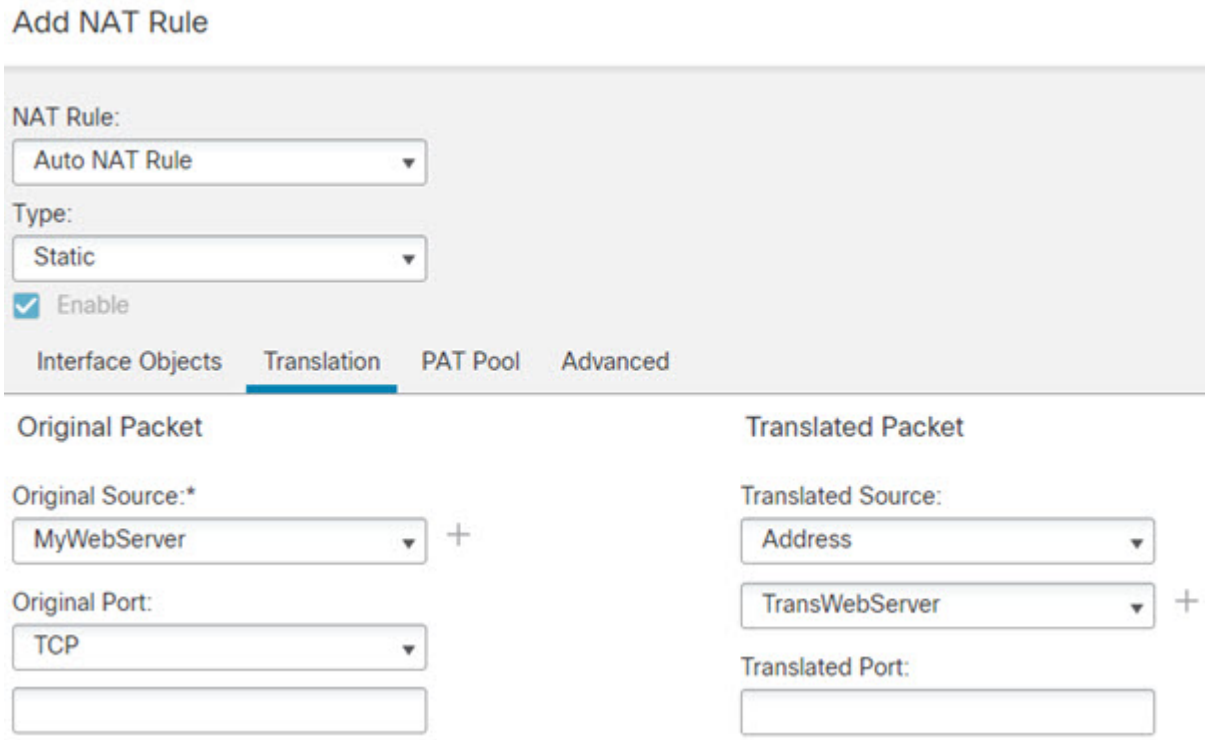


f) Click **Save**.

Step 7 Configure static NAT for the web server.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

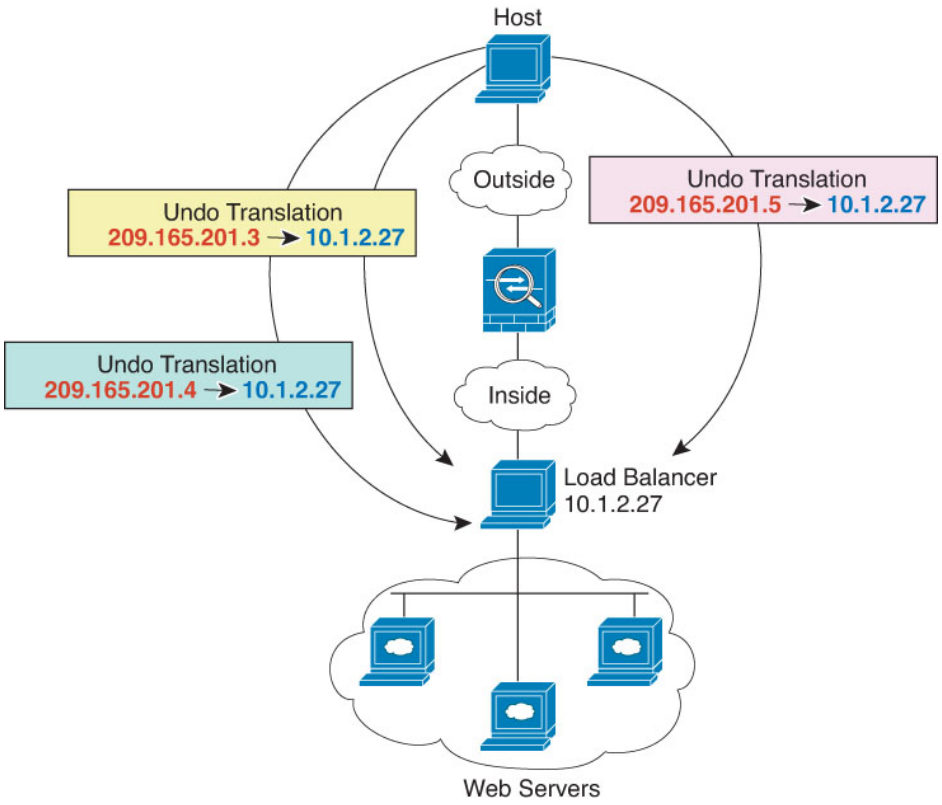


- **Type** = Static.
- **Source Interface** = outside.
- **Destination Interface** = inside.
- **Original Source** = myWebServer network object.
- **Translated Source** > **Address**= TransWebServer network object.

c) Click **Save**.

Step 8 Configure static NAT for the web server.

a) Click **Add Rule**.
b) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.
c) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = outside.
   - **Destination Interface Objects** = inside.
d) On **Translation**, configure the following:
   - **Original Source** = myWebServer network object.
   - **Translated Source** > **Address**= TransWebServer network object.



e) Click **Save**.

Step 9 Click **Save** on the NAT rule page.

Configure inside load balancer with multiple mapped addresses

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 360: Static NAT with One-to-Many for an Inside Load Balancer

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

Procedure

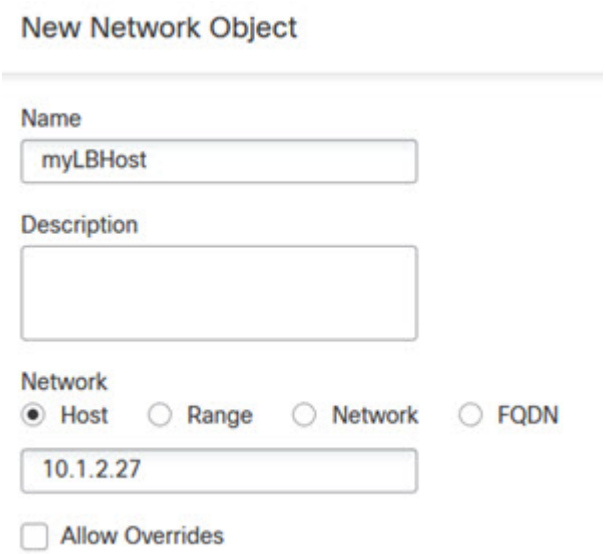
Step 1 Create a network object for the addresses to which you want to map the load balancer.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the addresses.

Name the network object (for example, myPublicIPs) and enter the network range 209.165.201.3-209.165.201.5.



d) Click **Save**.

Step 2 Create a network object for the load balancer.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, myLBHost), enter the host address 10.1.2.27.

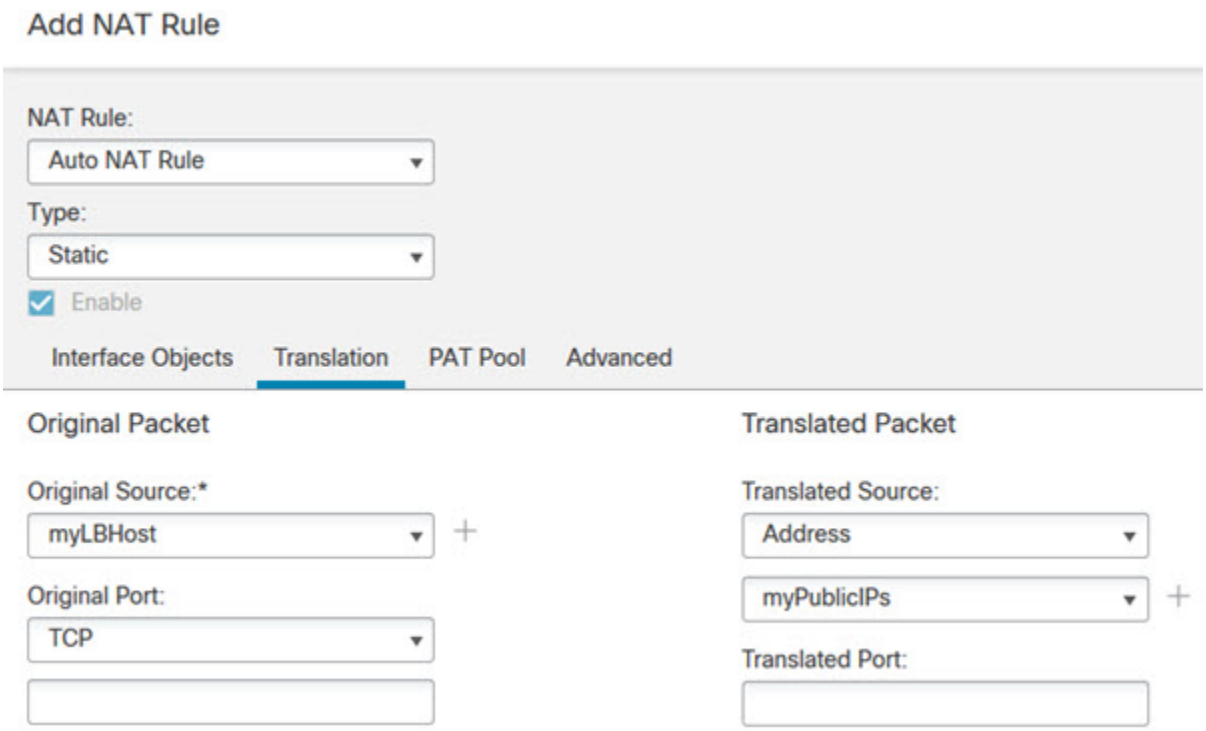
c) Click **Save**.

Step 3 Configure static NAT for the load balancer.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



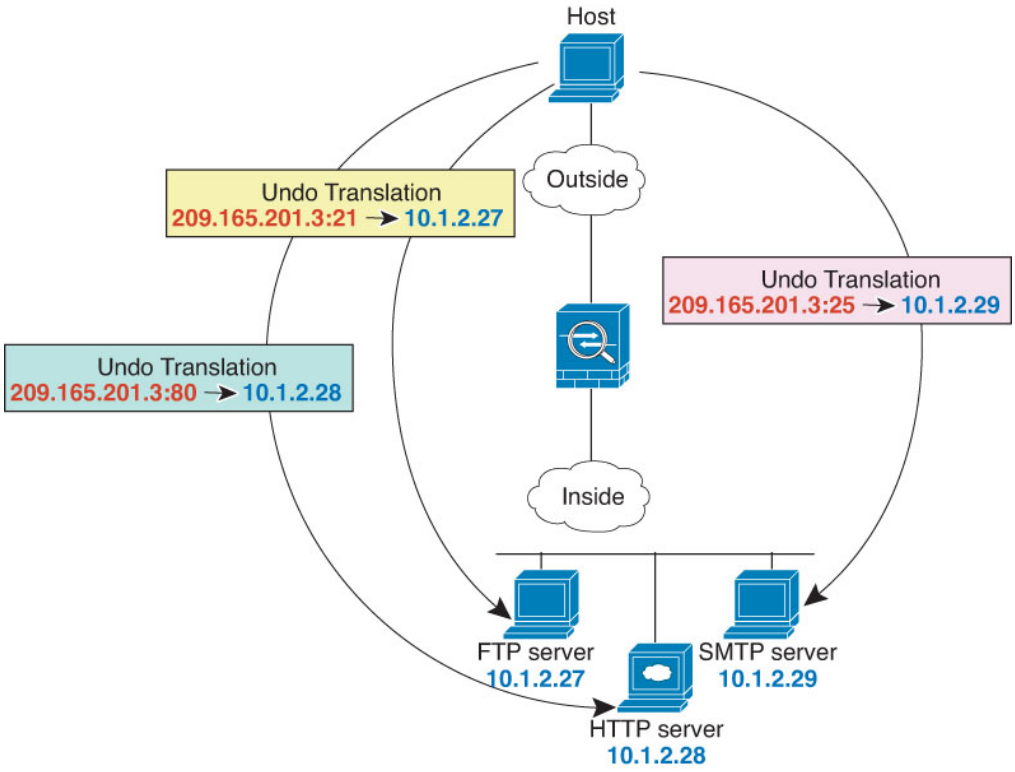
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myLBHost network object.
- **Translated Source** > **Address** = myPublicIPs network group.



f) Click **Save**.

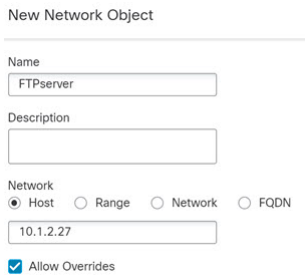
Step 4 Click **Save** on the NAT rule page.

Single address for FTP, HTTP, and SMTP (static auto NAT with port translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.

Figure 361: Static NAT-with-Port-Translation

Before you begin



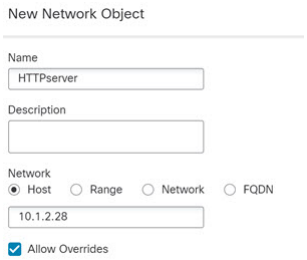
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select and click **Add Network** > **Add GroupObjects** > **Object Management** > **Interface**.

Procedure

Step 1 Create a network object for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Name the network object (for example, FTPserver), and enter the real IP address for the FTP server, 10.1.2.27.

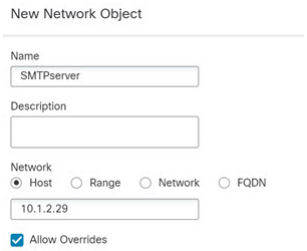


c) Click **Save**.

Step 2 Create a network object for the HTTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, HTTPserver), enter the host address 10.1.2.28.

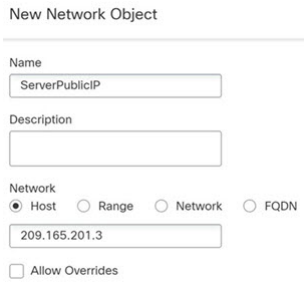


c) Click **Save**.

Step 3 Create a network object for the SMTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, SMTPserver), enter the host address 10.1.2.29.



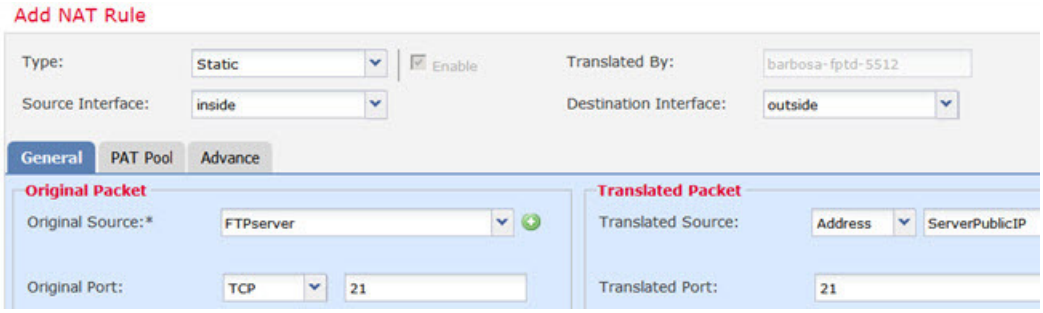
c) Click **Save**.

Step 4 Create a network object for the public IP address used for the three servers.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, ServerPublicIP) and enter the host address 209.165.201.3.

c) Click **Save**.



Step 5 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

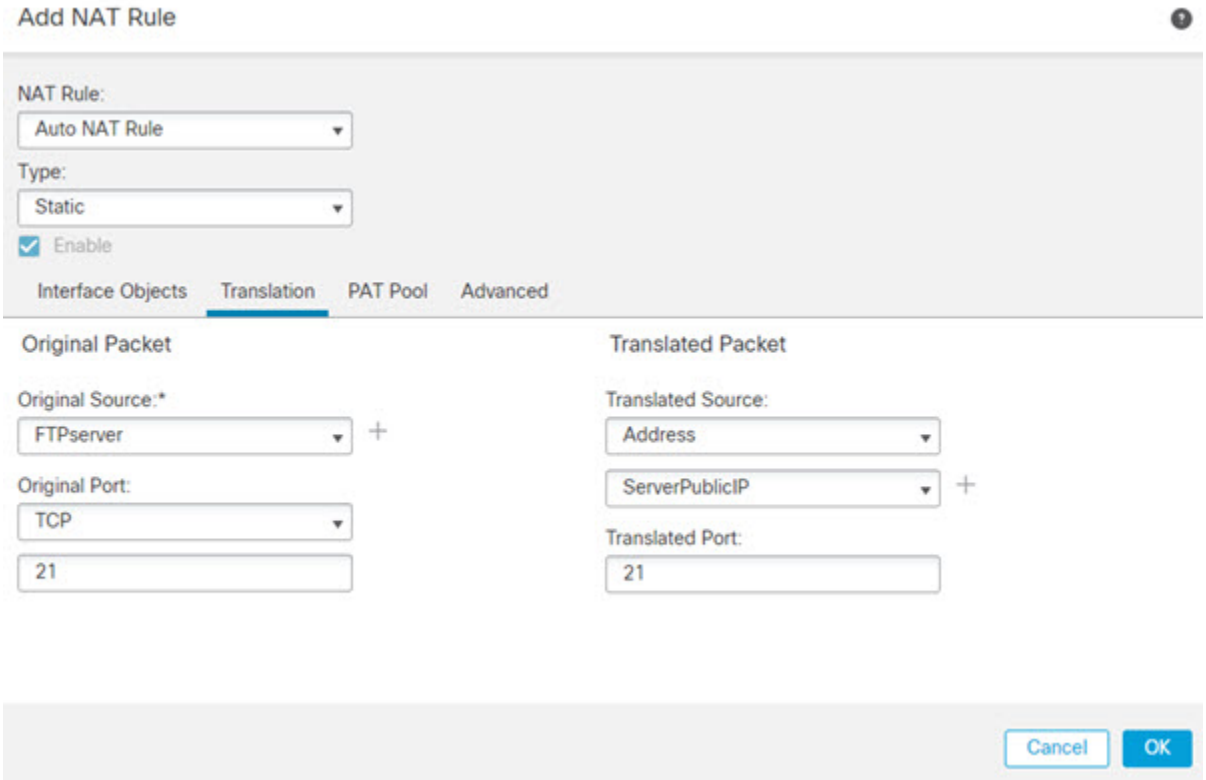
b) Click **Add NAT Rule** > **Add Auto NAT**.
c) Configure the following properties:

- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.

d) Click **Save**.

Step 6 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:



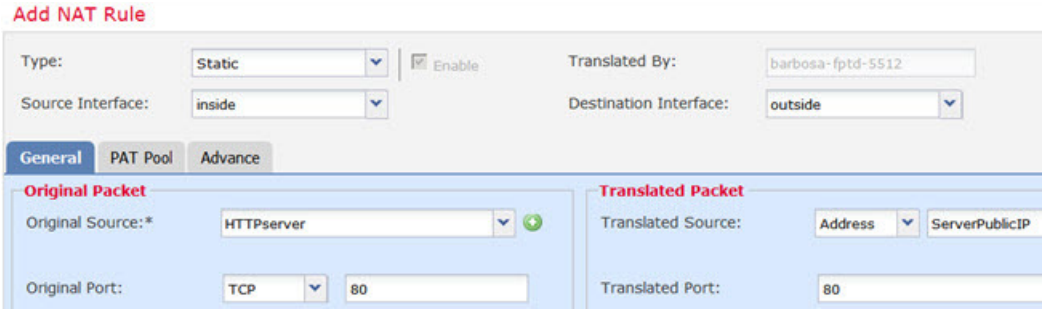
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.



f) Click **Save**.

Step 7 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

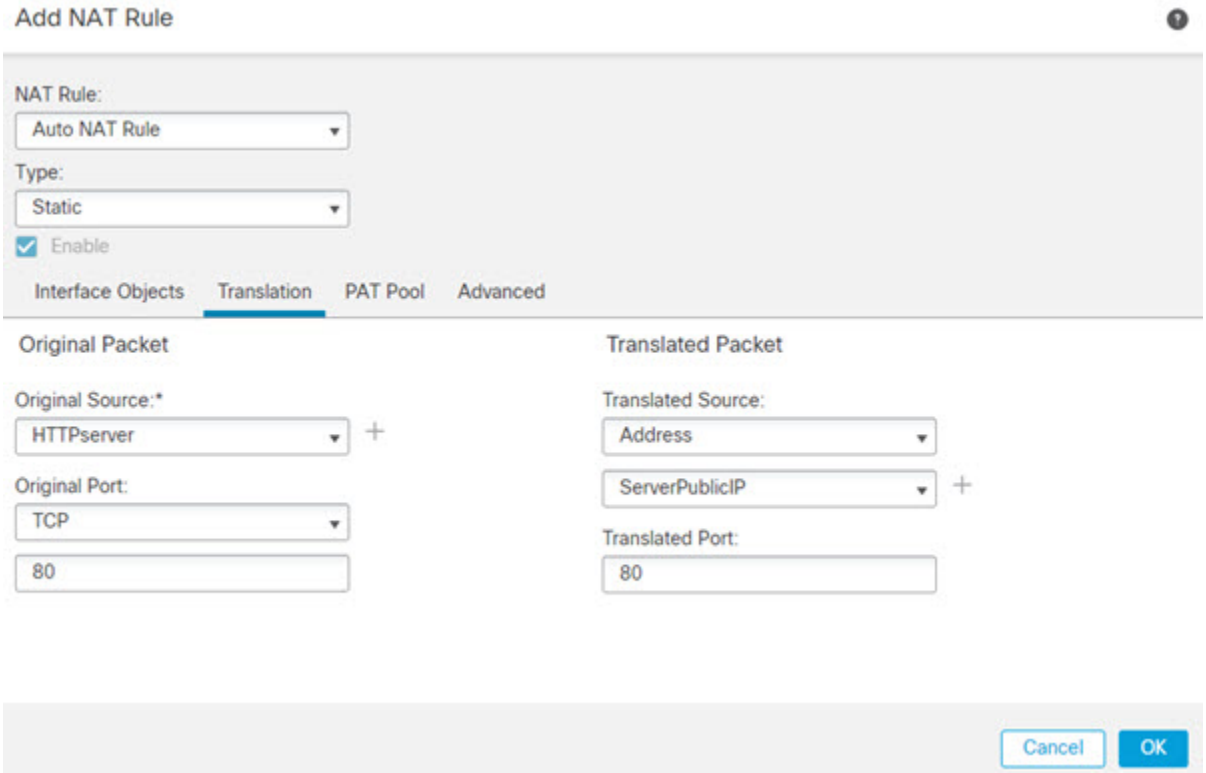
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = HTTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.

c) Click **Save**.

Step 8 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



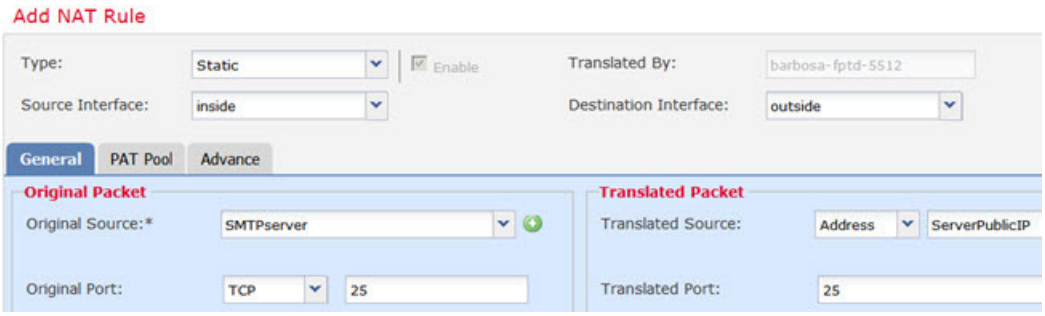
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = HTTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.



e) Click **Save**.

Step 9 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

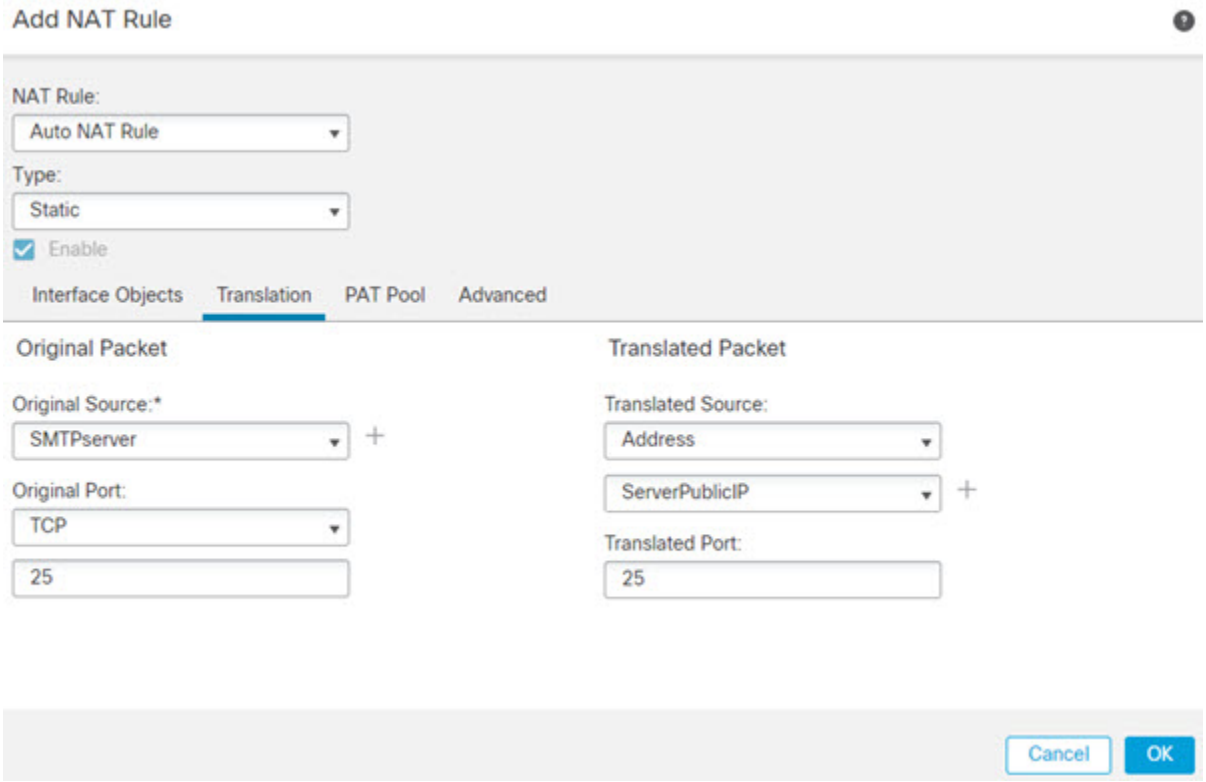
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.

c) Click **Save**.

Step 10 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



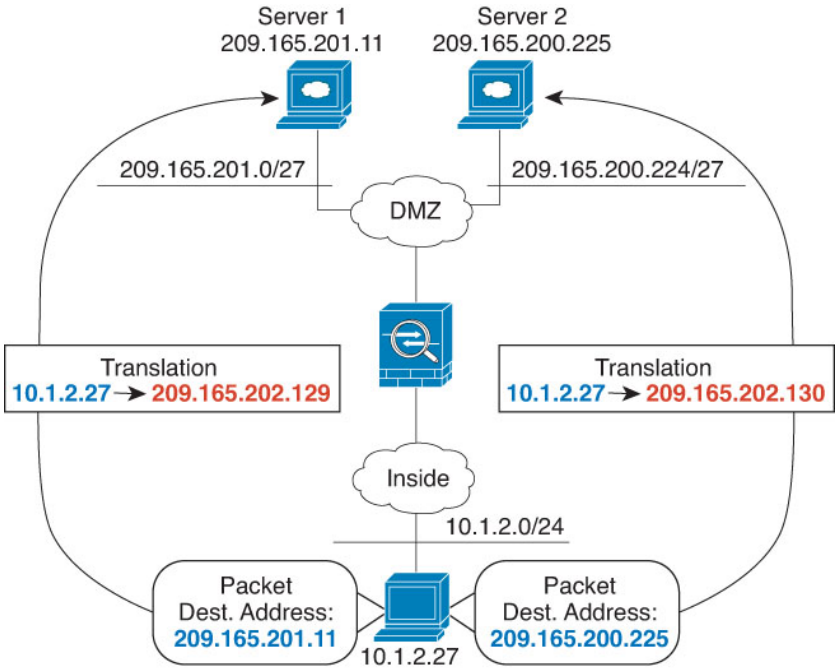
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.



e) Click **Save**.

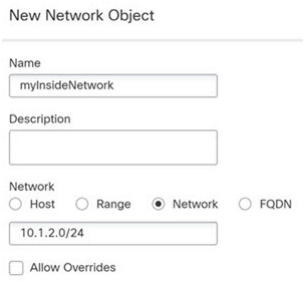
Step 11 Click **Save** on the NAT rule page.

Different translation depending on the destination (dynamic manual PAT)

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:*port*. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:*port*.

Figure 362: Manual NAT with Different Destination Addresses

Before you begin



Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Name the network object (for example, myInsideNetwork), and enter the real network address, 10.1.2.0/24.

c) Click **Save**.

Step 2 Create a network object for the DMZ network 1.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, DMZnetwork1) and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

c) Click **Save**.

Step 3 Create a network object for the PAT address for DMZ network 1.

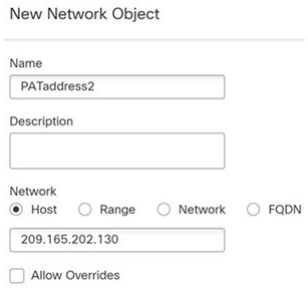
a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.

c) Click **Save**.

Step 4 Create a network object for the DMZ network 2.

a) Click **Add Network** > **Add Object**.

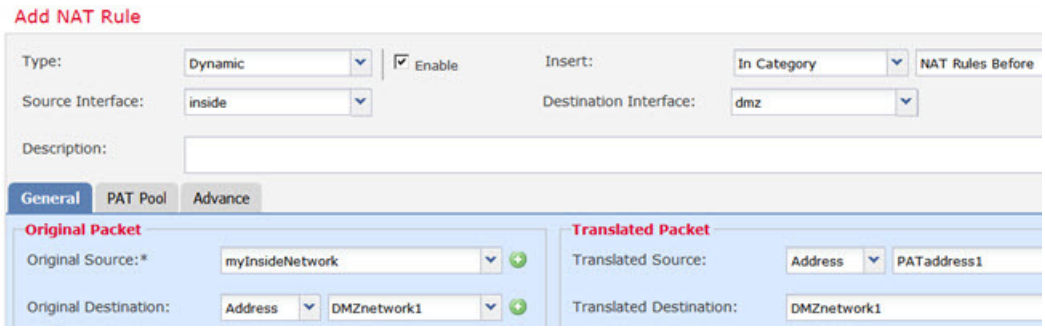


b) Name the network object (for example, DMZnetwork2) and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).

c) Click **Save**.

Step 5 Create a network object for the PAT address for DMZ network 2.

a) Click **Add Network** > **Add Object**.
b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.



c) Click **Save**.

Step 6 Configure dynamic manual PAT for DMZ network 1.

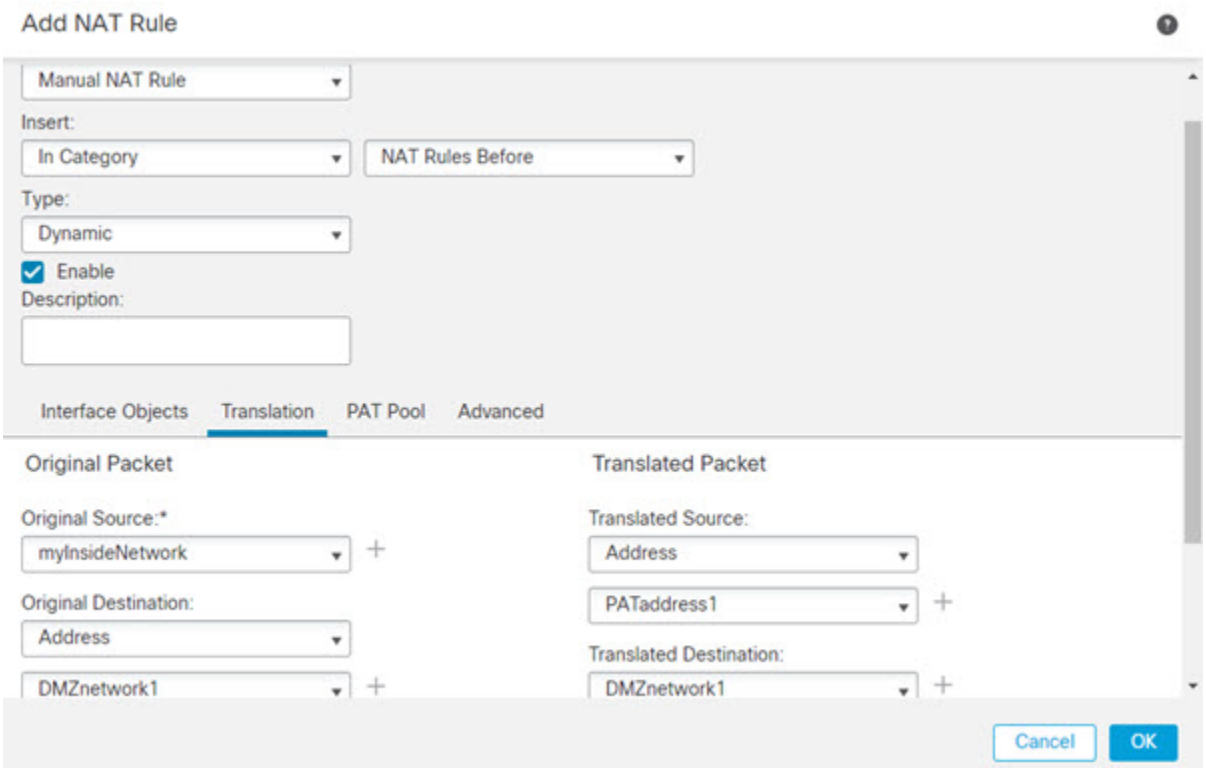
a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.
b) Click **Add NAT Rule** > **Add Manual NAT**.
c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

Note
Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.

d) Click **Save**.

Step 7 Configure dynamic manual PAT for DMZ network 1.



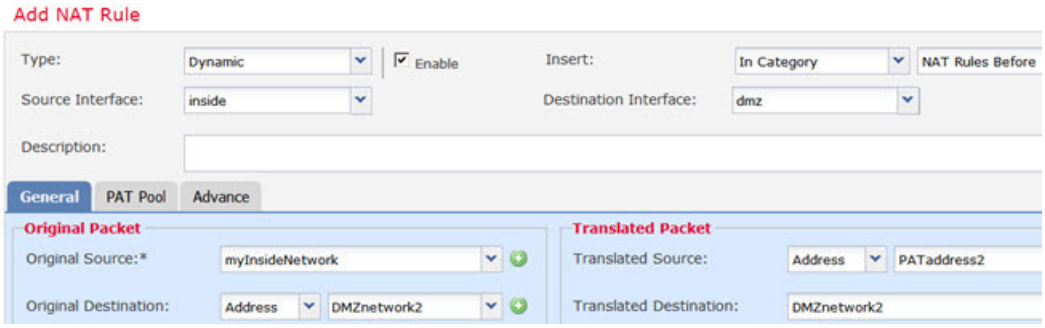
a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Manual NAT Rule.
   - **Type** = Dynamic.

d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:
   - **Original Source** = myInsideNetwork network object.
   - **Translated Source** > **Address**= PATaddress1 network object.
   - **Original Destination** > **Address** = DMZnetwork1 network object.
   - **Translated Destination** = DMZnetwork1 network object.

   Note
   Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.



f) Click **Save**.

Step 8 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add NAT Rule** > **Add Manual NAT**.

b) Configure the following properties:

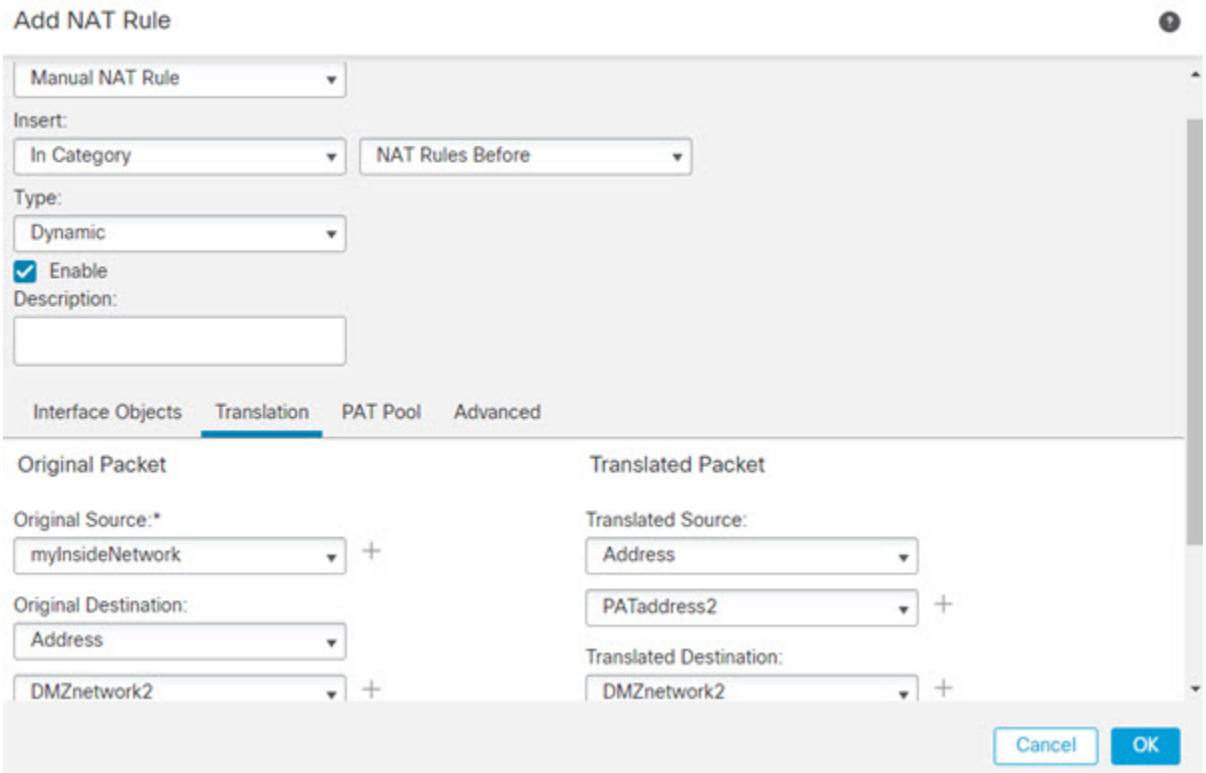
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.

c) Click **Save**.

Step 9 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add Rule**.

b) Configure the following properties:



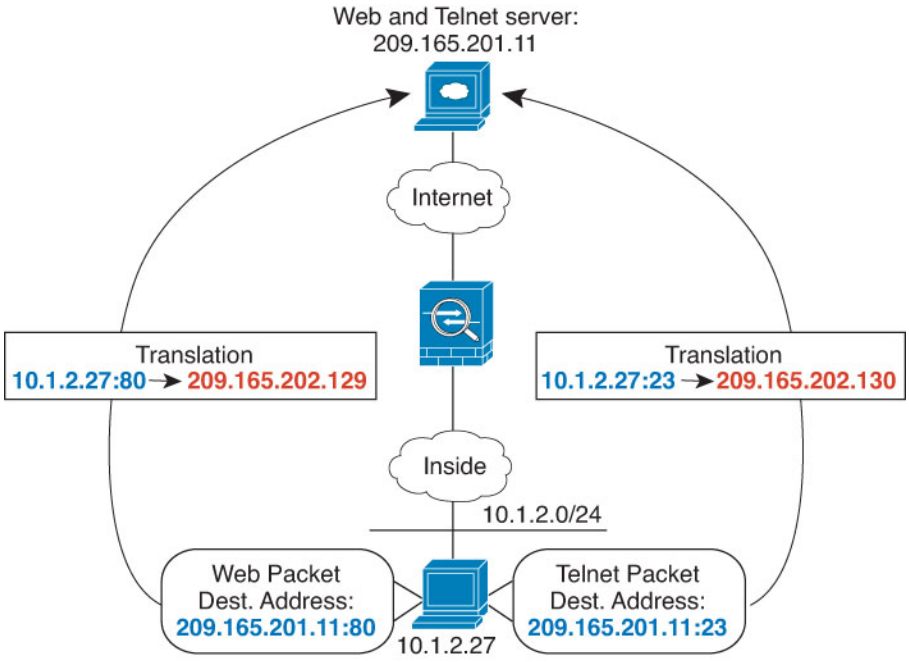
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.



e) Click **Save**.

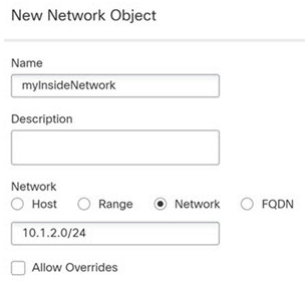
Step 10 Click **Save** on the NAT rule page.

Configure dynamic manual PAT with different destination ports

This illustration displays the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129: *port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130: *port*.

Figure 363: Manual NAT with Different Destination Ports

Before you begin



Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

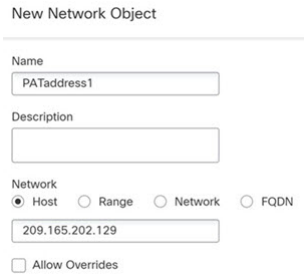
b) Name the network object (for example, myInsideNetwork) and enter the real network address, 10.1.2.0/24.

c) Click **Save**.

Step 2 Create a network object for the Telnet/Web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TelnetWebServer) and enter the host address 209.165.201.11.

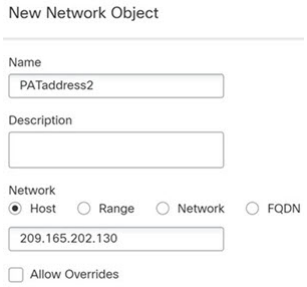


c) Click **Save**.

Step 3 Create a network object for the PAT address when using Telnet.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.



c) Click **Save**.

Step 4 Create a network object for the PAT address when using HTTP.

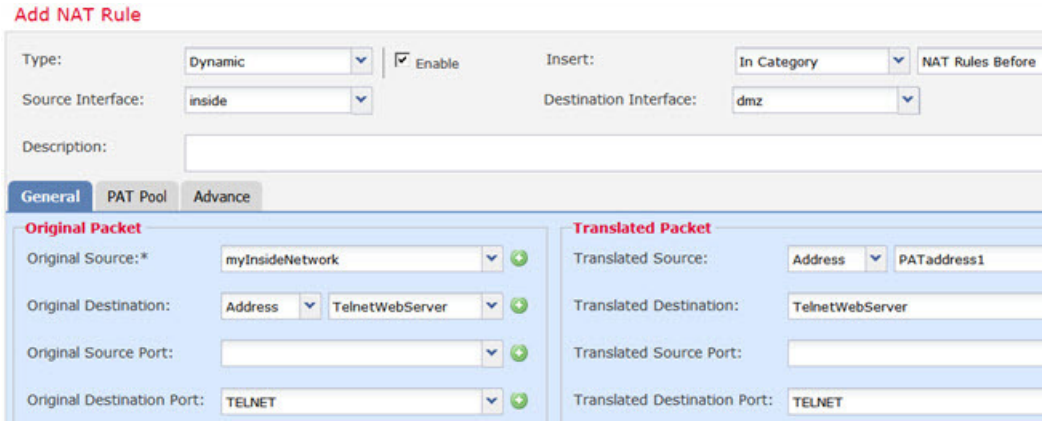
a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

Step 5 Configure dynamic manual PAT for Telnet access.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.



b) Click **Add NAT Rule** > **Add Manual NAT**.

c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.

- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress1 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

Note
Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

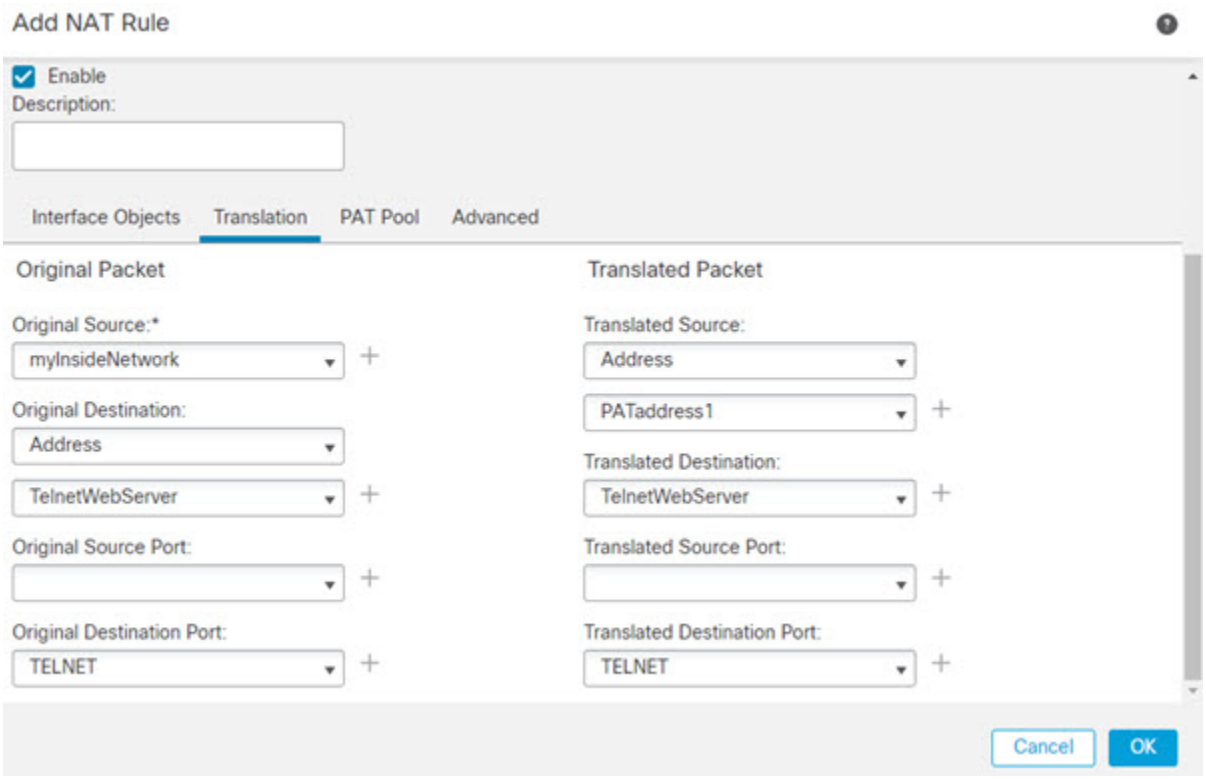
d) Click **Save**.

Step 6 Configure dynamic manual PAT for Telnet access.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:



- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

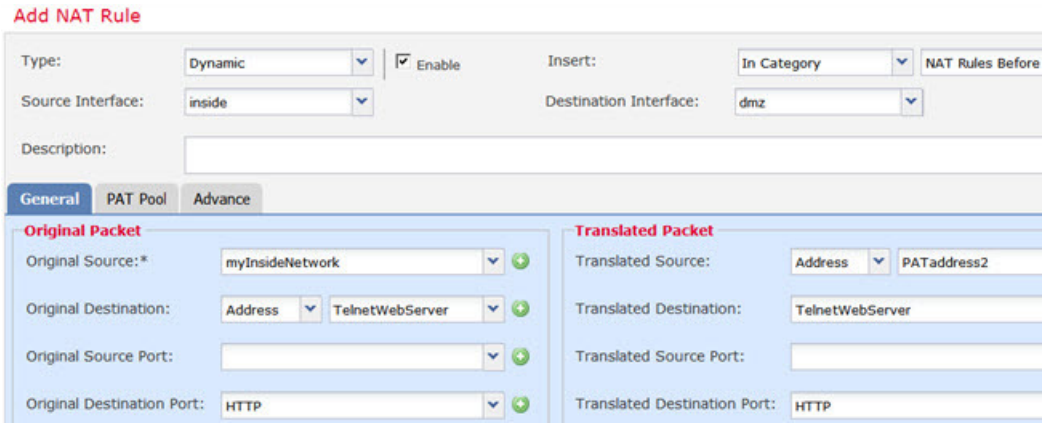
e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress1 network object.

- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

Note
Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

f) Click **Save**.



Step 7 Configure dynamic manual PAT for web access.

a) Click **Add NAT Rule** > **Add Manual NAT**.

b) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.

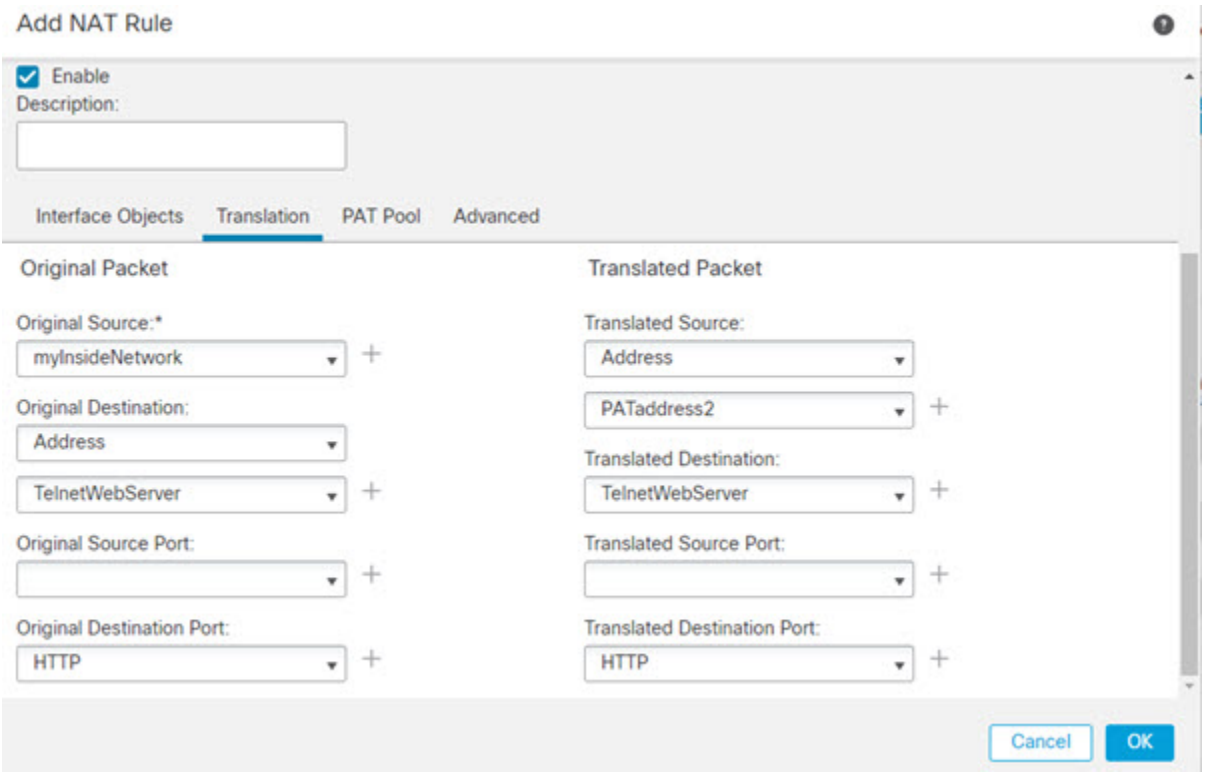
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).

c) Click **Save**.

Step 8 Configure dynamic manual PAT for web access.

a) Click **Add Rule**.

b) Configure the following properties:



- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

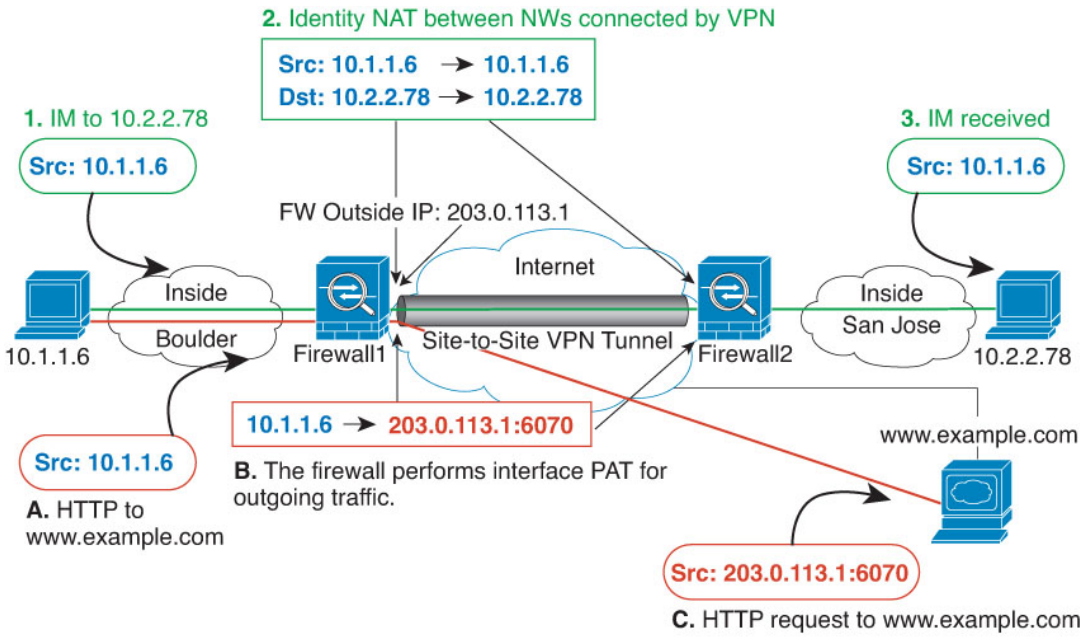
c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address** = PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).

e) Click **Save**.



Step 9 Click **Save** on the NAT rule page.

NAT and site-to-site VPN

When you create a policy-based site-to-site VPN using the management center VPN wizard (**Device > Site To Site**), you can select the NAT Exempt option to create the rules automatically. You can view the NAT exemptions for a device in the NAT policy page (**Device > NAT > NAT Exemptions**). If you do not want to configure NAT Exempt in the VPN wizard, you can use the following procedure for NAT exemption.

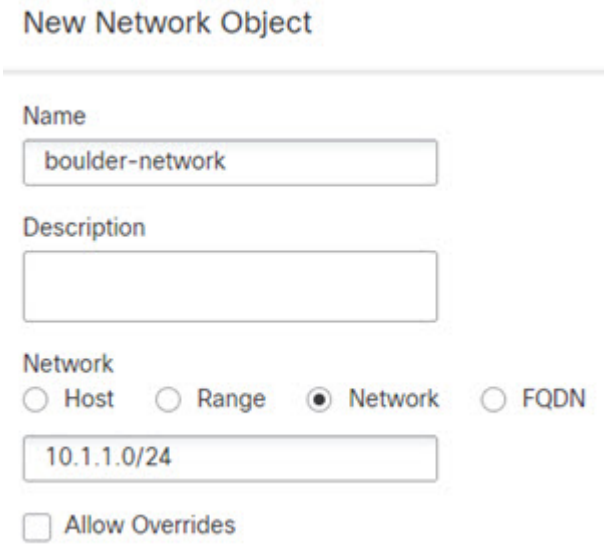
The following figure shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 364: Interface PAT and Identity NAT for Site-to-Site VPN

This example explains the configuration for Firewall1 (Boulder).

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the devices in the VPN. In this example, we will assume the interface objects are security zones named **inside-boulder** and **outside-boulder** for the Firewall1 (Boulder) interfaces. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

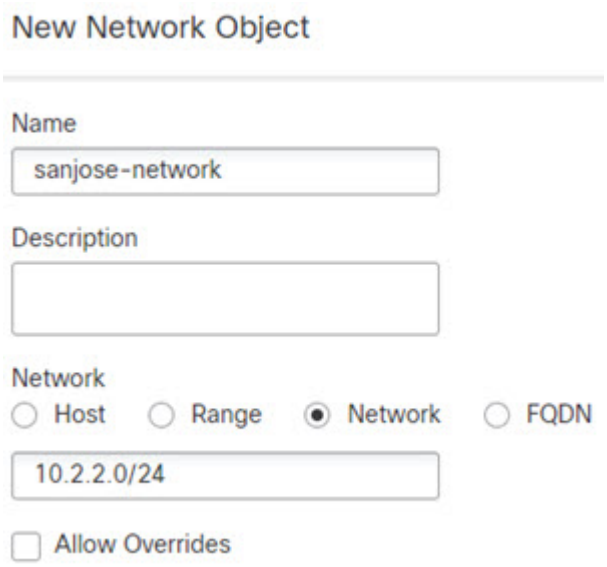


Procedure

Step 1 Create the objects to define the various networks.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Identify the Boulder inside network.



Name the network object (for example, boulder-network) and enter the network address, 10.1.1.0/24.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the inside San Jose network.

Name the network object (for example, sanjose-network) and enter the network address 10.2.2.0/24.

e) Click **Save**.

Step 2 Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

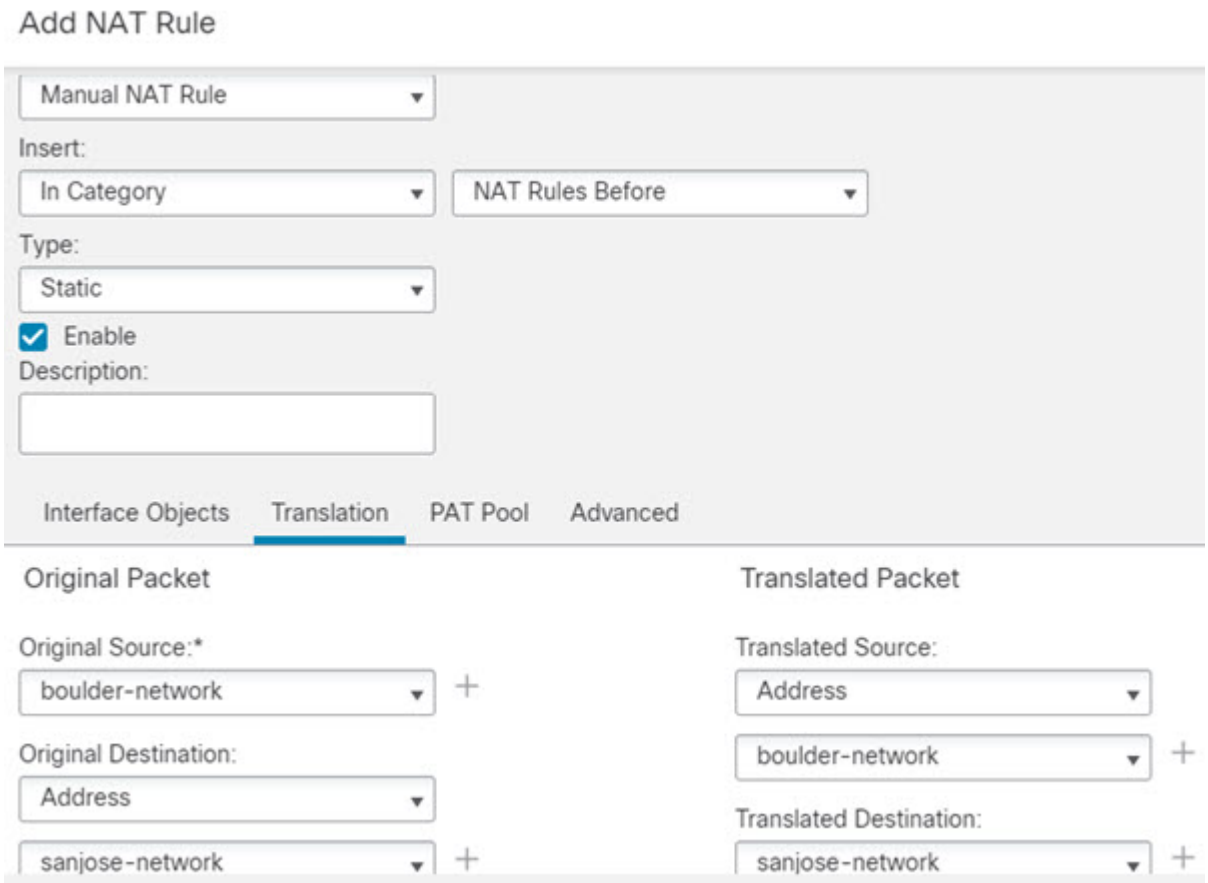
b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.

- **Type** = Static.

d) On **Interface Objects**, configure the following:



- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

e) On **Translation**, configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** > **Address** = boulder-network object.
- **Original Destination** > **Address** = sanjose-network object.
- **Translated Destination** = sanjose-network object.

Note
Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.

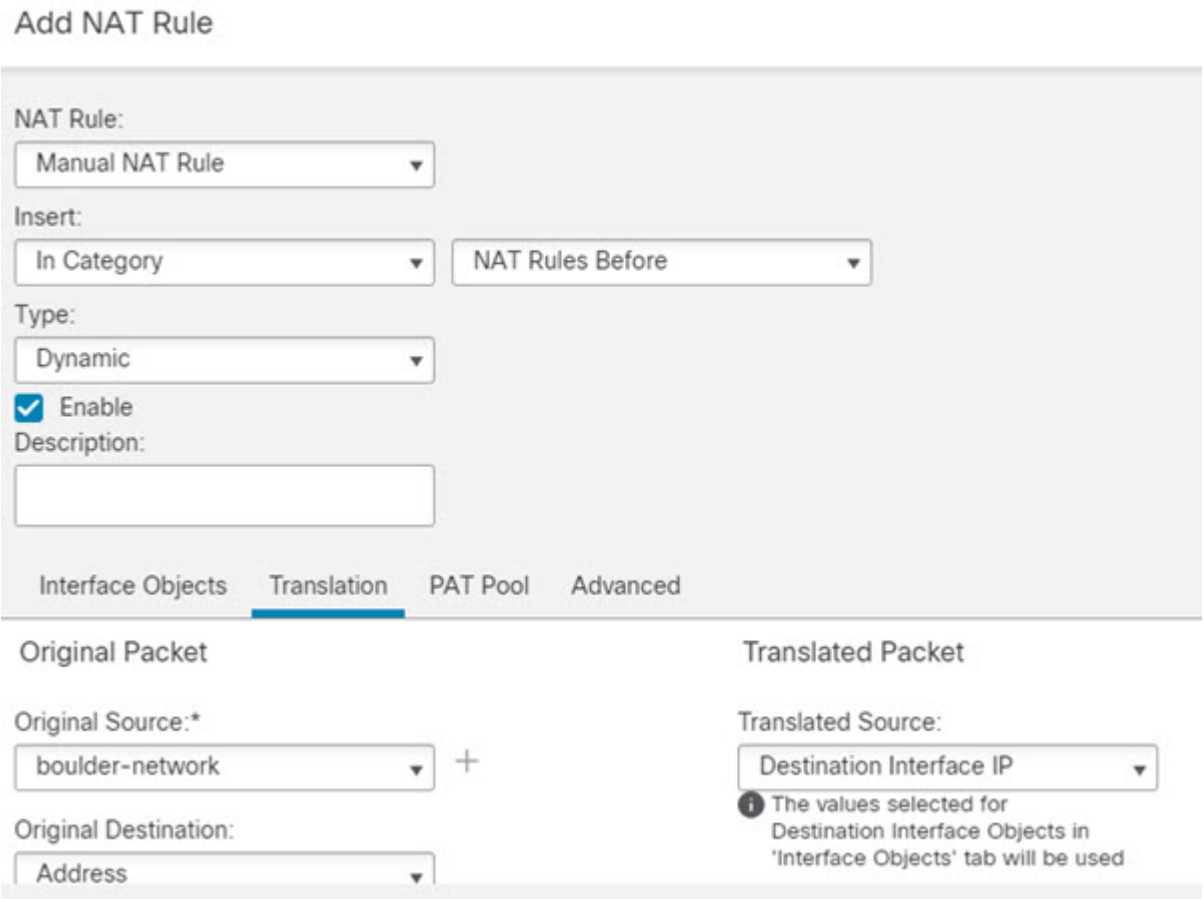
f) On **Advanced**, select **Do not proxy ARP on Destination interface**.

g) Click **Save**.

Step 3 Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

a) Click **Add Rule**.

b) Configure the following properties:



- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.
- **Insert Rule** = any position after the first rule. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section.

c) On **Interface Objects** , configure the following:

- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

d) On **Translation** , configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** = **Destination Interface IP**. This option configures interface PAT using the interface contained in the destination interface object.
- **Original Destination** > **Address** = any (leave blank).
- **Translated Destination** = any (leave blank).

e) Click **Save**.

Step 4 If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

DNS query and response rewriting using NAT

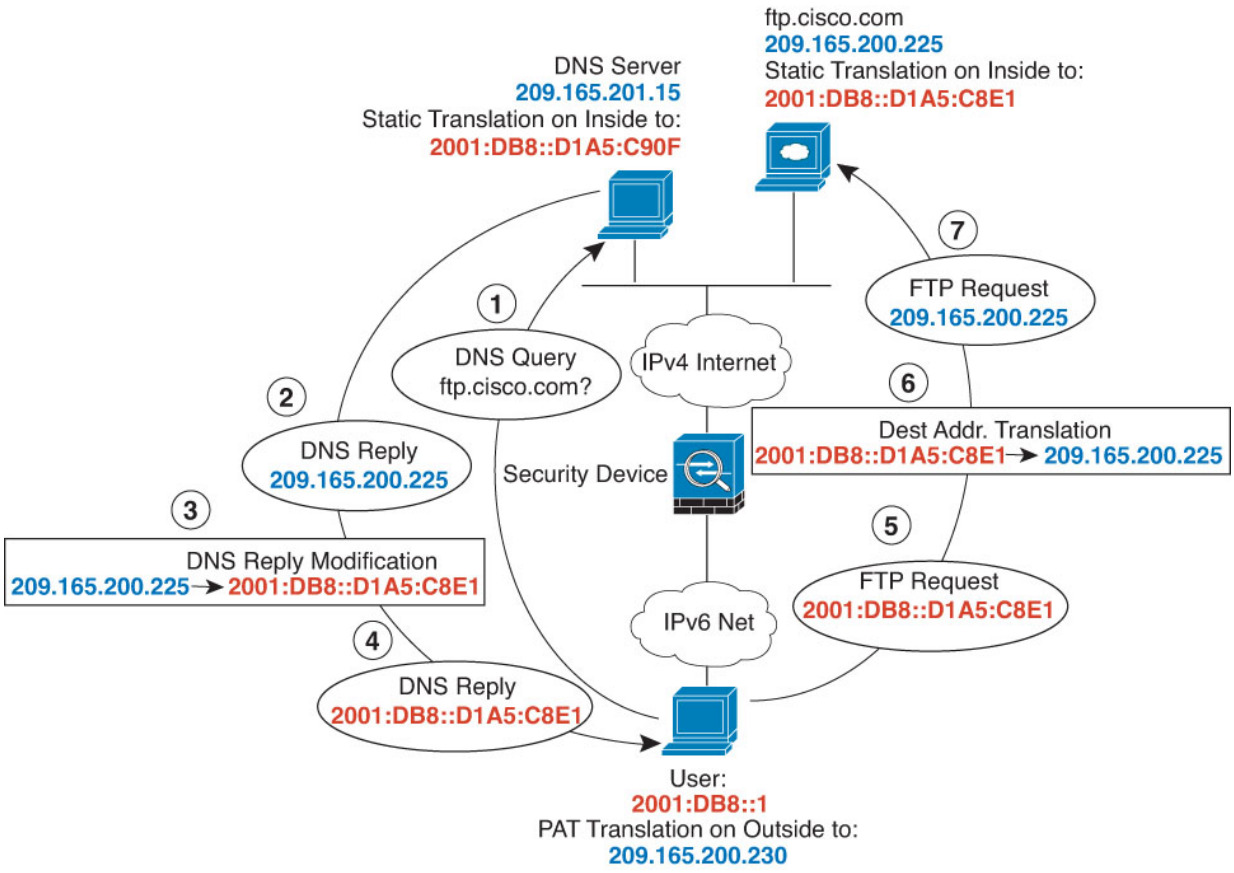
DNS rewrite is the process of modifying DNS replies so that the IP address returned in the DNS response is replaced with an address that matches the NAT configuration. It is used when a translated address must be returned to the requester instead of the original address in the DNS record. This function is also known as DNS doctoring.

This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value. This feature works with NAT44,NAT 66, NAT46, and NAT64.

The main circumstances when you would need to configure DNS rewrite on a NAT rule are:

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

DNS rewrite has the following limitations:



- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA record, and the PAT rule to use is ambiguous.
- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination address as well as the source address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the can not accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.
- You must enable DNS application inspection with DNS NAT rewrite enabled for NAT rules to rewrite DNS queries and responses. By default, DNS inspection with DNS NAT rewrite enabled is globally applied, so you probably do not need to change the inspection configuration.
- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.
- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

These topics provide examples of DNS rewrite in NAT rules.

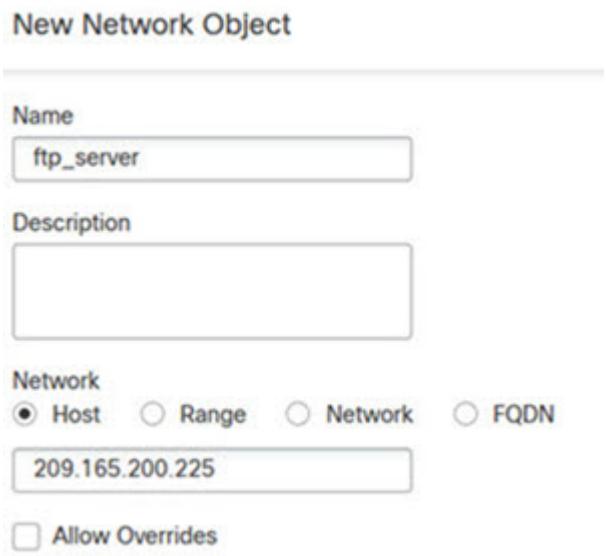
DNS64 reply modification

The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

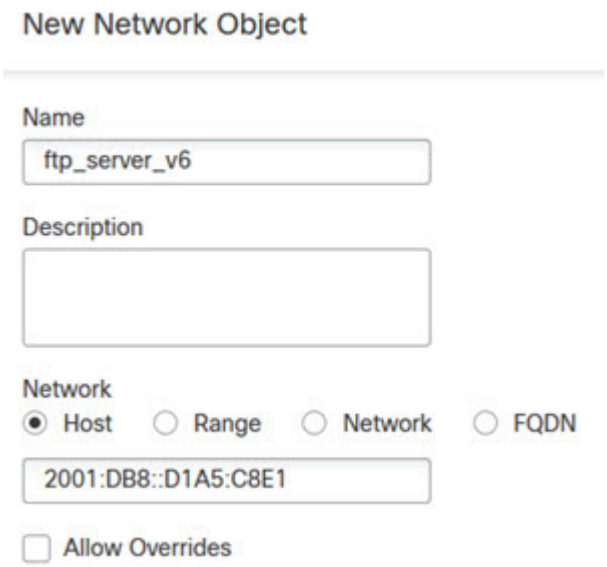


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.

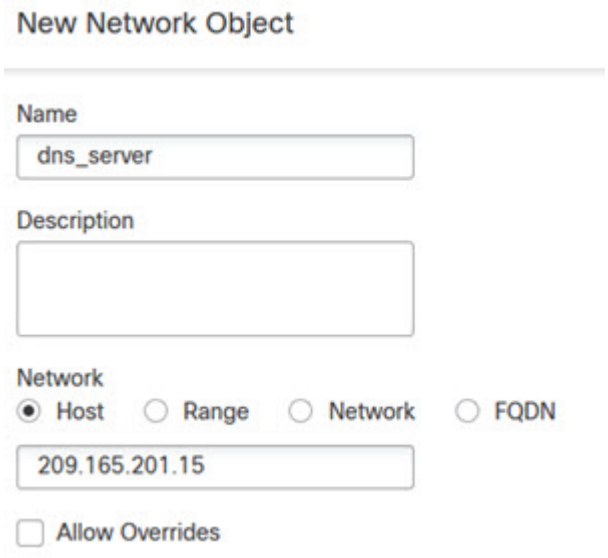


Name the network object (for example, ftp_server) and enter the host address, 209.165.200.225.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated IPv6 address.

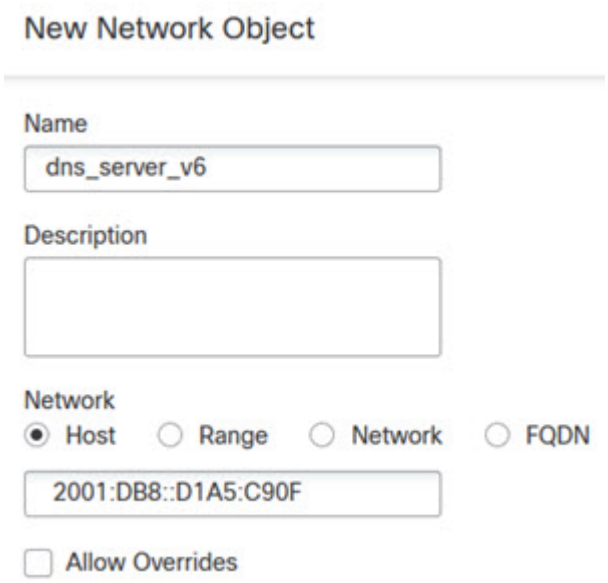
Name the network object (for example, ftp_server_v6) and enter the host address, 2001:DB8::D1A5:C8E1.



e) Click **Save**.

Step 2 Create the network objects for the DNS server.

a) Click **Add Network** > **Add Object** and define the DNS server's real address.

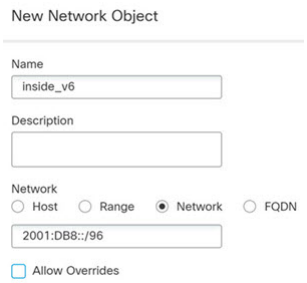


Name the network object (for example, dns_server) and enter the host address, 209.165.201.15.

b) Click **Save**.

c) Click **Add Network** > **Add Object** and define the DNS server's translated IPv6 address.

Name the network object (for example, dns_server_v6) and enter the host address, 2001:DB8::D1A5:C90F (where D1A5:C90F is the IPv6 equivalent of 209.165.201.15).

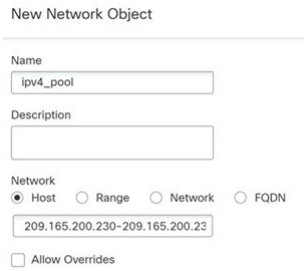


d) Click **Save**.

Step 3 Create the network objects for the inside network.

a) Click **Add Network** > **Add Object** and define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:DB8::/96.



b) Click **Save**.

Step 4 Create the network objects for the PAT pool.

a) Click **Add Network** > **Add Object** and define the IPv4 PAT pool for the inside IPv6 network.

Name the network object (for example, ipv4_pool) and enter the range 209.165.200.230-209.165.200.235.

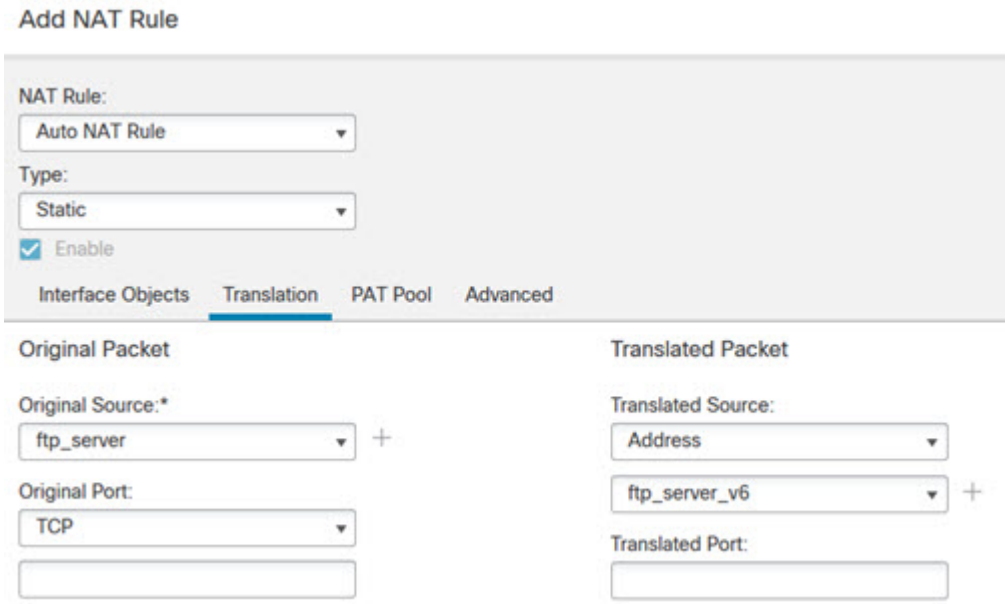
b) Click **Save**.

Step 5 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_v6 network object.

f) On **Advanced**, select the following options:

- **Translate DNS replies that match this rule**.
- **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

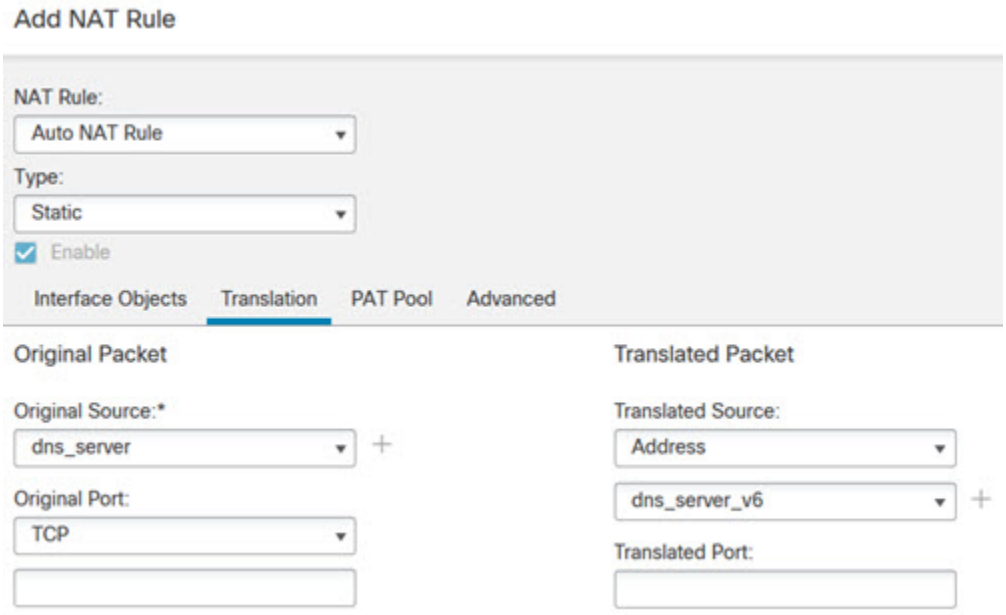
g) Click **OK**.

Step 6 Configure the static NAT rule for the DNS server.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:

- **Original Source** = dns_server network object.
- **Translated Source** > **Address** = dns_server_v6 network object.

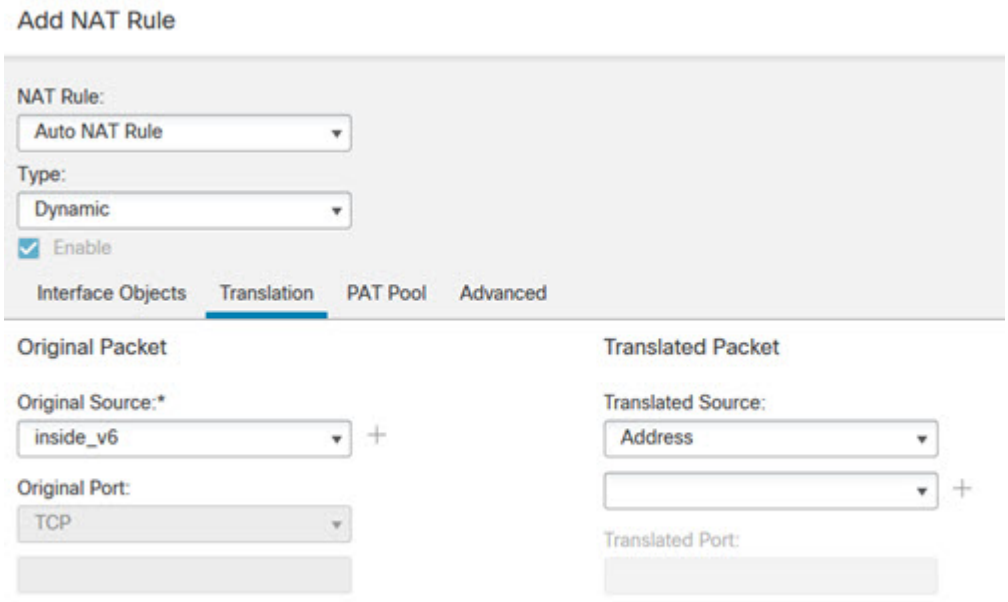
e) On **Advanced**, select **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

f) Click **OK**.

Step 7 Configure the dynamic NAT with a PAT pool rule for the inside IPv6 network.

a) Click **Add Rule**.

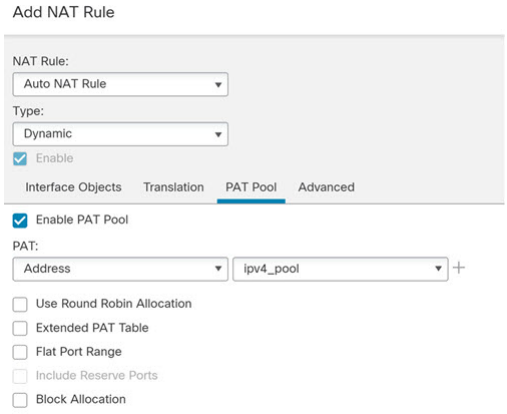
b) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

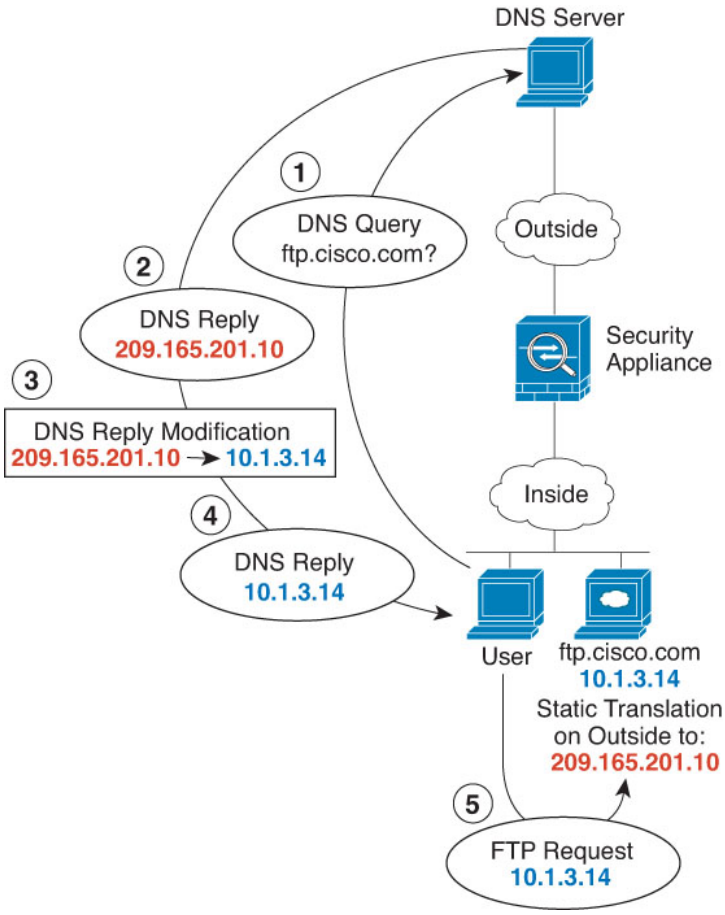


d) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = leave this field empty.

e) On **PAT Pool**, configure the following:

- **Enable PAT Pool** = select this option.
- **Translated Source** > **Address** = ipv4_pool network object.



f) Click **OK**.

Create DNS reply modification with DNS server on outside

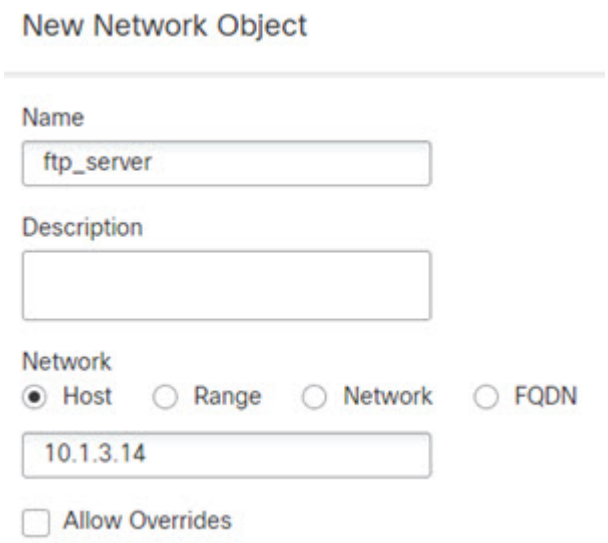
The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.

In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

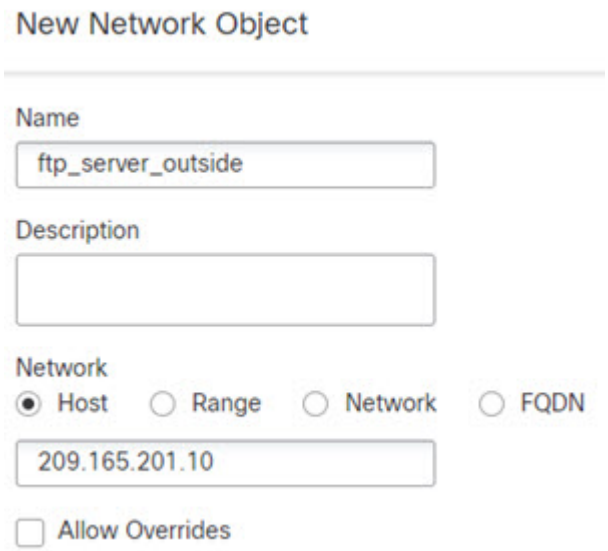


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 10.1.3.14.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_outside) and enter the host address, 209.165.201.10.

e) Click **Save**.

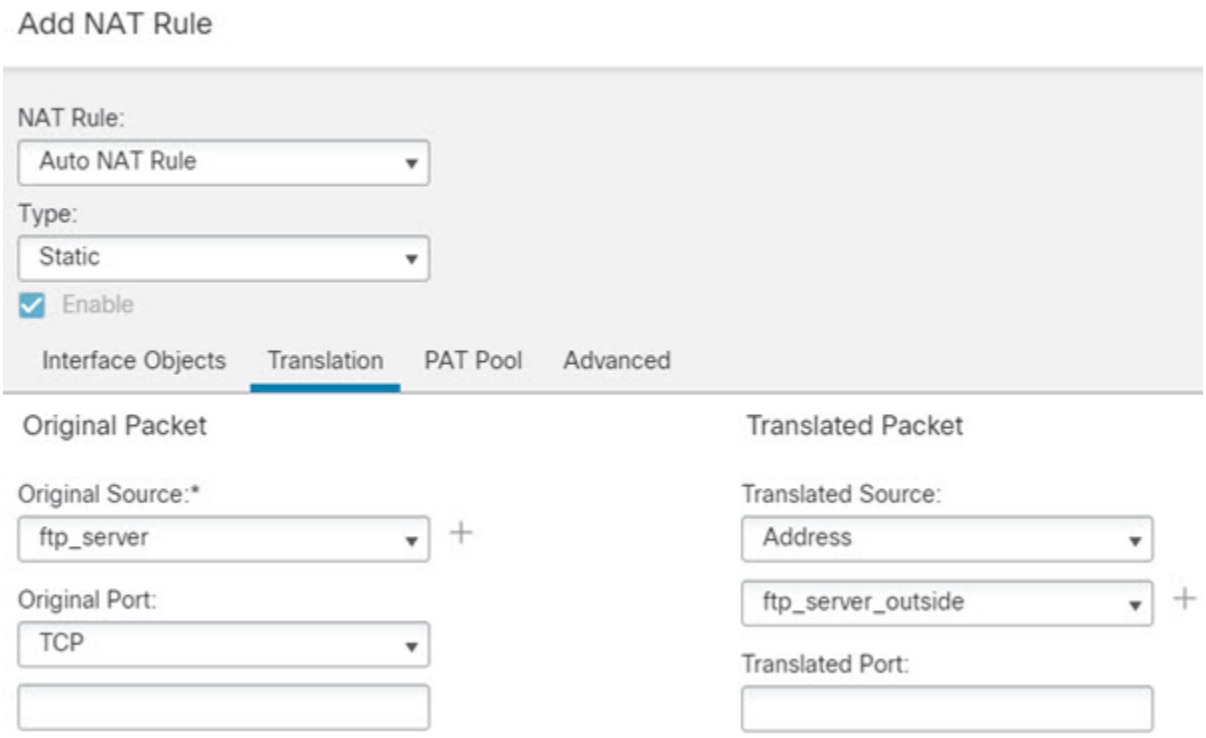
Step 2 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

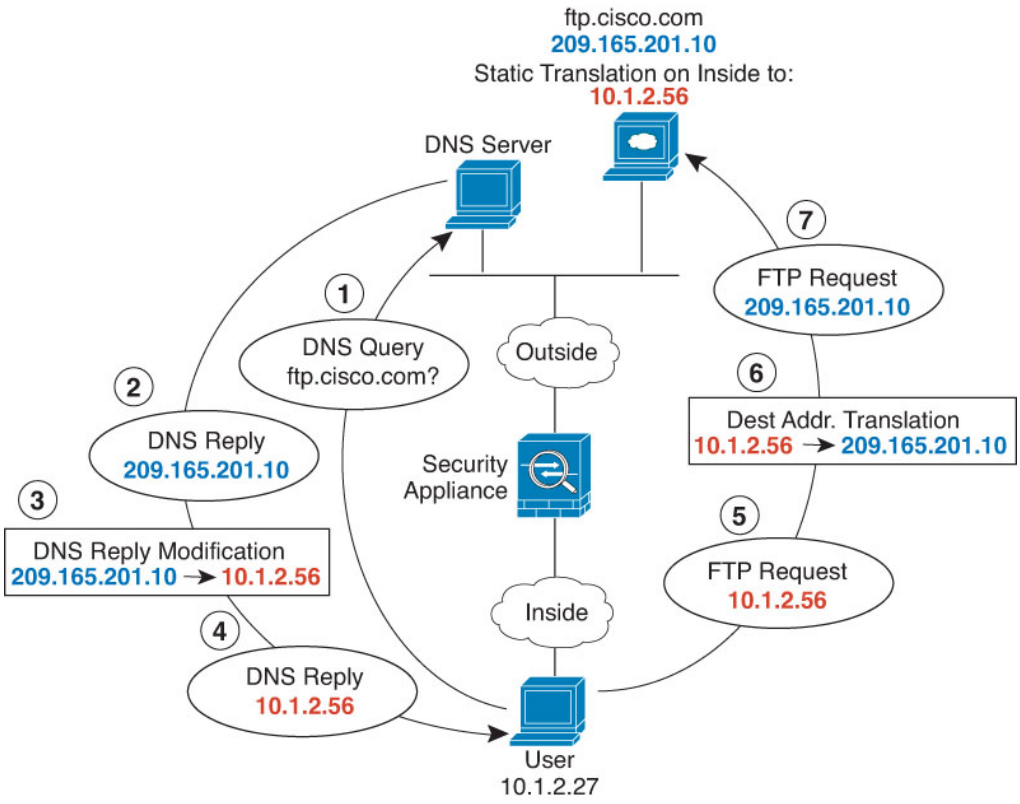


d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_outside network object.



f) On **Advanced**, select **Translate DNS replies that match this rule**.

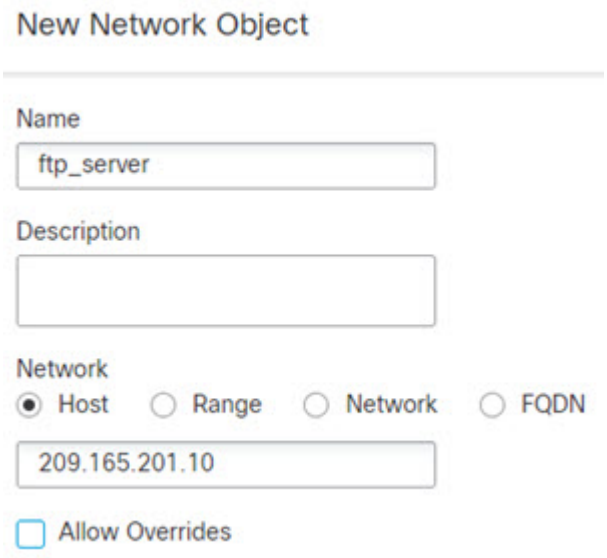
g) Click **OK**.

Configure DNS reply modification with DNS server on host network

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management** > **Interface**.

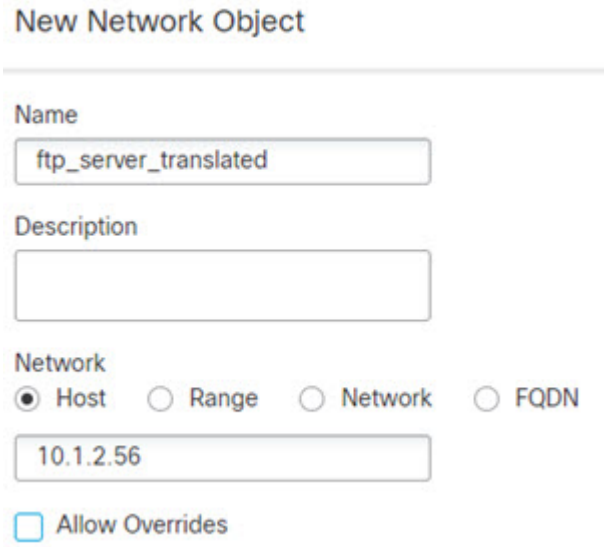


Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management** > **Network** and click **Add Network** > **Add Object**.

b) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 209.165.201.10.

c) Click **Save**.

d) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_translated) and enter the host address, 10.1.2.56.

e) Click **Save**.

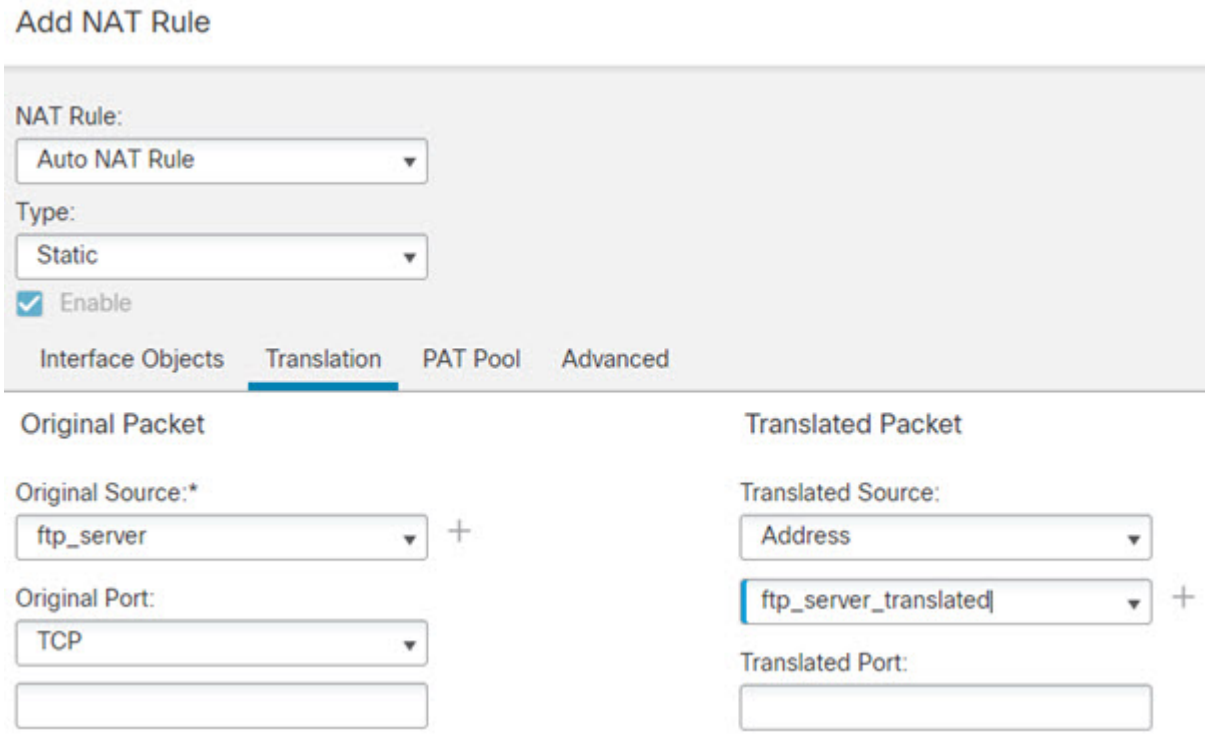
Step 2 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the Firewall Threat Defense NAT policy.

b) Click **Add Rule**.

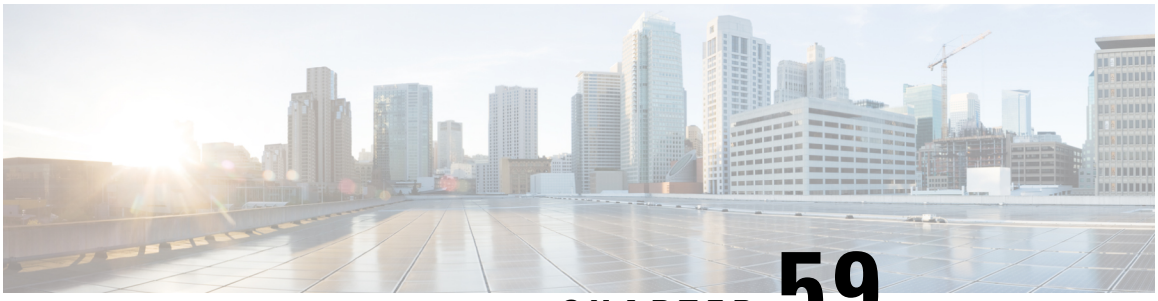
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.



e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_translated network object.

f) On **Advanced**, select **Translate DNS replies that match this rule**.

g) Click **OK**.

CHAPTER 59

Quality of Service

Quality of Service is a network management feature that:

- enables the policing of network traffic on Firewall Threat Defense devices.
- assists administrators in managing network traffic,
- provides guidelines for rate limiting.

- QoS, on page 1693
- QoS policies, on page 1694
- Requirements and prerequisites for QoS, on page 1694
- Guidelines and limitations for QoS policies, on page 1695
- Rate limiting with QoS policies, on page 1695

QoS

QoS is a traffic management mechanism that

- rate limits (polices) network traffic that is allowed or trusted by access control
- does not rate limit traffic that was fastpathed and
- is supported only on the routed interfaces of Firewall Threat Defense devices.

QoS interface limitations

QoS is supported only on the routed interfaces of Firewall Threat Defense devices. However, it does not support site-to-site VPN and VTI interfaces.

Logging Rate-Limited Connections

You cannot configure logging for QoS. A connection can be rate limited without being logged. Conversely, a logged connection may not be rate-limited. To view QoS details, you must separately log connection ends in your Cloud-Delivered Firewall Management Center database.

Connection events for rate-limited connections show how much traffic was dropped and the specific QoS configurations that applied. You can view this information in event views (workflows), dashboards, and reports.

QoS policies

A QoS policy is a configuration mechanism that

- governs rate limiting on managed devices
- can target multiple devices with each device having one deployed QoS policy at a time, and
- contains up to 63 QoS rules that handle network traffic in specified order.

QoS policy characteristics

QoS policies have these key characteristics:

-
- The system matches traffic to QoS rules in the order specified. The system rate limits traffic according to the first rule where all rule conditions match the traffic. Traffic not matching any of the rules is not rate limited.
- QoS rules can be limited by source or destination (routed) interfaces. The system enforces rate limiting *independently* on *each* of those interfaces and does not support an aggregate rate limit for a set of interfaces.
-
- You can independently rate limit download and upload traffic based on the connection initiator.

Note A device can have no more than 255 rules, including QoS rules. Exceeding this number causes a deployment warning necessitating a reduction in the number of rules..

Note QoS operates independently and is not subordinate to a main access control configuration. However, the access control and QoS policies deployed to the same device share identity configurations. For more infomration, see Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Requirements and prerequisites for QoS

This reference provides the requirements and prerequisites for implementing QoS, including supported models, domains, and user roles.

Access Admin

Network Admin

Guidelines and limitations for QoS policies

QoS rules and service policy rules (in the access control policy) are translated into firewall commands. There can be only one policy map per interface as the system combines QoS and service policy configurations automatically.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps using FlexConfig. For more powerful firewalls, such as the Firepower 4100, you can create up to 128 policy maps. Ensure not to exceed this limit to prevent deployment failures. You can check the device configuration using the CLI or the deployment transcript to see how rules are translated into commands.

Rate limiting with QoS policies

To perform policy-based rate limiting, configure and deploy QoS policies to managed devices. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose **Devices** > **QoS**.

Step 2 Click **New Policy** to create a new QoS policy and, optionally assign target devices; see Create a QoS policy, on page 1696.

You can also **Copy** ( ) or **Edit** ( ) an existing policy.

Step 3 Configure QoS rules; see Configuring QoS rules, on page 1698 and QoS rule conditions, on page 1700.

The QoS policy editor lists each rule in evaluation order and displays a summary of the rule conditions and rate limiting configurations. Use the right-click menu to manage rules, including moving, enabling, and disabling them.

This feature is helpful in larger deployments. You can **Filter by Device** to display only the rules that affect a specific device or group of devices. You can also search for rules, and the system matches text entered in the **Search Rules** field to rule names and condition values, including objects and object groups.

Note
Properly creating and ordering rules is a complex but essential to effective deployment. Careful planning is necessary to prevent rules from preempting each other, requiring additional licenses, or containing invalid

configurations. Icons in the interface represent comments, warnings, and errors. If issues exist, click **Show Warnings** to display a list. For more information, see Best practices for access control rules, on page 2058.

Step 4 Click **Policy Assignments** to identify which managed devices the policy targets; see Set target devices for a QoS policy , on page 1696.

Verify your choices, if you identified target devices during policy creation.

Step 5 Save the QoS policy.

Step 6 Since this feature must allow some packets to pass, configure your system to examine those packets.

Step 7 Deploy configuration changes.

The QoS policy is configured and deployed to the target devices, enabling policy-based rate limiting for network traffic.

Create a QoS policy

Create a QoS policy to establish the foundation for implementing rate limiting and traffic management rules on network devices.

The new QoS policy you create will not perform any rate limiting unless rules are added.

Procedure

Step 1 Choose **Devices** > **QoS**.

Step 2 Click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 (Optional) Choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy**, or drag and drop to the **Selected Devices**. To narrow the devices that appear, type a search string in the **Search** field.

Devices must be assigned before policy deployment.

Step 5 Click **Save**.

A new QoS policy is created and ready for configuration with rate limiting rules.

What to do next

- Configure and deploy the QoS policy; see Rate limiting with QoS policies, on page 1695.

Set target devices for a QoS policy

Before you begin

Ensure you are logged into the QoS policy editor and have the necessary access rights to configure system policies.

A QoS policy can target multiple devices, but each device can have one deployed QoS policy at a time.

Procedure

Step 1 In the QoS policy editor, click **Policy Assignments**.

Step 2 Build your target list:

- Add—Choose one or more **Available Devices**, then either click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete—Click **Delete** ( ) next to a single device, or choose multiple devices, right-click, then choose **Delete Selected**.
- Search—Enter a search string in the search field. Click **Clear** ( ) to clear the search.

Step 3 Click **OK** to save policy assignments.

Step 4 Click **Save** to save the policy.

The QoS policy is successfully configured with assigned target devices and is ready for deployment.

What to do next

- Deploy configuration changes.

Filter QoS rules by device

You can filter the list of QoS policy rules based on the device to which the rules apply. A rule's interface constraints determine if the rule affects a device.

Tip Hover your pointer over a rule criterion to see its value. If the criterion represents an object with device-specific overrides, the system displays the override value when you filter the rules list by that device. If the criterion represents an object with domain-specific overrides, the system displays the override value when you filter the rules list by devices in that domain.

Procedure

Step 1 In the policy editor, click **Rules**, then click **Filter by Device**.
A list of targeted devices and device groups appears.

Step 2 Check one or more check boxes to display only the rules that apply to those devices or groups. Or, check **All** to reset and display all of the rules.

Step 3 Click **OK**.

A message appears next to the button showing the filter used. To remove the filter, click the X in the message. Alternatively, select **All** in the Filter by device dialog box.

The QoS rules list displays only the rules that apply to the selected devices or device groups. It simplifies the process of reviewing and managing device-specific QoS policies.

Configuring QoS rules

QoS rules enable you to control and rate limit network traffic on specific interfaces by configuring rule properties, conditions, and traffic limits.

When you create or edit a rule, use the upper portion of the rule editor to configure general rule properties. Use the lower portion of the rule editor to configure rule conditions and comments.

Procedure

Step 1 On Rules of the QoS policy editor:

- Add Rule—Click **Add Rule**.
- Edit Rule—Click **Edit** ( ).

Step 2 Enter a **Name**.

Step 3 Configure rule components:

- Enabled—Specify whether the rule is **Enabled**.
- Apply QoS On—Select the interfaces you want to rate limit, either **Interfaces in Destination Interface Objects** or **Interfaces in Source Interface Objects**. Your choice must correspond with a populated interface constraint (not **any**).
- Traffic Limit Per Interface—Enter a **Download Limit** and an **Upload Limit** in Mbits/sec. The default value of **Unlimited** prevent matching traffic from being rate limited in that direction.
- Conditions—Click the corresponding condition you want to add. You must configure a source or destination interface condition, corresponding to your choice for **Apply QoS On**.
- Comments—Click **Comments**. To add a comment click **New Comment**, enter a comment, and click **OK**. You can edit or delete this comment until you save the rule.

For detailed information on rule components, see QoS rule components, on page 1699.

Step 4 Save the rule.

Step 5 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste.

Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 6 Click **Save** to save the policy.

The QoS rule you created or modified is saved to the policy and configured with your set traffic limits and conditions.

What to do next

- Deploy configuration changes.

Best practices for access control rules, on page 2058

QoS rule components

QoS rules consist of several key components that control traffic rate limiting and filtering behavior. Understanding these components helps you configure effective quality of service policies.

QoS rules include these main components:

- State (Enabled/Disabled): Controls whether the rule is active and enforced by the system.
- Interfaces (Apply QoS On): Specifies which interfaces the rate limiting applies to.
- Traffic Limit Per Interface: Sets the rate limiting values for matching traffic.
- Conditions: Defines the traffic criteria that must be matched for the rule to apply.
- Comments: Provides documentation and change tracking for the rule.

State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Interfaces (apply QoS on)

You cannot save a QoS rule that rate limits all traffic. For each QoS rule, apply QoS on one of the options:

- Interfaces in Source Interface Objects—Rate limits traffic through the rule's source interfaces. If you choose this option, you must add at least one source interface constraint (cannot be **any**).
- Interfaces in Destination Interface Objects—Rate limits traffic through the rule's destination interfaces. If you choose this option, you must add at least one destination interface constraint (cannot be **any**).

Traffic limit per interface

A QoS rule enforces rate limiting *independently* on *each* interface specified with the Apply QoS On option. Aggregate rate limits cannot be applied to a group of interfaces.

You can rate limit traffic by Mbits per second. The default value of **Unlimited** prevents matching traffic from being rate limited.

You can independently rate limit download and upload traffic. The system determines download and upload directions based on the connection initiator.

If you specify a limit greater than the interface's maximum throughput, the system does not rate limit matching traffic. Maximum throughput may be affected by an interface's hardware configuration, which you specify in each device's properties (**Devices** > **Device Management**).

Conditions

Conditions specify the specific traffic that the rule handles. You can configure each rule with multiple conditions. Traffic must meet all conditions to match the rule. Each condition type has its own tab in the rule editor. For more information, see QoS rule conditions, on page 1700.

Comments

Each time you save changes to a rule, add comments. You might summarize the overall configuration for users, or note any changes made and the reasons.

In the policy editor, the system displays how many comments a rule has. In the rule editor, use the Comments tab to view existing comments and add new ones.

QoS rule conditions

Conditions specify the traffic the rule handles. You can configure each rule with multiple conditions. All conditions must be met for traffic to match the rule. Each condition type has its own tab in the rule editor. You can rate limit traffic using these conditions.

Custom SGT rule conditions, on page 1704

Interface rule conditions

An interface rule condition is a network traffic control that

- controls traffic by its source and destination interfaces,
- uses predefined interface objects called security zones or interface groups to build interface conditions, and
- improves system performance by constraining rules to specific interfaces.

Interface rule condition characteristics

Interface objects segment your network by grouping interfaces across multiple devices to manage and classify traffic flow. For more information, refer to Interfaces, on page 2980.

QoS rules can be applied only on routed interfaces.

Note Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on whether the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

User rule condition example

Configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 98: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Recommendation: use URL conditions for website access control

Use URL conditions to control the websites that users on your network can access.

For complete information, see URL filtering with category and reputation, on page 2086.

Custom SGT rule conditions

A custom SGT rule condition is a traffic filtering mechanism that

- Use manually created SGT objects to filter traffic. Do not rely on ISE SGTs from a server.
- Correspond to the SGT attributes on the traffic to be controlled.
- Exclude user control considerations when using custom SGT traffic.

SGT traffic control without ISE configuration

If you do not configure ISE or ISE-PIC as an identity source, you can control traffic using Security Group Tags (SGTs) that were **not** assigned by ISE. SGTs specify traffic source privileges in a trusted network.

ISE SGT versus custom SGT rule conditions

Certain rules allow you to control traffic based on assigned SGT. The rule type and identity source configuration determine whether ISE-assigned SGTs or custom SGTs are used to match traffic with assigned SGT attributes.

Condition Type	Requires	SGTs Listed in Rule Editor
ISE SGT	ISE identity source	SGTs obtained by querying the ISE server, automatically updated metadata
Custom SGT	No ISE or ISE-PIC identity source	Static SGT objects you create

Note If using ISE SGTs to match traffic, any packet will match an ISE SGT rule if the SGT associated with the packet source IP address is recognized in ISE, even without an assigned SGT attribute.

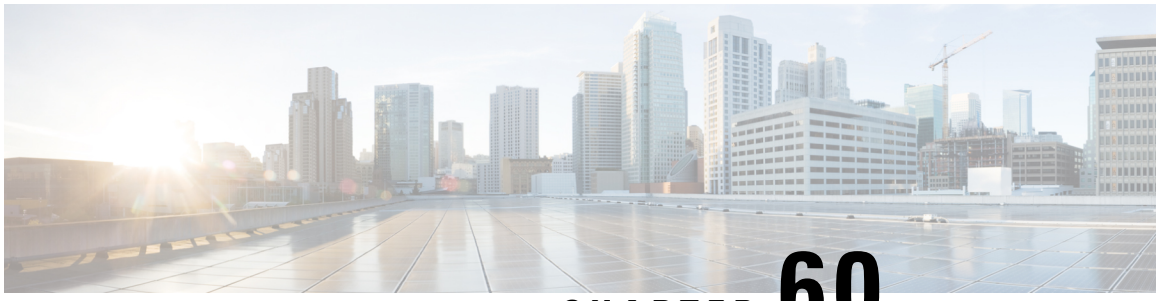
Autotransition from custom Security Group Tags to ISE Security Group Tags

An autotransition from custom Security Group Tags (SGTs) to ISE Security Group Tags is a system process that automatically adjusts rule configuration when you configure ISE/ISE-PIC as an identity source after creating rules with custom Security Group Tags.

System behavior during autotransition

If you create rules that match custom SGTs, then configure ISE or ISE-PIC as an identity source, the system will:

- Disable **Security Group Tag** options: The system retains existing SGT objects, but you cannot modify them or add new ones.
- Retain existing rules: Existing rules with custom SGT conditions remain, but they do not match traffic, and you cannot add more custom SGT conditions.



If you configure ISE, it is recommended to delete or disable existing rules with custom Security Group Tag conditions and use ISE attribute conditions to match traffic with Security Group Tag attributes.

CHAPTER 60

Secure Connections Overview

A virtual private network (VPN) connection establishes a secure tunnel between endpoints over a public network such as the Internet.

This chapter applies to Remote Access and Site-to-site VPNs on Secure Firewall Threat Defense devices. It describes the Internet Protocol Security (IPsec), the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and SSL standards that are used to build site-to-site and remote access VPNs.

- VPN types, on page 1709
- VPN basics, on page 1710
- VPN packet flow, on page 1713
- IPsec flow offload, on page 1713
- VPN licensing, on page 1714
- VPN encryption and performance, on page 1714
- Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups, on page 1720
- VPN topologies, on page 1720

VPN types

VPN types are network connection categories that

- provide secure, encrypted connections between remote locations and private networks
- support deployment models including remote access and site-to-site configurations, and
- use various protocols including SSL and IPsec for establishing secure tunnels.

Supported VPN connection types

The Cloud-Delivered Firewall Management Center supports these types of VPN connections:

- Remote Access VPNs in Firewall Threat Defense devices.

  Remote access VPNs provide secure, encrypted connections, or tunnels, between remote users and your company's private network. These connection use two devices: a VPN endpoint device, which is a workstation or mobile device with VPN client capabilities, and a VPN headend device, or secure gateway, at the edge of the corporate private network.

  Secure Firewall Threat Defense devices can be configured to support Remote Access VPNs over SSL or IPsec IKEv2 by the Cloud-Delivered Firewall Management Center. When acting as secure gateways,

these devices authenticate remote users, authorize access, and encrypt data to provide secure connections to your network. Only these devices support remote access VPN connections, managed by the Cloud-Delivered Firewall Management Center.

Secure Firewall Threat Defense secure gateways support the Secure Client full tunnel client. This client is required to provide secure SSL IPsec IKEv2 connections for remote users. This client automatically installs when a connection is established, so network administrators do not need to manually install or configure it on remote computers. It is the only client supported on endpoint devices.

- Site-to-site VPNs in Firewall Threat Defense devices.

  A site-to-site VPN connects networks in different geographic locations. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers. These peers can use either IPv4 and IPv6 addresses. Site-to-site tunnels are built using the Internet Protocol Security (IPsec) protocol suite and IKEv1 or IKEv2. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel.

VPN basics

A VPN is a secure networking technology that

- uses tunneling to create secure connections between remote users and private corporate networks over public TCP/IP networks such as the Internet
- employs IPsec-based technologies with ISAKMP (IKE) and IPsec tunneling standards to build and manage tunnels, and
- enables bidirectional data transfer through tunnel endpoints that encapsulate and unencapsulate packets.

VPN tunnel management capabilities

ISAKMP and IPsec accomplish these tunnel management functions:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

After the site-to-site VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. A connection consists of the IP addresses

and hostnames of the two gateways, the subnets behind them, and the method the two gateways use to authenticate to each other.

VPN deployments use two primary device types:

- Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.
- Spokes: Devices that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

Internet Key Exchange (IKE)

Internet Key Exchange (IKE) is a key management protocol that

- authenticates IPsec peers
- negotiates and distributes IPsec encryption keys, and
- automatically establishes IPsec security associations (SAs).

IKE negotiation phases and policies

The IKE negotiation comprises two phases:

- Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2.
- During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec.

Each phase uses proposals to negotiate a connection.

An IKE policy is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins when each peer agrees on a common IKE policy. This policy defines security parameters to protect subsequent IKE negotiations. IKEv1 policies contain a single set of algorithms and a modulus group. In an IKEv2 policy, you can select multiple algorithms and modulus groups for peers to choose from during the Phase 1 negotiation. You may create a single IKE policy, or create multiple policies to give higher priority to preferred options. For site-to-site VPNs, you can create an IKE policy. IKEv1 and IKEv2 each support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. A lower priority number indocates a higher priority for the policy.

To define an IKE policy, specify:

- A unique priority (1 to 65,543, with 1 being the highest priority).
- An encryption method for the IKE negotiation to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to verify the sender's identity, and to confirm that the message is unchanged during transit.
- For IKEv2, a separate pseudorandom function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm.
- A Diffie-Hellman group to determine the strength of the encryption key determination algorithm. The device uses this algorithm to derive the encryption and hash keys.

- An authentication method, to ensure the identity of the peers.
- A limit to the time the device uses an encryption key before replacing it.

When IKE negotiation begins, the initiating peer sends all its policies to the remote peer. The remote peer searches for a match with its own policies, in priority order. IKE policies match if both peers use the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values. The SA lifetime must be less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter value from the remote peer policy applies. By default, the Cloud-Delivered Firewall Management Center deploys an IKEv1 policy with the lowest priority for all VPN endpoints to ensure a successful negotiation.

IPsec

IPsec is a secure method for setting up a VPN that:

- provides data encryption at the IP packet level,
- transmits data over a public network through tunnels, which are secure, logical communication paths between two peers, and
- secures traffic that enters an IPsec tunnel by a combination of security protocols and algorithms.

With IPsec, data is transmitted over a public network through tunnels.

IPsec proposal policy components

An IPsec proposal policy defines the settings for IPsec tunnels. An IPsec proposal includes one or more crypto maps that are applied to the VPN interfaces in the devices. A crypto map combines all the components required to set up IPsec security associations, including:

- A proposal (or transform set) combines security protocols and algorithms that secure traffic in an IPsec tunnel. During the IPsec security association (SA) negotiation, peers search for a matching proposal. Apply the selected proposal to create an SA that protects data flows in the crypto map's access list and secures VPN traffic. There are separate IPsec proposals for IKEv1 and IKEv2. In IKEv1 proposals (or transform sets), you set one value for each parameter. In IKEv2 proposals, you can configure multiple encryption and integration algorithms for a single proposal.
- A crypto map combines all components required to set up IPsec security associations (SA), including IPsec rules, proposals, remote peers, and other parameters that are necessary to define an IPsec SA. When two peers try to establish an SA, they must each have at least one compatible crypto map entry.

  Dynamic crypto map policies are used in site-to-site VPNs when an unknown remote peer tries to start an IPsec security association with the local hub. The hub does not initiate the security association negotiation. Dynamic crypto policies allow remote peers to exchange IPsec traffic with a local hub, even if the hub does not know the remote peer's identity. A dynamic crypto map policy creates a crypto map entry before configuring all parameters. IPsec negotiation then dynamically configures the missing parameters to match a remote peer's requirements.

  Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply dynamic crypto map policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

Note Simultaneous IKEv2 dynamic crypto map is not supported for the same interface for both remote access and site-to-site VPNs in a Firewall Threat Defense device.

VPN packet flow

VPN packet flow is a security process that

- requires explicit permission through access control before allowing traffic to pass through,
- decrypts incoming tunnel packets before sending them to the Snort process,
- processes outgoing packets through Snort before encryption, and
- blocks tunnel traffic to the public source when the tunnel is down.

Access control requirements

Access control identifies the protected networks for each endpoint node of a VPN tunnel and determines which traffic is allowed to pass through the Firewall Threat Defense device and reach the endpoints. For remote access VPN traffic, a group policy filter or an access control rule must be configured to permit VPN traffic flow.

IPsec flow offload

IPsec flow offload is a performance optimization feature that

- offloads IPsec connections to field-programmable gate array (FPGA) or specialized hardware components after initial setup
- improves device performance by handling pre-decryption, decryption, pre-encryption, and encryption processing in hardware, and
- is enabled by default on supporting device models while allowing system software to handle inner flow security policies.

IPsec flow offload characteristics

After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device. This process improves device performance.In the Secure Firewall 1200 series, IPsec connections are offloaded to the Marvell Cryptographic Accelerator (CPT) to improve device performance.

Offloaded operations include pre-decryption and decryption processing on ingress and egress. The system software applies your security policies for traffic within the inner flow.

IPsec flow offload applies to these device types:

- Secure Firewall 1200

- Secure Firewall 3100
- Secure Firewall 4200

IPsec flow offload is also used when the device's VTI loopback interface is enabled.

For asymmetric flows in cluster distributed site-to-site VPN mode, IPsec flow offload lets the flow owner decrypt IPsec traffic in hardware that was forwarded over the cluster control link. This feature is not configurable and is always available with IPsec flow offload.

By default, the system enables IPsec flow offload on supported device models. To change the configuration, use FlexConfig to implement the **flow-offload-ipsec** command. For more information, refer to the ASA command reference.

VPN licensing

You do not need any specific license to enable VPN on a Firewall Threat Defense device, it is available by default.

The Cloud-Delivered Firewall Management Center determines whether to allow or block the usage of strong encryption in the Firewall Threat Defense device based on the export-controlled functionality in the device. You can enable this functionality when you register with the Cisco Smart License Manager. If you are using the evaluation license, or you did not enable export-controlled functionality, you cannot use strong encryption.

Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this functionality in Cloud-Delivered Firewall Management Center.

If you created your VPN configurations with an evaluation license and later upgraded your license to a smart license with export-controlled functionality, check and update your encryption algorithms to use stronger encryption so that the VPNs function properly. Do not use DES-based encryption, as it is not supported.

VPN encryption and performance

When you configure VPN tunnel encryption, provide sufficient protection and maintain efficiency by balancing security and performance.

Because a VPN tunnel typically traverses a public network, most likely the Internet, you need to encrypt the connection to protect the traffic. You define the encryption and other security techniques with IKE policies and IPsec proposals. Using stronger tunnel encryption may lower system performance.

If your device license allows strong encryption, you can choose from a range of encryption and hash algorithms and Diffie-Hellman groups. This document does not provide specific guidance on which options you should choose. If you operate within a larger corporation or other organization, there might already be defined standards that you need to meet. If not, take the time to research the options.

Comply with security certification requirements

Review your certification requirements and the available options to plan your VPN configuration. Many VPN settings have options that allow you to comply with various security certification standards.

Decide encryption algorithms for VPN policies

When deciding which encryption algorithms to use for the IKE policy or IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN.

- For IKEv2, you can configure multiple encryption algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order.
- For IKEv1, you can select a single option only.
- For IPsec proposals, the algorithm is used by the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-.

If your device license qualifies for strong encryption, you can choose from the available encryption algorithms. If you are not qualified for strong encryption, you can select DES only.

Strong encryption license considerations

Note If you are qualified for strong encryption, before upgrading from the evaluation license to a smart license, check and update your encryption algorithms for stronger encryption so that the VPN configuration works properly. Choose AES-based algorithms. DES is not supported if you are registered using an account that supports strong encryption. After registration, you cannot deploy changes until you remove all uses of DES.

Available encryption algorithms

- AES-GCM—(IKEv2 only) Advanced Encryption Standard in Galois or Counter Mode is a block cipher mode that provides confidentiality and data-origin authentication. It offers greater security than AES.

  AES-GCM offers three different key strengths: 128-bit, 192-bit, and 256-bit keys. Longer keys increase security but reduce performance. NSA Suite B, a set of cryptographic algorithms that devices must support to meet federal cryptographic strength standards, requires GCM.
- AES—Advanced Encryption Standard is a symmetric cipher algorithm that provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-bit, 192-bit, and 256-bit keys. Longer keys increase security but reduce performance.
- DES—Data Encryption Standard, which encrypts using 56-bit keys, is a symmetric secret-key block algorithm. If your license account does not meet the requirements for export controls, this is your only option.
- Null, ESP-Null—A null encryption algorithm provides authentication without encryption. This method is not secure; use at your own discretion.

Decide which hash algorithms to use

In IKE policies, the hash algorithm creates a message digest to ensure your messages remain secure. In IKEv2, you can choose one hash algorithm for integrity and another for the pseudo-random function (PRF).

In IPsec proposals, the Encapsulating Security Protocol (ESP) uses the hash algorithm for authentication. In IKEv2 IPsec proposals, this is called the integrity hash. In IKEv1 IPsec proposals, the algorithm name has the ESP- prefix and an -HMAC suffix.

The system arranges your settings from the most secure to the least secure and negotiates with the peer in that order. For IKEv1, select only one option.

Select a hash algorithm that meets your security and performance needs:

- SHA (Secure Hash Algorithm)—The standard SHA (SHA1) produces a 160-bit digest.

  These SHA-2 options provide increased security and are available for IKEv2 configurations. Choose one if you require NSA Suite B cryptography compliance.

  - SHA256—Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
  - SHA384—Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
  - SHA512—Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

- Null or None (NULL, ESP-NONE)—(IPsec Proposals only) AUse a null hash algorithm only for testing purposes. If you select one of the AES-GCM options as the encryption algorithm, choose the null integrity algorithm. For these encryption standards, the integrity hash is ignored even if you choose a non-null option.

Decide which Diffie-Hellman modulus group to use

You can use Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus increases security but requires more processing time. You must have a matching modulus group on both peers.

For AES encryption, use Diffie-Hellman (DH) Group 5 or higher to support the large key sizes required by AES. IKEv1 policies do not support all of the groups.

To implement the NSA Suite B cryptography specification, use IKEv2 and select one of the elliptic curve Diffie-Hellman (ECDH) options: 19, 20, or 21. Elliptic curve options and groups that use a 2048-bit modulus reduce exposure to attacks such as Logjam.

For IKEv2, you can configure multiple groups. The system orders the settings from the most secure to the least secure, then negotiates with the peer using that order. For IKEv1, you can select only a single option.

- 14—Diffie-Hellman Group 14: 2048-bit modular exponential (MODP) group. Considered good protection for 192-bit keys.
- 15—Diffie-Hellman Group 15: 3072-bit MODP group.
- 16—Diffie-Hellman Group 16: 4096-bit MODP group.
- 19—Diffie-Hellman Group 19: National Institute of Standards and Technology (NIST) 256-bit elliptic curve modulo a prime (ECP) group.
- 20—Diffie-Hellman Group 20: NIST 384-bit ECP group.
- 21—Diffie-Hellman Group 21: NIST 521-bit ECP group.
- 31—Diffie-Hellman Group 31: Curve25519 256-bit EC Group.

Decide VPN authentication methods

A VPN authentication method is a security mechanism that

- validates the identity of peers in a VPN connection
- enables secure communication between network devices, and
- ensures that only authorized devices can establish VPN connections.

Available authentication methods

VPNs support two primary authentication methods:

- **Preshared keys**: A secret key shared between two peers and used by IKE during the authentication phase. The same shared key must be configured at each peer or the IKE SA cannot be established.
- **Digital certificates**: Use RSA key pairs to sign and encrypt IKE key management messages. Certificates provide proof of communication between two peers.

VPN type support varies by authentication method.

Table 99: VPN authentication method support

VPN Type	Preshared Keys	Digital Certificates
Site-to-site IKEv1 and IKEv2	Supported	Supported
Remote Access (SSL and IPsec IKEv2)	Not supported	Supported

When you use digital certificate authentication, you need a Public Key Infrastructure (PKI) defined for peers to obtain digital certificates from a Certification Authority (CA). CAs manage certificate requests and issue certificates to participating network devices, providing centralized key management for all participating devices.

Preshared keys are difficult to manage for large networks. CAs make it easier to manage and scale your IPsec network. With a CA, you do not need to configure keys between all encrypting devices. Register each device with the CA to request its certificate. Devices with their own certificates and the CA's public key can authenticate other devices within the CA's domain.

Pre-shared keys

A pre-shared key is a secret key that

- enables you to share authentication credentials between two peers
- is used by IKE in the authentication phase, and
- must be configured identically on each peer or the IKE SA cannot be established.

Key configuration options

To configure pre-shared keys, select either a manual key or an automatically generated key. Specify this key in the IKEv1 or IKEv2 options. When you deploy your configuration, the key is configured on all devices in the topology.

PKI infrastructure and digital certificates

A PKI infrastructure is a centralized key management system that

- provides defined policies, procedures, and roles supporting public key cryptography
- generates, verifies, and revokes public key certificates, commonly known as digital certificates, and
- manages key pairs consisting of public and private keys for VPN endpoints to sign and encrypt messages.

Public key cryptography and certificate components

In public key cryptography, each endpoint of a connection has a key pair consisting of both a public and a private key. The key pairs are used by the VPN endpoints to sign and encrypt messages. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other, securing the data flowing over the connection.

Generate a general-purpose RSA, ECDSA, or EDDSA key pair for signing and encryption. Alternatively, generate separate key pairs for each purpose. Separate signing and encryption keys help to reduce key exposure. SSL uses a key for encryption, while IKE uses a key for signing. Separate keys for each purpose minimize exposure.

Certificates also ensure non-repudiation by providing proof that communication between two peers occurred.

You can obtain CA certificates by:

- Using the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA's certificate from the CA server
- Manually copying the CA's certificate from another participating device

Trustpoints represent the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

A PKCS#12, or PFX, file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Digital certificates or identity certificates

When you use digital certificates as the authentication method for VPN connections, peers are configured to obtain digital certificates from a Certificate Authority (CA). CAs are trusted authorities that sign certificates to verify their authenticity, thereby guaranteeing the identity of the device or user.

Digital certificates contain these components:

- The digital identification of the owner for authentication, such as name, serial number, company, department, or IP address.

- A public key needed to send and receive encrypted data to the certificate owner.
- The secure digital signature of a CA.

The certificate enrollment process includes these steps:

1. CA servers manage public CA certificate requests and issue certificates to participating network devices as part of a PKI.
2. Each participating device enrolls individually with a CA server, which validates identities and creates an identity certificate.
3. Each participating peer sends their identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates.

Certificate enrollment

Using a PKI improves the manageability and scalability of your VPN because you do not have to configure preshared keys between all encrypting devices. Instead, enroll each participating device with a CA server, which validates identities and creates an identity certificate for the device. After completing enrollment, each participating peer sends its identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates. For more information about enrolling Firewall Threat Defense device certificates, refer to Certificate enrollment objects, on page 2997.

Certificate authority certificates

In order to validate a peer’s certificate, each participating device must retrieve the CA's certificate from the server. A CA certificate is used to sign other certificates. It is self-signed and called a root certificate. This certificate contains the CA's public key, which you use to decrypt and validate the CA's digital signature and the contents of the received peer's certificate.

To obtain the CA certificate:

- Use the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA’s certificate from the CA server
- Manually copy the CA's certificate from another participating device

Trustpoints

Once enrollment is complete, a trustpoint is created in the managed device. It is the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and one enrolled identity certificate.

PKCS#12 file

A PKCS#12 file, or PFX file holds the server certificate, intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

Revocation checking

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

Deprecated hash algorithms, encryption algorithms, and Diffie-Hellman modulus groups

Update your VPN configuration to use supported DH and encryption algorithms before upgrading to Firewall Threat Defense 6.70 or later.

- Update your IKE proposals and IPSec policies to match the ones supported in Firewall Threat Defense 6.70 or later.
- Deploy the configuration changes after updating to supported algorithms.

Support has been removed for these less secure ciphers from Firewall Threat Defense Version 6.70:

- **Diffie-Hellman GROUP 5** is deprecated for IKEv1 and IKEv2.
- Diffie-Hellman groups 2 and 24 have been removed.
- **Encryption algorithms**: 3DES, AES-GMAC, AES-GMAC-192, and AES-GMAC-256 have been removed.

Note **DES** continues to be supported in evaluation mode or for users who do not satisfy export controls for strong encryption.

NULL is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.

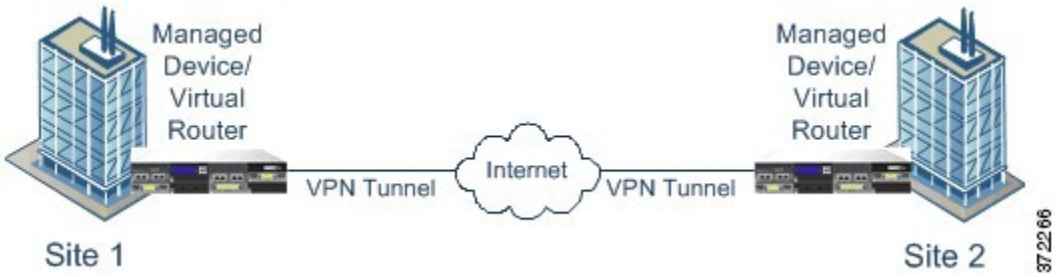
VPN topologies

When you create a new VPN topology you must give it a unique name, specify a topology type, and select the IKE version. You can select from three types of topologies, each containing a group of VPN tunnels:

- Point-to-point (PTP) topologies establish a VPN tunnel between two endpoints.
- Hub and spoke topologies establish a group of VPN tunnels connecting a hub endpoint to a group of spoke endpoints.
- Full mesh topologies establish a group of VPN tunnels among a set of endpoints.

There is no default pre-shared key for VPN authentication. You must define a pre-shared key manually or let the system generate it automatically. When choosing automatic, the Cloud-Delivered Firewall Management Center generates a pre-shared key and assigns it to all the nodes in the topology.

Point-to-point VPN topologies



A point-to-point VPN topology is a network configuration that

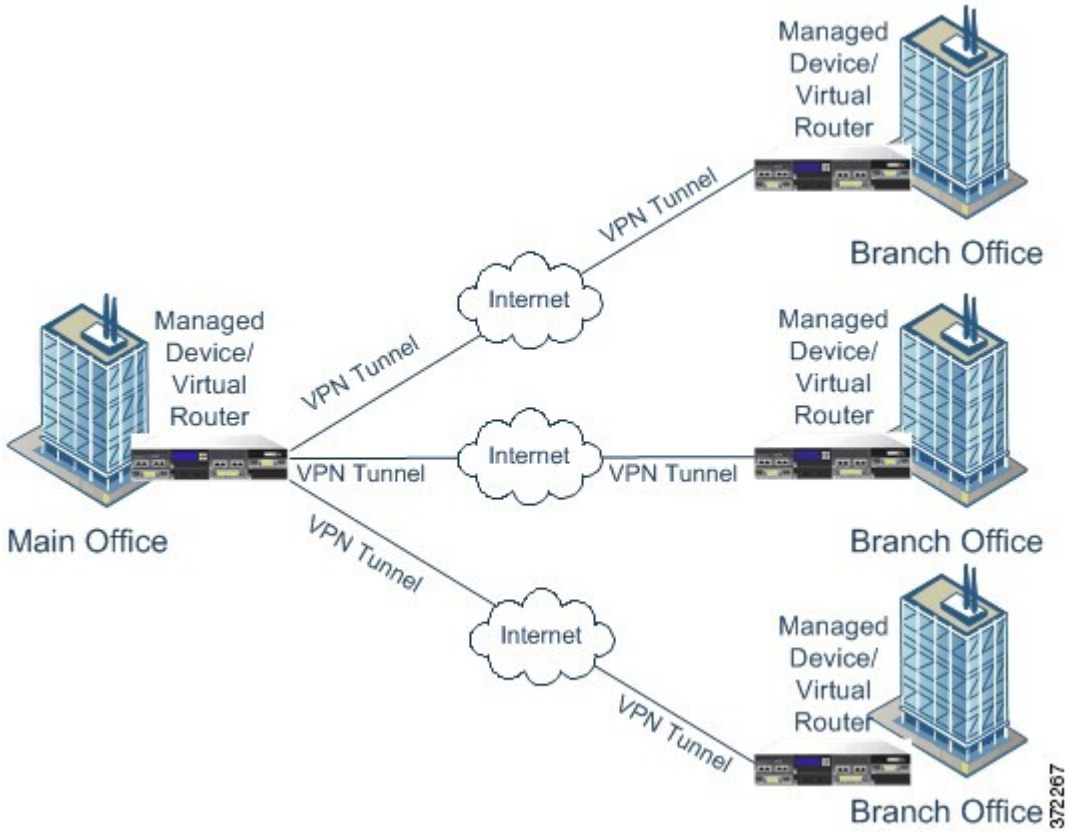
- enables two endpoints to communicate directly with each other

- allows you to configure the two endpoints as peer devices, and
- permits either device to start the secured connection.

This diagram displays a typical point-to-point VPN topology.

Figure 365: Point-to-point VPN topology

Hub and spoke VPN topology



A hub and spoke VPN topology is a network architecture that

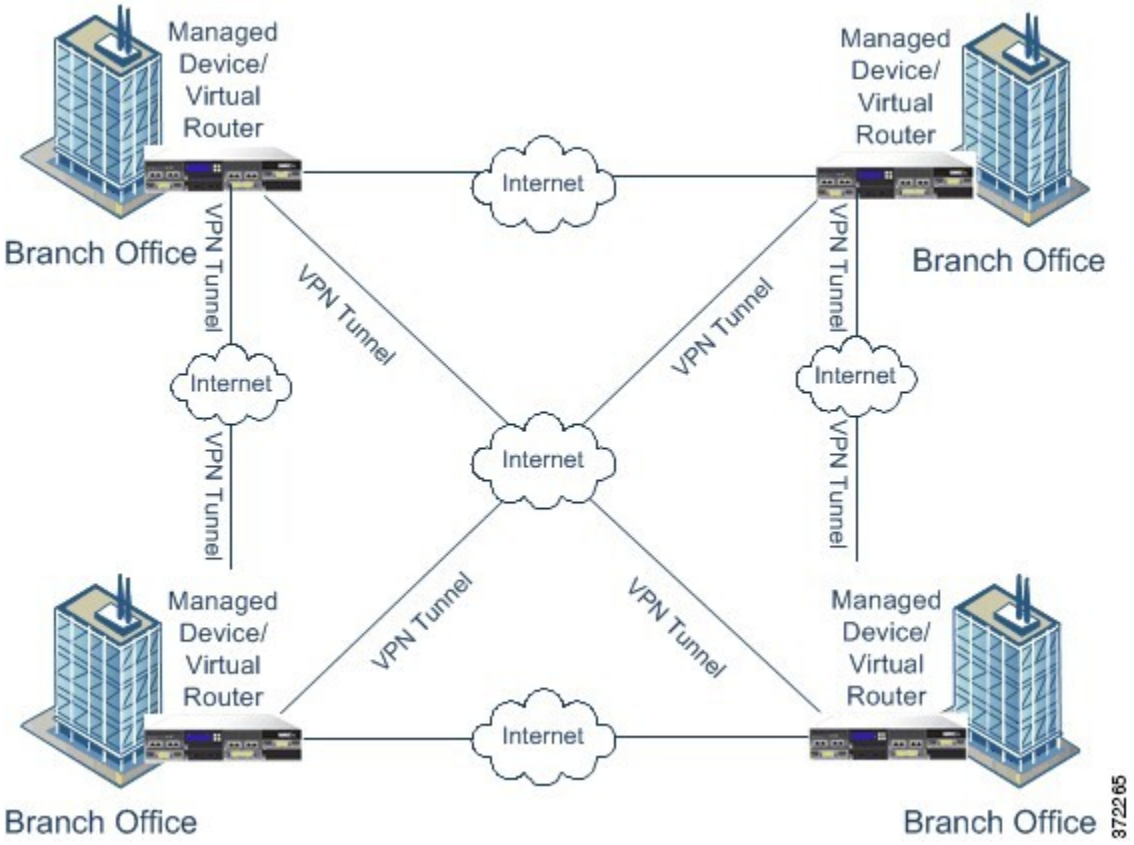
- connects a central endpoint (hub node) with multiple remote endpoints (spoke nodes)
- establishes each connection between the hub node and an individual spoke endpoint as a separate VPN tunnel, and
- enables hosts behind any of the spoke nodes to communicate with each other through the hub node.

The hub and spoke topology commonly represent a VPN that connects an organization's main and branch office locations using secure connections over the Internet or other third-party network. These deployments provide all employees with controlled access to the organization's network. Typically, the hub node is located at the main office. Spoke nodes are located at branch offices and start most of the traffic.

This diagram displays a typical hub and spoke VPN topology.

Figure 366: Hub and spoke VPN topology diagram

Full mesh VPN topology



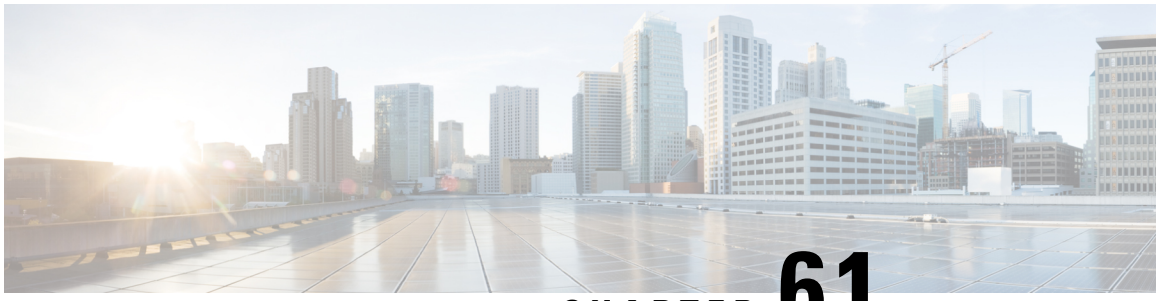
A full mesh VPN topology is a network configuration that

- allows all endpoints to communicate with every other endpoint by an individual VPN tunnel
- offers redundancy so that when one endpoint fails, the remaining endpoints can still communicate with each other, and
- commonly represents a VPN that connects a group of decentralized branch office locations.

The number of VPN-enabled managed devices you deploy in this configuration depends on the level of redundancy you require.

This diagram displays a typical full mesh VPN topology.

Figure 367: Full mesh VPN topology



Implicit topologies

Implicit topologies are complex VPN network configurations that

- combine elements from the three main VPN topologies (full mesh, hub-and-spoke, and point-to-point)
- create more advanced network architectures than individual topology types, and
- provide customized connectivity solutions for specific network requirements.

Types of implicit topologies

- **Partial mesh**: A network where some devices use a full mesh topology, while others form either hub-and-spoke or point-to-point connections with some fully meshed devices. The partial mesh does not offer the redundancy found in a full mesh but costs less to implement. Peripheral networks use partial mesh topologies to connect to a fully meshed backbone.
- **Tiered hub-and-spoke**: A network of hub-and-spoke topologies where devices act as a hub in some topologies and as a spoke in others. Spoke groups can send traffic to their closest hub.
- **Joined hub-and-spoke**: A combination of two topologies (hub-and-spoke, point-to-point, or full mesh) that connect to form a point-to-point tunnel. For example, a joined hub-and-spoke topology could comprise two hub-and-spoke topologies, with the hubs acting as peer devices in a point-to-point topology.

CHAPTER 61

Site-to-Site VPN

- Site-to-site VPN, on page 1725
- Types of site-to-site VPN topologies, on page 1728

- Deploy a SASE tunnel on Umbrella, on page 1769
- Secure traffic using Cisco Secure Access and Firewall Threat Defense devices, on page 1776
- Monitor site-to-site topologies, on page 1781

Site-to-site VPN

A site-to-site VPN is a secure, encrypted VPN tunnel between two networks in different geographic locations. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers.

Site-to-site VPN features

Secure Firewall Threat Defense site-to-site VPN supports these features:

- IPsec IKEv1 & IKEv2 protocols.
- Certificates and automatic or manual preshared keys for authentication.
- IPv4 & IPv6 addresses. All combinations of inside and outside are supported.
- Static and dynamic interfaces.
- HA environments for both Cloud-Delivered Firewall Management Center and Firewall Threat Defense.
- VPN alerts when the tunnel goes down and tunnel statistics.
- IKEv1 and IKEv2 back-up peer configuration for point-to-point extranet and hub-and-spoke VPNs.
- Extranet device as hub in 'Hub and Spokes' deployments.

- Dynamic IP address for a managed endpoint pairing with extranet device in 'Point to Point' deployments and for extranet device as an endpoint.

VPN topologies

VPN topology configuration requires specifying a unique name, a topology type, IKE version selection, and authentication method. The Cloud-Delivered Firewall Management Center configures site-to-site VPNs on Firewall Threat Defense devices only.

You can select from three types of topologies, containing one or more VPN tunnels:

- Point-to-point (PTP) deployments establish a VPN tunnel between two endpoints.
- Hub and Spoke deployments establish a group of VPN tunnels connecting a hub endpoint to a group of spoke nodes.
- Full Mesh deployments establish a group of VPN tunnels among a set of endpoints.

In the Cloud-Delivered Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

IPsec and IKE

In the Cloud-Delivered Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

Authentication

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

Extranet Devices

Each topology type can include extranet devices, devices that you don't manage in Cloud-Delivered Firewall Management Center. These include:

- Cisco devices that Cloud-Delivered Firewall Management Center supports, but for which your organization isn't responsible. Such as spokes in networks managed by other organizations within your company, or a connection to a service provider or partner's network.
- Non-Cisco devices. You can't use Cloud-Delivered Firewall Management Center to create and deploy configurations to non-Cisco devices.

Add non-Cisco devices, or Cisco devices not managed by the Cloud-Delivered Firewall Management Center, to a VPN topology as "Extranet" devices. Also specify the IP address of each remote device.

Guidelines for configuring site-to-site VPN in Secure Firewall Threat Defense devices

General guidelines

- Site-to-site VPN supports ECMP zone interfaces.
- Configure all nodes in a topology with either crypto ACL or a protected network. You cannot configure a topology with crypto ACL on one node and protected network on another.
- Configure a VPN connection across domains by using an extranet peer for the endpoint not in the current domain.
- You can backup Firewall Threat Defense VPNs using the Cloud-Delivered Firewall Management Center backup.
- Configure unique local IKE identity for all tunnels across all your VPN topologies.
- Ensure that IKE ports 500 and 4500 are not already in use and that no active PAT translations exist on those ports before configuring a site-to-site VPN. Configuring a site-to-site VPN on ports that are already in use will cause the service to fail to start.
- When configuring a site-to-site VPN between two devices managed by the same Cloud-Delivered Firewall Management Center, do not configure the devices as backup peers. Instead, configure one of the peer devices in the topology as an extranet device.
- If a spoke is part of multiple topologies with the same hub, for the Local Tunnel (IKE) Identity, we recommend that you use Key ID instead of an IP address.

  If the spoke uses an IP address as its local identity, the hub creates only one tunnel group. The spoke is then mapped to a specific virtual template interface, so the connection works with only one topology.

Limitations for configuring site-to-site VPN in Threat Defense devices

General limitations

- IKEv1 does not support CC/UCAPL-compliant devices. IKEv2 is recommended for these devices.
- VPN does not support network objects with a 'range' option.
- Firewall Threat Defense VPNs do not support PDF export and policy comparison.
- Tunnel status is not updated realtime, but at an interval of five minutes in the Cloud-Delivered Firewall Management Center.
- You cannot use the double quote character (") in pre-shared keys, replace it if already in use.

Crypto ACL limitations

- Cloud-Delivered Firewall Management Center supports only point-to-point VPN with crypto ACL and does not support tunnel health events.

- Cloud-Delivered Firewall Management Center does not verify the device interface address verification for transport mode when you select a crypto ACL.
- There is no support for automatic mirror ACE generation. Mirror ACE generation for the peer is a manual process on either side.

Topology management limitations

- You cannot move a VPN topology between domains.
- There is no per-tunnel or per-device edit option for Firewall Threat Defense VPNs, you can edit only the whole topology.

Types of site-to-site VPN topologies

This table provides an overview of the different site-to-site VPN topology options available for secure network connectivity configuration.

Site-to-Site VPN Topology	Description	More Information
SD-WAN Topology	Configure a secure branch network using the SD-WAN wizard. This wizard simplifies and automates VPN and routing configuration of your network using a hub and spoke topology, enabling SD-WAN capabilities.	SD-WAN wizard for secure branch network deployment, on page 1789
Route-Based VPN	Configure secure traffic dynamically between peers in a network based on routing over Virtual Tunnel Interfaces (VTIs).	Create a route-based site-to-site VPN, on page 1754
Policy-Based VPN	Configure secure traffic between peers in a network based on a static policy using protected networks.	Configure a policy-based site-to-site VPN, on page 1731
SASE Topology	Configure an IPsec IKEv2 tunnel from a Firewall Threat Defense device to Secure Access or an Umbrella Secure Internet Gateway (SIG). This tunnel forwards all internet-bound traffic to Secure Access or Umbrella SIG for inspection and filtering.	Secure traffic using Cisco Secure Access and Firewall Threat Defense devices, on page 1776 Configure a SASE tunnel for Umbrella, on page 1773

License requirements for site-to-site VPN

This topic lists the license requirements for setting up various types of site-to-site VPN connections.

License requirements for policy-based and route-based VPN

With the Essentials license, you can set up policy-based and route-based VPNs on your Firewall Threat Defense devices.

Depending on whether export-controlled functionality is enabled in your Smart License account, Cloud-Delivered Firewall Management Center determines whether to allow or block the usage of strong crypto on devices. To verify if export-controlled functionality is enabled for your Smart License account, choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Note If you use an evaluation license, or if you have not enabled the export-controlled functionality, you cannot use strong encryption for your VPN connections.

License requirements for deploying a SASE tunnel on Umbrella

To deploy SASE tunnels on Umbrella from Cloud-Delivered Firewall Management Center, you must enable your Smart License account with the export-controlled functionality. If this functionality is not enabled, you can only create a SASE topology, you cannot deploy tunnels on Umbrella.

Licenses for automatic tunnel between Secure Accessand Firewall Threat Defense devices

- Cloud-Delivered Firewall Management Center Essentials (formerly Base) license must allow export-controlled functionality. Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this in Cloud-Delivered Firewall Management Center.

Note Evaluation license does not support this feature.

- Cisco Secure Access Essentials subscription license must be available.

Prerequisites for site-to-site VPN

Supported interfaces

Topology Type	Interface Type

Policy-Based	• Physical interfaces
	  • Non-management
	  • Interface Mode must be either Routed or None
	• Subinterface interfaces
	• Redundant interfaces
	• Etherchannel interfaces
	• VLAN interfaces

Route-Based	Static Virtual Tunnel Interfaces

Note The maximum number of supported security associations (SA) depends on the maximum VPN peers for your platform. For more information about maximum VPN peers, refer the data sheet of the Secure Firewall Threat Defense device.

General prerequisites

- You must have administrator privileges.
- You must be in a leaf domain to perform the site-to-site VPN configurations.

Manage site-to-site VPNs

You can view, create, modify, and deploy site-to-site VPN configurations and manage their deployment status.

The **Site-to-Site VPN** page provides a snapshot of site-to-site VPN tunnels. You can view the status of the tunnels and filter the tunnels based on the device, topology, or tunnel type. The page lists 20 topologies per page and you can navigate between pages to view more topology details. You can click individual VPN topologies to expand and view details of the endpoints.

Before you begin

For certificate authentication of your site-to-site VPNs, you must prepare the devices by allocating trustpoints as described in Certificates, on page 3079.

Procedure

Select **Devices** > **VPN** > **Site to Site** to manage your Firewall Threat Defense site-to-site VPN configurations and deployments.

The page lists the site-to-site VPNs topologies and indicates the status of tunnels using color codes:

- Active (Green)–There is an active IPsec Tunnel.
- Unknown (Amber)–No tunnel establishment event has been received from the device yet.
- Down (Red)–There are no active IPsec tunnels.
- Deployment Pending–Topology has not been deployed on the device yet.

Choose one of these actions:

- **Refresh**—View the updated status of the VPNs.
- **Add**—Create new policy based or route-based Site to Site VPNs.
- **Edit**—Modify the settings of an existing VPN topology.

  Note
  You cannot edit the topology type after you initially save it. To change the topology type, delete the topology and create a new one.

  Two users shouldn't edit the same topology simultaneously; however, the web interface doesn't prevent simultaneous editing.

- **Delete**—To delete a VPN deployment, click **Delete** ( ).
- Deploy—Choose **Deploy** > **Deploy**; see Deploy configuration changes, on page 202.

  Note
  Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

Configure a policy-based site-to-site VPN

Configure a policy-based site-to-site VPN to establish secure communication channels between network endpoints using crypto maps and specified network topologies.

Procedure

Step 1 Choose **Devices > Site To Site**. Then click **+ Site To Site VPN**, or edit a listed VPN topology.

Step 2 Enter a unique **Topology Name** and click the **Policy Based (Crypto Map)** radio button, and choose the **Network Topology** for this VPN.

Step 3 Choose the IKE versions to use during IKE negotiations. Check the **IKEv1** or **IKEv2** check box.

Default is IKEv2. Select either or both options as appropriate; select IKEv1 if any device in the topology doesn't support IKEv2.

You can also configure a backup peer for point-to-point extranet VPNs. For more information, see Firewall Threat Defense VPN endpoint options, on page 1732.

Step 4 Required: Add Endpoints for this VPN deployment by clicking **Add** (+) for each node in the topology.

Configure each endpoint field as described in Firewall Threat Defense VPN endpoint options, on page 1732.

- For Point to point, configure **Node A** and **Node B**.
- For Hub and Spoke, configure a **Hub Node** and **Spoke Nodes**
- For Full Mesh, configure multiple **Nodes**

Step 5 (Optional) Specify non-default IKE options for this deployment as described in Firewall Threat Defense VPN IKE options, on page 1736

Step 6 (Optional) Specify non-default IPsec options for this deployment as described in Firewall Threat Defense VPN IPsec options, on page 1739

Step 7 (Optional) Specify non-default Advanced options for this deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1741 and click **Save**.

The policy-based site-to-site VPN is configured with the specified endpoints, IKE settings, and topology options.

What to do next

Deploy configuration changes.

Note Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

If you get an alert that your VPN tunnel is inactive even when the VPN session is up, follow the VPN troubleshooting instructions to verify and ensure that your VPN is active.

Firewall Threat Defense VPN endpoint options

Devices > Site To Site. Then click **+ Site To Site VPN**, or edit a listed VPN topology. Click the **Endpoints** tab.

Fields

Device

Choose an endpoint node for your deployment:

- A Firewall Threat Defense device managed by this Cloud-Delivered Firewall Management Center
- A Firewall Threat Defense high availability container managed by this Cloud-Delivered Firewall Management Center
- An **Extranet** device, any device (Cisco or third party) not managed by this Cloud-Delivered Firewall Management Center .

Device Name

For extranet devices only, provide a name for this device. We recommend naming it such that it is identifiable as an unmanaged device.

Interface

If you chose a managed device as your endpoint, choose an interface on that managed device.

For 'Point to Point' deployments, you can also configure an endpoint with dynamic interface. An endpoint with a dynamic interface can pair only with an extranet device and can't pair with an endpoint, which has a managed device.

You can configure device interfaces at **Devices** > **Device Management Add/Edit device** > **Interfaces**.

IP Address

- If you choose an extranet device, a device not managed by the Cloud-Delivered Firewall Management Center, specify an IP address for the endpoint.

  For an extranet device, select **Static** and specify an IP address or select **Dynamic** to allow dynamic extranet devices.

- If you chose a managed device as an endpoint, choose a single IPv4 address or multiple IPv6 addresses from the drop-down list. These IP addresses are already assigned to this interface on the managed device.

- All endpoints in a topology must have the same IP addressing scheme. IPv4 tunnels can carry IPv6 traffic and vice versa. The **Protected Networks** define which addressing scheme the tunneled traffic uses.

- If the managed device is a high-availability container, choose from a list of interfaces.

This IP is Private

Check the check box if the endpoint resides behind a firewall with network address translation (NAT).

Note Use this option only when the peer is managed by the same Cloud-Delivered Firewall Management Center and don't use this option if the peer is an extranet device.

Public IP address

If you checked the **This IP is Private** check box, specify a public IP address for the firewall. If the endpoint is a responder, specify this value.

Connection Type

Specify the allowed negotiation as bidirectional, answer-only, or originate-only. Supported combinations for the connection type are:

Table 100: Connection Type Supported Combinations

Remote Node	Central Node
Originate-Only	Answer-Only
Bi-Directional	Answer-Only

Remote Node	Central Node
Bi-Directional	Bi-Directional

Certificate Map

Choose a preconfigured certificate map object, or click **Add** (+) to add a certificate map object. The certificate map defines what information is necessary in the received client certificate to be valid for VPN connectivity. See Certificate map objects, on page 3058 for details.

Protected Networks

Caution Hub and Spoke topology—To avoid traffic drop for a dynamic crypto map, ensure that you don't select the protected network *any* for both the endpoints.

If the protected network is configured as *any*, on both the endpoints, the crypto ACL that works upon the tunnel is not generated.

Defines the networks that are protected by this VPN endpoint. Select the networks by selecting the list of Subnet/IP Address that define the networks that are protected by this endpoint. Click **Add** (+) to select from available Network Objects or add new Network Objects. See Create a network object, on page 2985 . Access control lists are generated from the choices made here.

- **Subnet/IP Address (Network)** —VPN endpoints can't have the same IP address and protected networks in a VPN endpoint pair cannot overlap. If protected networks for an endpoint contain IPv4 or IPv6 entries, the other endpoint's protected network must have at least one entry of the same type (IPv4 or IPv6). If it doesn't, the other endpoint's IP address must be of the same type and not overlap with the entries in the protected network. (Use /32 CIDR address blocks for IPv4 and /128 CIDR address blocks for IPv6.) If both of these checks fail, the endpoint pair is invalid.

Note By default, **Reverse Route Injection is enabled** check box is enabled in Cloud-Delivered Firewall Management Center.

Subnet/IP Address (Network) remains the default selection.

When you've selected Protected Networks as *Any* and observe default route traffic being dropped, disable the Reverse Route Injection. Choose **VPN** > **Site to Site** . Edit a VPN and then click **IPsec** > **Enable Reverse Route Injection** . Deploy the configuration changes to remove set reverse-route (Reverse Route Injection) from the crypto map configuration and remove the VPN-advertised reverse route that causes the reverse tunnel traffic to be dropped.

- **Access List (Extended)** —An extended access list provides the capability to control the type of traffic that will be accepted by this endpoint, like GRE or OSPF traffic. Traffic may be restricted either by address or port. Click **Add** (+) to add access control list objects.

Note Access Control List is supported only in the point to point topology.

Exempt VPN traffic from network address translation

Check this check box to exempt the VPN traffic from the Network Address Translation (NAT) rules.

If you do not exempt the VPN traffic from the NAT rules, the traffic gets dropped or is not routed through the VPN tunnel to the remote device. After you enable this option, you can view the NAT exemptions for the device in the NAT policy page (**Devices** > **NAT** , and click **NAT Exemptions**).

Inside interfaces directly connected to the internal network

Specify the security zone or interface group for the inside interface(s) where the protected networks reside. By default, the inside interface is any.

Click **+** to configure one or more interfaces from a security zone or an interface group that can map to one or more inside interfaces. Ensure that the interface type of the security zone or an interface group is Routed.

Advanced Settings

Enable Dynamic Reverse Route Injection —Reverse Route Injection (RRI) enables routes to be automatically inserted into the routing process, for the networks and hosts protected by a remote tunnel endpoint. Dynamic RRI routes are created only upon the successful establishment of IPsec security associations (SA's).

Note

- Dynamic RRI is supported only on IKEv2, and not supported on IKEv1 or IKEv1 + IKEv2.
- Dynamic RRI isn't supported on originate-only peer, Full Mesh topology, and Extranet peer.
- In Point-to-Point, only one peer can have dynamic RRI enabled.
- Between Hub and Spoke, only one of the endpoints can have dynamic RRI enabled.
- Dynamic RRI cannot be combined with a dynamic crypto map.

Send Local Identity to Peers —Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email address can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, see **Cisco Umbrella SIG User Guide**.

VPN Filter—Select an extended access list from the list or click **Add** to create a new extended access list object to filter the site-to-site VPN traffic.

The VPN filter provides more security and filters site-to-site VPN data using an extended access list. The extended access list object selected for the VPN filter lets you filter pre-encrypted traffic before entering the VPN tunnel and decrypted traffic that exits a VPN tunnel. The **sysopt permit-vpn** option, when enabled, would bypass the access control policy rules for the traffic coming from the VPN tunnel. When the **sysopt permit-vpn** option is enabled, the VPN filter helps in identifying and filtering the site-to-site VPN traffic.

Note The VPN filter is supported only on point to point, and hub and spoke topologies. It isn't supported on mesh topology.

For hub and spoke topology, you can choose to override the hub VPN filter on the spoke endpoints in case a different VPN filter needs to enabled on a specific tunnel.

Select the **Override VPN Filter on the Hub** option to override the hub VPN filter on the spokes. Select the **Remote VPN Filter** extended access list object or create an access list to override.

Note For an extranet device as a spoke, only the **Override VPN filter on the Hub** option is available.

For more information about sysopt permit-VPN, see Firewall Threat Defense advanced site-to-site VPN tunnel options , on page 1743 .

NAT Traversal (NAT-T)

NAT-T allow seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices. You cannot disable NAT Traversal (NAT-T) per VPN using the Cloud-Delivered Firewall Management Center UI. This option is available from Version 7.4.1. You can use FlexConfig to disable NAT-T. You can add the **crypto map** *map-name seq-num* **set nat-t-disable** command in the FlexConfig object. For example, **crypt map CSM_outside_map 1 set nat-t-disable**.

Note You must create the FlexConfig object with Deployment as 'EveryTime' and Type as 'Append'. This setting removes the command and adds it back for each deployment. If you configure Deployment as 'Once', then the command will be removed in the next deployment. You must be careful when you configure the FlexConfig object with this command. If Cloud-Delivered Firewall Management Center changes the sequence number, the deployment will fail.

Firewall Threat Defense VPN IKE options

For the versions of IKE you have chosen for this topology, specify the **IKEv1/IKEv2 Settings**.

Note Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Devices > Site To Site. Then click **+ Site To Site VPN**, or edit a listed VPN topology. Click the **IKE** tab.

Fields

Policy

Choose the required IKEv1 or IKEv2 policy objects from the predefined list or create new objects to use. You can choose multiple IKEv1 and IKEv2 policies. IKEv1 and IKEv2 support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. The lower the priority number, the higher the priority.
We recommend that you do NOT use values such as 10, 20 and so on because the default IKEv2 policy for remote access VPN can have these values as its priority value. Before deployment, verify that the priority values of the IKE policies (site-to-site and remote access VPN) do NOT conflict.

Note When upgrading from Version 7.4.x or earlier—where the IKEv2 policy priority field is optional—to Version 7.6.x or later—where it is mandatory—leaving the priority field blank may lead to IKEv2 policy configuration issues and affect network traffic. To avoid these problems, ensure that a priority value is set for all IKEv2 policies either before or after the upgrade.

For details, see IKE policies, on page 3071

Authentication Type

Site-to-site VPN supports two authentication methods, pre-shared key and certificate. For an explanation of the two methods, see Decide VPN authentication methods, on page 1717.

Note In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

- **Pre-shared Automatic Key**—The Cloud-Delivered Firewall Management Center automatically defines the pre-shared key for this VPN. Specify the **Pre-shared Key Length**, the number of characters in the key. The range is 1 to 27.

  The character " (double quote) isn't supported as part of pre-shared keys. If you've used " in a pre-shared key, ensure that you change the character after you upgrade to Secure Firewall Threat Defense 6.30 or higher.

- **Pre-shared Manual Key**—Manually assign the pre-shared key for this VPN. Specify the **Key** and then reenter the same to **Confirm Key**.

  When you choose this option for IKEv2, the **Enforce hex-based pre-shared key only** check box appears, check if desired. If enforced, you must enter a valid hex value for the key, an even number of 2-256 characters, using numerals 0-9, or A-F.

- **Certificate**—When you use certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

  In the **Certificate** field, select a preconfigured certificate enrollment object. This enrollment object generates a trustpoint with the same name on the managed device. The certificate enrollment object should be associated with and installed on the device, post which the enrollment process is complete, and then a trustpoint is created.

  A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.

  Before you select this option, note these requirements:

  - Ensure you've enrolled a certificate enrollment object on all the endpoints in the topology—A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections. For instructions on creating a certificate enrollment object, see Add certificate enrollment objects, on page 2999, and for instructions on enrolling the object on the endpoints see one of these as applicable:
    - Install a certificate using self-signed enrollment, on page 3084
    - Install a certificate using EST enrollment, on page 3084
    - Install a certificate using SCEP enrollment, on page 3085
    - Install a certificate using manual enrollment, on page 3086
    - Install a certificate using a PKCS12 file, on page 3087

Note For a site-to-site VPN topology, ensure that the same certificate enrollment object is enrolled in all the endpoints in the topology. For further details, see the table below.

- Refer to this table to understand the enrollment requirement for different scenarios. Some of the scenarios require you to override the certificate enrollment object for specific devices. See Manage object overrides, on page 2941 to understand how to override objects.

Certificate Enrollment Types	Device identity certificate for all endpoints is from the same CA		Device identity certificate for all endpoints is from different CAs
	Device-specific parameters are NOT specified in the certificate enrollment object	Device-specific parameters are specified in the certificate enrollment object	
Manual	No override required	Override required	Override required
EST	No override required	Override required	Override required

Certificate Enrollment Types	Device identity certificate for all endpoints is from the same CA		Device identity certificate for all endpoints is from different CAs
	Device-specific parameters are NOT specified in the certificate enrollment object	Device-specific parameters are specified in the certificate enrollment object	
SCEP	No override required	Override required	Override required
PKCS	Override required	Override required	Override required
Self-signed	NOT applicable	NOT applicable	NOT applicable

- Understand the VPN certificate limitations mentioned in Secure Firewall Threat Defense VPN certificate guidelines and limitations, on page 3079.

Note If you use a Windows Certificate Authority (CA), the default application policies extension is **IP security IKE intermediate**. If you use this default setting, you must select the **Ignore IPsec Key Usage** option in the Advanced Settings section on the **Key** tab in the **PKI Certificate Enrollment** dialog box for the object you select. Otherwise, the endpoints can't complete the site-to-site VPN connection.

Firewall Threat Defense VPN IPsec options

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure Endpoints for a Point to Point Topology and click the **IPsec** tab.

Note Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

Crypto-Map Type

A crypto map combines all the components required to set up IPsec security associations (SA). When two peers try to establish an SA, they must each have at least one compatible crypto map entry. IPsec security negotiation uses the proposals defined in the crypto map entry to protect the data flows specified by that crypto map's IPsec rules. Choose static or dynamic for this deployment's crypto-map:

- **Static**—Use a static crypto map in a point-to-point or full mesh VPN topology.
- **Dynamic**—Dynamic crypto-maps essentially create a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer's requirements.

  Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply these policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

IKEv2 Mode

For IPsec IKEv2 only, specify the encapsulation mode for applying ESP encryption and authentication to the tunnel. This determines what part of the original IP packet has ESP applied.

- **Tunnel mode**—(default) Encapsulation mode is set to tunnel mode. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), hiding the ultimate source and destination addresses and becoming the payload in a new IP packet.

  The major advantage of tunnel mode is that you don't need to modify the end systems to receive the benefits of IPsec. This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it onto the destination system. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

- **Transport preferred**—Encapsulation mode is set to transport mode with an option to fall back to tunnel mode if the peer doesn't support it. In transport mode only the IP payload is encrypted, and the original IP headers are left intact. Therefore, the admin must select a protected network that matches the VPN interface IP address.

  This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. With transport mode, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the layer 4 header is encrypted, which limits examination of the packet.

- **Transport required**— Encapsulation mode is set to transport mode only, falling back to tunnel mode is allowed. If the endpoints can't successfully negotiate transport mode, due to one endpoint not supporting it, the VPN connection is not made.

Proposals

Click **Edit** ( ) to specify the proposals for your chosen IKEv1 or IKEv2 method. Select from the available **IKEv1 IPsec Proposals** or **IKEv2 IPsec Proposals** objects, or create and then select a new one. See Configure an IKEv1 IPsec proposal object, on page 3070 and Configure an IKEv2 IPsec proposal object, on page 3071 for details.

Enable Security Association (SA) Strength Enforcement

Enabling this option ensures that the encryption algorithm used by the child IPsec SA isn't stronger (in terms of the number of bits in the key) than the parent IKE SA.

Enable Reverse Route Injection

Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Enable Perfect Forward Secrecy

Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list.

Modulus Group

The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing

time. The two peers must have a matching modulus group. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1716.

Lifetime Duration
The number of seconds a security association exists before expiring. The default is 28,800 seconds.

Lifetime Size
The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires. The default is 4,608,000 kilobytes. Infinite data isn't allowed.

ESPv3 Settings

Validate incoming ICMP error messages
Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

Enable 'Do Not Fragment' Policy
Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header.

Policy

- Copy DF bit—Maintains the DF bit.
- Clear DF bit—Ignores the DF bit.
- Set DF bit—Sets and uses the DF bit.

Enable Traffic Flow Confidentiality (TFC) Packets
Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

Note You can enable dummy Traffic Flow Confidentiality (TFC) packets at random lengths and intervals on an IPsec security association (SA). You must have an IKEv2 IPsec proposal set before enabling TFC.

Enabling TFC packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy doesn't work as expected when you enable the TFC packets.

Firewall Threat Defense advanced site-to-site VPN deployment options

The sections describe the advanced options you can specify in your site-to-site VPN deployment. These settings apply to the entire topology, all tunnels, and all managed devices.

Firewall Threat Defense VPN advanced IKE options

Advanced > IKE > ISAKAMP settings

IKE Keepalive

Enable or disables IKE Keepalives. You can set this option to EnableInfinite so that the device never starts the keepalive monitoring itself.

Threshold
Specifies the IKE keep alive confidence interval. This interval is the number of seconds allowing a peer to idle before beginning keepalive monitoring. The minimum and default interval is 10 seconds; the maximum interval is 3600 seconds.

Retry Interval
Specifies number of seconds to wait between IKE keep alive retries. The default is 2 seconds, the maximum is 10 seconds.

Identity Sent to Peers:
Choose the identity that the peers will use to identify themselves during IKE negotiations:

- **autoOrDN**(default)—Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
- **ipAddress**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

Note Enable or disable this option for all your VPN connections.

Peer Identity Validation
During IKE tunnel establishment, the peer provides its identity: either an IP address, a Fully Qualified Domain Name (FQDN), or a Distinguished Name (DN). It also presents a certificate, which contains none, some, or all of these fields.

If IKE peer identity validation is enabled, the Firewall Threat Defense compares the peer's identity to the respective field in the certificate to see if the information matches. If the information matches, then the peer's identity is validated and the Firewall Threat Defense establishes the tunnel. If the information does not match, the tunnel is not established.

- **Do not check**—Firewall Threat Defense does not validate the peer identity.
- **Required**—Firewall Threat Defense validates the peer identity.
- **If supported by cert**—Firewall Threat Defense validates the peer identity only if the peer provides a certificate.

Enable Aggressive Mode
Select this negotiation method for exchanging key information if the IP address isn't known and DNS resolution might not be available on the devices. Negotiation is based on hostname and domain name.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. This notification is disabled by default.

Advanced > IKE > IKEv2 security association (SA) settings

More session controls are available for IKE v2 that limit the number of open SAs. By default, there's no limit to the number of open SAs.

Cookie Challenge
Whether to send cookie challenges to peer devices in response to SA initiate packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:

- Custom
- Never (default)
- Always

Threshold to Challenge Incoming Cookies
The percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%.

Number of SAs Allowed in Negotiation
Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check.

Maximum number of SAs Allowed
Limits the number of allowed IKEv2 connections. Default is unlimited.

Enable Notification on Tunnel Disconnect
Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA doesn't match the traffic selectors for that SA. Sending this notification is disabled by default.

Firewall Threat Defense VPN advanced IPsec options

Advanced > IPsec > IPsec Settings

The advanced IPsec settings include these configuration options:

- **Enable Fragmentation Before Encryption**: This option lets traffic travel across NAT devices that don't support IP fragmentation. It doesn't impede the operation of NAT devices that do support IP fragmentation.
- **Path Maximum Transmission Unit Aging**: Check to enable Path Maximum Transmission Unit (PMTU) Aging, the interval to reset the PMTU of a Security Association (SA).
- **Value Reset Interval**: Enter the number of minutes at which the PMTU value of an SA is reset to its original value. The range is 10 to 30 minutes, default is unlimited.

Firewall Threat Defense advanced site-to-site VPN tunnel options

This topic lists the advanced site-to-site VPN tunnel options.

Navigation path

Devices > Site To Site, then click **+ Site To Site VPN**, or edit a listed VPN Topology. Click the **Advanced** tab, and select **Tunnel** in the navigation pane.

Tunnel options

Only available for Hub and Spoke, and Full Mesh topologies. This section doesn’t appear for Point to Point configurations.

- **Enable Spoke to Spoke Connectivity through Hub**—Disabled by default. Choosing this field enables the devices on each end of the spokes to extend their connection through the hub node to the other device.

NAT settings

- **Keepalive Messages Traversal**—Enabled by default. This parameter is a global setting that enables NAT-T for all endpoints within a topology. Check this check box to enable keepalive messages for NAT traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there's a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow.

  NAT traversal allows seamless communication between the peer Firewall Threat Defense devices when there are NAT devices between these devices. For hub and spoke topologies, this option is available only for the spoke.

  If you select this option, configure the **Interval**, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 5 to 3600 seconds. The default is 20 seconds.

TrustSec (SGT) settings

- **Enable SGT propagation over Virtual Tunnel Interfaces**—Cisco TrustSec uses Security Group Tags (SGTs) to control access and enforce traffic on a network. This option enables SGT propagation over SVTIs and DVTIs of the VPN topology. To enable SGT propagation on a specific SVTI or DVTI, configure it in individual devices. Note that the Firewall Threat Defense device must be Version 10.0.0 and later.

Access control for VPN traffic

Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)—By default, the Firewall Threat Defense applies access control policy inspection on the decrypted traffic. Enable this option to bypass the ACL inspection. The Firewall Threat Defense still applies the VPN Filter ACL and authorization ACL downloaded from the AAA server to the VPN traffic.

Enable or disable the option for all your VPN connections. If you disable this option, ensure that the traffic is allowed by the access control policy or prefilter policy.

Note For route-based VPNs, **sysopt permit-vpn** does not work. You must always create access control rules to allow route-based VPN traffic.

Certificate map settings

- **Use the certificate map configured in the Endpoints to determine the tunnel**—If this option is enabled (checked), the tunnel is determined by matching the contents of the received certificate to the certificate map objects configured in the endpoint nodes.
- **Use the certificate OU field to determine the tunnel**—Indicates that if a node isn't determined based on the configured mapping (the above option) if selected, then use the value of the organizational unit (OU) in the subject distinguished name (DN) of the received certificate to determine the tunnel.

- **Use the IKE identity to determine the tunnel**—Indicates that if a node isn't determined based on a rule matching or taken from the OU (the above options) if selected, then the certificate-based IKE sessions are mapped to a tunnel based on the content of the phase1 IKE ID.
- **Use the peer IP address to determine the tunnel**—Indicates that if a tunnel isn't determined based on a rule matching or taken from the OU or IKE ID methods (the above options) if selected, then use the established peer IP address.

Configure virtual tunnel interfaces

Cloud-Delivered Firewall Management Center supports a routable logical interface called the Virtual Tunnel Interface (VTI).

Virtual tunnel interfaces

A virtual tunnel interface is a routable logical interface that

- does not require static mapping of IPsec sessions to a physical interface
- associates the IPsec tunnel endpoint with a virtual interface, and
- supports static and dynamic routing policies.

Virtual tunnel interface capabilities

Cloud-Delivered Firewall Management Center supports VTIs as an alternative to policy-based VPN. VTIs support route-based VPN with IPsec profiles attached to the end of each tunnel. VTIs use static or dynamic routes. The device encrypts or decrypts the traffic from or to the tunnel interface and forwards it according to the routing table. Deployments become easier, and having VTI which supports route-based VPN with dynamic routing protocol also satisfies many requirements of a virtual private cloud. Cloud-Delivered Firewall Management Center enables you to easily migrate from crypto-map based VPN configuration to VTI-based VPN.

You can configure route-based VPN with static or dynamic VTI using the site-to-site VPN wizard. Traffic is encrypted using static route, BGP, OSPFv2/v3, or EIGRP.

You can create a routed security zone, add VTI interfaces to it, and define access control rules for the decrypted traffic control over the VTI tunnel.

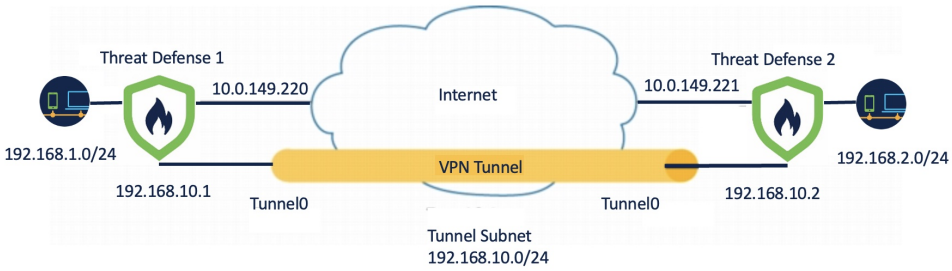
There are two types of VTI interfaces: static VTI and dynamic VTI.

You can create VTI-based VPNs between:

- Two Firewall Threat Defense devices.
- A Firewall Threat Defense and public cloud.
- One Firewall Threat Defense and another Firewall Threat Defense with service provider redundancy.
- A Firewall Threat Defense and any other device with VTI interfaces.
- A Firewall Threat Defense and another device with policy-based VPN configuration.

For more information, see Static VTI, on page 1746 and Dynamic VTI, on page 1747.

Static VTI



A static VTI is a virtual tunnel interface that

- uses tunnel interfaces to create a tunnel that is always-on between two sites
- requires defining a physical interface as a tunnel source, and
- supports a maximum of 1024 VTIs per device.

To create a static VTI interface in the Management Center, see Add a VTI interface, on page 1752.

The figure shows a VPN topology using static VTIs.

Figure 368: Static VTI VPN topology

On Threat Defense 1:

- Static VTI IP address is 192.168.10.1
- Tunnel source is 10.0.149.220
- Tunnel destination is 10.0.149.221

On Threat Defense 2:

- Static VTI IP address is 192.168.10.2
- Tunnel source is 10.0.149.221
- Tunnel destination is 10.0.149.220

Benefits of SVTI

Static VTI provides these benefits:

- Minimizes and simplifies configuration.

  You do not have to track all remote subnets for a crypto map access list, and configure complex access lists or crypto maps.

- Provides a routable interface.

  Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3, and static routes.

- Supports backup VPN tunnels
- Supports load balancing using ECMP.

- Supports virtual routers.
- Provides differential access control for VPN traffic.

  You can configure a VTI with a security zone and use it in an AC policy. This configuration:

  - Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
  - Provides differential access-control for VPN traffic across different VPN tunnels.

Dynamic VTI

A dynamic VTI is a VPN interface that

- uses a virtual template for dynamic instantiation and management of IPsec interfaces
- dynamically generates a unique virtual access interface for each VPN session
- supports multiple IPsec security associations and accepts multiple IPsec selectors proposed by the spoke.

Benefits of dynamic VTI

- Minimizes and simplifies configuration.

  You do not have to configure complex access lists or crypto maps.
- Simplifies management.
  - Easily manage peer configuration for large enterprise hub and spoke deployments.
  - Use only one dynamic VTI for multiple spokes, instead of configuring one static VTI per spoke.
- Provides a routable interface.

  Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3.
- Simplifies scaling

  Addition of new spokes does not require any additional VPN configuration on the hub. You may need to update NAT and routing configurations depending upon the setup.
- Support for backup VPN tunnels.
- Supports dynamic spokes.

  You do not have to update the hub configuration for spoke's DHCP IP address changes.
- Conserves IP addresses.
  - Uses the IP unnumbered interface functionality to borrow the IP address from another physical or loopback interface.
  - All virtual access interfaces associated to a dynamic VTI use the same IP address.
- Supports virtual routers.
- Provides differential access control for VPN traffic.

You can configure a VTI with a security zone and use it in an AC policy. This configuration:

- Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
- Provides differential access-control for VPN traffic across different VPN tunnels.

How Does the Cloud-Delivered Firewall Management Center Create a Dynamic VTI Tunnel for a VPN Session

When a spoke initiates a tunnel request with the hub:

1. The spoke initiates an IKE exchange with the hub for a VPN connection.
2. The hub authenticates the spoke.
3. The Cloud-Delivered Firewall Management Center assigns a dynamic virtual template on the hub for the spoke.

   The virtual template dynamically generates a virtual access interface on the hub. This interface is unique for the VPN session with the spoke.
4. The hub establishes a dynamic VTI tunnel with the spoke using the virtual access interface.
   a. The hub and spoke exchange traffic over the tunnel using:
      - Specific traffic proposed by the spokes over IKE exchanges.
      - BGP/OSPF/EIRGP protocols over the IPsec tunnel.
   b. After the VPN session ends, the tunnel disconnects and the hub deletes the corresponding virtual access interface.

To create a dynamic VTI interface in the Cloud-Delivered Firewall Management Center, see Add a VTI interface, on page 1752.

To configure a route-based site-to-site VPN using dynamic VTI, see Configure dynamic VTI for a route-based site-to-site VPN, on page 1765.

Virtual Routers and Dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router.

A virtual router associated with:

- A dynamic VTI is called an Indoor VRF (IVRF).
- A tunnel source interface is known as Front Door VRF (FVRF).

A dynamic VTI and its corresponding protected network interface must be part of the same virtual router. You must map the borrow IP interface and the dynamic VTI to the same virtual router. A tunnel source interface can be part of multiple virtual routers.

To configure virtual routers using dynamic VTI for a route-based site-to-site VPN, refer to Configure a virtual router with dynamic VTI, on page 1765.

For more information about a configuration example, refer to Secure traffic from networks with multiple virtual routers over a site-to-site VPN with dynamic VTI, on page 1409

Guidelines for virtual tunnel interfaces

General configuration guidelines

- VTIs are only configurable in IPsec mode.
- Dynamic VTI supports only Firewall Threat Defense devices from Version 7.3.
- You can use static, BGP, EIGRP IPv4, OSPFv2/v3 routes for traffic using the tunnel interface.
- In an HA configuration with dynamic routing, the standby device cannot access the known subnets through the VTI tunnels as these tunnels are created with the active IP address.
- For static and dynamic VTI, ensure that you don't use the borrow IP interface as the tunnel source IP address for any VTI interface.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the value of the TTL hop is more than one if you use BGP.
- If NAT has to be applied, the IKE and ESP packets are encapsulated in the UDP header.
- Ensure that you remove unused transform sets from route-based IKE VPN configurations. If you have unused transform sets, the VPN tunnels may not come up and encapsulation and decapsulation will not happen. Use **show run crypto** and **show VPN-sessiondb detail l2l** commands to view the transform sets.

IPv6 address guidelines

- VTI supports IPv6 addresses.
- You can use an IPv6 address for the tunnel source interface and use the same address as the tunnel endpoint.

- The Cloud-Delivered Firewall Management Center supports the following combinations of VTI IP (or internal networks IP version) over public IP versions: IPv6 over IPv6, IPv4 over IPv6, IPv4 over IPv4, and IPv6 over IPv4.
- VTI supports static and dynamic IPv6 addresses as the tunnel source and destination.
- The tunnel source interface can have IPv6 addresses and you can specify the tunnel endpoint address. If you don't specify the address, by default, the device uses the first IPv6 global address in the list as the tunnel endpoint.

IKE support and guidelines

- Static VTI supports IKE v1 and v2.
- Dynamic VTI supports only IKE version v2, and uses IPsec for sending and receiving data between the tunnel's source and destination.
- IKE and IPsec security associations are re-keyed continuously regardless of data traffic in the tunnel. This ensures that VTI tunnels are always up.
- Tunnel group name must match what the peer sends as its IKEv1 or IKEv2 identity.
- For IKEv1 in LAN-to-LAN tunnel groups, you can use names which aren't IP addresses, if the tunnel authentication method is digital certificates and/or the peer is configured to use aggressive mode.

MTU behavior

- MTU for VTIs is automatically set based on the underlying physical interface.
- For dynamic VTI, the virtual access interface inherits MTU from the configured tunnel source interface. If you don't specify the tunnel source interface, the virtual access interface inherits the MTU from the source interface from which the device accepts the VPN session request.

VTI scaling and guidelines

- Configure a maximum of 1024 static and dynamic VTIs in a device.

  While calculating the VTI count, consider nameif subinterfaces, portchannel configurations, and platform VLAN limitations.
- If you configure more than 400 VTIs in a device in a high-availability setup, configure 45 seconds as the unit holdtime.

Routing protocol support

VTI supports multiple routing protocols for different IP versions.

- VTI supports IPv6 BGP.
- VTI supports IPv4 EIGRP.
- VTI supports IPv4 and IPv6 OSPF.

ECMP configuration guidelines

- Configure spokes' static VTIs in an ECMP zone to load balance application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down.

- You can associate VTI interfaces with ECMP zones and configure ECMP static routes to achieve these benefits:
  - Load balancing (Active/Active VTIs)—Connection can flow over any of the parallel VTI tunnels.
  - Seamless connection migration—When a VTI tunnel becomes unreachable, the flows are seamlessly migrated to another VTI interface that is configured in the same zone.
  - Asymmetric routing—Forward traffic flow through one VTI interface and configure the reverse traffic flow through another VTI interface.

  For information on configuring ECMP, see ECMP routing methods, on page 1431.

Access control rule guidelines

- By default, all traffic sent through a VTI is encrypted.
- Access control rules can be applied on a VTI interface to control traffic through VTI.
- For route-based VPNs, Bypass Access Control policy for decrypted traffic (**sysopt connection permit-VPN**) does not work. You must always create access control rules to allow route-based VPN traffic.

Crypto map guidelines

- If you use dynamic crypto maps and dynamic VTIs in your site-to-site VPNs, only the dynamic VTI tunnels will come up. This behaviour occurs because both the crypto maps and dynamic VTIs try to use the default tunnel group. We recommend that you migrate your site-to-site VPNs to dynamic VTIs or use static crypto maps with their own tunnel-groups.
- VTI and crypto map configurations can coexist on the same physical interface if the peer address configured in the crypto map and the tunnel destination for the VTI are different.

Topology guidelines

- Dynamic VTI supports only the hub and spoke topology in the management center.
- We recommend that you configure only a single hub for a route-based hub and spoke topology. To configure a topology with multiple hubs for a set of spokes, with one hub as the backup hub, configure multiple topologies with a single hub and the same set of spokes.

Dynamic VTI and virtual router guidelines

- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

Firewall mode guideline

Configure VTI only in routed mode.

Limitations for Virtual Tunnel Interfaces

This topic lists the limitations for configuring Virtual Tunnel Interfaces in Management Center.

General limitations

- VTIs do not support clustering.
- VTI tunnel interfaces are not supported for SNMP or Syslog in Platform Settings.

Static VTI limitations

- Only 20 unique IPSec profiles are supported.
- In policy-based routing, you can configure VTI only as an egress interface.
- You cannot configure a VTI interface as a network interface for a remote access VPN policy.

Dynamic VTI limitations

- Dynamic VTI does not support ECMP , VRF in multi-instance, Clustering, IKEv1, or QoS.
- If a spoke has a dynamic IP address and a hub has a dynamic VTI behind a NAT, the tunnel status will be unknown.
- For a dynamic extranet, when multiple spokes establish a connection, the site-to-site monitoring dashboard does not show the individual tunnels.
- If you configure a hub with dynamic VTI behind NAT with dynamic spokes, the VPN monitoring data will not be accurate.
- You cannot configure a VTI interface as a network interface for a remote access VPN policy.

Backup VTI limitations

- Flow resiliency across tunnel failovers isn't supported. For example, the clear text TCP connection gets lost after a tunnel failover, and you need to reinitiate any FTP transfer that took place during the failover.
- Certificate authentication isn't supported in backup VTI.

Add a VTI interface

For configuring a route-based site-to-site VPN, you must create a VTI interface on the devices at both the nodes of the VTI tunnel.

When you specify the tunnel type as dynamic and configure the related parameters, the Cloud-Delivered Firewall Management Center generates a dynamic virtual template. The virtual template dynamically generates the virtual access interface that is unique for each VPN session.

Before you begin

Configure a loopback interface for redundancy of static and dynamic VTI VPN tunnels. For more information, see Configure a loopback interface, on page 1053.

For a Secure Firewall 1200/3100/4200device, IPsec flow offload is also used when the device's VTI loopback interface is enabled.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the **Edit** icon next to the device on which you want to create a VTI interface.

Step 3 Choose **Add Interfaces > Virtual Tunnel Interface**.

In the **Add Virtual Tunnel Interface** dialog box, configure these parameters:

a) Select the **Tunnel Type** as **Static** or **Dynamic**, and enter the name and description for the interface. By default, the interface is enabled.

b) (Optional) Choose a security zone from the **Security Zone** drop-down list to add the static VTI or dynamic VTI interface to that zone. In the **Priority** field, enter the priority to load balance the traffic across multiple VTIs.

If you want to perform traffic inspection based on a security zone, add the VTI interface to the security zone and configure an access control (AC) rule. To permit the VPN traffic over the tunnel, you need to add an AC rule with this security zone as the source zone.

The priority range is from 0 to 65535. The lowest number has the highest priority. This option is not applicable for dynamic VTI.

c)

d) Depending on the tunnel type, do one of the following:

- For a dynamic VTI, enter a unique ID in the range of 1 to 10413 in the **Template ID** field.
- For a static VTI, enter a unique tunnel ID in the range of 0 to 10413 in the **Tunnel ID** field.

e) (Optional for dynamic VTI) Choose the tunnel source interface from the **Tunnel Source** drop-down list.

The VPN tunnel terminates at this interface, a physical or loopback interface. Choose the IP address of the interface from the drop-down list. You can select the IP address irrespective of the IPsec tunnel mode. In case of multiple IPv6 addresses, select the address that you want to use as the tunnel endpoint.

f) Under **IPSec Tunnel Mode**, click the **IPv4** or **IPv6** radio button to specify the traffic type over the IPsec tunnel.

g) Under **IP Address**:

- **Configure IP**: Enter the IPv4 or IPv6 address for the static VTI interface. You cannot configure an IP address for a dynamic VTI interface. Use the **Borrow IP** field for the dynamic VTI interface.
- **Borrow IP (IP unnumbered)**: Choose a physical or loopback interface from the drop-down list, the VTI interface inherits this IP address.

  Ensure that you use an IP address different from the tunnel source IP address. You can use this option for a static or dynamic VTI interface.

  Click Add + to configure a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface.

Step 4 Click **OK**.

Step 5 Click **Save**.

Create a route-based site-to-site VPN

You can configure a route-based site-to-site VPN for the following two topologies:

- **Point to Point**: Configure VTIs on both nodes of the tunnel and use the wizard to configure the VPN.
- **Hub and Spoke**: Configure VTIs on the hub and the spokes. Configure the hub with a dynamic VTI and spokes with static VTIs.

You can configure an extranet device as the hub and managed devices as spokes. You can configure multiple hubs and spokes, and also configure backup hubs and spokes.

- For extranet hubs and spokes, you can configure multiple IPs as backup.
- For managed spokes, you can configure a backup static VTI interface along with the primary VTI interface.

For more information on VTI, see Virtual tunnel interfaces, on page 1745.

Note All references to VTI stands for static VTI and dynamic VTI, unless mentioned.

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**.

Step 2 Click **+ Site To Site VPN**.

Step 3 Enter a name for the VPN topology in the **Topology Name** field.

Step 4 Choose **Route Based (VTI)** and do one of the following:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, refer to Configure endpoints for a point-to-point VPN topology, on page 1755.
- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, refer to Configure endpoints for a hub and spoke topology, on page 1757.

Step 5 (Optional) Specify the **IKE**, **IPsec**, and **Advanced** options and click **Save**.

For more information, refer to these topics:

- Firewall Threat Defense VPN IKE options, on page 1736
- Firewall Threat Defense VPN IPsec options, on page 1739
- Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1741

What to do next

After you configure VTI interfaces and VTI tunnel on both the devices, you must configure:

- A routing policy to route the VTI traffic between the devices over the VTI tunnel. For more information, see Configure routing and AC policies for VTI, on page 1766.
- An access control rule to allow encrypted traffic. Choose **Policies** > **Access Control**.

Configure endpoints for a point-to-point VPN topology

Configure these parameters to configure endpoints for a route-based site-to-site VPN for the **Point to Point** topology nodes:

Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Create a route-based site-to-site VPN, on page 1754 and click the **Endpoints** tab.

Procedure

Step 1 Under **Node A**, in the **Device** drop-down menu, select the name of the registered device (Firewall Threat Defense) or extranet as the first endpoint of your VTI tunnel.

For an extranet peer, specify the following parameters:

a. Specify the name of the device.

b. Enter the primary IP address in the **Endpoint IP address** field. If you configure a backup VTI, add a comma and, specify the backup IP address.

c. Click **OK** .

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

Note
The AWS VPC has **AES-GCM-NULL-SHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NULL-SHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

Step 2 For a registered device, you can specify the VTI interface for Node A from the **Virtual Tunnel Interface** drop-down list.

The selected tunnel interface is the source interface for Node A and the tunnel destination for Node B.

If you want to create a new interface on Node A, click the Add + icon and configure the fields as described in Add a VTI interface, on page 1752 .

If you want to edit the configuration of an existing VTI, select the VTI in the **Virtual Tunnel Interface** drop-down field and click **Edit VTI**.

Step 3 If your Node A device is behind a NAT device, check the **Tunnel Source IP is Private** check box. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.

Step 4 **Send Local Identity to Peers** —Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address** —Use the IP address of the interface for the identity.
- **Auto** —Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID** —Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname** —Use the fully qualified hostname.
- **Key ID** —Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to a Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, see **Cisco Umbrella SIG User Guide** .

Step 5 (Optional) Click **Add Backup VTI** to specify an extra VTI as the backup interface and configure the parameters.

Note
Ensure that both peers of the topology do not have the same tunnel source for the backup VTI. A device cannot have two VTIs with the same tunnel source and tunnel destination; hence, configure a unique tunnel source and tunnel destination combination.

Though the virtual tunnel interface is specified under Backup VTI, the routing configuration determines which tunnel to be used as primary or backup.

Step 6 Expand **Advance Settings** to configure additional configurations for the device. For more information, see Configure advanced settings for a point-to-point topology in a route-based VPN, on page 1757 .

Step 7 Repeat the above procedure for Node B and click **OK** .

What to do next

- (Optional) Specify the **IKE** options for the deployment as described in Firewall Threat Defense VPN IKE options, on page 1736.
- (Optional) Specify the **IPsec** options for the deployment as described in Firewall Threat Defense VPN IPsec options, on page 1739.
- (Optional) Specify the **Advanced** options for the deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1741.
- Click **Save**.
- To route traffic to the VTI, choose **Devices** > **Device Management** , edit the threat defense device and click the **Routing** tab.

  You can configure the static routes, or use BGP, OSPF v2/v3, or EIGRP for routing the VPN traffic.
- To permit VPN traffic, choose **Policies** > **Access Control heading** > **Access Control**. Add a rule specifying the security zone of the VTI. For a backup VTI, ensure that you include the backup VTI in the same security zone as that of the primary VTI.

Configure advanced settings for a point-to-point topology in a route-based VPN

Configure advanced settings to enhance the functionality and security of a point-to-point topology in a route-based VPN beyond the basic configuration parameters.

Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in Configure endpoints for a point-to-point VPN topology, on page 1755 and expand **Advance Settings**.

Procedure

Step 1 Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.

Step 2 Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

Step 3 Choose one of the following from the **Connection Type** drop-down list:

Answer Only: The device can only respond when a peer device initiates a connection, it can't initiate any connection.

Bidirectional: The device can initiate or respond to a connection. This is the default option.

Configure endpoints for a hub and spoke topology

You can create a route-based site-to-site VPN using dynamic VTI only for hub and spoke topologies. The hub can use only a dynamic VTI and the spokes can use only static VTI interfaces. You can also configure an extranet device as a hub.

Configure these parameters to configure endpoints for a route-based site-to-site VPN for the **Hub and Spoke** topology nodes:

Before you begin

Configure the basic parameters for a hub and spoke topology in a route-based VPN as described in Create a route-based site-to-site VPN, on page 1754 and click the **Endpoints** tab.

Procedure

Step 1 Under **Hub Nodes**:

a) Click Add + to configure the hub node in the **Add Endpoint** dialog box.

b) Choose a hub from the **Device** drop-down list.

Note
A Firewall Threat Defense device running on software version 7.2 can't be configured as a hub. It must be an extranet or a device running on software version 7.3 or later.

For an extranet hub, configure these parameters:

1. Enter the name of the device.

2. Enter the primary IP address. If you configure a backup VTI, add a comma, and then specify the backup IP address.
3. Click **OK**.

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

Note
The AWS VPC has **AES-GCM-NULL-SHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NULL-SHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list.

Tunnel source configuration is mandatory for a dynamic VTI as the management center needs this information to determine the tunnel destination of the spoke.

Click Add + to add a new dynamic VTI. We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

If you want to edit an existing dynamic VTI, select the interface, and click **Edit VTI**.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
e) Click **Routing Policy** to configure the routing policy for the hub.
f) Click **AC Policy** to configure the access control policy.
g) Expand **Advance Settings** to configure additional configurations on the hub. For more information, see Configure advanced settings for hub and spokes in a route-based VPN, on page 1760 .
h) Click **OK**.

Step 2 Under **Spoke Nodes**:

a) Click Add + to configure the spoke in the **Add Endpoint** dialog box.
b) Choose a spoke from the **Device** drop-down list.

For an extranet spoke, configure these parameters:

1. Enter the name of the device.
2. In **Endpoint IP Address**, choose one of these options:
   - **Static**: Enter the IP address of the device, and the backup IP address, if required.
   - **Dynamic**: Choose this option to dynamically assign the IP addresses for the extranet spokes.
3. Click **OK**.

c) Choose a static VTI from the **Static Virtual Tunnel Interface** drop-down list.

Click Add + to add a new static VTI. Tunnel IP of the static VTI is auto populated, ensure that this IP address is unique for the spoke.

If you want to edit an existing static VTI, select the interface, and click **Edit VTI**.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box. The management center needs the tunnel source interface address to configure the tunnel destination

IP address on the spokes. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.

e) (Optional) **Send Local Identity to Peers** —Check this check box to send the local identity information to the peer device. Choose one of the following parameters from the **Local Identity Configuration** drop-down list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be less than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows Firewall Threat Defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure internet Gateway (SIG).

For more information about configuring a unique tunnel ID on Umbrella, see *Cisco Umbrella SIG User Guide* .

f) (Optional) Click **Add Backup VTI** to specify an extra VTI interface as the backup interface.

Note
Ensure that both peers of the topology do not have backup VTI configured on the same tunnel source. For instance, if Peer A is having two VTIs (primary and a backup) configured with a single tunnel source interface, say, 10.10.10.1/30, then Peer B also can't have its 2 VTIs with a single tunnel source IP, say 20.20.20.1/30.

Though the virtual tunnel interface is specified under backup VTI, the routing configuration determines which tunnel to be used as primary or backup.

g) Click **Routing Policy** to configure the routing policy for the spoke.
h) Click **AC Policy** to configure the access control policy.
i) Expand **Advance Settings** to configure additional configurations on the spoke and click **OK** . For more information, see Configure advanced settings for hub and spokes in a route-based VPN, on page 1760.

What to do next

1. (Optional) Specify the **IKE** options for the deployment as described in Firewall Threat Defense VPN IKE options, on page 1736.
2. (Optional) Specify the **IPsec** options for the deployment as described in Firewall Threat Defense VPN IPsec options, on page 1739.
3. (Optional) Specify the **Advanced** options for the deployment as described in Firewall Threat Defense advanced site-to-site VPN deployment options, on page 1741.
4. Click **Save**.

Configure advanced settings for hub and spokes in a route-based VPN

After configuring basic parameters for a hub and spoke in a route-based VPN, you can configure additional advanced settings to optimize the VPN topology's functionality and performance.

Before you begin

Configure the basic parameters for a hub and spoke in a route-based VPN as described in Configure endpoints for a hub and spoke topology, on page 1757 and expand **Advance Settings**.

Note Only the **Connection Type** field is applicable to the device with Version 7.2. The remaining fields don't apply to this version of the device.

Procedure

Step 1 Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.

For a hub, you must check this check box if you use BGP as the routing protocol. This configuration ensures that the loopback IP address is shared in the BGP routing table.

For a spoke, this option is enabled by default.

Step 2 Add the **Protected Networks** to define the networks protected by the VPN endpoint. Click Add + to select a protected network.

For a hub, configure the protected networks behind the hub. This information and the spoke's protected network generate the spoke access list.

You cannot create a static route for a virtual access interface on a hub with dynamic VTI. The hub creates and deletes these interfaces dynamically during tunnel establishment and termination.

For a spoke, configure the spoke's protected network.

To enable static routing for the spokes, after you configure the endpoints for your topology, click the **IPsec** tab and check the **Enable Reverse Route Injection** check box.

You do not need this option if you use BGP, OSPF, or EIGRP.

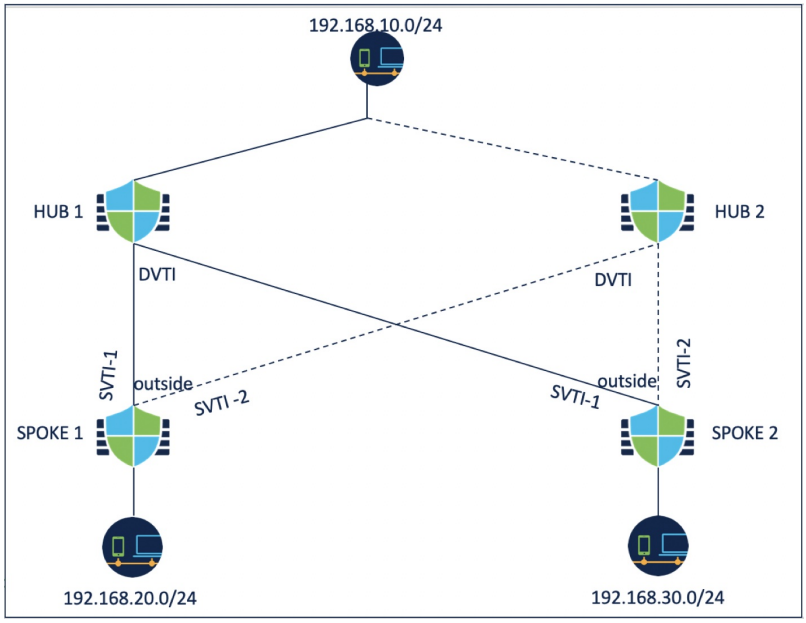
Step 3 Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

For a hub: During an IKE exchange, the hub advertises the dynamically created virtual access interfaces to the spokes, and the spokes advertise their VTI IP addresses to the hub.

For a spoke: By default, this option is enabled.

Step 4 In the **Connection Type** drop-down list, choose one of the following:

Answer Only: The device can only respond when a peer device initiates a connection, it can't initiate any connection.



Bidirectional: The device can initiate or respond to a connection. This is the default option.

Configure multiple hubs in a route-based VPN

You can configure a topology with multiple hubs for a set of spokes. With one hub as the backup hub, you can configure multiple topologies with a single hub and the same set of spokes.

In this example, there are two hubs connected to the same set of spokes. Hub 1 is the primary hub and Hub 2 is the secondary hub. To configure this network in the Cloud-Delivered Firewall Management Center, you must configure two route-based hub and spoke topologies:

- Topology 1: Hub 1 connected to spoke 1 and spoke 2.
- Topology 2: Hub 2 connected to spoke 1 and spoke 2.

To configure topology 1:

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site** and click **+ Site To Site VPN**.

Step 2 Enter a name for the VPN topology in the **Topology Name** field.

Step 3 Choose **Route Based (VTI)** and do one of these topologies:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, see Configure endpoints for a point-to-point VPN topology, on page 1755.
- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, see Configure endpoints for a hub and spoke topology, on page 1757.

Step 4 Configure the IKE version and click the **Endpoints** tab.

Step 5 Under **Hub Nodes**:

a) Click Add + to add the hub.
b) Choose Hub 1 from the **Device** drop-down list.
c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list or click Add + to add a new dynamic VTI.

We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
e) Click **Routing Policy** to configure the routing policy for the hub. You can configure dynamic routing using BGP.
f) Expand **Advance Settings**. You can configure these advanced settings for the hub to enable IKEv2 routing, which can be used if you do not use dynamic routing.

- (Optional) Check the **Send Virtual Tunnel Interface IP to the peers** check box.
- Check the **Allow incoming IKEv2 routes from the peers** check box for the hub to accept routes from the spokes and update the routing table.
- Choose **Connection Type** as Bidirectional from the drop-down list.

g) Click **OK**.

Step 6 Under **Spoke Nodes**:

a) Click Add + to add a spoke.
b) Choose Spoke 1 from the **Device** drop-down list.
c) Choose SVTI-1 as the static VTI for the spoke from the **Static Virtual Tunnel Interface** drop-down list or click Add + to add a new static VTI.

Choose the outside interface as the tunnel source of SVTI-1. Tunnel IP of SVTI-1 is autopopulated, ensure that this IP address is unique for spoke 1 across peers in both the topologies.

d) Expand **Advance Settings**. If you do not use dynamic routing, you can configure these settings to enable IKEv2 routing for the spoke.

- Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.
- Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the peers.
- Choose **Connection Type** as Bidirectional from the drop-down list.

e) Click **OK**.
f) Repeat steps 5a to 5e to add spoke 2. Configure SVTI-1 as the static VTI of spoke 2.

Step 7 Configure the IKE and IPSec parameters as required or use the default values.

What to do next

1. Configure topology 2 with hub 2, spoke 1, and spoke 2.

Configure SVTI-2 as the static VTI of spoke 1 and SVTI-2 as the static VTI of spoke 2 (refer the above illustration). Tunnel source for SVTI-2 should be the same outside interface.

2. For each spoke, configure the routing policy. For more information, see Configure routing for multiple hubs in a route-based VPN, on page 1763.
3. Verify the configuration and tunnel statuses. For more information, see Verify multiple hubs configuration in a route-based VPN, on page 1764.

Configure routing for multiple hubs in a route-based VPN

Configure dynamic routing using BGP on both hub and spoke devices, and implement Policy Based Routing on spokes to enable proper traffic routing in a route-based VPN topology with multiple hubs.

Before you begin

Configure topology 1 and 2 as explained in Configure multiple hubs in a route-based VPN, on page 1761.

Procedure

Step 1 Configure dynamic routing for the hub using BGP.

a) Choose **Devices** > **Device Management**, and click **Edit** ( ) then click the **Routing** tab.
b) In the left pane, choose **General Settings > BGP**.
c) Check the **Enable BGP** check box and enter the **AS number**.

You can configure the other fields AS per your requirement.

d) Click **Save**.
e) On the left pane, choose **BGP > IPv4**.
f) Check the **Enable IPv4** check box.
g) Click the **Neighbor** tab, click **Add** and configure these parameters.

1. **IP Address**: Enter the tunnel interface IP address of Spoke 1.
2. **Remote AS**: AS number of Spoke 1.
3. Check the **Enabled Address** check box.
4. Click **OK**.

Repeat the above steps to add Spoke 2 as a neighbor.

h) Click **Save**.
i) Click the **Networks** tab and click **Add** to advertise the network behind the hub to the peers.

Step 2 Configure dynamic routing for the spokes using BGP.

The BGP configuration for the spokes is similar to that of the hub except for these differences:

- Configure Hub 1 and Hub 2 AS the neighbors for both the spokes and use the tunnel interface IP address of the hubs.
- When you configure networks, use the network behind each spoke.

Step 3 Configure Policy Based Routing on the spokes.

a) In the left pane, choose **Policy Based Routing** and click **Add**.
b) Choose the **Ingress Interface** from the drop-down list.
c) Click **Add** to configure a Match ACL.

For example, for spoke 1, source network is 192.168.20.0/24 and destination network is 192.168.10.0/24.

d) Choose Egress Interfaces from the **Send to** drop-down list.
e) Choose Order from the **Interface Ordering** drop-down list.
f) Select the SVTI-1 and SVTI-2 interfaces AS the egress interfaces.
g) Click **Save**.

If you want to use the hubs as a load-balancing pair, you must configure ECMP.

Step 4 Deploy the configurations on the hub and spokes.

What to do next

Verify the configurations and tunnel statuses. For more information, see Verify multiple hubs configuration in a route-based VPN, on page 1764.

Verify multiple hubs configuration in a route-based VPN

To verify the multiple hub configurations and the tunnel statuses.

- After the deployment, check the tunnel status.
- Use these show commands for each endpoint to verify the configurations:
  - **show run route-map**
  - **show run access-list**
  - **show route-map**
  - **show route**

Route traffic through a backup VTI tunnel

A backup VTI tunnel ensures traffic continuity by providing an alternative path when the primary VTI tunnel fails to route traffic in route-based VPN configurations.

You can deploy the backup VTI tunnel in these scenarios:

- Both peers having service provider redundancy backup.

  In this case, there are two physical interfaces, acting as the tunnel sources for the two VTIs of the peers.

- Only one of the peers has service provider redundancy backup.

  In this case, there's an interface backup on only one side of the peer and on the other end, there is only one tunnel source interface.

Before you begin

Ensure that you review the guidelines and limitations. For more information, refer to Guidelines for virtual tunnel interfaces, on page 1749.

Procedure

Step 1 Create the VTI interface.

For more information, refer to Add a VTI interface, on page 1752

Step 2 In the **Add Endpoint** dialog box of the **Create New VPN Topology** wizard, click **Add Backup VTI** to configure the respective backup interface for each peer.

For more information, refer to

- Configure endpoints for a point-to-point VPN topology, on page 1755
- Configure endpoints for a hub and spoke topology, on page 1757

Step 3 Choose **Devices > Device Management**, and edit the threat defense device and click **Routing** to configure the routing policy.

Step 4 Choose **Policies > Access Control** to configure the access control policy.

Configure dynamic VTI for a route-based site-to-site VPN

To configure dynamic VTI for a route-based site-to-site VPN in the Management Center:

Step	Do This	More Information
1	Create a dynamic VTI interface on the hub.	Add a VTI interface, on page 1752
2	Create static VTI interfaces on the spokes.	Add a VTI interface, on page 1752
3	Create a route-based site-to-site VPN.	Create a route-based site-to-site VPN, on page 1754
4	Configure the routing policy and the access control policy.	Configure endpoints for a hub and spoke topology, on page 1757

Configure a virtual router with dynamic VTI

To configure a virtual router with dynamic VTI for a route-based site-to-site VPN in the Management Center:

Step	Do This	More Information
1	Create a route-based site-to-site VPN with a dynamic VTI interface on the hub and static VTI(s) on the spoke(s).	Create a route-based site-to-site VPN, on page 1754
2	Create a virtual router.	Create a virtual router, on page 1386

Step	Do This	More Information
3	Assign the interfaces to the virtual router.	Configure a virtual router, on page 1387
4	Configure routing policies for the hub and spoke.	Configure endpoints for a hub and spoke topology, on page 1757
5	Configure access control policies for the hub and spoke.	Configure endpoints for a hub and spoke topology, on page 1757

Configure routing and AC policies for VTI

After you configure VTI interfaces and the VTI tunnel on both the devices, you must configure these parameters:

- A routing policy to route VTI traffic between the devices over the VTI tunnel.
- An access control rule to allow encrypted traffic.

Procedure

Step 1 Configure routing for VTI interfaces.

For the VTI interfaces, you can configure static route or routing protocols such AS BGP, EIGRP, OSPF/OSPFv3.

a. Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

b. Click **Routing**.

c. Configure static route, or BGP, EIGRP, OSPF/OSPFv3.

Routing	Parameters	More Information
Static Route	• **Interface**—Select the VTI interface. For a backup tunnel, select the backup VTI interface. • **Selected Network**—Remote peer's protected network. • **Gateway**—Remote peer's tunnel interface IP address. For a backup tunnel, select the remote peer's backup tunnel interface IP address. • **Metric**—For a backup tunnel, configure a different metric to handle the failover of the traffic flow over the backup tunnel. **Note** DVTI does not support static routes.	Add a static route, on page 1361

Routing	Parameters	More Information

BGP	• Under **General Settings** > **BGP**, enable BGP, provide the AS number of the local device, and add Router ID (if you choose Manual).
	• Under **BGP**, enable IPv4/IPv6 and click the **Neighbor** tab to configure the neighbors.
	  • **IP Address**—Remote peer's VTI interface IP address. For a backup tunnel, add a neighbor with the remote peer's backup VTI interface IP address.
	  • **Remote AS**—Remote peer's AS number.
	• Click the **Redistribution** tab, select the **Source Protocol** AS Connected to enable connected route redistribution.
		Configure BGP, on page 1496

Routing	Parameters	More Information
EIGRP	• Enable EIGRP, provide the AS number of the local device, and select the networks or hosts that participate in the EIGRP routing process. • Click the **Neighbors** tab and define the static neighbors for the EIGRP process. • To advertise summary addresses from a VTI interface, click the **Summary Address** tab, choose the VTI interface from the **Interface** drop-down. From the **Network** drop-down, choose the network to be summarized. • Click the **Interfaces** tab to configure the interface-specific EIGRP routing properties for the VTI interface. To enable EIGRP split-horizon on the interface, check the **Split Horizon** check box. You can also configure the **Hold Time** that is advertised by the device in the EIGRP hello packets.	
OSPF	• Check the **Process 1** check box, and choose the OSPF role. • Click the **Interface** tab and choose a VTI interface.	OSPFv2 configuration, on page 1454
OSPFv3	• Check the **Process 1** and **Enable Process 1** check boxes, and choose the OSPFv3 role. • Click the **Interface** tab and choose a VTI interface.	OSPFv3 configuration, on page 1467

Step 2 Add an access control rule to the access control policy on the device to allow encrypted traffic between the VTI tunnels with these settings:

a. Create the rule with the Allow action.

b. Select the VTI security zone of the local device AS the source zone and the VTI security zone of the remote peer AS the destination zone.

c. Select the VTI security zone of the remote peer AS the source zone and the VTI security zone of the local device AS the destination zone.

For more information about configuring an access control rule, see Create and edit access control rules, on page 2066.

View virtual tunnel interface details

You can view details of dynamic and static VTIs of route-based VPNs on the device. For every VPN topology, you can also view details of all the dynamically generated virtual access interfaces associated with each dynamic VTI.

Before you begin

- Supported device for static VTIs: Firewall Threat Defense Version 7.0 and later
- Supported device for dynamic VTIs: Firewall Threat Defense Version 7.3 and later

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center, choose **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click the **Virtual Tunnels** tab.

For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP. You can also view if path monitoring is enabled for each interface.

Deploy a SASE tunnel on Umbrella

Guidelines for configuring SASE tunnels on Umbrella

SASE topology supports:

- Only PSK-based authentication
- IKEv2
- High availability

General configuration guidelines

- Cloud-Delivered Firewall Management Center does not discover tunnels created directly on Umbrella or by other applications.

- You can add only devices managed by the Cloud-Delivered Firewall Management Center as endpoints for the SASE topology. You cannot add extranet devices.

  For high availability pairs, the HA pair names appear in the endpoint list.

- If you check the **Deploy configuration on threat defense nodes** check box in the wizard, the Umbrella SASE topology configuration is deployed on the Firewall Threat Defense only after the tunnels are deployed on Umbrella.

  The Cloud-Delivered Firewall Management Center requires the local tunnel ID to deploy the Umbrella configuration in Firewall Threat Defense. Umbrella generates the complete tunnel ID (*<prefix>@<umbrella generated ID>*-umbrella.com) only after the Cloud-Delivered Firewall Management Center deploys the tunnel on Umbrella.

Version migration guideline (Pre-version 7.3)

You must create new SASE topologies in version 7.3 and delete the existing SASE topologies because Cloud-Delivered Firewall Management Center does not recognize topologies using Umbrella data center as an extranet hub created before version 7.3 as SASE topologies.

Deployment status and monitoring guideline

You can track the tunnel deployment status in three places:

- Cisco Umbrella Configuration dialog box of the wizard
- Notifications page under the Deployments and Tasks tabs
- Site to Site VPN Monitoring dashboard

Tunnel deletion guidelines

- You cannot edit or delete a SASE topology while deployment to Umbrella is in progress.
- When you delete a tunnel from Cloud-Delivered Firewall Management Center and if it is unable to delete the tunnel from Umbrella, you must manually delete it by logging into Umbrella.

Limitations for configuring SASE tunnels on Umbrella

SASE topology does not support these features:

- Clustering
- Certificate-based authentication
- IKEv1

Deploy a SASE tunnel on Umbrella

This section provides instructions to deploy a SASE tunnel on Umbrella from a Firewall Threat Defense device using the Cloud-Delivered Firewall Management Center.

Step	Do This	More Info
1	Review the guidelines and limitations.	Guidelines for configuring SASE tunnels on Umbrella, on page 1769

Step	Do This	More Info
2	Ensure that you meet the prerequisites.	Prerequisites for configuring Umbrella SASE tunnels, on page 1771
3	Configure Cisco Umbrella connection settings.	• Configure Cisco Umbrella Connection Settings • Map Management Center Umbrella parameters and Cisco Umbrella API keys, on page 1771
4	Configure a SASE tunnel on Umbrella.	Configure a SASE tunnel for Umbrella, on page 1773
5	View the status of the SASE tunnel.	View SASE tunnel status, on page 1775

Prerequisites for configuring Umbrella SASE tunnels

License prerequisites

- You must have a Cisco Umbrella Secure Internet Gateway (SIG) Essentials subscription.
- You must enable your Smart License account with the export-controlled features to deploy tunnels on Umbrella from the Cloud-Delivered Firewall Management Center. If this license is not enabled, you can only create a SASE topology. You cannot deploy tunnels on Umbrella.

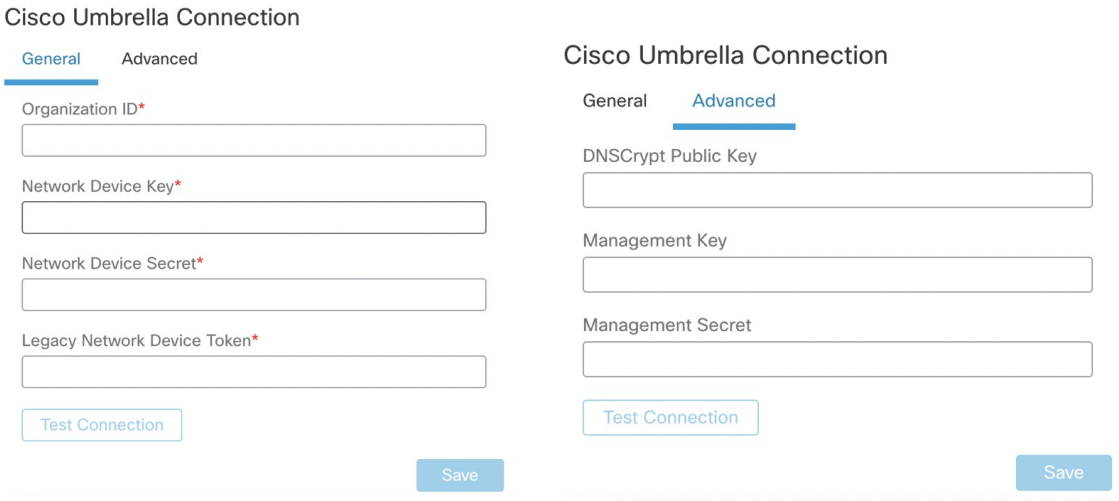
General prerequisites

- You must establish an account with Cisco Umbrella at https://umbrella.cisco.com, log into Umbrella at http://login.umbrella.com, and obtain the required information to establish connection to Cisco Umbrella.
- You must register Cisco Umbrella with the Cloud-Delivered Firewall Management Center and configure the management key and the management secret in the Cisco Umbrella Connection Settings. The management center requires the management key and management secret to fetch the datacenter details from the Cisco Umbrella cloud. You must also configure the Organization ID, Network Device Key, Network Device Secret, and the Legacy Network Device Token in the Cisco Umbrella Connection Settings.

  For more information, refer to:

  - Configure Cisco Umbrella Connection Settings
  - Map Management Center Umbrella parameters and Cisco Umbrella API keys, on page 1771

- Ensure that Umbrella data center is reachable from the Firewall Threat Defense.
- You can deploy a tunnel only between Cisco Umbrella and a Firewall Threat Defense version 7.1.0 and later.



Map Management Center Umbrella parameters and Cisco Umbrella API keys

To register Cisco Umbrella with the Cloud-Delivered Firewall Management Center and configure the Umbrella parameters in the Cloud-Delivered Firewall Management Center, you must complete these steps:

1. Log in to Cisco Umbrella.
2. Choose **Admin > API Keys > Legacy Keys**.

3. Generate and copy the required API keys.
4. Use the API keys to configure the Cisco Umbrella connection parameters in the Cloud-Delivered Firewall Management Center.

This figures show the parameters that you must configure in the Cisco Umbrella Connection in the Cloud-Delivered Firewall Management Center. DNScrypt Public Key is an optional parameter.

This figure shows the Cisco Umbrella API keys that you must use to register the Cisco Umbrella with the Cloud-Delivered Firewall Management Center.

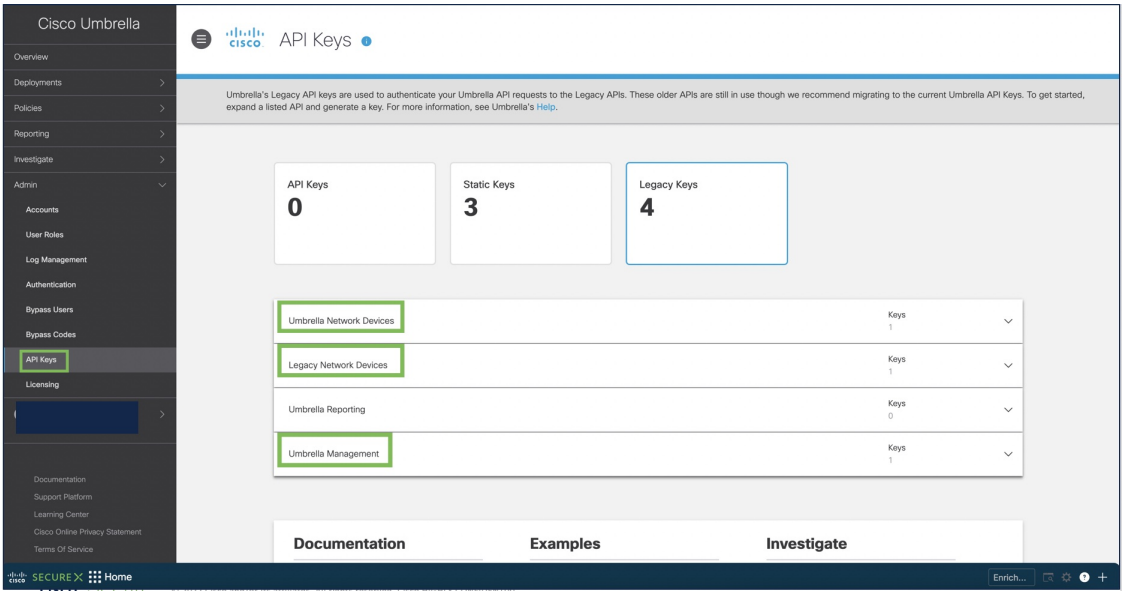


Table 101: Map Cloud-Delivered Firewall Management Center Umbrella Parameters and Cisco Umbrella API Keys

Management Center Parameter	Cisco Umbrella API Keys
Network Device Key Network Device Secret	Umbrella Network Devices
Legacy Network Device Token	Legacy Network Devices
Management Key Management Secret	Umbrella Management

Configure a SASE tunnel for Umbrella

Configure a SASE tunnel to establish secure connectivity between threat defense devices and Cisco Umbrella data centers for cloud-delivered security services.

SASE (Secure Access Service Edge) tunnels provide secure connections to Umbrella data centers, enabling cloud-based security functions. These tunnels use IKEv2 with pre-shared keys for authentication and static VTI interfaces for routing traffic.

Before you begin

Ensure that you review the prerequisites and guidelines in Prerequisites for configuring Umbrella SASE tunnels, on page 1771 and Guidelines for configuring SASE tunnels on Umbrella, on page 1769.

Follow these steps to configure a SASE tunnel for Umbrella:

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**, click **+SASE Topology** and enter a unique **Topology Name**.

Step 2 **Pre-shared Key**: This key is auto-generated according to the Umbrella PSK requirements. For a single topology, the pre-shared key is common for all threat defense spokes and Umbrella.

The device and Umbrella share this secret key, and IKEv2 uses it for authentication. If you want to configure this key, it must be between 16 and 64 characters in length, include at least one uppercase letter, one lowercase letter, one numeral, and have no special characters. Each topology must have a unique pre-shared key. If a topology has multiple tunnels, all the tunnels have the same pre-shared key.

Step 3 Choose a data center from the **Umbrella Data center** drop-down list. (Configure routing on the Firewall Threat Defense to ensure reachability of the umbrella DC from the Firewall Threat Defense.)

Step 4 Click **Add** to add a Firewall Threat Defense node.

a) Choose a Firewall Threat Defense from the **Device** drop-down list.

Only devices managed by the Cloud-Delivered Firewall Management Center appear in the list. For high availability pairs, the HA pair names appear in the endpoint list.

b) Choose a static VTI interface from the **VPN Interface** drop-down list.

To create a new static VTI interface, click Add +. The **Add Virtual Tunnel Interface** dialog box appears with the following pre-populated default configurations.

- Tunnel Type is static.

- Name is <*tunnel_source interface logical name*>+ static_vti +<*tunnel ID*>. For example, outside_static_vti_2.
- Tunnel ID is auto-populated with a unique ID.
- Tunnel Source Interface is auto-populated with an interface with an 'outside' prefix.
- IPsec tunnel mode is IPv4.
- IP address is from the 169.254.x.x/30 private IP address range.

c) Enter a prefix for the local tunnel ID in the **Local Tunnel ID** field.

The prefix can have a minimum of eight characters and a maximum of 100 characters. Umbrella generates the complete tunnel ID (<*prefix*>@<*umbrella generated ID*>-umbrella.com) after the management center deploys the tunnel on Umbrella. The management center then retrieves and updates the complete tunnel ID and deploys it on the threat defense device. Each tunnel has a unique local tunnel ID.

d) Click **Save** to add the endpoint device to the topology.

You can add multiple endpoints in a SASE topology.

Step 5 Click **Next** to view the summary of the Umbrella SASE tunnel configuration.

- **Endpoints** pane: Displays the summary of the configured endpoints.
- **Encryption Settings** pane: Displays the default IKEv2 policies and IKEv2 IPsec transform sets for the topology.

Step 6 Check the **Deploy configuration on threat defense nodes** check box to trigger deployment of the network tunnels to the threat defense. This deployment occurs after the tunnels are deployed on Umbrella. Local tunnel ID is required for the threat defense deployment.

Step 7 Click **Save**.

This action:

a. Saves the topology in the management center.

b. Triggers deployment of the network tunnels to the Umbrella.

c. Triggers deployment of the network tunnels to the threat defense devices, if the option is enabled. This action commits and deploys all the updated configurations and policies, including non-VPN policies, since the last deployment on the device.

d. Opens the **Cisco Umbrella Configuration** window and displays the status of the tunnel deployment on Umbrella. For more details, see View SASE tunnel status, on page 1775.

What to do next

For the interesting traffic intended to flow through the SASE tunnel, configure a PBR policy with a specific match criteria to send the traffic through the VTI interface.

Ensure that you configure a PBR policy for each endpoint of the SASE topology.

View SASE tunnel status

After configuring Umbrella SASE topology, you need to monitor the tunnel deployment status and verify that the configuration has been successfully pushed to Umbrella.

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site**.

Step 2 Click **+SASE Topology**.

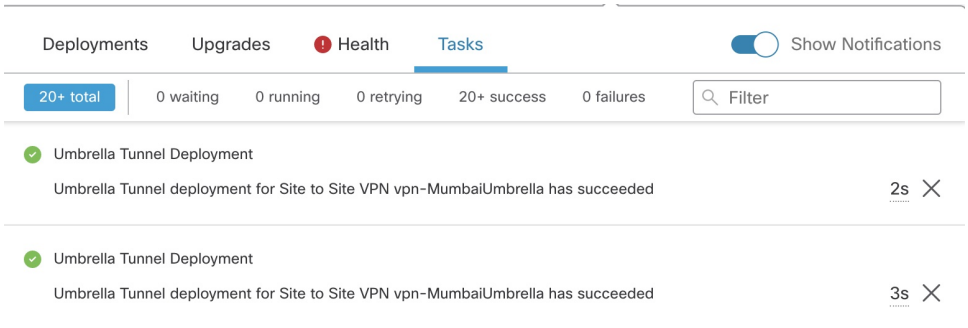
Step 3 Enter a unique **Topology Name**, **Pre-shared Key**, choose a data center, add a device, and click **Next**.

Step 4 View the summary of the Umbrella SASE Tunnel configuration and click **Save**.

The **Cisco Umbrella Configuration** window appears.

You can view the topology details such as name, data center, data center IP address, start, and end time of the tunnel deployment.

You can view the deployment status of the tunnels on Umbrella. The different tunnel deployment statuses are:



- Pending: The management center hasn't pushed the configuration to Umbrella.
- Success: The management center successfully configured a tunnel on Umbrella.
- In Progress: The management center is deploying the tunnel on Umbrella.
- Failure: The management center couldn't configure a tunnel on Umbrella.

If the status appears as pending, or failure, use the transcript to troubleshoot the tunnel creation. Click the **Transcript** button to view the transcript details such as the APIs, request payload, and the response received from Umbrella.

Step 5 Click **Umbrella Dashboard** to view the network tunnels in Cisco Umbrella.

Step 6 View the Umbrella tunnel deployment status in:

- The **Notifications** page under the **Deployments** and **Tasks** tabs.

Secure traffic using Cisco Secure Access and Firewall Threat Defense devices

Cisco Secure Access is a cloud-based security service edge (SSE) solution that protects against internet threats and enables secure access to the internet, SaaS applications, and private resources from any location.

Benefits of using Secure Access

Secure Firewall seamlessly integrates with Secure Access for various use cases primarily for:

- **Enhanced visibility and control for remote users**: Secure Access extends security policies beyond the physical branch perimeter to protect users regardless of location, providing the same level of threat protection and access controls equivalent to on-premises, creating consistent security enforcement.
- **Simplified security architecture**: Secure Access integrates with a Firewall Threat Defense device to consolidate multiple security functions such as Secure Web Gateway, Cloud Access Security Broker (CASB), Data Loss Prevention (DLP), and cloud firewall. This consolidation provides a single-pane-of-glass experience for policy management across branch deployments and cloud-delivered security services.

Benefits of using SASE wizard to automate Secure Access tunnels from Firewall Threat Defense

You can automatically create secure tunnels between Firewall Threat Defense and Secure Access using Cloud-Delivered Firewall Management Center. The SASE wizard provides a guided workflow to handle the tunnel setup across both the products, helping you avoid switching between consoles or manually matching tunnel parameters.

- Reduce tunnel setup time and configuration errors.
- Secure internet, cloud, and private application access through Secure Access.
- Simplify operations for distributed enterprise environments.

Licenses for automatic tunnel between Secure Access and Firewall Threat Defense devices

This topic lists the required licenses for using the SASE wizard to establish automatic tunnels between Threat Defense devices and Secure Access.

- Cloud-Delivered Firewall Management Center Essentials (formerly Base) license must allow export-controlled functionality. Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this in Cloud-Delivered Firewall Management Center.

Note Evaluation license does not support this feature.

- Cisco Secure Access Essentials subscription license must be available.

Prerequisites for an automatic tunnel between Secure Access and Firewall Threat Defense devices

This topic provides the prerequisites required to establish an automatic tunnel between Secure Access and Firewall Threat Defense devices for secure traffic integration.

- Integrate a Cisco Security Cloud Control tenant with a Secure Access organization.
- Configure basic routing and access control policies to route traffic between the Secure Access data center and the Firewall Threat Defense device.
- Firewall Threat Defense devices must be Version 7.2.0 and later.

Guidelines for an automatic tunnel between Secure Access and Firewall Threat Defense devices

General guidelines

- Set up routing in the Firewall Threat Defense device to route traffic over the tunnel.
- Delete the Firewall Threat Defense device from the topology and add it again with the required routing configuration to update routing settings in a SASE topology.
- When change management is enabled, tunnels are not deployed automatically to Secure Access. Manually deploy tunnels to Secure Access from the **Site-to-Site VPN** page after the change management ticket is approved.

Multi-ISP SASE topology guidelines

- To create a multi-ISP SASE topology, you must establish multiple tunnels from a Firewall Threat Defense device to the same Secure Access region using different interfaces. Since each SASE topology supports only one WAN interface, use the SASE wizard to create multiple topologies.
- When you configure multi-ISP SASE topologies that use the same region and device but different VPN interfaces, ensure that all topologies have identical settings. The tunnel ID prefix, passphrase, and routing configurations must match across all topologies.
- To update routing settings in a multi-ISP SASE topology, delete the Firewall Threat Defense device from each topology and add it again with the required configuration. Ensure that routing settings are consistent across all topologies.

Limitation for automatic tunnel between Secure Access and Firewall Threat Defense devices

Clustering is not supported.

Configure automatic tunnel between Secure Access and Firewall Threat Defense devices using SASE wizard

The SASE wizard simplifies tunnel creation from Firewall Threat Defense devices to Secure Access by automating multiple steps.

Before you begin

Ensure that you review Prerequisites for an automatic tunnel between Secure Access and Firewall Threat Defense devices, on page 1777 .

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site** , and click **Add** .

Step 2 In the **Topology Name** field, enter a name for the SASE topology.

Step 3 Click the **SASE Topology** radio button and click **Create** .

Step 4 Configure a Secure Access region by choosing a region from the **Region** drop-down list:

A Secure Access region is a cluster of data centers in a specific geographic area.

Step 5 Configure Firewall Threat Defense nodes:

a) Click **Add** and configure the parameters in the **Add Threat Defense Node** dialog box.

b) From the **Device** drop-down list, choose a Firewall Threat Defense device.

Note
Only Firewall Threat Defense devices managed by Cloud-Delivered Firewall Management Center are displayed in this list. Extranet devices won't appear in the list.

c) From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface that establishes a VPN connection with Secure Access .

Step 6 Configure **Tunnel ID and passphrase** .

a) In the **Prefix for tunnel ID** field, enter a prefix containing 8 to 30 characters. The prefix can contain alphabets, numbers, period (.), underscore (_), and dash (-).

Secure Access uses this prefix to generate the complete tunnel ID after the Cloud-Delivered Firewall Management Center deploys the tunnel in Secure Access . The tunnel ID format is < *prefix* >@< *org* >< *hub* >.sse.cisco.com.

b) The passphrase is auto generated. However, you can regenerate or enter a different passphrase. In the **Passphrase** field, enter a passphrase containing 16 to 64 characters. The passphrase must contain at least one upper-case alphabet, one lower-case alphabet, and one number, and cannot include special characters.

c) Confirm the passphrase.

d) Click **Next** .

Step 7 Configure **NAT or routing** :

a) Check the **Enable NAT/outbound only** check box to enable Network Address Translation (NAT) for correct routing and identification.

Use this option if the IP address of the subnet behind this tunnel group overlaps with the IP address in your network. When this option is selected, the tunnel group supports only outbound traffic and cannot provide access to private applications hosted at this site.

Note
Routing options are unavailable when the network contains overlapping subnets.

b) Configure one of these options for **Routing** :

- Click the **Static routing** radio button.

  Use the **Network IP addresses** field to add the IP addresses of networks for this tunnel group. Add all the public and private addresses used internally by your organization.

- Click the **Dynamic routing** radio button.

  Use this option to advertise your internal networks over BGP.

  In the **AS number** field, enter the AS number of the device. This value must match the device's BGP AS number in the routing settings of the device.

c) Click **Next** .

Step 8 Check the **Deploy to Threat Defense devices** check box to trigger deployment of all the configurations besides the Secure Access auto tunnel configurations that are yet to be deployed on the device.

Step 9 Click **Finish** to save and validate the configurations, and create the SASE topology.

The wizard performs these actions:

- Saves all Firewall Threat Defense device configurations in Cloud-Delivered Firewall Management Center .
- Pushes the configurations to Secure Access.
- Creates virtual tunnel interfaces (VTIs) on the device.
- Creates a SASE VPN topology.
- Triggers deployment of all the configurations besides the Secure Access auto tunnel configurations that are yet to be deployed in the device if the **Deploy to Threat Defense devices** option is enabled.
- Opens the **Configuration of Secure Access Tunnels** dialog box, which displays the status of the tunnel deployment in Secure Access .

  Click the **Transcript Details** ( ) button to view transcript details such as the APIs, request payload, and the responses received from Secure Access .

You can view the SASE topology in the **Site-to-Site VPN & SD-WAN** page (**Devices** > **VPN** > **Site to Site**).

What to do next

1. Create an extended Access Control List (ACL).

   This ACL defines the specific DNS and web traffic intended for routing through the tunnel to Secure Access . For more information, refer to Configure an extended ACL object, on page 2949 .

2. Configure the static route to the next hop of the VTI interface.
3. Create a policy-based routing (PBR) policy.

   Use the newly created extended ACL within a policy-based routing policy to direct the defined DNS and web traffic through the tunnel to Secure Access for security inspection. For more information, refer to Configure policy-based routing policy, on page 1548 .
4. When you create multiple SASE topologies for a multi-ISP setup, configure ECMP zones with the VPN interfaces to balance the load of application traffic.
5. Perform validation. For more information, refer to Validate Secure Access integration with Firewall Threat Defense devices, on page 1780 .

Validate Secure Access integration with Firewall Threat Defense devices

You can validate the integration between Secure Access and Threat Defense devices by checking tunnel statuses and viewing transcript details.

Verify tunnel statuses in Cloud-Delivered Firewall Management Center

To view the SASE topology tunnel details in the site-to-site VPN dashboard, choose **Overview** > **Dashboards** > **Site to Site VPN**.

To view more details about each tunnel:

1. For each tunnel, hover your cursor over a topology and click the **View** () icon.
2. Click the **CLI Details** tab.
3. Click **Maximize View**. You can view the output of these commands:
   - **show crypto ipsec sa peer**: Shows the number of packets that are transmitted through the tunnel.
   - **show VPN-sessiondb detail l2l filter ipaddress**: Shows detailed data for the VPN connection.

Verify tunnel statuses in Secure Access

1. In Secure Access, choose **Connect > Network Connections > Network Tunnel Groups**.
2. Click a network tunnel group to view details.

   In the **Network Tunnels** area, the primary and secondary tunnels will be displayed:
   - **Primary1** tunnel originates from the branch's outside interface and connects to the primary Secure Access data center.
   - **Secondary1** tunnel also originates from the branch's outside interface but connects to the secondary data center, serving as a standby for continuous connectivity.

View transcript details

In the **Configuration of Secure Access Tunnels** dialog box, click the **Transcript Details** () button to view the transcript details such as the APIs, request payload, and the responses received from Secure Access.

Transcript details are not available in these scenarios:

- When you delete a Network Tunnel Group (NTG) or an endpoint.
- When you configure any multi-ISP tunnel after configuring the primary tunnel.

Monitor site-to-site topologies

This section provides information about the different ways to monitor your site-to-site topologies.

Monitor site-to-site VPNs using Site-to-Site VPN summary page

You can view a summary of your site-to-site VPN topologies in the **Site-to-Site VPN Summary** page. For each topology, you can view details such as VPN type, network topology, VPN interfaces, VPN devices, and tunnel statuses.

You can edit or delete the topology using the edit and delete buttons. For SASE topology VPNs, you have options to deploy, edit and delete any topology.

Monitor site-to-site VPNs using Site-to-Site VPN dashboard

Choose **Overview** > **Dashboards** > **Site to Site VPN** to open the site to site dashboard.

The **Site-to-Site VPN** dashboard provides a snapshot and status of the site-to-site VPN tunnels. You can view the list of tunnels between peer devices and the status of each tunnel: Active, Inactive, or No Active Data. You can filter the data in the table according to the topology, device, and status. The dashboard shows live data and you can also configure the refresh interval.

Benefits of the dashboard

The dashboard provides these benefits:

- Identify problematic VPN tunnels and troubleshoot them.
- Verify connectivity between the site-to-site VPN peers devices.
- Monitor the health of the VPN tunnels to provide uninterrupted VPN connectivity between sites.
- Use Packet tracer to troubleshoot VPN tunnels.

Widgets of the dashboard

- **Tunnel Status**—A table listing the tunnel status of the site-to-site VPNs , including the SASE tunnels for Umbrella, configured using the Cloud-Delivered Firewall Management Center. For more information, refer to Tunnel status widget, on page 1782.
- **Tunnel Summary**—Aggregated status of the tunnels in a donut graph.
- **Topology**—Status of tunnels summarized by topology.

Status of VPN tunnels

The different VPN tunnel statuses that you can view in the Site-to-Site dashboard are:

- **Inactive**—A policy-based (crypto map-based) VPN tunnel is inactive if all the IPSec tunnels are down. A VTI or and SASE topology VPN tunnel is down if the tunnel encounters any configuration or connectivity issues.
- **Active**—In the Cloud-Delivered Firewall Management Center, policy-based site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. A policy-based VPN tunnel is in the Active state if the Cloud-Delivered Firewall Management Center identifies interesting traffic through the tunnel after the deployment. An IKE tunnel is up only if a minimum of one IPsec tunnel is up.

  Route-based VPN (VTI) and SASE topology VPN tunnels do not require interesting traffic to be in the Active state. They are in the Active state if they are configured and deployed without errors.
- **No Active Data**—Policy-based and SASE topology VPN tunnels remain in the No Active Data state until there is a traffic flow event through the tunnel for the first time. The No Active Data state also lists the policy-based and route-based VPNs that have been deployed with errors.

Important notes about tunnel statuses in Cloud-Delivered Firewall Management Center

- The VPN statuses in the Cloud-Delivered Firewall Management Center are event-based. The Cloud-Delivered Firewall Management Center does not initiate status updates. Hence, there might be mismatches between the tunnel statuses in the dashboard and the Firewall Threat Defense . You can view the correct status in the **CLI Details** tab of the **Tunnel Status** widget.
- When a Firewall Threat Defense switches over to a secondary Firewall Threat Defense , there is a mismatch between the status of the VPN tunnels in the Cloud-Delivered Firewall Management Center and the Firewall Threat Defense . When the device switches back to the primary device, the correct tunnel status appears.
- The Cloud-Delivered Firewall Management Center does not update the tunnel status of Firewall Threat Defense devices earlier than 7.3 after the devices reboot. We recommend that you bring the tunnel down using the command **vpn-sessiondb logoff index** and bring it up using the packet tracer.

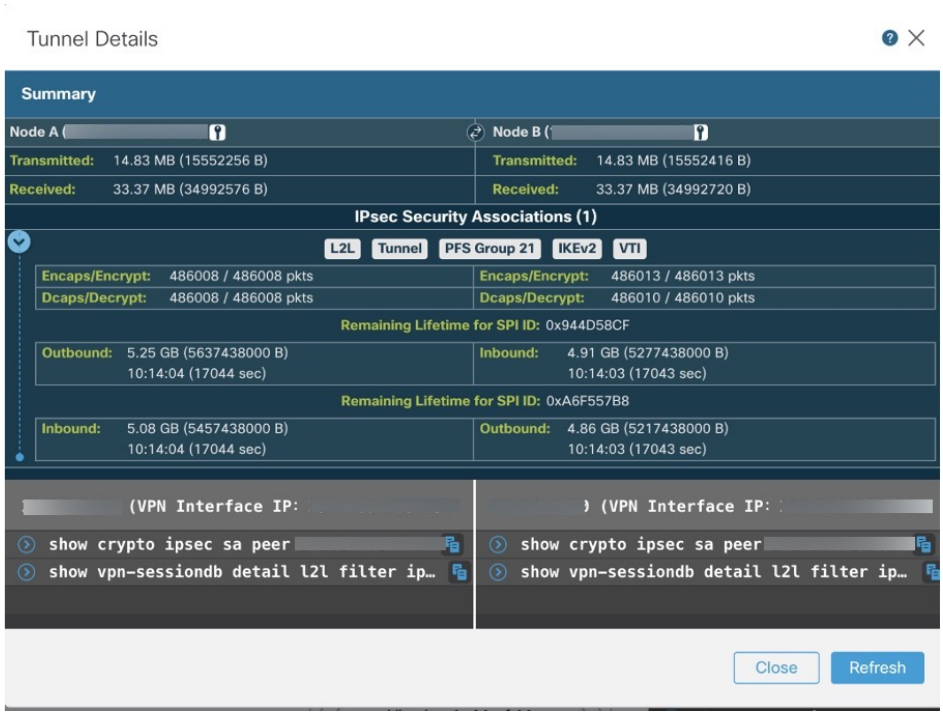
Limitations of the dashboard

- The table shows the list of site-to-site , including SASE topology, VPNs that are deployed. It does not show the tunnels that are created and not deployed.
- The table does not show the information about the backup tunnels of policy-based VPNs and backup VTIs.
- For cluster deployments, the table does not show director change in real-time data. It shows only the director information that existed when the VPN was deployed. The director change reflects in the table only after the tunnel AM redeployed after the change.

Tunnel status widget

This widget lists the site-to-site VPNs, including SASE topology VPN, configured using the Cloud-Delivered Firewall Management Center and their tunnel statuses.

Features of the widget



Hover over a topology and click **View** ( ) to view these details about the topology:

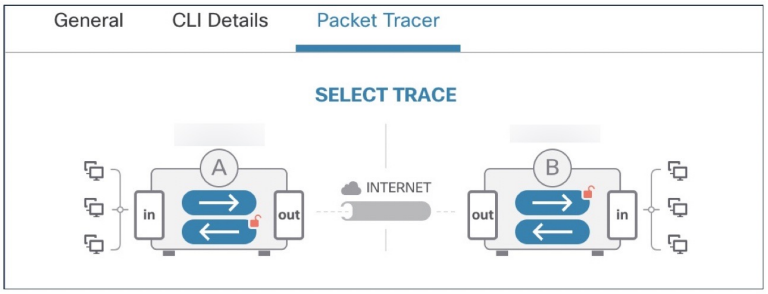
- **General**—Displays more information about the nodes such as IP address and interface name.
- **CLI Details**—Displays the CLI outputs for the following commands:
  - **show crypto ipsec sa peer**: Displays the IPsec SAs built between Node A and B.
  - **show vpn-sessiondb l2l filter ipaddress** : Displays information about VPN sessions.

  For an extranet device, no command output appears.

  Important details about the IKE and IPsec sessions, derived from the above command outputs, appear in a summarized, and user-friendly format. You can view the details of both nodes at a time. The icon next to the node name specifies the authentication type: preshared key or client certificate. The details include IKE statistics per tunnel and IPsec SA statistics as shown below:

Figure 369: Tunnel Status > View > CLI Details

- **Packet Tracer**—Use packet tracer to troubleshoot the VPN tunnels.



Packet Tracer

Packet tracer allows you to troubleshoot VPN tunnels between two threat defense devices. You can check if the VPN connection between device A and device B is up. This tool performs these actions:

- Injects a packet into the device and tracks the packet flow from the ingress to the egress ports.
- Simulates traffic after you configure the ingress interfaces of the devices along with the protected networks.

- Evaluates the packet against modules such as flow and route lookups, ACLs, protocol inspection, NAT, and QoS.

Figure 370: Packet Tracer

For each device, the tool runs an encrypted trace and a decrypted trace (packet is treated as decrypted VPN traffic). You can run four different traces between the ingress and egress ports of the devices. Click the individual encrypt and decrypt options to enable or disable the trace.

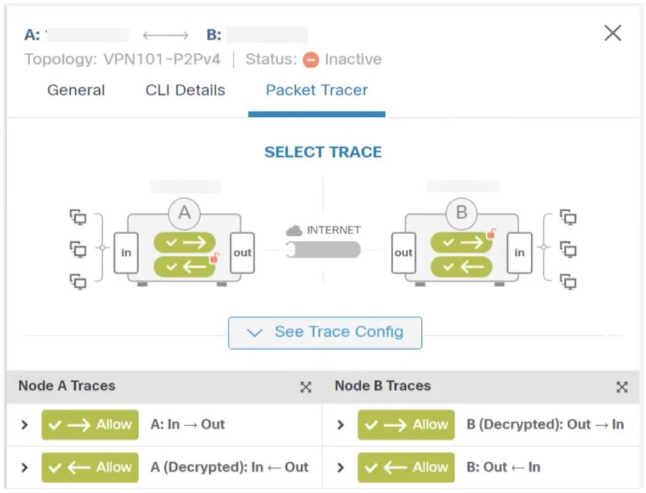
When you run the trace, the tool executes the trace sequentially in the following order:

1. Encrypted trace of A.
2. Decrypted trace of B.
3. Encrypted trace of B.
4. Decrypted trace of A.

After the trace completes, you can view the output of the trace with the results of each module.

Note You cannot run a decrypt trace for route-based (VTI-based) VPNs.

To run the Packet Tracer:



1. Click **See Detailed Config** to view the VPN interface name, VPN interface IP address, VTI interface name, and the VTI Interface IP address.
2. (Optional) Choose a protocol from the **Protocol** drop-down list. You can choose ICMP/8/0, TCP, or UDP.

   ICMP/8/0 is the default option. If you choose ICMP/8/0, 8 indicates the ICMP type as Echo Request and 0 indicates the ICMP code. If you choose TCP or UDP, choose the destination port from the **Destination Port** drop-down list. The range is from 0 to 65535.
3. Choose the ingress interface for both the devices on which to trace the packet from the **Ingress Interface** drop-down lists.
4. Enter an IP address from the same subnet as the ingress interface in the **Protected Network IP Address** fields.
5. Click **Trace Now**.

   After you initiate the trace, you can view if the trace is successful or not for each module. If the tunnel is down, the path appears in red. If the tunnel is up, the path appears in green. If a tunnel is down, click

Re-trace to run the tool again. For a crypto-map based VPN, when the tunnel is inactive with no interesting traffic, the initial trace can be red. Click **Re-trace** to run the trace again.

Figure 371: Packet Tracer after a Successful Trace

Extranet Nodes: You can initiate a packet trace for VPN tunnels with one node as an extranet. For an extranet node, you cannot choose the ingress interface. The remaining steps for the packet trace are the same. You can't run trace on the extranet side.

For example, if Node A is a managed threat defense and Node B is an extranet:

- Configure the ingress interface for node A.
- Configure the protected network for Node A and B.
- Click **Trace Now**. The traces appear for Node A and not for Node B.

Site-to-site VPN connection event monitoring

The site-to-site VPN connection event allows you to know if the VPN encrypts or do not encrypts the connection and helps you to troubleshoot connectivity issues, especially in multi-hop VPN deployments. The event dashboard of the Cloud-Delivered Firewall Management Center displays the IP address of the VPN peer (peer's IKE address) which encrypts or decrypts the traffic and displays the VPN action.

The VPN actions displayed are:

- If the connection is decrypted by the VPN, the column **Decrypt Peer** displays the IP address of the peer's address from where the flow was received and displays **Decrypt** as the VPN action.
- If the connection is encrypted by the VPN, the column **Encrypt Peer** displays the IP address of the VPN peer to which the flow is sent and displays **Encrypt** as the VPN action.
- If the VPN server cascades the connection, it gets decrypted on one tunnel and gets re-encrypted on another tunnel. In this case, both **Encrypt Peer** and **Decrypt Peer** IP addresses get appears in the event. The column **VPN Action** displays **VPN Routing** as the action to indicate that the connection transit through the VPN server.

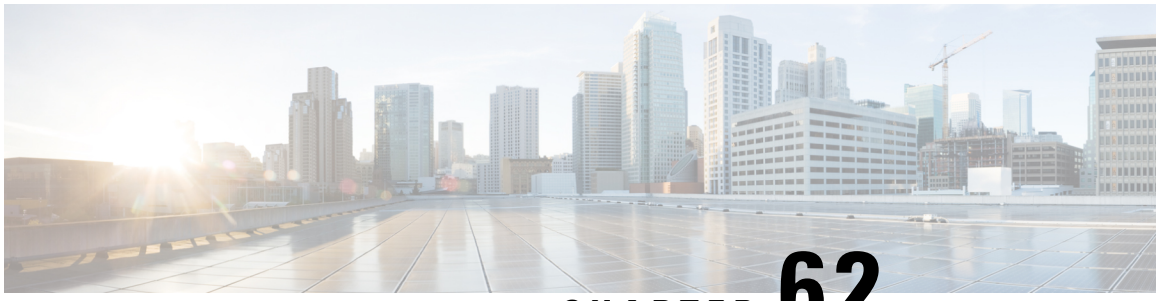
If you enable the **Bypass Access Control Policy for decrypted traffic (sysopt permit-VPN)** option, the system bypasses the access control policy and do not log events for decrypted traffic. This option is disabled by default and all decrypted traffic in the VPN tunnel undergoes ACL inspection.

View site-to-site VPN connection events

Access the connection event viewer of the Cloud-Delivered Firewall Management Center to know if the VPN encrypts or do not encrypts the connection traffic and to retrieve the VPN peer details.

Before you begin

Ensure that you enable logging of connection events at the beginning of connection and at the end of connection in the access control rule.



Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 Choose these columns:

- Decrypt Peer
- Encrypt Peer
- VPN Action

Step 3 Click **Apply**.

CHAPTER 62

SD-WAN

This chapter describes the SD-WAN capabilities supported in Management Center.

- SD-WAN capabilities, on page 1787
- SD-WAN features, on page 1788
- SD-WAN wizard for secure branch network deployment, on page 1789
- Monitor SD-WAN topologies, on page 1805

SD-WAN capabilities

SD-WAN capabilities are software-defined networking features that

- replace traditional WAN routers and are agnostic to WAN transport technologies
- provide dynamic, policy-based, application path selection across multiple WAN connections, and
- support service chaining for additional services such as WAN optimization and firewalls.

SD-WAN capabilities in Secure Firewall

As organizations expand their operations across multiple branch locations, ensuring secure and streamlined connectivity becomes paramount. Deploying a secure branch network infrastructure involves complex configurations, which can be time-consuming and prone to configuration errors if not handled properly. However, organizations can overcome these challenges by leveraging Management Center and Threat Defense devices for a simplified and secure branch deployment.

By integrating Secure Firewall as a foundational component of the branch network architecture, organizations can establish a strong security baseline while simplifying the deployment process. This approach enables organizations to enforce unified security policies, optimize traffic routing, and ensure resilient connectivity.

Some of the SD-WAN capabilities supported on the Cisco Secure Firewall include:

- **Simplified management:**
  - SASE: Umbrella auto tunnel deployment
  - Dynamic VTI (DVTI) hub spoke topology simplification
- **Application awareness:**
  - Direct Internet Access (DIA) for public cloud and guest user

- Policy based routing (PBR) using applications as a match criteria
- Local tunnel ID support for Umbrella

- **Increased usable bandwidth:**
  - ECMP support for load balancing across multiple ISPs and VTIs
  - Application-based load balancing using PBR
- **High availability with near zero network downtime:**
  - Dual ISP configuration
  - Optimal path selection based on application-based interface monitoring.
- **Secure elastic connectivity:**
  - Route-based (VTI) VPN tunnels between headquarters (hub) and branches (spokes)
  - IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP over VTI
  - DVTI hubs that support spokes with static or dynamic IP

SD-WAN features

This table lists the SD-WAN features of Management Center, including their introduction releases and links to detailed information.

Table 102: SD-WAN features

Feature	More Information
Secure traffic using Cisco Secure Access and Firewall Threat Defense devices	Secure traffic using Cisco Secure Access and Firewall Threat Defense devices, on page 1776
Configure settings to carry SGT over the SD-WAN tunnels using SD-WAN wizard.	SD-WAN wizard for secure branch network deployment, on page 1789
Support for ECMP in hubs and BFD for SVTI and DVTI.	SD-WAN wizard for secure branch network deployment, on page 1789
Use PBR to handle traffic based on advanced custom application detector.	Policy-Based Routing, on page 1541
Management of Remote Branch (HA) with Dual WAN Support	SD-WAN summary dashboard, on page 1805
PBR Support for Custom Applications	Policy-Based Routing, on page 1541
SD-WAN Wizard	SD-WAN wizard for secure branch network deployment, on page 1789

Feature	More Information
Application monitoring using SD-WAN Summary dashboard	SD-WAN summary dashboard, on page 1805
SD-WAN Summary Dashboard	SD-WAN summary dashboard, on page 1805
Policy-based routing with user identity and SGTs	Policy-Based Routing, on page 1541
Policy-based routing using HTTP path monitoring	Policy-Based Routing, on page 1541
Loopback interface support for VTIs	Loopback interfaces, on page 1052
Support for dynamic VTI (DVTI) with site-to-site VPN	Dynamic VTI, on page 1747
Umbrella auto tunnel	Deploy a SASE Tunnel on Umbrella
Support for IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP for VTIs	BGP, on page 1491 OSPF, on page 1447 EIGRP, on page 1479
Route-based site-to-site VPN with hub and spoke topology	Create a route-based site-to-site VPN, on page 1754
Policy-based routing with path monitoring	Policy-Based Routing, on page 1541
Site to Site VPN Monitoring Dashboard	Monitor Site-to-Site VPNs Using Site-to-Site VPN Dashboard
Direct Internet Access/Policy Based Routing	Policy-Based Routing, on page 1541
Equal-Cost-Multi-Path (ECMP) zone with WAN interfaces	ECMP, on page 1431
ECMP zone with VTI interfaces	ECMP, on page 1431
Backup VTI for route-based site-to-site VPN	Route traffic through a backup VTI tunnel, on page 1764
Support for static VTI (SVTI) with site-to-site VPN	Static VTI, on page 1746

SD-WAN wizard for secure branch network deployment

The SD-WAN wizard in Management Center

- simplifies and automates VPN tunnel and routing configuration between centralized headquarters (hubs) and remote branch sites (spokes)
- creates route-based VPN tunnels and automates tasks such as generating tunnel interfaces, assigning IP addresses, and configuring BGP for the SD-WAN overlay network

- provides seamless routing by enabling hubs to act as route reflectors that determine the best routing path based on spokes' active and backup tunnels.

Hub and spoke network components

The SD-WAN wizard configures two types of network components:

- Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.
- Spokes: Devices in remote branches that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

The SD-WAN wizard provides these benefits:

- Simplifies and automates the VPN and routing configuration of your SD-WAN network.
- Requires minimal user input
- Easily adds multiple branches at a time
- Provides easy dual ISP configurations
- Enables network scaling

Guidelines for using SD-WAN wizard

General guidelines

- When you create security zones or interface groups, choose **Routed** as the **Interface Type**.
- Use the spoke security zone to configure an access control policy that allows tunnel traffic to and from the spokes.
- If a spoke is part of multiple SD-WAN topologies, ensure that you use the same local community tag and learned route community tag in each SD-WAN topology. Note that the local community tags and learned route community tags must be different from each other.
- Configure unique local IKE identity for all tunnels across all your SD-WAN VPN topologies.
- Ensure that the spokes in an SD-WAN topology do not have the same protected network.

IP address configuration guidelines

- When you configure IP address pools for spokes, ensure the following:
  - The **Allow Overrides** check box must be unchecked.
  - If you are using multiple pools, the IP addresses of the pools must not overlap.
  - IP addresses must not overlap with any of the interfaces on the spoke.
- If a device has only IPv6 address configurations, you must configure the BGP router ID with a loopback or physical interface that has an IPv4 address (**Devices** > **Device Management**, and click **Routing** > **General Settings** > **BGP**).

Dual-ISP topology guidelines

- In a dual-hub SD-WAN topology, the hubs can be in different geographic locations and have different protected networks behind them. To ensure direct communication between these networks, ensure that you configure the following:
  - A point-to-point route-based VPN topology between the two hubs (**Devices** > **VPN** > **Site to Site**, and click **Add** > **Route-Based VPN**).
  - A dynamic routing protocol between the hubs (**Devices** > **Device Management**, click the device name and click **Routing**).
- In SD-WAN topologies with dual ISPs on spokes, the tunnel identity and the tunnel source of the spokes must be unique.

VTI guidelines

- When you configure the DVTIs of two hubs, ensure that they have the same IPsec tunnel mode (IPv4 or IPv6).
- Use distinct DVTIs for SD-WAN and route-based VPNs to avoid IPsec profile conflicts and errors.
- Configure the spokes' static VTIs in an ECMP zone to load balance the application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down. Note that you must configure the spokes' static VTIs and not the physical interfaces in the ECMP zone. This configuration is not part of the SD-WAN wizard.
- Ensure that you shutdown a DVTI virtual template before you change the IP address of a DVTI's numbered interface.

Limitations for using SD-WAN wizard

The SD-WAN wizard has these limitations and restrictions:

- You can configure a maximum of two hubs in an SD-WAN topology using the wizard.
- For each spoke, you can use only one WAN interface per topology. However, for dual-ISP setups, you can configure a second SD-WAN topology with the second WAN interface. For more information, see Sample configurations for dual-ISP deployment using SD-WAN wizard, on page 1797.
- SD-WAN wizard does not support the following:
  - IKEv1
  - Cluster devices are not supported on the hub and spoke because VTI is not supported on cluster devices.
  - Extranet hubs and spokes such as ASA, Cisco IOS, Cisco Viptela, Umbrella, Meraki, or vendor devices.

License requirements to use the SD-WAN wizard

Ensure that export-controlled features are enabled in your Smart License to configure an SD-WAN topology in Cloud-Delivered Firewall Management Center.

To verify if export-controlled functionality is enabled for your Smart License account, choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Prerequisites for using SD-WAN wizard

Ensure that you review these prerequisites before you configure your SD-WAN topology using the SD-WAN wizard.

Device prerequisites

- Hub devices must be Version 7.6.0 and later.
- Spoke devices must be Version 7.3.0 and later.

General prerequisites

- You must be an Admin user.
- The Firewall Threat Defense devices must have an internet-routable public IP address. The IP address can be static or dynamic.
- Assign appropriate logical names and IP addresses to the interfaces of the Firewall Threat Defense devices. For example, use *inside* for the interface connected to the LAN, and *outside* for the interface connected to the internet or WAN.
- If you are using certificate-based authentication, you must enroll the certificates in the hub and spokes.
- Configure routing, NAT, and AC policies to ensure underlay connectivity between the devices.

Configure an SD-WAN topology using the SD-WAN wizard

The SD-WAN wizard allows you to easily configure VPN tunnels between your centralized headquarters and remote branch sites.

Before you begin

Ensure that you review Prerequisites for using SD-WAN wizard, on page 1792 and Guidelines for using SD-WAN wizard, on page 1790.

Procedure

Step 1 Choose **Devices** > **VPN** > **Site to Site** , and click **Add**.

Step 2 Enter a name for the SD-WAN VPN topology in the **Topology Name** field.

Step 3 Click the **SD-WAN Topology** radio button and click **Create**.

Step 4 Configure a hub:

a) Click **Add Hub**.

b) From the **Device** drop-down list, choose a hub.

c) Click **+** next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a dynamic VTI for the hub.

The **Add Virtual Tunnel Interface** dialog box is prepopulated with default configurations. However, you must configure the **Tunnel Source**, and the **Borrow IP Address**. For more information, refer to Add a dynamic virtual tunnel interface for a hub, on page 1797.

d) In the **Hub Gateway IP Address** field, enter the public IP address of the hub's VPN interface or the tunnel source of the dynamic VTI to which the spokes connect.

This IP address is auto populated if the interface has a static IP address. If hub is behind a NAT device, you must manually configure the post-NAT IP address.

e) From the **Spoke Tunnel IP Address Pool** drop-down list, choose an IP address pool or click **+** to create an address pool.

When you add spokes, the wizard auto generates spoke tunnel interfaces, and assigns IP addresses to these spoke interfaces from this IP address pool.

f) Click **Add** to save the hub configuration.

g) (Optional) To add a secondary hub, repeat Step 4a to Step 4f.

h) Check the **ECMP** check box to enable Equal Cost Multi-Path (ECMP) on the dynamic VTIs of hub devices with Version 10.0 or later.

All virtual access interfaces on the hub connecting to the same spoke are grouped into an ECMP zone. This feature load balances traffic through multiple paths to a spoke.

Step 5 Configure spokes:

Click **Add Spoke** to add a single spoke device, or click **Add Spokes (Bulk Addition)** to add multiple spokes to your topology.

- Click **Add Spoke**. In the **Add Spoke** dialog box, configure the following parameters:

  a. From the **Device** drop-down list, choose a spoke.

  b. From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

  c. Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from this device to the remote peer. By default, this option is enabled.

  d. Choose one of the following options from the **Identity Type** drop-down list:

  - **Key ID**—(Default value) This value is auto populated as < sd-wan topologyname >_< device_IP_address >, for example, sdwantopo1_192.168.0.200. You can also specify a key ID of your choice.
  - **Email ID**—Specify an email ID up to 127 characters.
  - **IP Address**—IP address of the spoke's VPN interface.
  - **Auto**—IP address of the spoke's VPN interface for pre-shared key authentication or the certificate Distinguished Name (DN) for certificate-based authentication.
  - **Hostname**—Fully qualified hostname of the spoke.

  e. Click **Save** to save the spoke configuration.

- Click **Add Spokes (Bulk Addition)**. In the **Add Bulk Spokes** dialog box, configure the following parameters:

a. Choose one or more devices from the **Available Devices** list and click **Add** to move the devices to **Selected Devices** .

b. Use one of the following methods to select the VPN interfaces of the spokes:

- Click the **Interface Name Pattern** radio button and specify a string to match the logical name of the internet or WAN interface of the spokes, for example, outside*, wan*.

  If the spoke has multiple interfaces with the same pattern, the first interface that matches the pattern is selected for the topology.

- Click the **Security Zone** radio button and choose a security zone with the VPN interfaces of the spokes from the drop-down list, or click + to create a security zone.

c. Click **Next**.

The wizard validates if the spokes have interfaces with the specified pattern. Only the validated devices are added to the topology.

d. Click **Add**.

e. Click **Next**.

For each spoke, the wizard automatically selects the hub's DVTI as the tunnel source IP address.

Note
If the hub’s tunnel source IP address is an IPv6 address, the wizard automatically selects the first IPv6 address of the spokes' selected interface. To edit the IPv6 address of a spoke's tunnel source, click the edit icon next to a spoke, choose an IPv6 address from the **IP Address** drop-down list, and click **Save**.

Step 6 Configure authentication settings for the devices in the SD-WAN topology:

a) **Authentication Type**—For device authentication, you can use a manual pre-shared key, an auto-generated pre-shared key, or a certificate.

- **Pre-shared Manual Key**—Specify the pre-shared key for the VPN connection.
- **Pre-shared Automatic Key**—(Default value) The wizard automatically defines the pre-shared key for the VPN connection. Specify the key length in the **Pre-shared Key Length** field. The range is 1 to 127.
- **Certificate**—When you use certificates as the authentication method, the peers obtain digital certificates from a CA server in your PKI infrastructure, and use them to authenticate each other.

b) Choose one or more algorithms from the **Transform Sets** drop-down list.

c) Choose one or more algorithms from the **IKEv2 Policies** drop-down list.

Step 7 Configure the SD-WAN settings:

This step involves the auto generation of spoke tunnel interfaces, and BGP configuration of the overlay network.

a) From the **Spoke Tunnel Interface Security Zone** drop-down list, choose a security zone or click + to create a security zone to which the wizard automatically adds the spokes' auto-generated Static Virtual Tunnel Interfaces (SVTIs).

b) Check the **Enable BGP on the VPN Overlay Topology** check box to automate BGP configurations such as neighbor configurations between the overlay tunnel interfaces and basic route redistribution from the directly connected LAN interfaces of the hubs and spokes.

c) In the **Autonomous System Number** field, enter an Autonomous System (AS) number.

AS number is a unique number for a network with a single routing policy. BGP uses AS numbers to identify networks. The spoke's BGP neighbor configuration is generated based on the corresponding hub's AS number. Range is from 0 to 65536.

- If all the hubs and spokes are in the same region, by default, **64512** is the AS number.
- If the primary and secondary hubs are in different regions, the primary hub and the spokes are configured with **64512** as the AS number, and the secondary hub is configured with a different AS number.

d) In the **Community Tag for Local Routes** field, enter the BGP community attribute to tag connected and redistributed local routes. This attribute enables easy route filtering.

e) Check the **Redistribute Connected Interfaces** check box and choose an interface group from the drop-down list or click **+** to create an interface group with connected inside or LAN interfaces for BGP route redistribution in the overlay topology.

f) Check the **Enable Multiple Paths for BGP** check box to allow multiple BGP routes to be used at the same time to reach the same destination. This option enables BGP to load-balance traffic across multiple links.

Note that when you enable this option, BGP multipath is enabled only for spokes.

g) (Optional) Check the **Secondary Hub is in Different Autonomous System** check box. This check box appears only if you have a secondary hub in this topology.

h) In the **Autonomous System Number** field, enter the AS number for the secondary hub.

i) In the **Community Tag for Learned Routes** field, enter the BGP community attribute to tag routes learned from other SD-WAN peers over the VPN tunnel. This attribute is required only for eBGP configuration when the secondary hub has a different AS number. This field appears only if you have configured two hubs in the SD-WAN topology.

Step 8 Configure **Advanced Settings**.

a) From the **Identity Sent to Peers** drop-down list, choose the identity that the peers will use to identify themselves during IKE negotiations.

- **autoOrDN**—(Default value) Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication.
- **IP Address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **Hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

b) Configure **TrustSec (SGT) Settings**.

Enable SGT propagation over Virtual Tunnel Interfaces—Cisco TrustSec uses Security Group Tags (SGTs) to control access and enforce traffic on a network. This option enables SGT propagation over SVTIs and DVTIs of the VPN topology. To enable SGT propagation on a specific SVTI or DVTI, configure it in individual devices. Note that the Firewall Threat Defense device must be Version 10.0.0 and later.

c) Configure **Bidirectional Forwarding Detection (BFD) Settings**.

Enable Bidirectional Forwarding Detection Routing—BFD is a protocol for detecting forwarding path failures. This option enables BFD routing protocol on the SVTIs and DVTIs. When BFD detects a path failure, traffic is rerouted over the newly identified path. Note that the Firewall Threat Defense device must be Version 10.0.0 and later.

1. From the **Interval** drop-down list, choose the unit of interval, microseconds or milliseconds, at which BFD control packets are sent.
2. In the **Multiplier** field, enter the number of consecutive missed BFD control packets allowed before declaring that the peer is unavailable. The range is 3 to 50 packets.
3. In the **Minimum Transmit and Receive Interval** field, enter the minimum transmit and receive interval of the BFD control packets. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.

Step 9 Click **Finish** to save and validate the SD-WAN topology.

You can view the topology in the **Site-to-Site VPN Summary** page (**Devices** > **VPN** > **Site to Site**). After you deploy the configurations to all the devices, you can see the status of all the tunnels in this page.

What to do next

- View the auto-generated spoke SVTIs and their IP addresses—Click the edit icon next to the spoke configuration and click **View Generated Tunnel Interfaces** .
- We recommend that you enable ECMP on the spoke SVTIs. Choose **Devices** > **Device Management**, and click **Routing** > **ECMP**.
- Deploy the configurations on the hub and spokes. Choose **Deploy** . Select devices and click **Deploy** .
- Verify the SD-WAN topology tunnel statuses. For more information, see Verify tunnel statuses of an SD-WAN topology, on page 1802.
- Configure ACLs for the spokes' tunnel interface security zones. Choose **Policies** > **Access Control heading** > **Access Control**.
- We recommend that you enable BGP multipath on hubs. To enable BGP multipath on hubs:
  1. Choose ECMP **Devices** > **Device Management** , and click **Routing**.
  2. Under **General Settings**, click **BGP**.
  3. Check the **Enable BGP** check box to enable BGP.
  4. In the **AS Number** field, enter the AS number that you configured in the SD-WAN topology.
  5. Click **Save**.
  6. In the left pane, choose **BGP > IPv4 or IPv6**, and click the **General** tab.
  7. In the **Forward Packets over Multiple Paths** section, click the edit icon.
  8. Configure values for **Number of Paths** and **IBGP number of paths**. We recommend that you configure these values as 8.

- For more information about configuration examples using SD-WAN wizard, refer to Sample configurations for dual-ISP deployment using SD-WAN wizard, on page 1797.
- Configure a PBR policy on each spoke for application-aware routing based on the application performance metrics of the WAN interfaces. For more information, refer to Route Application Traffic from the Branch to the Internet Using Direct Internet Access (DIA).

Add a dynamic virtual tunnel interface for a hub

In the SD-WAN wizard, you must configure a DVTI for each hub. DVTI uses a virtual template to dynamically generate a unique virtual access interface for each VPN session.

Before you begin

In the SD-WAN wizard, click **Add Hub**, and choose a hub from the **Device** drop-down list.

Procedure

Step 1 Click + next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a DVTI for the hub.

The **Add Virtual Tunnel Interface** dialog box appears with the following prepopulated default configurations.

a. **Tunnel Type**: Dynamic.

b. **Name**: <*tunnel_source_interface_logical name*>_dynamic_vti_<*tunnel_ID*>. For example, outside_dynamic_vti_1.

c. **Enabled** check box: Checked by default.

d. **Template ID**: Unique ID for the DVTI.

e. **Tunnel Source**: Physical interface that is the source of the DVTI and is auto populated by default.

f. **IPsec Tunnel Mode**: IPv4, by default.

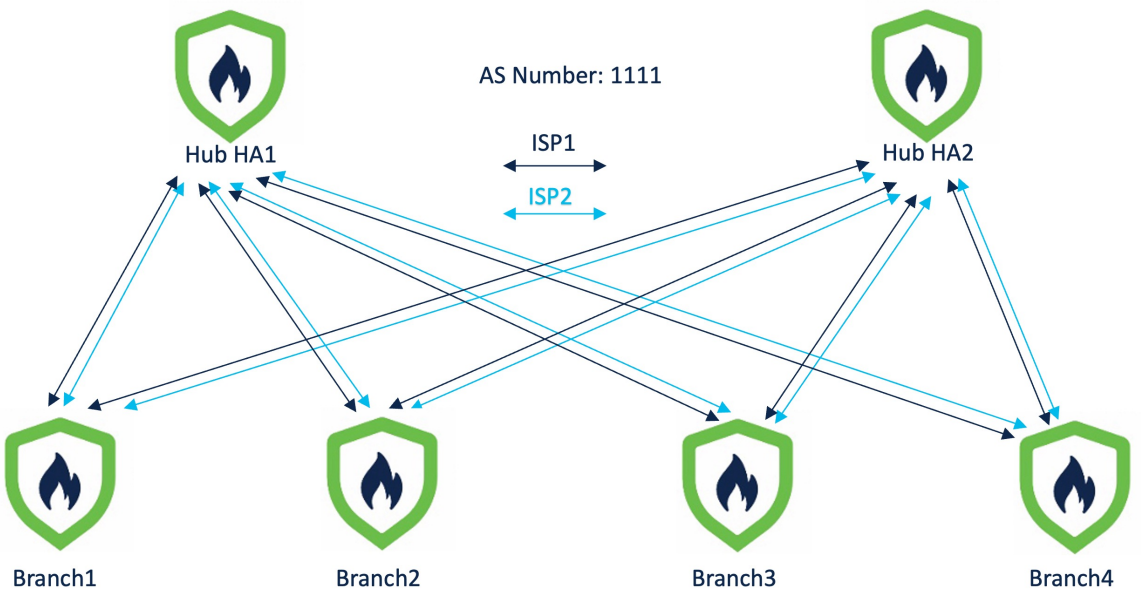
Step 2 Choose a security zone for the dynamic VTI from the **Security Zone** drop-down list.

Step 3 Choose a physical or loopback interface from the **Borrow IP** drop-down list, the dynamic VTI interface inherits this IP address.

Ensure that you use an IP address different from the tunnel source IP address. We recommend that you use a loopback IP address.

Step 4 Click **OK** to save the dynamic VTI.

Sample configurations for dual-ISP deployment using SD-WAN wizard



Here are some sample configurations that demonstrate how to implement dual-ISP deployment using the SD-WAN wizard for redundancy and load balancing across multiple internet service providers.

Dual ISP deployment: Two hubs and four spokes in the same region

In this dual ISP topology, the hubs and the spokes are in a single region, with AS number AS 1111. The hubs and spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol to exchange routing information.

- Hub HA1 and Hub HA2 are hub Threat Defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke Threat Defense devices at the branches.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 372: Dual ISP topology with two hubs and four spokes in the same region

To configure this topology, you must create two SD-WAN topologies using the SD-WAN wizard.

SD-WAN topology 1

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2, Branch3, Branch4
AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP1
Number of Tunnels	8

The total number of tunnels in SD-WAN Topology 1 is 8.

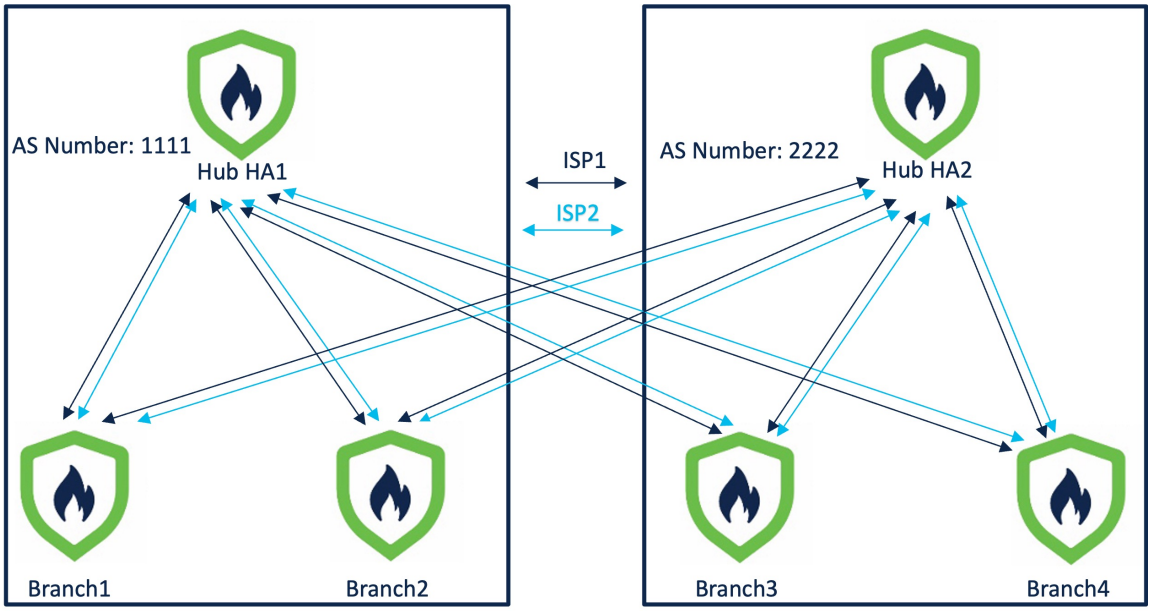
SD-WAN topology 2

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2, Branch3, Branch4
AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP2
Number of Tunnels	8

The total number of tunnels in SD-WAN Topology 2 is 8.

The total number of VPN tunnels for this dual ISP deployment is 16.

Note If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.



Dual ISP deployment: Two hubs and four spokes in different regions

In this dual ISP topology, the hubs are in different regions, and have two directly connected spokes each. The hubs and their directly connected spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol, and the hubs use External Border Gateway Protocol (eBGP) to exchange routing information.

Topology components

- Hub HA1 and Hub HA2 are hub Threat Defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke Threat Defense devices at the branches.
- HQ1, Branch1, and Branch2 are in a single region with AS number AS 1111.
- HQ2, Branch3, and Branch4 are in a single region with AS number AS 2222.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 373: Dual ISP topology with two hubs and four spokes in different regions

To configure this topology, you must create the four SD-WAN topologies using the SD-WAN wizard:

SD-WAN topology 1

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2
AS Number	1111
Secondary AS Number	2222
VPN Interface (Spoke Tunnel Source)	ISP1

The number of tunnels in SD-WAN Topology 1 is 4.

SD-WAN topology 2

Parameter	Value
Primary Hub	Hub HA1
Secondary Hub	Hub HA2
Spokes	Branch1, Branch2
AS Number	1111

Parameter	Value
Secondary AS Number	2222
VPN Interface (Spoke Tunnel Source)	ISP2

The number of tunnels in SD-WAN Topology 2 is 4.

SD-WAN topology 3

Parameter	Value
Primary Hub	Hub HA2
Secondary Hub	Hub HA1
Spokes	Branch3, Branch4
AS Number	2222
Secondary AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP1

The number of tunnels in SD-WAN Topology 3 is 4.

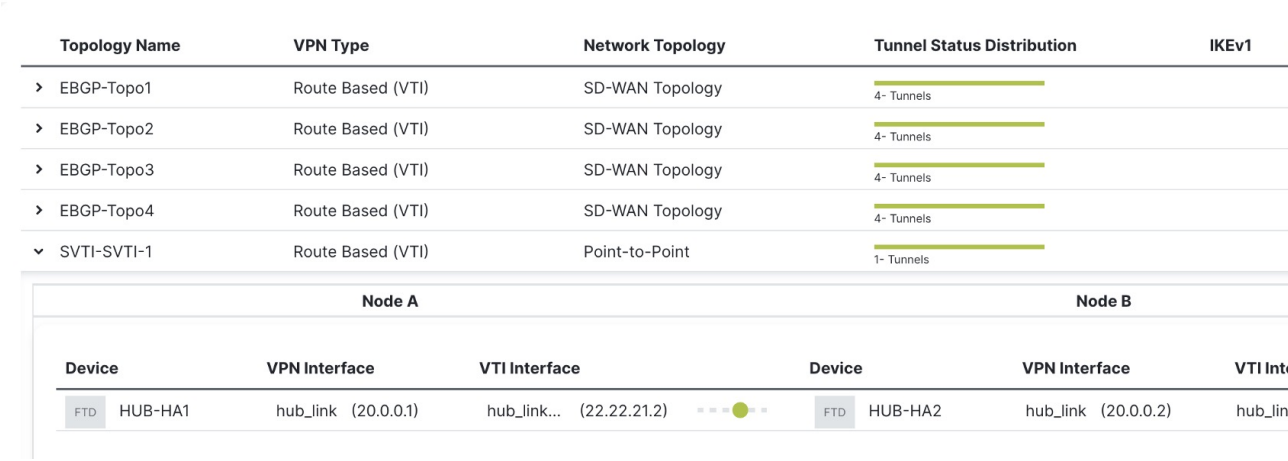
SD-WAN topology 4

Parameter	Value
Primary Hub	Hub HA2
Secondary Hub	Hub HA1
Spokes	Branch3, Branch4
AS Number	2222
Secondary AS Number	1111
VPN Interface (Spoke Tunnel Source)	ISP2

The number of tunnels in SD-WAN Topology 4 is 4.

The total number of VPN tunnels for this dual ISP deployment is 16.

Note If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.

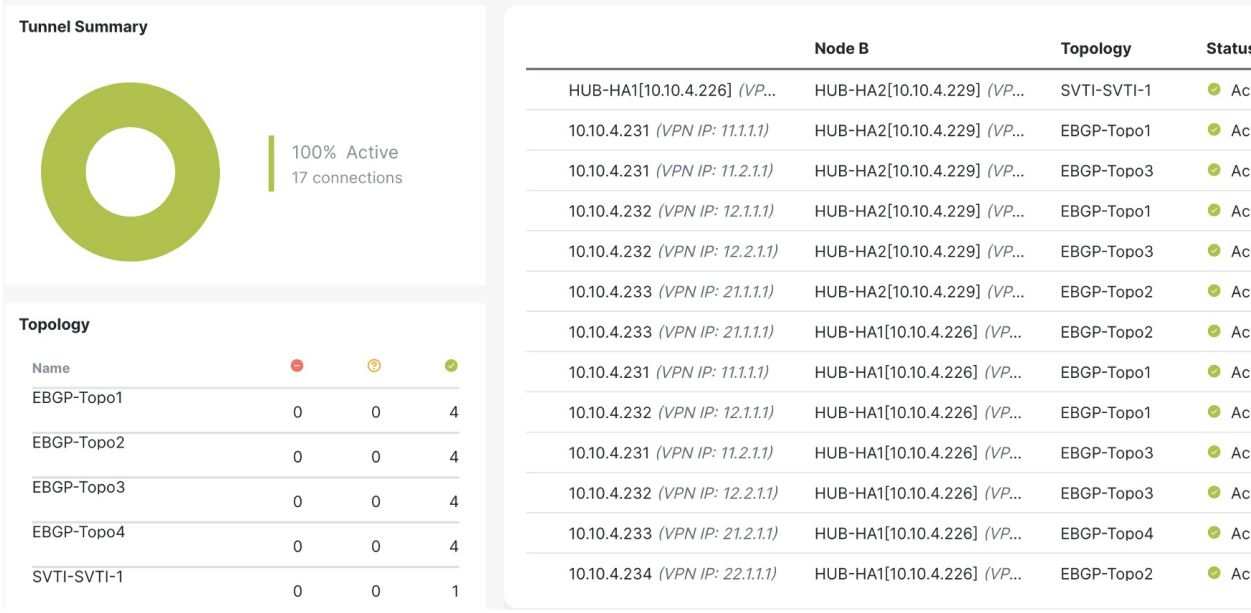


Verify tunnel statuses of an SD-WAN topology

You can verify the tunnel statuses of SD-WAN topologies, including checking VPN tunnel status in the Site-to-Site VPN Summary page and Dashboard, viewing virtual tunnel interfaces on devices, and verifying BGP routing configuration on hubs and branches.

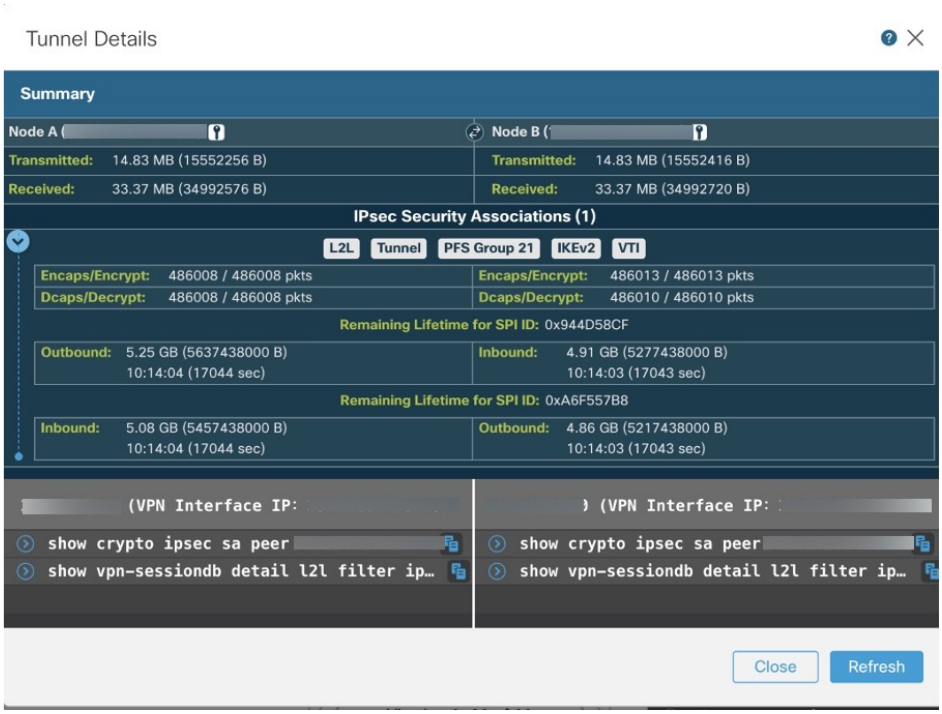
Verify tunnel statuses on the Site-to-Site VPN summary page

To verify if the VPN tunnels of the SD-WAN topologies are up, choose **Devices** > **VPN** > **Site to Site**.



This example shows the five SD-WAN topologies with two hubs and four spokes in different regions that are connected to dual ISPs:

Verify tunnel statuses on the Site-to-Site VPN dashboard

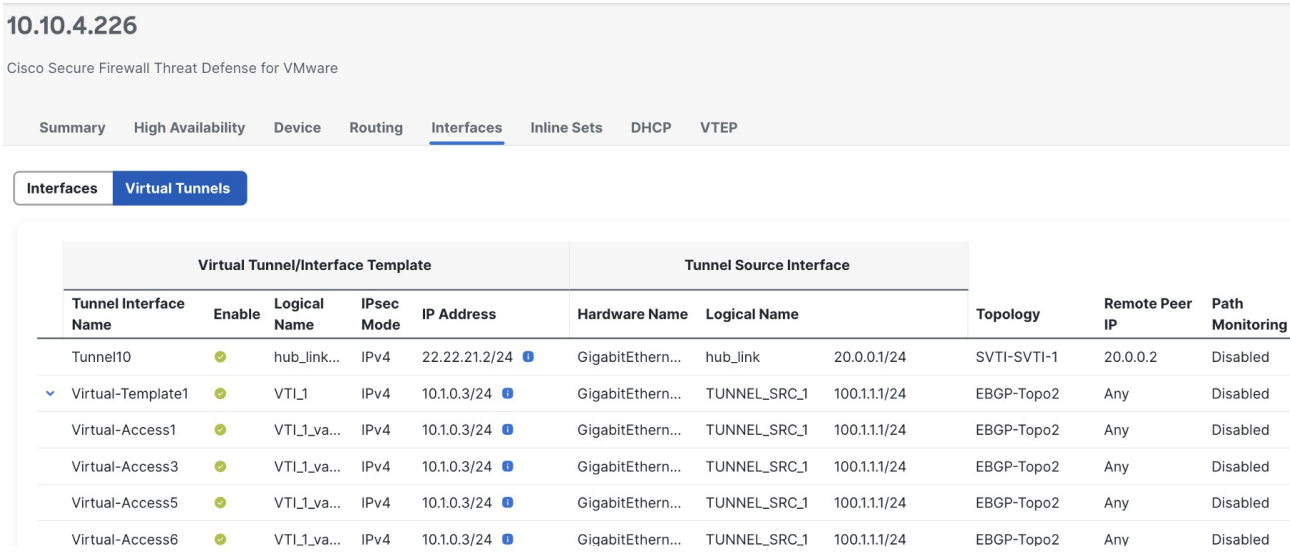


To view details of the SD-WAN VPN tunnels, choose **Overview** > **Dashboards** > **Site to Site VPN**.

This example shows the VPN tunnels for an SD-WAN topology with two hubs and four spokes in different regions that are connected to dual ISPs:

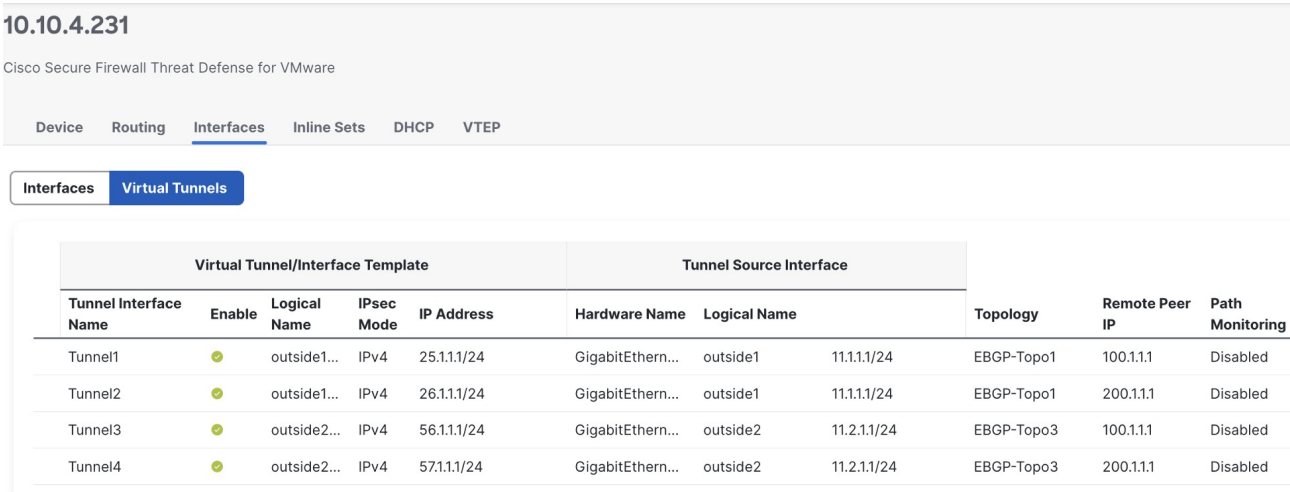
To view more details of each VPN tunnel:

1. Hover over a tunnel.
2. Click the **View Full Information** ( ) icon. A pane with tunnel details and more actions is displayed.
3. Click the **CLI Details** tab in the side pane to view the show commands and details of the IPsec security associations.



View virtual tunnel interfaces of the devices

To view the dynamic VTIs of hubs and static VTIs of spokes:



1. Choose **Devices** > **Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Interface** tab.
4. Click the **Virtual Tunnels** tab.

   For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP.

This image shows an example of the virtual access interfaces created dynamically by a hub's DVTI:

This image shows an example of the static tunnel virtual interfaces (SVTIs) created on a spoke by the SD-WAN wizard:

The SD-WAN wizard assigns IP addresses to these tunnel interfaces from the IP address pool of the hub.

Verify routing in the hub and branch devices

To verify the BGP configuration of the hubs and spokes of the SD-WAN topologies:

1. Choose **Devices** > **Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Device** tab.
4. Click **CLI** in the **General** card. The **CLI Troubleshoot** window appears.
5. Enter one of these commands in the **Command** field and click **Execute**:
   - **show route**
   - **show BGP summary**

Monitor SD-WAN topologies

This section provides information about the different ways to monitor your SD-WAN topologies.

SD-WAN summary dashboard

The SD-WAN Summary dashboard (**Overview** > **Dashboards** > **SD-WAN SummaryAnalysis** > **SD-WAN Summary**) provides a snapshot of your WAN devices and their interfaces. This dashboard helps you to:

- Identify issues with the underlay and overlay (VPN) topologies.
- Troubleshoot VPN issues using the existing **Health Monitoring**, **Device Management**, and **Site-to-Site Monitoring** pages.
- Monitor application performance metrics of WAN interfaces. The threat defense steers application traffic based on these metrics.

For clusters, this dashboard displays application performance metrics of only the control node and not the data nodes.

WAN device criteria

A WAN device must meet one of these criteria:

- The device must be a VPN peer.
- The device must have WAN interface.

WAN interface criteria

A WAN interface must meet one of these criteria:

- The interface has IP address-based path monitoring enabled on it.

- The interface has a Policy Based Routing (PBR) policy with at least one application configured to monitor it.

For more information about PBR policy and path monitoring, see Policy-Based Routing, on page 1541.

Uplink decisions

Click **Uplink Decisions** to view the **VPN Troubleshooting** page. You can view syslogs with ID: 880001. These syslogs show the threat defense interfaces through which it steers traffic based on the configured PBR policy.

To view the above syslogs and to view the data on this dashboard, ensure that you review Prerequisites for using SD-WAN summary dashboard, on page 1806.

Prerequisites for using SD-WAN summary dashboard

Ensure that you review these prerequisites before using the SD-WAN summary dashboard.

General prerequisites

- You must be an Admin, Security Analyst, or Maintenance user to view this dashboard. See Secure Firewall Management Center and Cloud-delivered Firewall Management Center User Role Mapping for more information.
- Threat Defense devices must be Version 7.2 or later.
- Enable IP-based path monitoring and HTTP-based application monitoring on the WAN interfaces.

  To do this:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click the edit icon adjacent to the interface that you want to edit.
  4. Click the **Path Monitoring** tab.
  5. Check the **Enable IP based Monitoring** check box.
  6. Check the **Enable HTTP based Application Monitoring** check box.
  7. Click **OK**.

- Configure a PBR policy with at least one application configured to monitor it:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **Policy Based Routing**.
  5. Click **Add**.
  6. From the **Ingress Interface** drop-down list, choose an interface.
  7. Click **Add** to configure a forwarding action.

8. Configure the parameters.
9. Click **Save**.

- To view syslogs when you click **Uplink Decisions**, you must:
  - Choose **Devices** > **Platform Settings** and create or edit a threat defense policy.
  - In the left pane, click **Syslog**.
  - Click the **Logging Setup** tab.
  - Check the **Enable Logging** check box to turn on the data plane system logging for the threat defense device.
  - Click the **All Logs** radio button to enable logging of all the troubleshooting syslog messages.

    or

    Click the **VPN Logs** radio button to enable logging of only the VPN troubleshooting messages.
  - Click **Save**.

Monitor WAN devices and interfaces using the SD-WAN summary dashboard

The SD-WAN Summary dashboard has these widgets :

- WAN connectivity, on page 1807
- VPN topology, on page 1808
- interface throughput, on page 1808
- Device inventory, on page 1808
- WAN device health, on page 1808

WAN connectivity

This widget provides a summary of the WAN interfaces statuses. It shows the number of WAN interfaces that are in the **Online**, **Offline** or **No Data** states. Note that you cannot monitor subinterfaces using this widget.

Click **View All Interfaces** to view more details about the interfaces in the health monitor page.

If a WAN interface is in the **Offline** or **No Data** state, you can troubleshoot it from the health monitor page:

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click the **Interface** tab to view the interface status and aggregate traffic statistics for a specific time.

   Alternatively, you can click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

VPN topology

This widget provides a summary of the site-to-site VPN tunnel statuses. It shows the number of **Active**, **Inactive**, and **No Active Data** VPN tunnels.

Click **View All Connections** to view the VPN tunnel details in the **Site-to-site VPN Monitoring** dashboard.

If the tunnels are in the **Inactive** or **No Active Data** state, you can troubleshoot using the **Site-to-site VPN Monitoring** dashboard. In the **Tunnel Status** widget, hover your cursor over a topology, click **View** ( ) and do one of these actions:

- Click the **CLI Details** tab to view the details of the VPN tunnels.
- Click the **Packet Tracer** tab to use the packet tracer tool for the topology.

interface throughput

This widget monitors the average throughput of the WAN interfaces during the chosen time period.

The interface throughput is classified into four bands. These details aid in cost planning and resourcing. You can choose a time range for the widget data from the **Show Last** drop-down list. The range is from 15 minutes to two weeks.

Click **View Health Monitoring** to view more details about the interface in the health monitor page.

Device inventory

This widget lists all the managed WAN devices and groups them according to the model.

Click **View Device Management** to view more details about the device in the **Device Management** page.

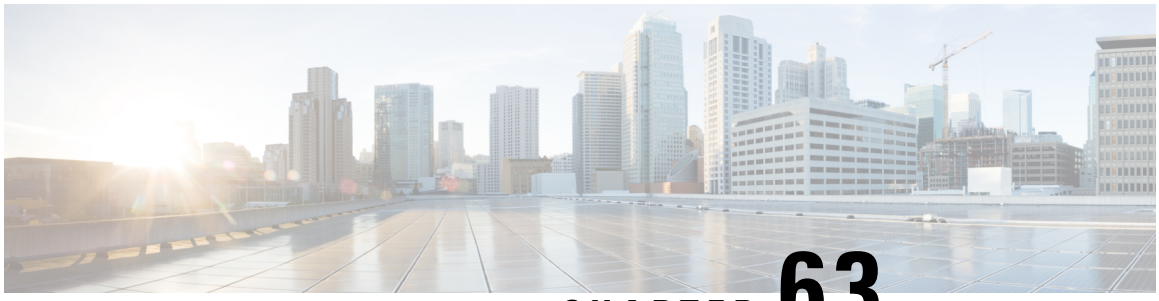
WAN device health

This widget displays the device count according to the health of the WAN devices. You can view the number of devices with errors, warnings, or those that are in **Disabled** state.

Click **View Health Monitoring** to view the alarms, and quickly identify, isolate, and resolve issues.

If the health of a device is affected, you can troubleshoot it from the health monitor page.

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.



A device can be in **Disabled** state for multiple reasons, including these:

- Management interface is disabled.
- Device is powered off.
- Device is being upgraded.

Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard

You can monitor application performance metrics of WAN interfaces using the **Application Monitoring** tab of the SD-WAN Summary dashboard. These metrics include Jitter, Round Trip Time (RTT), Mean Opinion Score (MOS), and Packet Loss.

By default, the metrics data is refreshed every 5 minutes. You can change the refresh time; the range is from 5 to 30 minutes. You can view the metrics in tabular and graphical formats. For each WAN interface, the latest metric value appears in the table. For graphical data, you can choose a time interval of up to 24 hours to view the metrics data for the corresponding WAN interfaces.

CHAPTER 63

Remote Access VPN

Remote Access virtual private network (VPN) allows individual users to connect to your network from a remote location using a computer or other supported devices connected to the Internet. This allows mobile workers to connect from their home networks or a public Wi-Fi network, for example.

The following topics explain how to configure remote access VPN for your network.

- Remote Access VPN Overview, on page 1811
- License Requirements for Remote Access VPN, on page 1817
- Requirements and Prerequisites for Remote Access VPN, on page 1817
- Guidelines and Limitations for Remote Access VPNs, on page 1818
- Configuring a New Remote Access VPN Connection, on page 1821
- Create a Copy of an Existing Remote Access VPN Policy, on page 1831
- Set Target Devices for a Remote Access VPN Policy, on page 1831
- Associate Local Realm with Remote Access VPN Policy, on page 1832
- Additional Remote Access VPN Configurations, on page 1832
- Customizing Remote Access VPN AAA Settings, on page 1890
- Advanced Secure Client Configurations, on page 1910
- Remote Access VPN Examples, on page 1919
- Monitor Remote Access VPNs, on page 1924

Remote Access VPN Overview

Secure Firewall Threat Defense provides secure gateway capabilities that support remote access SSL and IPsec-IKEv2 VPNs. The full tunnel client, Secure Client, provides secure SSL and IPsec-IKEv2 connections to the security gateway for remote users. When the client negotiates an SSL VPN connection with Firewall Threat Defense, it connects using Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS)

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to Firewall Threat Defense devices. The client gives remote users the benefits of an SSL or IPsec-IKEv2 VPN client without the need for network administrators to install and configure clients on remote computers. The Secure Client for Windows, Mac, and Linux is deployed from the secure gateway upon connectivity. The Secure Client apps for Apple iOS and Android devices are installed from the platform app store.

Use the Remote Access VPN policy wizard to set up SSL and IPsec-IKEv2 remote access VPNs with basic capabilities. Then, enhance the policy configuration as you want and deploy it to your Firewall Threat Defense secure gateway devices.

Remote Access VPN Features

The following table describes the features of Secure Firewall Threat Defense remote access VPN:

Table 103: Remote access VPN features

	Description
Secure Firewall Threat Defense remote access VPN features	• SSL and IPsec-IKEv2 remote access using the Secure Client. • Cloud-Delivered Firewall Management Center supports all combinations such as IPv6 over an IPv4 tunnel. • Configuration support on both Cloud-Delivered Firewall Management Center and Firewall Device Manager. Device-specific overrides. • Support for both Cloud-Delivered Firewall Management Center and Firewall Threat Defense HA environments. • Support for multiple interfaces and multiple AAA servers. • Rapid Threat Containment support using RADIUS CoA or RADIUS dynamic authorization. • Support for DTLS v1.2 protocol with Cisco Secure Client version 4.7 or higher. • Secure Client modules support for additional security services for remote access VPN connections. • VPN load balancing.

	Description
AAA features	• Server authentication using self-signed or CA-signed identity certificates. • AAA username and password-based remote authentication using RADIUS server or LDAP or AD. • RADIUS group and user authorization attributes, and RADIUS accounting. • Double authentication support using an additional AAA server for secondary authentication. • NGFW Access Control integration using VPN Identity. • LDAP or AD authorization attributes using Cloud-Delivered Firewall Management Center web interface. • Support for single sign-on using SAML 2.0. • Support for multiple identity provider trustpoints with Microsoft Azure that can have multiple applications for the same Entity ID, but a unique identity certificate. • Restrict remote access VPN connections based on their geolocations.
VPN tunneling features	• Address assignment. • Split tunneling. • Split DNS. • Client Firewall ACLs. • Session Timeouts for maximum connect and idle time.
Remote access VPN monitoring features	• New VPN Dashboard Widget showing VPN users by various characteristics such as duration and client application. • Remote access VPN events including authentication information such as username and OS platform. • Tunnel statistics available using the Firewall Threat Defense Unified CLI.

Secure Client Components

Secure Client Deployment

Your remote access VPN policy can include the Secure Client Image and the Secure Client Profile for distribution to connecting endpoints. Or, the client software can be distributed using other methods. See the *Deploy Cisco Secure Client* chapter in the Cisco Secure Client (including AnyConnect) Administrator Guide, Release 5.

Without a previously installed client, remote users enter the IP address in their browser of an interface configured to accept SSL or IPsec-IKEv2 VPN connections. Unless the security appliance is configured to redirect http:// requests to https://, remote users must enter the URL in the form https://*address*. After the user enters the URL, the browser connects to that interface and displays the login screen.

After a user logs in, if the secure gateway identifies the user as requiring the VPN client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure connection, and either remains or uninstalls itself (depending on the security appliance configuration) when the connection stops. In the case of a previously installed client, after login, the Firewall Threat Defense security gateway examines the client version and upgrades it as necessary.

Secure Client Operation

When the client negotiates a connection with the security appliance, the client connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

When an IPsec-IKEv2 VPN client initiates a connection to the secure gateway, negotiation consists of authenticating the device through Internet Key Exchange (IKE), followed by user authentication using IKE Extended Authentication (Xauth). The group profile is pushed to the VPN client and an IPsec security association (SA) is created to complete the VPN.

Secure Client Profile and Editor

The Secure Client Profile is a group of configuration parameters, stored in an XML file that the VPN client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can configure a profile using the Secure Client Profile Editor. This editor is a convenient GUI-based configuration tool that is available as part of the Secure Client software package. It is an independent program that you run outside of the Cloud-Delivered Firewall Management Center.

Remote Access VPN Authentication

Remote Access VPN Server Authentication

Secure Firewall Threat Defense secure gateways always use certificates to identify and authenticate themselves to the VPN client endpoint.

While you use the Remote Access VPN Policy Wizard, you can enroll the selected certificate on the targeted Firewall Threat Defense device. In the wizard, under **Access & Certificate** phase, select “Enroll the selected certificate object on the target devices” option. The certificate enrollment gets automatically initiated on the specified devices. As you complete the remote access VPN policy configuration, you can view the status of

the enrolled certificate under the device certificate homepage. The status provides a clear standing as to whether the certificate enrollment was successful or not. Your remote access VPN policy configuration is now fully completed and ready for deployment.

Obtaining a certificate for the secure gateway, also known as PKI enrollment, is explained in Certificates, on page 3079. This chapter contains a full description of configuring, enrolling, and maintaining gateway certificates.

Remote Access VPN Client AAA

For both SSL and IPsec-IKEv2, remote user authentication is done using usernames and passwords only, certificates only, or both.

Note If you are using client certificates in your deployment, they must be added to your client's platform independent of the Secure Firewall Threat Defense or Cloud-Delivered Firewall Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

AAA servers enable managed devices acting as secure gateways to determine who a user is (authentication), what the user is permitted to do (authorization), and what the user did (accounting). Some examples of the AAA servers are RADIUS, LDAP/AD, TACACS+, and Kerberos. For Remote Access VPN on Firewall Threat Defense devices, AD, LDAP, and RADIUS AAA servers are supported for authentication.

Refer to the section Understanding Policy Enforcement of Permissions and Attributes to understand more about remote access VPN authorization.

Before you add or edit the remote access VPN policy, you must configure the Realm and RADIUS server groups you want to specify. For more information, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325 and Add a RADIUS server group, on page 2943.

Without DNS configured, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames, it can only resolve IP addresses.

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

Note If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as `sAMAccountName`.) For more information, see User Naming Attributes on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

For more information, see the Identity policies, on page 2505 and Access Control Policies, on page 1997 sections.

Related Topics

Configure AAA Settings for Remote Access VPN, on page 1835

Understanding Policy Enforcement of Permissions and Attributes

The Secure Firewall Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from an external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the Firewall Threat Defense device. If the Firewall Threat Defense device receives attributes from the external AAA server that conflicts with those configured on the group policy, then attributes from the AAA server always take the precedence.

The Firewall Threat Defense device applies attributes in the following order:

1. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
2. **Group policy configured on the Firepower Threat Defense device**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the Firewall Threat Defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.
3. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy applied to the user before authentication.

Note The Firewall Threat Defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. The attributes on the group policy assigned to the connection profile are used for the user session, if they are not overridden by user attributes or the group policy from the AAA server as indicated above.

Related Topics

Configure AAA Settings for Remote Access VPN, on page 1835

Understanding AAA Server Connectivity

LDAP, AD, and RADIUS AAA servers must be reachable from the Firewall Threat Defense device for your intended purposes: user-identity handling only, VPN authentication only, or both activities. AAA servers are used in remote access VPN for the following activities:

- **User-identity handling**— the servers must be reachable over the Management interface.

  On the Firewall Threat Defense, the Management interface has a separate routing process and configuration from data interfaces.

- **VPN authentication**—the servers must be reachable over a data interface or the Management interface.

  To use the Management interface, you must explicitly select Management as the source interface. Other management-only interfaces cannot be used.

To use the same AAA servers for both activities, we recommend specifying the Management interface as the source interface.

For more information about various interfaces, see Regular Firewall Interfaces, on page 1039.

After deployment, use the following CLI commands to monitor and troubleshoot AAA server connectivity from the Firewall Threat Defense device:

- **show aaa-server** to display AAA server statistics.
- **show network** and **show network-static-routes** to view the Management interface default route and static routes.
- **show route** to view data traffic routing table entries.
- **ping system** and **traceroute system** to verify the path to the AAA server through the Management interface.
- **ping interface** *ifname* and **traceroute** *destination* to verify the path to the AAA server through the data interfaces.
- **test aaa-server authentication** and **test aaa-server authorization** to test authentication and authorization on the AAA server.
- **clear aaa-server statistics** *groupname* or **clear aaa-server statistics protocol** *protocol* to clear AAA server statistics by group or protocol.
- **aaa-server** *groupname* **active host** *hostname* to activate a failed AAA server, or **aaa-server** *groupname* **fail host** *hostname* to fail a AAA server.
- **debug ldap level**, **debug aaa authentication**, **debug aaa authorization**, and **debug aaa accounting**.

License Requirements for Remote Access VPN

Threat Defense License

Firewall Threat Defense remote access VPN requires Strong Encryption and one of the following licenses for Secure Client:

- Secure Client Advantage
- Secure Client Premier
- Secure Client VPN Only

Admin

Guidelines and Limitations for Remote Access VPNs

Remote Access VPN Policy Configuration

- You can add a new remote access VPN policy only by using the wizard. You must proceed through the entire wizard to create a new policy; the policy will not be saved if you cancel before completing the wizard.
- Two users must **not** edit a remote access VPN policy at the same time; however, the web interface does not prevent simultaneous editing. If this occurs, the last saved configuration persists.
- Moving a Secure Firewall Threat Defense device from one domain to another domain is not possible if remote access VPN policy is assigned to that device.
- Remote access VPN does not support SSL while using ECMP. We recommend that you use IPsec-IKEv2.
- Remote access VPN does not support clustering.
- Remote access VPN connectivity could fail if there is a misconfigured Firewall Threat Defense NAT rule.
- If you are using DHCP to provide IP addresses to the client, and the client cannot obtain an address, check the NAT rules. Any NAT rule that applies to the RA VPN network should include the route lookup option. Route lookup can help ensure the DHCP requests are sent to the DHCP server through an appropriate interface.
- Whenever IKE ports 500/4500 or SSL port 443 is in use or when there are some PAT translations that are active, the Secure Client IPSec-IKEv2 or SSL remote access VPN cannot be configured on the same port as it fails to start the service on those ports. These ports must not be used on the Firewall Threat Defense device before configuring remote access VPN policy.
- While configuring remote access VPNs using the wizard, you can create in-line certificate enrollment objects, but you cannot use them to install the identity certificate. Certificate enrollment objects are used for generating the identity certificate on the Firewall Threat Defense device being configured as the remote access VPN gateway. Install the identity certificate on the device before deploying the remote access VPN policy to the device.

  For more information about how to install the identity certificate based on the certificate enrollment object, see Use the object manager, on page 2932.
- The ECMP zone interfaces can be used in remote access VPN with IPsec enabled.
- The ECMP zone interfaces cannot be used in remote access VPN with SSL enabled. Deployment of remote access VPN (SSL enabled) configuration fails if all the remote access VPN interfaces that belong to security zones or interface groups also belong to one or more ECMP zones. However, if only some of the remote access VPN interfaces belonging to the security zones or interface groups also belongs to one or more ECMP zones, deployment of the remote access VPN configuration succeeds excluding those interfaces.
- After you change the remote access VPN policy configurations, re-deploy the changes to the Firewall Threat Defense devices. The time it takes to deploy configuration changes depends on multiple factors such as complexity of the policies and rules, type and volume of configurations you send to the device, and memory and device model. Before deploying remote access VPN policy changes, review the Best practices for deploying configuration changes, on page 200.

- Issuing commands such as **curl** against the RA VPN headend is not directly supported, and might not have desirable results. For example, the headend does not respond to HTTP HEAD requests.
- Firewall Threat Defense does not accept remote access VPN sessions if the third-party client sends a null user agent.
- You can configure browser proxy using FlexConfig.
- When **Bypass Access Control policy for decrypted traffic** is disabled on a Firewall Threat Defense and ISE issues a DACL, traffic is first matched against the ACP: if permitted, it proceeds to DACL checking; if denied, it bypasses DACL matching.

Concurrent VPN Sessions Capacity Planning (Firewall Threat Defense Virtual Models)

The maximum concurrent VPN sessions are governed by the installed Firewall Threat Defense Virtual smart-licensed entitlement tier, and enforced via a rate limiter. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the licensed device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firewall Threat Defense Virtual5	50
Firewall Threat Defense Virtual10	250
Firewall Threat Defense Virtual20	250
Firewall Threat Defense Virtual30	250
Firewall Threat Defense Virtual50	750
Firewall Threat Defense Virtual100	10,000

Concurrent VPN Sessions Capacity Planning (Hardware Models)

The maximum concurrent VPN sessions are governed by platform-specific limits and have no dependency on the license. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firepower 1010	75
Firepower 1120	150
Firepower 1140	400
Firepower 2110	1500
Firepower 2120	3500
Firepower 2130	7500

Device Model	Maximum Concurrent Remote Access VPN Sessions
Firepower 2140	10,000
Secure Firewall 3110	3000
Secure Firewall 3120	6000
Secure Firewall 3130	15,000
Secure Firewall 3140	20,000
Firepower 4100, all models	10,000
Firepower 9300 appliance, all models	20,000
ISA 3000	25

For capacity of other hardware models, contact your sales representative.

Note The Firewall Threat Defense device denies the VPN connections once the maximum session limit per platform is reached. The connection is denied with a syslog message. Refer the syslog messages %ASA-4-113029 and %ASA-4-113038 in the syslog messaging guide. For more information, see Cisco Secure Firewall ASA Series Syslog Messages.

Controlling Cipher Usage for VPN

To prevent use of ciphers greater than DES, pre-deployment checks are available at the following locations in the Cloud-Delivered Firewall Management Center:

Devices > **Platform Settings**, click **Edit** and then **SSL**.

Devices > **VPN** > **Remote Access**, click **Edit**, and then from **Advanced** drop-down list, choose **IPsec**.

For more information about SSL settings and IPsec, see Configure SSL settings, on page 1278 and Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1866.

Authentication, Authorization, and Accounting

Configure DNS on each device in the topology in to use remote access VPN. Without DNS, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames; it can only resolve IP addresses.

You can configure DNS using the **Platform Settings**. For more information, see Configure DNS server settings, on page 1246 and DNS server groups, on page 2965.

Client Certificates

If you are using client certificates in your deployment, they must be added to your client's platform independent of the Secure Firewall Threat Defense or Cloud-Delivered Firewall Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

Unsupported Features of Secure Client

The only supported VPN client is the Cisco Secure Client. No other clients or native VPNs are supported. Clientless VPN is not supported for VPN connectivity; it is only used to deploy the Secure Client using a web browser.

Note Using multiple Secure Client packages on Firewall Threat Defense devices can increase memory usage and affect the device's performance. We recommend that you do not use multiple Secure Client packages on low-end threat defense devices to avoid continuous reboots because of memory exhaustion.

The following Secure Client features are not supported when connecting to a Firewall Threat Defense secure gateway:

- TACACS, Kerberos (KCD Authentication and RSA SDI), and SDI.

Configuring a New Remote Access VPN Connection

This section provides instructions to configure a new remote access VPN policy with Secure Firewall Threat Defense devices as VPN gateways and Cisco Secure Client as the VPN client.

Step	Do This	More Info
1	Review the guidelines and prerequisites.	Guidelines and Limitations for Remote Access VPNs, on page 1818 Prerequisites for Configuring Remote Access VPN, on page 1822
2	Create a new remote access VPN policy using the wizard.	Create a New Remote Access VPN Policy, on page 1822
3	Update the access control policy deployed on the device.	Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1825
4	(Optional) Configure a NAT exemption rule if NAT is configured on the device.	(Optional) Configure NAT Exemption, on page 1826
5	Configure DNS.	Configure DNS, on page 1827
6	Add Secure Client Profile.	Add Secure Client Profile XML File, on page 1827
7	Deploy the remote access VPN policy.	Deploy configuration changes, on page 202
8	(Optional) Verify the remote access VPN policy configuration.	Verify the Configuration, on page 1830

Prerequisites for Configuring Remote Access VPN

- Deploy Secure Firewall Threat Defense devices and configure Cloud-Delivered Firewall Management Center to manage the device with required licenses with export-controlled features enabled. For more information, see VPN licensing, on page 1714.
- Configure the certificate enrollment object that is used to obtain the identity certificate for each Firewall Threat Defense device that act as a remote access VPN gateway.
- Configure any AD or LDAP realms being used by remote access VPN policies.
- During migration of Firewall Threat Defense with remote access VPN, the realm (LDAP, AD or even local) used in remote access VPN policy should be preconfigured on Cloud-Delivered Firewall Management Center before you migrate the policy.
- Ensure that the AAA server is reachable from the Firewall Threat Defense device. Configure routing (**Devices** > **Device Management**, click the **Edit** icon. From the left pane, choose **Routing**) to ensure connectivity to the AAA servers.

  For remote access VPN double authentication, ensure that both the primary and secondary authentication servers are reachable from the Firewall Threat Defense device.
- Purchase and enable one of the following Cisco Secure Client licenses: Secure Client Advantage, Secure Client Premier, or Secure Client VPN Only to enable the Firewall Threat Defense remote access VPN.
- Download the latest Secure Client image files from Cisco Software Download Center.

  On your Cloud-Delivered Firewall Management Center web interface, go to **Objects** > **Object Management** > **VPN** > **Secure Client File** and add the new Secure Client image files.
- Create a security zone or interface group that contains the network interfaces that users will access for VPN connections. See Interfaces, on page 2980.
- Download the Secure Client Profile Editor from Cisco Software Download Center to create the Secure Client profile. You can use the standalone profile editor to create a new or modify an existing Secure Client profile.

Create a New Remote Access VPN Policy

The Remote Access VPN Policy Wizard guides you to quickly and easily set up remote access VPNs with basic capabilities. You can further enhance the policy configuration by specifying additional attributes as you want and deploy it to your Secure Firewall Threat Defense secure gateway devices.

Before you begin

- Ensure that you complete all the prerequisites listed in Prerequisites for Configuring Remote Access VPN, on page 1822.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Add** to create a new remote access VPN policy with basic policy configuration, using the Remote Access VPN Policy wizard.

You must proceed through the entire wizard to create a new policy; the policy is not saved if you cancel before you complete the wizard.

Step 3 Select the target devices and protocols.

The Firewall Threat Defense devices that you select here functions as your remote access VPN gateways for the VPN client users.

You can select Firewall Threat Defense devices when you create a remote access VPN policy or change them later. See Set Target Devices for a Remote Access VPN Policy, on page 1831.

You can select **SSL** or **IPSec-IKEv2**, or both the VPN protocols. Firewall Threat Defense supports both the protocols to establish secure connections over a public network through VPN tunnels.

Note
Firewall Threat Defense does not support IPSec tunnels with NULL encryption. If you have selected IPSec-IKEv2, make sure that you do not choose NULL encryption for IPSec IKEv2 proposal. See Configure an IKEv2 IPsec proposal object, on page 3071.

For SSL settings, see Configure SSL settings, on page 1278.

Step 4 Click **Next**.

Step 5 Configure the **Connection Profile** and **Group Policy** settings.

A connection profile specifies a set of parameters that define how the remote users connect to the VPN device. The parameters include settings and attributes for authentication, address assignments to VPN clients, and group policies. Firewall Threat Defense device provides a default connection profile named *DefaultWEBVPNGroup* when you configure a remote access VPN policy.

For more information, see Configure Connection Profile Settings, on page 1832.

Step 6 Configure the **Authentication, Authorization & Accounting** settings.

For information about configuring,

- AAA settings, see Configure AAA Settings for Remote Access VPN, on page 1835
- LDAP attribute maps, see Configuring LDAP Attribute Mapping, on page 1858
- SAML 2.0 single sign-on authentication, see Configuring a SAML Single Sign-On Authentication, on page 1908

Step 7 Configure the **Client Address Assignment** settings.

Client IP address can be assigned from AAA server, DHCP server and IP address pools. When multiple options are selected, IP address assignment is done in the order of AAA server, DHCP server, and IP address pool. Assignment of client IP addresses from the AAA server is supported only for realm and RADIUS authorization. Ensure that realm or RADIUS server is configured to provide client IP address.

Step 8 Configure the **Group Policy** settings.

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience for VPN users. You configure attributes such as user authorization profile, IP addresses, Secure Client settings, VLAN mapping, and user session settings and so on using the group policy. The

RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile. For more information, see Configuring Group Policies, on page 1857.

Step 9 Click **Next**.

Step 10 Select the **Secure Client Image** that the VPN users will use to connect to the remote access VPN.

The Secure Client provides secure SSL or IPSec (IKEv2) connections to the Secure Firewall Threat Defense device for remote users with full VPN profiling to corporate resources. After the remote access VPN policy is deployed on the Firewall Threat Defense device, VPN users can enter the IP address of the configured device interface in their browser to download and install the Secure Client.

For information about configuring the client profile and client modules, see Group policy options for Secure Client, on page 3065.

Step 11 Click **Next**.

Step 12 Configure **Network Interface for Incoming VPN Access**.

Interface objects segment your network to help you manage and classify traffic flow. A security zone object simply groups interfaces. These groups may span multiple devices; you can also configure multiple zones interface objects on a single device. There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

(Optional) Check the **Enable DTLS on member interfaces** check box, if required. DTLS is applicable only for SSL protocol.

Step 13 Configure **Device Certificates**.

Device certificate (also called Identity certificate) identifies the VPN gateway to the remote access clients. Select a certificate which is used to authenticate the VPN gateway. From the **Certificate Enrollment** drop-down list, choose a certificate or click **+** to add a certificate to authenticate the VPN gateway.

Step 14 Configure **Service Access Control**.

You can use a service access object to control remote clients' access to VPN on Firewall Threat Defense devices with Version 7.7 or later. This object provides geolocation-based access control to clients before VPN authentication. By default, there is no access control for RAVPN, and remote clients can connect from any geolocation unless specified by a service access object. For more information, see Manage VPN Access of Remote Users Based on Geolocation, on page 1886and Configure a service access object, on page 2952.

Step 15 Configure **Access Control for VPN Traffic** .

By default, all decrypted traffic in the VPN tunnel is subjected to the Access Control Policy. Check the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** check box to bypass decrypted traffic from the Access Control Policy. This option bypasses the Access Control Policy inspection, but VPN filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

Note
If you select this option, you need not update the access control policy for remote access VPN as specified in Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1825.

Step 16 Click **Next**.

Step 17 View the **Summary** of the remote access VPN policy configuration.

The Summary page displays all the remote access VPN settings you have configured so far and provides links to the additional configurations that need to be performed before deploying the remote access VPN policy on the selected devices.

Click **Back** to make changes to the configuration, if required.

Step 18 Click **Finish** to complete the basic configuration for the remote access VPN policy.

When you complete the Remote Access VPN Policy Wizard, the policy listing page appears. Later, set up DNS configuration, configure access control for VPN users, and enable NAT exemption (if necessary) to complete a basic remote access VPN Policy configuration.

What to do next

Use the Remote Access VPN dashboard (**Overview** > **Dashboards** > **Remote Access VPN**) to monitor real-time data from active remote access VPN sessions on the devices. You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

Update the Access Control Policy on the Secure Firewall Threat Defense Device

Before deploying the remote access VPN policy, you must update the access control policy on the targeted Secure Firewall Threat Defense device with a rule that allows VPN traffic. The rule must allow all traffic coming in from the outside interface, with source as the defined VPN pool networks and destination as the corporate network.

Note If you have selected the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** option on the Access Interface tab, you need not update the access control policy for remote access VPN.

Enable or disable the option for all your VPN connections. If you disable this option, make sure that the traffic is allowed by the access control policy or pre-filter policy.

For more information, see Configure Access Interfaces for Remote Access VPN, on page 1851.

Before you begin

Complete the remote access VPN policy configuration using the Remote Access VPN Policy wizard.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** on the access control policy that you want to update.

Step 3 Click **Add Rule** to add a new rule.

Step 4 Specify the **Name** for the rule and select **Enabled**.

Step 5 Select the **Action**, **Allow** or **Trust**.

Step 6 Select the following on the **Zones** tab:

a) Select the outside zone from Available Zones and click **Add to Source**.

b) Select the inside zone from Available Zones and click **Add to Destination**.

Step 7 Select the following on the **Networks** tab:

a) Select the inside network (inside interface and/or a corporate network) from Available networks and click **Add to Destination**.

b) Select the VPN address pool network from **Available Networks** and click **Add to Source Networks**.

Step 8 Configure other required access control rule settings and click **Add**.

Step 9 Save the rule and access control policy.

(Optional) Configure NAT Exemption

NAT exemption exempts addresses from translation and allows both translated and remote hosts to initiate connections with your protected hosts. Like identity NAT, you do not limit translation for a host on specific interfaces; you must use NAT exemption for connections through all interfaces. However, NAT exemption enables you to specify the real and destination addresses when determining the real addresses to translate (similar to policy NAT). Use static identity NAT to consider ports in the access list.

When you configure static identity NAT for remote access or site-to-site VPN, you must configure NAT with the route lookup option. Without route lookup, the Firewall Threat Defense sends traffic out of the interface specified in the NAT command, regardless of what the routing table says. For example, you do not want the Firewall Threat Defense to send the DHCP scope traffic through an incorrect interface; it will never return to the interface IP address. The route lookup option lets the Firewall Threat Defense send, or intercept, the traffic directly on the interface IP address instead of through the interface. For traffic from the VPN client to a host on the inside network, the route lookup option will still result in the correct egress interface (inside), so normal traffic flow is not affected.

Before you begin

Check if NAT is configured on the targeted devices where remote access VPN policy is deployed. If NAT is enabled on the targeted devices, you must define a NAT policy to exempt VPN traffic.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, click **Devices** > **NAT**.

Step 2 Select a NAT policy to update or click **New Policy** > **Threat Defense NAT** to create a NAT policy with a NAT rule to allow connections through all interfaces.

Step 3 Click **Add Rule** to add a NAT rule.

Step 4 On the Add NAT Rule window, select the following:

a) Select the NAT Rule as **Manual NAT Rule**.

b) Select the Type as **Static**.

c) Click **Interface Objects** and select the Source and destination interface objects.

Note

This interface object must be the same as the interface selected in the remote access VPN policy.

For more information, see Configure Access Interfaces for Remote Access VPN, on page 1851.

a) Click **Translation** and select the source and destination networks:

- **Original Source** and **Translated Source**
- **Original Destination** and **Translated Destination**

Step 5 On the Advanced tab, select **Do not proxy ARP on Destination Interface**.

Do not proxy ARP on Destination Interface—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router.

Step 6 Click **OK**.

Configure DNS

Configure DNS on each Firewall Threat Defense device in order to use remote access VPN. Without DNS, the devices cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames. It can only resolve IP addresses.

Procedure

Step 1 Configure DNS server details and domain-lookup interfaces using the Platform Settings. For more information, see Configure DNS server settings, on page 1246 and DNS server groups, on page 2965.

Step 2 Configure split-tunnel in group policy to allow DNS traffic through remote access VPN tunnel if the DNS server is reachable through VNP network. For more information, see Configure a group policy object, on page 3062.

Add Secure Client Profile XML File

The Secure Client Profile is a group of configuration parameters stored in an XML file that the client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can create the Secure Client Profile using the Secure Client Profile Editor, a GUI-based configuration tool that is available as part of the Secure Client software package. It is an independent program that you run outside of the Cloud-Delivered Firewall Management Center. For more information about Secure Client Profile Editor, see Cisco Secure Client (including AnyConnect) Administrator Guide.

Before you begin

A Secure Firewall Threat Defense remote access VPN policy requires assignment of the Secure Client Profile to the VPN clients. You can attach the client profile to a group policy.

Download the Secure Client Profile Editor from Cisco Software Download Center.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy which you want to update.

Step 3 Click **Edit** on the connection profile to which you want to add the Secure Client profile.

Step 4 Click **Edit Group Policy**. If you choose to add a new group policy, click **Add**.

Step 5 Choose **Secure Client** > **Profile**.

Step 6 Choose a profile from the **Client Profile** drop-down list. If you choose to add a new client profile, click **Add** and do the following:

a) Specify the profile **Name**.

b) Click **Browse** and select the Secure Client Profile XML file.

Note
For two-factor authentication, make sure that the timeout is set to 60 seconds or more in the Secure Client profile.

c) Click **Save**.

Step 7 Save your changes.

(Optional) Configure Split Tunneling

Split tunnel allows VPN connectivity to a remote network across a secure tunnel and also to a network outside VPN tunnel. Configure split tunneling if you want to allow your VPN users to access an outside network while they remain connected to the remote access VPN. To configure a split-tunnel list, you must create a Standard Access List or Extended Access List.

For more information, see Configuring Group Policies, on page 1857.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy for which you want to configure split tunneling.

Step 3 Click **Edit** on the required connection profile.

Step 4 Click **Add** to add a group policy or click **Edit Group Policy**.

Step 5 Choose **General** > **Split Tunneling**.

Step 6 From the **IPv4 Split Tunneling** or **IPv6 Split Tunneling** list, select **Exclude networks specified below** and then select the networks that you want to exclude from VPN traffic.

The default setting allows all traffic over the VPN tunnel.

Step 7 Click **Standard Access List** or **Extended Access List**, and select an access list from the drop-down or add a new one.

Step 8 If you choose to add a new standard or extended access list, do the following:

a) Specify the **Name** for the new access list and click **Add**.
b) Choose **Allow** from the **Action** drop-down.
c) Select the network traffic that you want to allow over the VPN tunnel and click **Add**.

Step 9 Save your changes.

Related Topics

Access lists, on page 2948

(Optional) Configure Dynamic Split Tunneling

Dynamic split tunneling allows you to fine-tune split tunneling based on DNS domain names. You can configure domains that must be included or excluded in the remote access VPN tunnel. Excluded domains are not blocked. Instead, traffic to those domains is kept outside the VPN tunnel. For example, you could send traffic to Cisco WebEx on the public Internet, thus freeing bandwidth in your VPN tunnel for traffic that is targeted to servers within your protected network. For more information about configuring this feature, see Configure AnyConnect Dynamic Split Tunnel on FTD Managed by FMC.

Before you begin

You can configure this feature using the Cloud-Delivered Firewall Management Center and Firewall Threat Defense from versions 7.0 or later. If you have an older version of the Cloud-Delivered Firewall Management Center, you can configure it using FlexConfig as instructed in the Advanced AnyConnect VPN Deployments for Firepower Threat Defense with FMC.

Procedure

Step 1 Configure the group policy to use Dynamic Split Tunnel.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click **Edit** on the remote access VPN policy for which you want to configure dynamic split tunneling.
c) Click **Edit** on the required connection profile.
d) Click **Edit Group Policy**.

Step 2 Configure the Secure Client custom attribute in the **Add/Edit Group Policy** dialog box.

a) Click the Secure Client tab.
b) Click **Custom Attributes** and click **+**.
c) Choose **Dynamic Split Tunneling** from the **Secure Client Attribute** drop-down list.
d) Click **+** to create a new custom attribute object.
e) Enter the name for the custom attribute object.
f) **Include domains**—Specify domain names that will be included in the remote access VPN tunnel.

You can include domains in the tunnel that will be excluded based on IP addresses.

g) **Exclude domains**—Specify domain names that will be excluded from the remote access VPN.

Excluded domains are not blocked, traffic to these domains is kept outside the VPN tunnel.

h) Click **Save**.

i) Click **Add**.

Step 3 Verify the configured custom attribute and click **Save** to save the group policy.

Step 4 Click **Save** to save the connection profile.

Step 5 Click **Save** to save the remote access VPN policy.

What to do next

1. Deploy the configuration to Firewall Threat Defense.
2. Verify the configured dynamic split tunnel configuration on the Firewall Threat Defense and the Secure Client. For more information, see Verify Dynamic Split Tunneling Configuration, on page 1830.

Verify Dynamic Split Tunneling Configuration

On the Firewall Threat Defense

Use the following commands to verify the dynamic split tunneling configuration:

- **show running-config webvpn**
- **show running-config anyconnect-custom-data**
- **show running-config group-policy** <*group-policy-name*>

On the Secure Client

Click the Statistics () icon and choose **VPN > Statistics**. You can confirm the domains under the Dynamic Split Exclusion/Inclusion category.

Verify the Configuration

Procedure

Step 1 Open a web browser on a machine on the outside network.

Step 2 Enter the URL of the Firewall Threat Defense remote access VPN gateway device.

Step 3 Enter the username and password when prompted, and click **Logon**.

Note
Connection to the VPN establishes automatically if you install Secure Client on the system.

The VPN prompts you to download Secure Client if Secure Client is not installed.

Step 4 Download Secure Client if it is not installed and connect to the VPN.
The Secure Client installs itself. On successful authentication, you establish connection to the Secure Firewall Threat Defense remote access VPN gateway. The remote access VPN enforces the applicable identity or QoS policy according to your VPN policy configuration.

Create a Copy of an Existing Remote Access VPN Policy

You can copy an existing remote access VPN policy to create a new one with all the settings, including the connection profiles and access interfaces. You can then assign devices to the new policy and deploy the VPN on the assigned devices as required.

Note Users with read-only permission for remote access VPN cannot create copy of the VPN. Users with read-only privileges in the domain can copy the remote access VPNs.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.
Step 2 Click **Copy** on the policy that you want to copy.
Step 3 Specify a **Name** for the new remote access VPN.
Step 4 Click **OK**.

What to do next

To assign devices to the new policy, see Set Target Devices for a Remote Access VPN Policy, on page 1831.

Set Target Devices for a Remote Access VPN Policy

After you create remote access VPN policy, you can assign the policy to threat defense devices.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.
Step 2 Click **Edit** ( ) next to the remote access VPN policy that you want to edit.
Step 3 Click **Policy Assignments**.
Step 4 Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add**. You can also drag and drop the available devices to select.

- To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

Step 5 Click **OK**.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Associate Local Realm with Remote Access VPN Policy

You can associate local realm to remote access VPN policy to enable local user authentication.

For information about creating and managing realms, see Manage a realm, on page 2341.

For information about configuring local user authentication for remote access VPNs, see Configure AAA Settings for Remote Access VPN, on page 1835.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** ( ) next to the remote access VPN policy that you want to edit.

Step 3 Click the link next to **Local Realm**.

Step 4 Select the **Local Realm Server** from the list, or click **Add** to add a new local realm.

Step 5 Click **OK**.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Additional Remote Access VPN Configurations

Configure Connection Profile Settings

Remote Access VPN policy contains the connection profiles targeted for specific devices. These policies pertain to creating the tunnel itself, such as, how AAA is accomplished, and how addresses are assigned (DHCP or Address Pools) to VPN clients. They also include user attributes, which are identified in group policies configured on the Firewall Threat Defense device or obtained from a AAA server. A device also

provides a default connection profile named *DefaultWEBVPNGroup*. The connection profile that is configured using the wizard appears in the list.

If you decide to grant different rights to different groups of VPN users, then you can add specific connection profiles for each of the user groups and maintain multiple connection profiles in your remote access VPN policy.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Select a **Connection Profile** and click **Edit**.

Step 4 (Optional) If you choose to add new connection profile, click **Add**.

Step 5 Configure IP Addresses for VPN Clients.
Configure IP Addresses for VPN Clients, on page 1833

Step 6 (Optional) Update AAA Settings for remote access VPNs.
Configure AAA Settings for Remote Access VPN, on page 1835

Step 7 (Optional) Create or update Aliases.
Create or Update Aliases for a Connection Profile, on page 1850

Step 8 Save your changes.

Configure IP Addresses for VPN Clients

Client address assignment allows you to assign IP addresses for the remote access VPN users.

You can assign IP Address for remote VPN clients from the local IP address pools, DHCP Servers, and AAA servers. The AAA servers are assigned first, followed by others. Configure the **Client Address Assignment** policy in the **Advanced** tab to define the assignment criteria. The IP pools defined in this connection profile will only be used if no IP pools are defined in group policy associated with the connection profile, or the system default group policy **DfltGrpPolicy**.

IPv4 Address Pools—SSL VPN clients receive new IP addresses when they connect to the Firewall Threat Defense device. Address pools define a range of addresses that remote clients can receive. You can add a maximum of six pools for IPv4 and IPv6 addresses each.

Note You can use the IP address from the existing IP pools in the Cloud-Delivered Firewall Management Center or create a new pool using the **Add** option. Also, you can create an IP pool in Cloud-Delivered Firewall Management Center using the **Objects** > **Object Management** > **Address Pools** path. For more information, see Configure address pools, on page 2954.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Existing remote access policies are listed.

Step 2 Select a remote access VPN policy and click the edit icon.

Step 3 Select the connection profile that you want to update and click the edit icon.

Step 4 Under the **Client Address Assignment** tab, do the following:

Step 5 Click + next to **Address Pools**:

a) Click + next to **Address Pools** to add IP addresses, and select **IPv4** or **IPv6** to add the corresponding address pool. Select the IP address pool from **Available Pools** and click **Add**.

Note
If you share your remote access VPN policy among multiple Secure Firewall Threat Defense devices, bear in mind that all devices share the same address pool unless you use device-level object overrides to replace the global definition with a unique address pool for each device. Unique address pools are required to avoid overlapping addresses in cases where the devices are not using NAT.

b) Click + next to **Available Pools** in the **Address Pools** window to add a new IPv4 or IPv6 address pool. When you choose the IPv4 pool, provide a starting and ending IP address. When you choose to include a new IPv6 address pool, enter **`Number of Addresses`** in the range 1-16384. Select the **Allow Overrides** option to avoid conflicts with IP address when objects are shared across many devices. For more information, see Configure address pools, on page 2954.

c) Click **OK**.

If you plan to edit the IP address pools, we recommend that you perform the following steps during a maintenance window:

1. Unassign the device from the remote access VPN.
2. Select the device and click **Deploy**.

   This deployment removes all the remote access VPN configurations from the device, terminates the remote access VPN sessions, the sessions are not reestablished.
3. Click the edit icon next to the IP address pools to edit it, edit any other remote access VPN configurations, if required, on the Cloud-Delivered Firewall Management Center.
4. Assign the device to the updated remote access VPN policy.
5. Deploy the configurations on the device.

   The remote access VPN clients can connect to the device after the maintenance window.

Step 6 Click + next to **DHCP Servers** to add DHCP servers:

Note
The DHCP server address can be configured only with IPv4 address.

a) Specify the name and DHCP (Dynamic Host Configuration Protocol) server address as network objects. Click **Add** to choose the server from the object list. Click **Delete** to delete a DHCP server.

b) Click **Add** in the **New Objects** page to add a new network object. Enter the new object name, description, network, and select the **Allow Overrides** option as applicable. For more information, see Create a network object, on page 2985 and Allow object overrides, on page 2941.

c) Click **OK**.

Step 7 Click **Save**.

Related Topics

Configure Connection Profile Settings, on page 1832

Configure AAA Settings for Remote Access VPN

Before you begin

- Ensure that the required machine and user certificates are deployed on the endpoints. For information about Firewall Threat Defense certificates, see Manage Firewall Threat Defense certificates, on page 3080.
- Configure Secure Client profiles with required certificates. For more information, see *Cisco Secure Client (including AnyConnect) Administrator Guide*.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Select a connection profile to update AAA settings, click **Edit** and then choose**AAA**.

Step 4 Select the following for **Authentication**:

- **Authentication Method**—Determines how a user is identified before being allowed access to the network and network services. It controls access by requiring valid user credentials, which are typically a username and password. It may also include the certificate from the client. Supported authentication methods are **AAA only**, **Client Certificate only**, and **AAA + Client Certificate**.

  When you select the **Authentication Method** as:

  - **AAA Only**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must select the **Authorization Server** and **Accounting Server** manually.
  - **SAML**—Each user is authenticated using the SAML single sign-on server. For more information, see Single Sign-On Authentication with SAML 2.0, on page 1906.

    Override Identity Provider Certificate—Select to override the primary identity provider certificate of the SAML provider with an IdP certificate specific to a connection profile or SAML application. Select the IdP certificate from the drop-down.

    Microsoft Azure can support multiple applications for the same entity ID. Each application (mapped to a different connection profile) requires a unique certificate. If you want to retain an existing entity ID for the single-sign-on object in current connection profile and use a different IdP certificate, you can select this option.

    This enables support for multiple SAML applications per Microsoft Azure SAML identity provider.

    The primary identity certificate is configured in the single sign-on server object.

    For information about configuring a single sign-on server object, see Add a single sign-on server, on page 2946.

    Choose your **SAML Login Experience** to configure a browser for SAML web authentication:

- **VPN client embedded browser**—Choose this option to use the browser embedded with the VPN client for web authentication. The authentication applies to the VPN connection only.
- **Default OS Browser**—Choose this option to configure the operating system that default or native browser that supports WebAuthN (FIDO2 standard for web authentication). This option enables single sign-on(SSO) support for web authentication methods such as biometric authentication.

  The default browser requires an external browser package for web authentication. The package Default-External-Browser-Package is configured by default. You can change the default external browser package by editing a remote access VPN policy and selecting the file under **Advanced** and choose **AnyConnect Client ImagesSecure Client Image**s, then click **Package File**.

  You can also add a new package file by selecting. **Objects** > **Object Management** > **VPN** > **Secure Client File** and then click **Add Secure Client File**.

- **Client Certificate Only**—Each user is authenticated with a client certificate. The client certificate must be configured on VPN client endpoints. By default, the user name is derived from the client certificate fields CN and OU. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

  Select **Enable multiple certificate authentication** to authenticate the VPN client using the machine and user certificates.

  If have enabled multiple certificate authentication, you can select one of the following certificates to map the username and authenticate the VPN user:

  - **First Certificate**—Select this option to map the username from the machine certificate sent from the VPN client.
  - **Second Certificate**—Select this option to map the username from the user certificate sent from the client.

  Note
  If you do not enable multiple certificate authentication, the user certificate (second certificate) is used for authentication by default.

  If you select the **Map specific field** option, which includes the username from the client certificate, the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

  The primary and Secondary fields pertaining to the **Map specific field** option contain these common values:

  - C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier)
  - EA (Email Address)
  - GENQ (Generational Qualifier)

- GN (Given Name)
- I (Initial)
- L (Locality)
- N (Name)
- O (Organisation)
- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

- **Client Certificate & AAA**— Each user is authenticated with both a client certificate and AAA server. Select the required certificate and AAA configurations for authentication.

  Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

- **Client Certificate & SAML**— Each user is authenticated with both a client certificate and SAML server. Select the required certificate and SAML configurations for authentication.
  - **Allow connection only if username from certificate and SAML are the same**—Select to allow VPN connection only if the username from the certificate matches the SAML single sign-on username.
  - **Use username from client certificate for Authorization**—When you choose the option to pick username from client certificate for authorization, you must configure the fields to pick from the client certificate.

    You can choose to map a specific filed as the username or use the entire distinguished name (DN) for authorization:
    - **Map specific field**— Select to include the username from the client certificate; the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively.
    - **Use entire DN as username**— The system automatically retrieves the user identity for authorization.

You can also create a Dynamic Access Policy (DAP) to match user-specific SAML assertion attributes or username to DAP certificate attributes. See Configure AAA criteria settings for a DAP record, on page 1932.

- **Authentication Server**—Authentication is the way a user is identified before being allowed access to the network and network services. Authentication requires valid user credentials, a certificate, or both. You can use authentication alone, or with authorization and accounting.

  Select an authentication server from the list if you have added a server already or else create an authentication server:

  - **LOCAL**—Use a local database from the Firewall Threat Defense for user authentication. To configure local authentication, Firewall Threat Defense must be Version 7.0 and later.
    - **Local Realm**—Select a local realm or click **Add** to configure a realm. See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
  - **Realm**—Configure an LDAP or AD realm. See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
  - **RADIUS Server Group**—Add a RADIUS server group object with RADIUS servers. See Add a RADIUS server group, on page 2943.
  - **Single Sign-On Server**—Create a single sign-on server object for SAML authentication. See Add a single sign-on server, on page 2946.

Fallback to LOCAL Authentication— The user is authenticated using the local database and the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured.

- **Use secondary authentication** — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

  Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the Secure Client login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

  You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

  Note
  By default, secondary authentication is not required.

  Authentication Server— Secondary authentication server to provide secondary username and password for VPN users.

  - **Fallback to LOCAL Authentication**— This user is authenticated using the local database and the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured.

  Select the following under **Username for secondary authentication**:

  - **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.
  - **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.
  - **Map username from client certificate**: Prefills the secondary username from the client certificate.

If you have enabled multiple certificate authentication, you can select one of the following certificates:

- **First Certificate**— Select this option to map the username from the machine certificate sent from the VPN client.
- **Second Certificate**— Select this option to map the username from the user certificate sent from the client.
- If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

  See **Authentication Method** descriptions for more information about primary and secondary field mapping.
- **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via Secure Client.
  - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.

- **Use secondary username for VPN session**: The secondary username is used for reporting user activity during a VPN session.

Step 5 Select the following for **Authorization**:

- **Authorization Server**—After authentication is complete, authorization controls the services and commands available to each authenticated user. Authorization works by assembling a set of attributes that describe what the user is authorized to perform, their actual capabilities, and restrictions. When you do not use authorization, authentication alone provides the same access to all authenticated users. Authorization requires authentication.

  To know more about how remote access VPN authorization works, see Understanding Policy Enforcement of Permissions and Attributes, on page 1816.

  When a RADIUS Server is configured for user authorization in the connection profile, the remote access VPN system administrator can configure multiple authorization attributes for users or user-groups. The authorization attributes that are configured on the RADIUS server can be specific for a user or a user-group. Once users are authenticated, these specific authorization attributes are pushed to the Firewall Threat Defense device.

  Note
  The AAA server attributes obtained from the authorization server override the attribute values that may have been previously configured on the group policy or the connection profile.

- Check **Allow connection only if user exists in authorization database** if desired.

  When enabled, the system checks the username of the client must exist in the authorization database to allow a successful connection. If the username does not exist in the authorization database, then the connection is denied.

- When you select a realm as the Authorization Server, you must configure an LDAP attribute map. You can choose a single server for authentication and authorization or a different servers. Click **Configure LDAP Attribute Map** to add LDAP attribute maps for authorization.

Note
Firewall Threat Defense does not support SAML Identity Provider as the Authorization server. If the Active Directory behind the SAML Identity Provider is reachable via Cloud-Delivered Firewall Management Center and Firewall Threat Defense, you can configure authorization following these steps:

- Add realm for the AD Server. See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
- Select the realm object as the Authorization Server in remote access VPN connection profile.
- Configure LDAP attribute map for the selected realm.

For information about configuring LDAP attribute maps, see Configuring LDAP Attribute Mapping, on page 1858.

Step 6 Select the following for **Accounting**:

- **Accounting Server**—Accounting is used to track the services that users are accessing and the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS server. Accounting information includes when sessions start and stop, usernames, the number of bytes that pass through the device for each session, the services used, and the duration of each session. This data can then be analyzed for network management, client billing, or auditing. You can use accounting alone or together with authentication and authorization.

  Specify the RADIUS Server Group object that will be used to account for the remote access VPN session.

Step 7 Select the following **Advanced Settings**:

- **Strip Realm from username**—Select to remove the realm from the username before passing the username on to the AAA server. For example, if you select this option and provide *domain\username*, the domain is stripped off from the username and sent to AAA server for authentication. By default this option is unchecked.
- **Strip Group from username**—Select to remove the group name from the username before passing the username on to the AAA server. By default this option is unchecked.

  Note
  A realm is an administrative domain. Enabling these options allows the authentication to be based on the username alone. You can enable any combination of these options. However, you must select both check boxes if your server cannot parse delimiters.

- **Password Management**—Enable managing the password for the remote access VPN users. Select to notify ahead of the password expiry or on the day the password expires.

Step 8 Click **Save**.

RADIUS Server Attributes for Secure Firewall Threat Defense

The Firewall Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from the external RADIUS server that are configured for authentication and/or authorization in the remote access VPN policy.

Note Secure Firewall Threat Defense devices support attributes with vendor ID 3076.

The following user authorization attributes are sent to the Firewall Threat Defense device from the RADIUS server.

- RADIUS attributes 146 and 150 are sent from Firewall Threat Defense devices to the RADIUS server for authentication and authorization requests.
- All three (146, 150, and 151) attributes are sent from Firewall Threat Defense devices to the RADIUS server for accounting start, interim-update, and stop requests.

Table 104: RADIUS Attributes Sent from Secure Firewall Threat Defense to RADIUS Server

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Connection Profile Name or Tunnel Group Name	146	String	Single	1-253 characters
Client Type	150	Integer	Single	2 = Secure Client SSL VPN, 6 = Secure Client IPsec VPN (IKEv2)
Session Type	151	Integer	Single	1 = Secure Client SSL VPN, 2 = Secure Client IPsec VPN (IKEv2)

Table 105: Supported RADIUS Authorization Attributes

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Access-Hours	Y	1	String	Single	Name of the time range, for example, Busine
Access-List-Inbound	Y	86	String	Single	Both of the Access-List attributes take the na ACL that is configured on the Firewall Threa device. Create these ACLs using the Smart CL Access List object type (select **Device** > **Adv Configuration** > **Smart CLI** > **Objects**). These ACLs control traffic flow in the inbou entering the Firewall Threat Defense device) (traffic leaving the Firewall Threat Defense direction.
Access-List-Outbound	Y	87	String	Single	

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Address-Pools	Y	217	String	Single	The name of a network object defined on the Fi Threat Defense device that identifies a subnet, wh be used as the address pool for clients connectin remote access VPN. Define the network object o **Objects** page and then associate the network obj a group policy or a connection profile.
Allow-Network-Extension-Mode	Y	64	Boolean	Single	0 = Disabled 1 = Enabled
Authenticated-User-Idle-Timeout	Y	50	Integer	Single	1-35791394 minutes
Authorization-DN-Field	Y	67	String	Single	Possible values: UID, OU, O, CN, L, SP, C, EA, GN, SN, I, GENQ, DNQ, SER, use-entire-name
Authorization-Required		66	Integer	Single	0 = No 1 = Yes
Authorization-Type	Y	65	Integer	Single	0 = None 1 = RADIUS 2 = LDAP
Banner1	Y	15	String	Single	Banner string to display for Cisco VPN remote a sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL
Banner2	Y	36	String	Single	Banner string to display for Cisco VPN remote a sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL. The string is concatenated to the Banner1 string , if con
Cisco-IP-Phone-Bypass	Y	51	Integer	Single	0 = Disabled 1 = Enabled
Cisco-LEAP-Bypass	Y	75	Integer	Single	0 = Disabled 1 = Enabled
Client Type	Y	150	Integer	Single	1 = Cisco VPN Client (IKEv1) 2 = Secure Clien VPN 3 = Clientless SSL VPN 4 = Cut-Through- = L2TP/IPsec SSL VPN 6 = Secure Client IPsec (IKEv2)
Client-Type-Version-Limiting	Y	77	String	Single	IPsec VPN version number string
DHCP-Network-Scope	Y	61	String	Single	IP Address
Extended-Authentication-On-Rekey	Y	122	Integer	Single	0 = Disabled 1 = Enabled
Framed-Interface-Id	Y	96	String	Single	Assigned IPv6 interface ID. Combines with Framed-IPv6-Prefix to create a complete assigne address. For example: Framed-Interface-ID=1:1 combined with Framed-IPv6-Prefix=2001:0db8::/ the assigned IP address 2001:0db8::1:1:1:1.

Attribute Name	Firewall Threat Defense	Attr. No.	Syntax/Type	Single or Multi- Valued	Description or Value
Framed-IPv6-Prefix	Y	97	String	Single	Assigned IPv6 prefix and length. Combines Framed-Interface-Id to create a complete ass address. For example: prefix 2001:0db8::/64 with Framed-Interface-Id=1:1:1:1 gives the 2001:0db8::1:1:1:1. You can use this attribut an IP address without using Framed-Interfac assigning the full IPv6 address with prefix le for example, Framed-IPv6-Prefix=2001:0db
Group-Policy	Y	25	String	Single	Sets the group policy for the remote access V You can use one of the following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*;
IE-Proxy-Bypass-Local		83	Integer	Single	0 = None 1 = Local
IE-Proxy-Exception-List		82	String	Single	New line (\n) separated list of DNS domains
IE-Proxy-PAC-URL	Y	133	String	Single	PAC address string
IE-Proxy-Server		80	String	Single	IP address
IE-Proxy-Server-Policy		81	Integer	Single	1 = No Modify 2 = No Proxy 3 = Auto detec Concentrator Setting
IKE-KeepAlive-Confidence-Interval	Y	68	Integer	Single	10-300 seconds
IKE-Keepalive-Retry-Interval	Y	84	Integer	Single	2-10 seconds

Table 106: RADIUS Attributes Sent to Secure Firewall Threat Defense

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Address-Pools	217	String	Single	The name of a network object defined on the Firewall Threat Defense device that identifies a subnet, which will be used as the address pool for clients connecting to the remote access VPN. Define the network object on the **Objects** page.
Banner1	15	String	Single	The banner to display when the user logs in.
Banner2	36	String	Single	The second part of the banner to display when the user logs in. Banner2 is appended to Banner1.

Attribute	Attribute Number	Syntax, Type	Single or Multi-valued	Description or Value
Downloadable ACLs	Cisco-AV-Pair	merge-dacl {before-avpair | after-avpair}		Supported via Cisco-AV-Pair configuration.
Filter ACLs	86, 87	String	Single	Filter ACLs are referred to by ACL name in the RADIUS server. It requires the ACL configuration to be already present on the Firewall Threat Defense device, so that it can be used during RADIUS authorization. 86=Access-List-Inbound 87=Access-List-Outbound
Group-Policy	25	String	Single	The group policy to use in the connection. You must create the group policy on the remote access VPN **Group Policy** page. You can use one of the following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*;
Simultaneous-Logins	2	Integer	Single	The number of separate simultaneous connections the user is allowed to establish, 0 - 2147483647.
VLAN	140	Integer	Single	The VLAN on which to confine the user's connection, 0 - 4094. You must also configure this VLAN on a subinterface on the Firewall Threat Defense device.

You must set the values of the IE-Proxy-Server-Method attribute returned from ISE to one of the following:

- IE_PROXY_METHOD_PACFILE: 8
- IE_PROXY_METHOD_PACFILE_AND_AUTODETECT: 11
- IE_PROXY_METHOD_PACFILE_AND_USE_SERVER: 12
- IE_PROXY_METHOD_PACFILE_AND_AUTODETECT_AND_USE_SERVER: 15

Firewall Threat Defense will deliver a proxy setting only if one of the above values is used for the IE-Proxy-Server-Method attribute.

Create or Update Aliases for a Connection Profile

Aliases contain alternate names or URLs for a specific connection profile. Remote access VPN administrators can enable or disable the Alias names and Alias URLs. VPN users can choose an Alias name when they connect to the Secure Firewall Threat Defense device. Aliases names for all connections configured on this device can be turned on or off for display. You can also configure the list of Alias URLs, which your endpoints

can select while initiating the remote access VPN connection. If users connect using the Alias URL, system will automatically log them using the connection profile that matches the Alias URL.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the policy that you want to modify.

Step 3 Click **Edit** on the connection profile for which you want to create or update aliases.

Step 4 Click **Aliases**.

Step 5 To add an Alias name, do the following:

a) Click **Add** under **Alias Names**.
b) Specify the **Alias Name**.
c) Select the **Enabled** check box in each window to enable the aliases.
d) Click **OK**.

Step 6 To add an Alias URL, do the following:

a) Click **Add** under **URL Alias**.
b) Select the **Alias URL** from the list or create a new URL object. For more information see Create a URL object, on page 3039.
c) Select the **Enabled** check box in each window to enable the aliases.
d) Click **OK**.

Step 7 Save your changes.

Configure Connection Profile Settings, on page 1832

Configure Access Interfaces for Remote Access VPN

The **Access Interface** table lists the interface groups and security zones that contain the device interfaces. These are configured for remote access SSL or IPsec IKEv2 VPN connections. The table displays the name of each interface group or security-zone, the interface trustpoints used by the interface, and whether Datagram Transport Layer Security (DTLS) is enabled.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Click the **Access Interface** tab.

Step 4 To add an access interface, click + and specify values for the following in the **Add Access Interface** dialog box:

a) **Access Interface**—Select the interface group or security zone to which the interface belongs.

The interface group or security zone must be a Routed type. Other interface types are not supported for remote access VPN connectivity.

b) Associate the **Protocol** object with the access interface by selecting the following options:

- **Enable IPSet-IKEv2**—Select this option to enable **IKEv2** settings.
- **Enable SSL**—Select this option to enable **SSL** settings.
  - Select **Enable Datagram Transport Layer Security**.

    When selected, it enables Datagram Transport Layer Security (DTLS) on the interface and allows the AnyConnect VPN module of Cisco Secure Client to establish an SSL VPN connection using two simultaneous tunnels—an SSL tunnel and a DTLS tunnel.

    Enabling DTLS avoids the latency and bandwidth problems associated with certain SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

    To configure SSL settings, and TLS and DTLS versions, see Configure SSL settings, on page 1279.

    To configure SSL settings for the AnyConnect VPN module of Cisco Secure Client, see Group policy options for Secure Client, on page 3065.
  - Select the **Configure Interface Specific Identity Certificate** check box and select **Interface Identity Certificate** from the drop-down list.

    If you do not select the Interface Identity Certificate, the **Trustpoint** will be used by default.

    If you do not select the Interface Identity Certificate or Trustpoint, the **SSL Global Identity Certificate** will be used by default.

c) Click **OK** to save the changes.

Step 5 Select the following under **Access Settings**:

- **Allow Users to select connection profile while logging in**—If you have multiple connection profiles, check this check box to allow user to select the correct connection profile during login. You must select this option for **IPsec-IKEv2** VPNs.

Step 6 Use the following options to configure **SSL Settings**:

- **Web Access Port Number**—The port to use for VPN sessions. The default port is 443.
- **DTLS Port Number**—The UDP port to use for DTLS connections. The default port is 443.
- **SSL Global Identity Certificate**— The selected **SSL Global Identity Certificate** will be used for all the associated interfaces if the **Interface Specific Identity Certificate** is not provided.

Step 7 For **IPsec-IKEv2 Settings**, select the **IKEv2 Identity Certificate** from the list or add an identity certificate.

Step 8 Configure **Service Access Control**. Choose a service access object from the **Service Access Object** drop-down list or click + to create a new object.

You can use a service access object to control remote clients' access to VPN on Firewall Threat Defense devices with Version 7.7 or later. This object provides geolocation-based access control to clients before VPN authentication. By default, there is no access control for RA VPN, and remote clients can connect from any geolocation unless specified by a service access object. For more information, see Manage VPN Access of Remote Users Based on Geolocation, on page 1886and Configure a service access object, on page 2952.

Step 9 Under the **Access Control for VPN Traffic** section, select the following option if you want to bypass access control policy:

- **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** — Decrypted traffic is subjected to Access Control Policy inspection by default. Enabling the Bypass Access Control policy for decrypted traffic option bypasses the ACL inspection, but VPN Filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

  Note
  If you select this option, you need not update the access control policy for remote access VPN as specified in Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1825.

Step 10 Click **Save** to save the access interface changes.

Configure Advanced Options for Remote Access VPN

Cisco Secure Client Image

Secure Client Image

The Secure Client provides secure SSL or IPsec (IKEv2) connections to the Firewall Threat Defense device for remote users with full VPN profiling to corporate resources. Without a previously-installed client, remote users can enter the IP address of an interface configured to accept clientless VPN connections in their browser to download and install the Secure Client. The Firewall Threat Defense device downloads the client that matches the operating system of the remote computer. After downloading, the client installs and establishes a secure connection. In case of a previously installed client, when the user authenticates, the Firewall Threat Defense device, examines the version of the client, and upgrades the client if necessary.

The Remote Access VPN administrator associates any new or additional Secure Client images to the VPN policy. The administrator can unassociate the unsupported or end of life client packages that are no longer required.

The Cloud-Delivered Firewall Management Center determines the type of operating system by using the file package name. If the user renamed the file without indicating the operating system information, the valid operating system type must be selected from the list box.

Download the Secure Client image file by visiting Cisco Software Download Center.

Related Topics

Adding a Secure Client Image to the Cloud-Delivered Firewall Management Center, on page 1853

Adding a Secure Client Image to the Cloud-Delivered Firewall Management Center

You can upload the Secure Client image to the Cloud-Delivered Firewall Management Center by using the **Secure Client File** object. For more information, see File objects, on page 3075. For more information about the client image, see Cisco Secure Client Image, on page 1853.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**, choose and edit a listed remote access policy, then choose the **Advanced** tab.

Step 2 Click **Add** to add a Secure Client image.

Step 3 Click **Add** in the **Available Secure Client Images** portion of the **Secure Client Images** dialog.

Step 4 Enter the **Name** and **Description**(optional) for the available Secure Client Image.

Step 5 Click **Browse**, locate and select the client image that you want to upload.

Step 6 Click **Save** to upload the image to the Cloud-Delivered Firewall Management Center.

When you upload the client image to the Cloud-Delivered Firewall Management Center, the operating system information for the image appears automatically.

Step 7 To change the order of client images, Click **Show Re-order buttons** and move the client image up or down.

Update Secure Client Image for Remote Access VPN Clients

When new Secure Client updates are available in Cisco Software Download Center, you can download the packages manually and add them to the remote access VPN policy so that the new client packages are upgraded on the VPN client systems according to their operating systems.

Before you begin

Instructions in this section help you update new Secure Client images to remote access VPN clients connecting to Secure Firewall Threat Defense VPN gateway. Ensure that the following configurations are complete before updating your Secure Client images:

- Download the latest Secure Client image files from Cisco Software Download Center.
- On your Cloud-Delivered Firewall Management Center web interface, go to **Objects** > **Object Management** > **VPN** > **Secure Client File** and add the new Secure Client image files.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 From **Advanced** drop-down menu, choose **AnyConnect Client ImagesSecure Client Image** and then click **Add**.

Step 4 Select a client image file from **Available Secure Client Images** and click **Add**.

If the required client image is not listed, click **Add** to browse and upload an image.

Step 5 Click **OK**.

Step 6 Save the remote access VPN policy.
After the remote access VPN policy changes are deployed, the new Secure Client images are updated on the Secure Firewall Threat Defense device that is configured as the remote access VPN gateway. When a new VPN user connects to the VPN gateway, the user gets the new Secure Client image to download depending on the operating system of the client system. For existing VPN users, the Secure Client image gets updated in their next VPN session.

Add a Cisco Secure Client External Browser Package to the Cloud-Delivered Firewall Management Center

If you have the Secure Client external browser package image on your local disk, use this procedure to upload the same to the Cloud-Delivered Firewall Management Center. After you upload the external browser package, you can update the external browser package for your remote access VPN connections.

You can upload the external browser package file to the Cloud-Delivered Firewall Management Center by using the **Secure Client File** object. For more information, see File objects, on page 3075.

Points to Remember

- Only one external browser package can be added to the Firewall Threat Defense device.
- After the external browser package is added to the Cloud-Delivered Firewall Management Center, the browser is pushed to the Firewall Threat Defense only after the external browser is enabled in the remote access VPN configuration.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**, choose and edit a listed remote access policy, then choose the **Advanced** tab.

Step 2 Click **Add** in the **Secure Client External Browser Package** portion of the **Secure Client Images** page.

Step 3 Enter the **Name** and **Description** for the Secure Client package.

Step 4 Click **Browse** and locate the external browser package file to upload.

Step 5 Click **Save** to upload the image to the Cloud-Delivered Firewall Management Center.

Note
If you want to update the remote access VPN connection with an existing external browser package, select the file from the **Package File** drop-down.

Step 6 Save the remote access VPN policy.

Remote Access VPN Address Assignment Policy

The Firewall Threat Defense device can use an IPv4 or IPv6 policy for assigning IP addresses to Remote Access VPN clients. If you configure more than one address assignment method, the Firewall Threat Defense device tries each of the options until it finds an IP address.

IPv4 or IPv6 Policy

You can use the IPv4 or IPv6 policy to address an IP address to remote access VPN clients. You must try with the IPv4 policy to begin and later followed by IPv6 policy.

- **Use Authorization Server**—Retrieves the address from an external authorization server on a per-user basis. If you are using an authorization server that has IP address configured, we recommend using this method. Address assignment is supported by RADIUS-based authorization server only. It is not supported for AD/LDAP. This method is available for both IPv4 and IPv6 assignment policies.
- **Use DHCP**—Obtains IP addresses from a DHCP server configured in a connection profile. You can also define the range of IP addresses that the DHCP server can use by configuring DHCP network scope in the group policy. If you use DHCP, configure the server in the **Objects** > **Object Management** > **Network** pane. This method is available for IPv4 assignment policies.

  For more information about DHCP network scope configuration, see Group policy general options, on page 3063.
- **Use an internal address pool**—Internally configured address pools are the easiest method of address pool assignment to configure. If you use this method, create the IP address pools in the **Objects** > **Object Management** > **Address Pools** pane and select the same in the connection profile. This method is available for both IPv4 and IPv6 assignment policies.
- **Allow reuse an IP address so many minutes after it is released**—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default, the delay is set to zero. If you want to extend the delay, enter the number of minutes in the range of 0–480 to delay the IP address reassignment. This configurable element is available for IPv4 assignment policies.

Configure Connection Profile Settings, on page 1832
Remote Access VPN Authentication, on page 1814

Configure Certificate Maps

Certificate maps let you define rules matching a user certificate to a connection profile based on the contents of the certificate fields. Certificate maps provide certificate authentication on secure gateways.

The rules or the certificate maps are defined in Certificate map objects, on page 3058.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Choose **Advanced** > **Certificate Maps**.

Step 4 Select the following options from the **General Settings for Connection Profile Mapping** pane:

Selections are priority-based, matching continues down the list of options when the first selection does not match. Matching is complete when the rules are satisfied. If the rules are not satisfied, the default connection profile listed at the bottom of this page is used for the connection. Select any, or all of the following options to establish authentication and to determine which connection profile (tunnel group) must be mapped to the client.

- **Use Group URL if Group URL and Certificate Map match different Connection profiles**

- **Use the configured rules to match a certificate to a Connection Profile**—Enable this to use the rules defined in the Connection Profile Maps.

Note
Configuring a certificate mapping implies certificate-based authentication. The remote user will be prompted for a client certificate regardless of the configured authentication method.

Step 5 Under the **Certificate to Connection Profile Mapping** section, click **Add Mapping** to create certificate to connection profile mapping for this policy.

a) Choose or create a **Certificate Map Name** object.
b) Select the **Connection Profile** that want to use if the rules in the certificate map object are satisfied.
c) Click **OK** to create the mapping.

Step 6 Click **Save**.

Configuring Group Policies

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

The group policy applied to a user is determined when the VPN tunnel is established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

Note There is no group policy attribute inheritance on the Firewall Threat Defense. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.
Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
Step 3 Choose **Advanced** > **Group Policies** > **Add**.
Step 4 Select group policies from the **Available Group Policy** list and click **Add**. You can select one or more group policies to associate with this remote access VPN policy.
Step 5 Click **OK** to complete the group policy selection.
Step 6 Save your changes.

Configure a group policy object, on page 3062

Configuring LDAP Attribute Mapping

An LDAP attribute name maps LDAP user or group attribute name to a Cisco-understandable name. The attribute map equates attributes that exist in the Active Directory (AD) or LDAP server with Cisco attribute names. You can map any standard LDAP attribute to a well-known vendor specific attribute (VSA). You can map one or more LDAP attributes to one or more Cisco LDAP attributes. When the AD or LDAP server returns authentication to the Firewall Threat Defense device during remote access VPN connection establishment, the Firewall Threat Defense device can use the information to adjust how the Secure Client completes the connection.

When you want to provide VPN users with different access permissions or VPN content, you can configure different VPN policies on the VPN server and assign these policy-sets to each user based on their credentials. You can achieve this in Firewall Threat Defense by configuring LDAP authorization, with LDAP attribute maps. In order to use LDAP to assign a group policy to a user, you must configure a map that maps an LDAP attribute.

An LDAP attribute map consists of three components:

- **Realm**—Specifies the name for the LDAP attribute map; the name is generated based on the selected realm.
- **Attribute Name Map**—Maps the LDAP user or group attribute name to Cisco-understandable name.
- **Attribute Value Map**—Maps value in the LDAP user or group attribute to the value of a Cisco attribute for the selected name mapping.

The group policies that are used in an LDAP attribute map get added to the list of group policies in the remote access VPN configuration. Removing a group policy from the remote access VPN configuration also removes the associated LDAP attribute mapping.

In versions 6.4 to 6.6, you can configure LDAP attribute maps only using FlexConfig. For more information, see Configure AnyConnect Modules and Profiles Using FlexConfig.

In versions 7.0 and later, you can use the following procedure:

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.

Step 3 Click **Advanced** > **LDAP Attribute Mapping**.

Step 4 Click **Add**.

Step 5 On the Configure LDAP Attribute Map page, select a **Realm** to configure the attribute map.

Step 6 Click **Add**.

You can configure multiple attribute maps. Each attribute map requires that you configure a name map and value maps.

Note

Ensure that you follow these guidelines while creating an LDAP attribute map:

- Configure at least one mapping for an LDAP attribute; multiple mappings with the same LDAP attribute name is not allowed.

- Configure a minimum of one name map to create an LDAP attribute map.
- You can remove any LDAP attribute map if the attribute map is not associated with any connection profile in the remote access VPN configuration.
- Use the correct spelling and capitalization in the LDAP attribute map for ***both*** the Cisco and LDAP attribute names and values.

a) Specify the **LDAP Attribute Name** and then select the required **Cisco Attribute Name** from the list.
b) Click **Add Value Map** and Specify the **LDAP Attribute Value** and **Cisco Attribute Value**.

Repeat this step to add more value maps.

Step 7 Click **OK** to complete LDAP attribute map configuration.

Step 8 Click **Save** to save the changes to the LDAP attribute mapping.

Example

For a detailed example, see Configure RA VPN with LDAP Authentication and Authorization for FTD.

Configuring VPN Load Balancing

About VPN Load Balancing

VPN load balancing in Firewall Threat Defense allows you group two or more devices logically and distribute remote access VPN sessions among the devices equally. VPN load balancing shares Secure Client VPN sessions among the devices in a load balancing group.

VPN load balancing is based on simple distribution of traffic without taking into account throughput or other factors. A VPN load-balancing group consists of two or more Firewall Threat Defense devices. One device acts as the director, and the other devices are member devices. Devices in a group do not need to be of the exact same type, or have identical software versions or configurations. Any Firewall Threat Defense device that supports remote access VPN can participate in a load balancing group. Firewall Threat Defense supports VPN load balancing with Secure Client SAML authentication.

All active devices in a VPN load-balancing group carry session loads. VPN load balancing directs traffic to the least-loaded device in the group, distributing the load among all devices. It makes efficient use of system resources and provides increased performance and high availability.

Components of VPN Load Balancing

Following are the components of VPN load balancing:

- **Load-balancing group**—A virtual group of two or more Firewall Threat Defense devices to share the VPN sessions.

A VPN load-balancing group can consist of Firewall Threat Defense devices of the same release or of mixed releases; but the device must support remote access VPN configuration.

See Configure Group Settings for VPN Load Balancing, on page 1860 and Configure Additional Settings for Load Balancing, on page 1861.

- **Director**—One device from the group acts a director. It distributes the load among other members in the group and participate is serving the VPN sessions.

  The director monitors all devices in the group, keeps track of how loaded each device is, and distributes the session load accordingly. The role of director is not tied to a physical device; it can shift among devices. For example, if the current director fails, one of the member devices in the group takes over that role and immediately becomes the new director.

- **Members**—Devices other than the director in a group are called members. They participate in load balancing and share the remote access VPN connections.

  Configure Settings for Participating Devices, on page 1862.

Prerequisites for VPN Load Balancing

- **Certificates**—Firewall Threat Defense's certificate must contain the IP addresses or FQDN of the director and members to which the connection is redirected. Or else, the certificate will be deemed untrusted. The certificate must use Subject Alternate Name (SAN) or wildcard certificate
- **Group URL**—Add the group URL for VPN load-balancing group IP address to the connection profiles. Specify a group URL to eliminate the need for the user to select a group at login.
- **IP Address Pool**—Choose unique IP address pool for member devices, and override the IP pool in Cloud-Delivered Firewall Management Center for each of the member devices.
- Devices that are behind Network Address Translation (NAT) can also be part of a load balancing group.

Guidelines and Limitations for VPN Load Balancing

- VPN load balancing is disabled by default. You must explicitly enable VPN load balancing.
- Only the Firewall Threat Defense devices that are co-located can be added to a load-balancing group.
- A load-balancing group must have a minimum of two Firewall Threat Defense devices.
- Devices in Firewall Threat Defense high availability can participate in a load-balancing group.
- Devices that are behind Network Address Translation (NAT) can also be part of a load balancing group.
- When a member or a director device goes down, remote access VPN connections that are served by that device will be dropped. You must initiate the VPN connection again.
- Identity certificate on each device must have Subject Alternate Name (SAN) or wildcard.

Configure Group Settings for VPN Load Balancing

You can enable VPN load balancing and configure group settings that are applicable to all the members of the load-balancing group. When you create the group, you can configure participation settings for load balancing.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 Click **Advanced** > **Load Balancing**.

Step 4 Click the **Enable Load balancing between member devices** toggle button to enable load balancing. The **Edit Group Configuration** page opens. Group parameters apply to all devices under the load-balancing group.

Step 5 Specify the **Group IPv4 Address** and **Group IPv6 Address** as applicable.

The IP address that you specify here is for the entire load-balancing group and the director opens this IP address for incoming VPN connections.

Step 6 Select the **Communication Interface** for the load-balancing group. Click **Add** to add an interface group or security zone.

Communication interface is a private interface through which the director and members share information about their load.

Step 7 Enter the **UDP Port** for communication between the director and members in a group. The default port is 9023.

Step 8 Enable the **IPsec Encryption** toggle button to activate IPsec encryption for the communication between the director and members.

Enabling the encryption establishes an IPsec tunnel between the director and members using a pre-shared key.

When you upgrade or downgrade Firewall Threat Defense devices with the **IPsec Encryption** option enabled, ensure there is no configuration mismatch between the Cloud-Delivered Firewall Management Center and the Firewall Threat Defense to prevent deployment failures.

Step 9 Enter **Encryption Key** for IPsec encryption and confirm the encryption key.

Step 10 Click **OK**.

Configure Additional Settings for Load Balancing

The additional settings for VPN load balancing include FQDN and IKEv2 redirection.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 Click **Advanced** > **Load Balancing**.

Step 4 Turn on the **Enable Load balancing between member devices** toggle button to enable load balancing if not done already.

Step 5 Click **Settings**.

Step 6 Turn on the **Send FQDN to peer devices instead of IP** toggle button to enable redirection using a fully qualified domain name.

By default, Firewall Threat Defense sends only IP addresses in VPN load balancing redirection to a client.

Step 7 Select one of the **IKEv2 Redirect** phases:

- **Redirect during SA authentication**
- **Redirect during SA initialization**

Step 8 Click **OK**.

Step 9 Save your changes.

Configure Settings for Participating Devices

The device participation settings determine how the devices share load in VPN load balancing. Configure a participating device by enabling VPN load balancing on the device and defining device-specific properties. These values vary from device to device. You can provide a priority number for the devices participating in load balancing. A higher priority number gives the device a better chance to become the director over other devices. But you cannot select a device to be the director of the group.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** next to the remote access VPN policy that you want to modify.

Step 3 Click **Advanced** > **Load Balancing**.

Step 4 Turn on the **Enable Load balancing between member devices** toggle button to enable load balancing if you have not enabled already.

Step 5 Configure **Device Participation** settings:

The **Device Participation** section lists all the target devices of the selected remote access VPN configuration. You can configure these devices to share the load of the incoming VPN sessions.

a) Turn on the **Load Balancing** toggle button to enable load balancing for a device and then click **Edit**.

b) Enter the device **Priority**.

By default, the device priority is set to 5. You can choose a number from 1 trough 10.

c) Specify the **IPv4 NAT** or **IPv6 NAT** address for VPN interface IP address if the device is behind NAT.

d) Click **OK**.

Step 6 Click **Save** to save the remote access VPN policy settings.

Configuring IPsec Settings for Remote Access VPNs

The IPsec settings are applicable only if you selected IPsec as the VPN protocol while configuring your remote access VPN policy. If not, you can enable IKEv2 using the Edit Access Interface dialog box. See Configure Access Interfaces for Remote Access VPN, on page 1851 for more information.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click **Advanced**.

The list of IPsec settings appears in a navigation pane on the left of the screen.

Step 4 Use the navigation pane to edit the following IPsec options:

a) **Crypto Maps**—The Crypto Maps page lists the interface groups on which IKEv2 protocol is enabled. Crypto Maps are auto generated for the interfaces on which IKEv2 protocol is enabled. To edit a Crypto Map, see Configure Remote Access VPN Crypto Maps, on page 1863. You can add or remove interface groups to the selected VPN policy in **Access Interface**. See Configure Access Interfaces for Remote Access VPN, on page 1851 for more information.

b) **IKE Policy**—The IKE Policy page lists all the IKE policy objects applicable for the selected VPN policy when Secure Client endpoints connect using the IPsec protocol. See IKE Policies in Remote Access VPNs, on page 1865 for more information. To add a new IKE policy, see Configure an IKEv2 policy object, on page 3073. Firewall Threat Defense supports only Secure Client IKEv2 clients. Third-party standard IKEv2 clients are not supported.

c) **IPsec/IKEv2 Parameters**—The IPsec/IKEv2 Parameters page enables you to modify the IKEv2 session settings, IKEv2 Security Association settings, IPsec settings, and NAT Transparency settings. See Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1866 for more information.

Step 5 Click **Save**.

Configure Remote Access VPN Crypto Maps

Crypto maps are automatically generated for the interfaces on which IPsec-IKEv2 protocol has been enabled. You can add or remove interface groups to the selected VPN policy in **Access Interface**. See Configure Access Interfaces for Remote Access VPN, on page 1851 for more information.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click the **Advanced** > **Crypto Maps**, and select a row in the table and click **Edit** to edit the Crypto map options.

Step 4 Select **IKEv2 IPsec Proposals** and select the transform sets to specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel.

Step 5 Select **Enable Reverse Route Injection** to enable static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

Step 6 Select **Enable Client Services** and specify the port number.

The Client Services Server provides HTTPS (SSL) access to allow the Secure Client Downloader to receive software upgrades, profiles, localization and customization files, CSD, SCEP, and other file downloads required

by the client. If you select this option, specify the client services port number. If you do not enable the Client Services Server, users will not be able to download any of these files that the Secure Client might need.

Note
You can use the same port that you use for SSL VPN running on the same device. Even if you have an SSL VPN configured, you must select this option to enable file downloads over SSL for IPsec-IKEv2 clients.

Step 7 Select **Enable Perfect Forward Secrecy** and select the **Modulus group**.

Use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the **Modulus Group** list.

Modulus group is the Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the modulus group that you want to allow in the remote access VPN configuration:

- 1—Diffie-Hellman Group 1 (768-bit modulus).
- 2—Diffie-Hellman Group 2 (1024-bit modulus).
- 5—Diffie-Hellman Group 5 (1536-bit modulus, considered good protection for 128-bit keys, but group 14 is better). If you are using AES encryption, use this group (or higher).
- 14—Diffie-Hellman Group 14 (2048-bit modulus, considered good protection for 128-bit keys).
- 19—Diffie-Hellman Group 19 (256-bit elliptical curve field size).
- 20—Diffie-Hellman Group 20 (384-bit elliptical curve field size).
- 21—Diffie-Hellman Group 21 (521-bit elliptical curve field size).
- 24—Diffie-Hellman Group 24 (2048-bit modulus and 256-bit prime order subgroup).

Step 8 Specify the **Lifetime Duration (seconds)**.

The lifetime of the security association (SA), in seconds. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

You can specify a value from 120 to 2147483647 seconds. The default is 28800 seconds.

Step 9 Specify the **Lifetime Size (kbytes)**.

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires.

You can specify a value from 10 to 2147483647 kbytes. The default is 4,608,000 kilobytes. No specification allows infinite data.

Step 10 Select the following **ESPv3 Settings**:

- **Validate incoming ICMP error messages**—Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

- **Enable 'Do Not Fragment' Policy**—Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header, and select one of the following from the **Policy** list:
  - Copy—Maintains the DF bit.
  - Clear—Ignores the DF bit.
  - Set—Sets and uses the DF bit.
- Select **Enable Traffic Flow Confidentiality (TFC) Packets**— Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

  Note
  Enabling traffic flow confidentiality (TFC) packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy does not work as expected when you enable the TFC packets. See Advanced group policy option fields and values, on page 3068.

  - Burst—Specify a value from 1 to 16 bytes.
  - Payload Size—Specify a value from 64 to 1024 bytes.
  - Timeout—Specify a value from 10 to 60 seconds.

Step 11 Click **OK**.

Interfaces, on page 2980

IKE Policies in Remote Access VPNs

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

Note Firewall Threat Defense supports only IKEv2 for remote access VPNs.

Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups in one policy. Since peers choose during the Phase 1 negotiation, this makes it possible to create a single IKE proposal, but consider creating multiple, different proposals to give higher priority to your most desired options. For IKEv2, the policy object does not specify authentication, other policies must define the authentication requirements.

An IKE policy is required when you configure a remote access IPsec VPN.

Configuring Remote Access VPN IKE Policies

The IKE Policy table specifies all the IKE policy objects applicable for the selected VPN configuration when Secure Client endpoints connect using the IPsec protocol. For more information, see IKE Policies in Remote Access VPNs, on page 1865.

Note Firewall Threat Defense supports only IKEv2 for remote access VPNs.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click **Advanced** > **IKE Policy**.

Step 4 Click **Add** to select from the available IKEv2 policies, or add a new IKEv2 policy and specify the following:

- **Name**—Name of the IKEv2 policy.
- **Description**—Optional description of the IKEv2 policy
- **Priority**—The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA).
- **Lifetime**— Lifetime of the security association (SA), in seconds
- **Integrity**—The Integrity Algorithms portion of the Hash Algorithm used in the IKEv2 policy.
- **Encryption**—The Encryption Algorithm used to establish the Phase 1 SA for protecting Phase 2 negotiations.
- **PRF Hash**—The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv2, you can specify different algorithms for these elements.
- **DH Group**—The Diffie-Hellman group used for encryption.

Step 5 Click **Save**.

Configure Remote Access VPN IPsec/IKEv2 Parameters

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 From the list of available VPN policies, select the policy for which you want to modify the settings.

Step 3 Click **Advanced** > **IPsec**> **IPsec/IKEv2 Parameters**.

Step 4 Select the following for **IKEv2 Session Settings**:

- **Identity Sent to Peers**—Choose the identity that the peers will use to identify themselves during IKE negotiations:
  - **Auto**—Determines the IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
  - **IP address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
  - **Hostname**—Uses the fully qualified domain name (FQDN) of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.
- **Enable Notification on Tunnel Disconnect**—Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. Sending this notification is disabled by default.
- **Do not allow device reboot until all sessions are terminated**—Check to enable waiting for all active sessions to voluntarily terminate before the system reboots. This is disabled by default.

Step 5 Select the following for **IKEv2 Security Association (SA) Settings**:

- **Cookie Challenge**—Whether to send cookie challenges to peer devices in response to SA initiated packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:
  - **Custom**—Specify **Threshold to Challenge Incoming Cookies**, the percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%. The default is 50%.
  - Always— Select to send cookie challenges to peer devices always.
  - Never— Select to never send cookie challenges to peer devices.
- **Number of SAs Allowed in Negotiation**—Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check. The default is 100 %.
- **Maximum number of SAs Allowed**—Limits the number of allowed IKEv2 connections.

Step 6 Select the following for **IPsec Settings**:

- **Enable Fragmentation Before Encryption**—This option lets traffic travel across NAT devices that do not support IP fragmentation. It does not impede the operation of NAT devices that do support IP fragmentation.
- **Path Maximum Transmission Unit Aging**—Check to enable PMTU (Path Maximum Transmission Unit) Aging, the interval to Reset PMTU of an SA (Security Association).
- **Value Reset Interval**—Enter the number of minutes at which the PMTU value of an SA (Security Association) is reset to its original value. Valid range is 10 to 30 minutes, default is unlimited.

Step 7 Select the following for **NAT Settings**:

- **Keepalive Messages Traversal**—Select whether to enable NAT keepalive message traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there is a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow. If you select this option, configure the interval, in seconds, between the keepalive signals sent

between the spoke and the middle device to indicate that the session is active. The value can be from 10 to 3600 seconds. The default is 20 seconds.

- **Interval**—Sets the NAT keepalive interval, from 10 to 3600 seconds. The default is 20 seconds.

Step 8 Click **Save**.

Customize Cisco Secure Client

You can configure the Secure Client customizations using the management center and deploy them to the VPN headend. The threat defense device distributes these customizations to the endpoint when a user connects from the Secure Client. Administrators can customize the following elements at the endpoint:

Table 107: Secure Client Customizations Available in Management Center

Customization	Description	More Info
GUI text and messages	Customize or localize Secure Client GUI text and informational/error messages.	Customize and Localize Secure Client GUI Text and Messages, on page 1872
Icons and images	Customize the logo, images, or icons of the Secure Client GUI.	Customize Secure Client Icons and Images, on page 1873
Scripts	Deploy scripts on the endpoint devices when a client establishes or disconnects a VPN session.	Deploy Scripts on Endpoint Devices Using Secure Client, on page 1874
Binaries	Deploy custom applications using Secure Client APIs.	Deploy Custom Applications Using Cisco Secure Client APIs, on page 1876
Custom Installer Transforms	Customize the Secure Client installer.	Customize the Secure Client Installer, on page 1877
Localized Installer Transforms	Localize the Secure Client installer.	Localize the Client Installer, on page 1877

Overview of the customization file

The customization file is an XML-based configuration object in the Threat Defense device that controls the visual appearance and layout of Secure Client to remote VPN users. It defines:

- Branding—logos and color schemes
- Page structure—logon page and portal layout
- Content elements—titles, banners, and button labels
- Messaging—error messages and other user-facing text

By default, a Threat Defense device has two customization objects:

- Template: A blank XML template file that you can update to add the required customizations. You cannot delete this file.
- DfltCustomization: An XML file with a set of URLs and basic customization to bring up the Secure Client. This is the default customization file.

  To view these customization files, run the **show import webvpn customization** command on the Threat Defense device:

```
FTD(config)# show import webvpn customization
Template
DfltCustomization
```

Customize the customization file

To update the **Template** XML file:

1. Export the file to disk0. You can rename the file, if required.

```
FTD(config)# export webvpn customization Template disk0:ABCTemplate
```

2. Copy the XML file to a remote PC.
3. Edit the XML file with the required customizations and copy it back to disk0.
4. Import the file to the Threat Defense device.

```
FTD(config)# import webvpn customization ABCTemplate disk0:ABCTemplate
```

5. Verify the customization files in the device.

```
FTD(config)# show import webvpn customization
Template
DfltCustomization
ABCTemplate
```

Note You can also update the **DfltCustomization** file using the same procedure as above. You can also rename this file.

Upload the customization file to Management Center

1. Choose **Objects** > **Object Management** > **VPN** > **Secure Client File** and click **Add Secure Client File**.
2. In the **Add Secure Client File** dialog box, configure these parameters:
   a. In the **Name** file, enter the name of the customization file.
   b. From the **File Type** drop-down list, choose **Secure Client VPN Profile**.
   c. Click **Browse**, locate and select the customization file that you want to upload.
   d. Click **Save**.
3. Choose **Devices** > **VPN** > **Remote Access**.
4. Click the edit icon next to the remote access VPN policy.

5. Click the **Advanced** tab.
6. In the left pane, click **Group policies**.
7. Click **+** to add a group policy.
8. In the **Add Group Policy** dialog box, configure these parameters:
   a. Enter a **Name** and optionally a **Description** for this policy.
   b. Click the **Secure Client** tab, and from the **Client Profile** drop-down list, choose the customization file.
   c. Click **Save**.
9. Choose this group policy as the selected policy in the **Group Policy** dialog box, click **OK**, and click **Deploy**.

Guidelines and Limitations for Secure Client Customizations

Guidelines

- Ensure that you import the xml file to the object defined as `DfltCustomization`. When you import the customization object, the Cloud-Delivered Firewall Management Center checks the XML code for validity.

  For example:

  ```
  hostname# import webvpn customization DfltCustomization
  disk0:/csm/defaultcustomizationwebvpn.xml
  ```

- Add the Windows Cisco Secure Client headend deployment package to the remote access VPN policy before deploying customization commands. This package must be included when supporting Windows, MacOS, or Linux clients.

General Limitations

- If there are any customizations earlier than 7.4 configured directly on the threat defense using the CLI, the management center removes these customizations during deployment.
- No clustering support.

Table 108: Limitations for Secure Client Customizations

Customization	Limitations

GUI Text and Message Customizations	• You must restart Secure Client before you use this customization.
	• No support for right-to-left languages.
	• Some strings are truncated in the GUI due to hardcoded field lengths.
	• Some messages are hardcoded in the client. For example:
	  • Status messages (during an update)
	  • Untrusted server messages
	  • Deferred update messages
	• Localization is version-specific.
	If an Administrator created a translation table based on a template of an old Secure Client version, the new messages do not appear to the remote users. The Administrator must merge the latest template with the translation table so that the table has the new messages. You can use third-party tools like Get text to perform the merge.

Icons and Images Customizations	• You must restart Secure Client before you use this customization. • The customization object names must match the Secure Client GUI filenames. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each OS, see the Cisco Secure Client Administrator Guide. • Images do not appear properly if the image size is not correct. The management center or the threat defense device does not verify the image size. • MacOS does not support customization of Secure Client images and icons.
Deploy Customized Scripts	• Secure Client runs only one OnConnect and one OnDisconnect script; however, these scripts may launch other scripts. • Scripts can only execute functions that the user has the right to invoke. • You cannot launch the OnConnect script from the Start Before Logon (SBL) GUI.
Deploy Custom Applications Using Cisco Secure Client APIs (Binaries)	• After you use this customization, if you deploy an updated version of the Secure Client on the management center, the client will download the update and replace your custom UI.

Customization	Limitations
Customize the Client Installer	• This customization is available only for Windows.

Customize and Localize Secure Client GUI Text and Messages

You can customize the Secure Client GUI text and the informational/error messages. You also can customize the GUI text and all messages to appear in a preferred language.

Customize GUI Text and Messages

To customize the GUI text or messages, you can edit the messages in the message file. You can update the messages to include more details in the error messages. For example:

- Modify any label in the login dialog box such as **Password** to **Domain Password**.
- Add your support contact details in the error messages.

Localize GUI Text and Messages

Threat defense devices use translation tables to translate the labels and user messages displayed in the Secure Client. When a user connects to the remote access VPN, the Secure Client identifies the locale set on the endpoint and downloads the translation file. Threat defense devices support 128 locales. By default, Secure Client is installed in English.

- For Cisco Secure Client 5.0, the default localization files for various languages are part of the application.
- For AnyConnect Clients 4.x, you can download the localization files for a few languages from Cisco.com and upload them to the management center.

How to Customize Secure Client GUI Text and Messages

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Get the base template or translation file either from the Secure Client package or from Cisco.com. For example, AnyConnect.po.

Step 2 Use a text editor to add the translations or customize the labels or messages.

Step 3 Update the **msgstr** string corresponding to each **msgid**.

Step 4 Save the file.

Step 5 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **GUI Text and Messages**.
e) From the **Language** drop-down list, choose a language for which you are adding the translation.

f) Click **Browse** and select the translation file. The supported file extensions are .po, .mo, and .txt.

Step 6 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Localization**.
d) Click **+** to select the translation file.
e) Click **Add**.
f) Click **OK**.

Step 7 Click **Save**.

Step 8 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, see Verify Secure Client Customizations, on page 1878.

Customize Secure Client Icons and Images

You can customize the logo, images, and icons of the Secure Client GUI using the management center.

To customize the logo, images, and icons of the Secure Client GUI, you must create a Secure Client customization object in the management center. The name of this customization object must match the Secure Client GUI filename. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each OS, see the Cisco Secure Client Administrator Guide.

For example, if you want to replace the corporate logo for Windows clients, you must create a customization object with the name as `company_logo` and add this customization object to the remote access VPN policy. If you use a different name for the customization object, the Secure Client installer does not change the component. However, if you deploy your own executable to customize the GUI, the customization object can have any name.

Location of all images files:

- Windows: **%PROGRAMFILES%\Cisco\Cisco Secure Client\res**
- Linux: **/opt/cisco/secureclient/resources** or **/opt/cisco/anyconnect/resources**
- macOS: Not supported

Note When the remote access VPN connection is established, the logo or images are downloaded to the client directory. Ensure that you restart the client for the updated logo or images to appear in your client.

How to Customize Secure Client Images and Icons

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create the icons or images using the correct extensions, and sizes.

Images do not appear properly if the image size is not correct. The management center or the threat defense device does not verify the image size.

For more information about the filenames, extensions, and sizes, see the Cisco Secure Client Administrator Guide.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization object.

Ensure that the customization object name matches the Secure Client GUI filenames. For more information about the filenames, see the Cisco Secure Client Administrator Guide.

d) From the **Customization Type** drop-down list, choose **Icon and Images**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the file. The supported file extensions are .png, .ico, and .jpeg.
g) Repeat the steps from 2a - f to add multiple icons and images.

Step 3 Add the customization object to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Icons and Images**.
d) Click **+** to select the file.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, see Verify Secure Client Customizations, on page 1878.

Deploy Scripts on Endpoint Devices Using Secure Client

Secure Client lets you download and run scripts when the following events occur:

- Establishment of a new client VPN session with the threat defense. The script triggered by this event is an OnConnect script because it requires this filename prefix. Reconnection of the VPN session does not trigger this script.
- Disconnection of a client VPN session with the threat defense. The script triggered by this event is an OnDisconnect script because it requires this filename prefix.

These scripts run asynchronously and do not delay the connection establishment or disconnection. They can be of any extension and must be executable on the endpoint. Secure Client identifies the OnConnect and OnDisconnect scripts by the filename. It looks for a file whose name begins with OnConnect or OnDisconnect regardless of the file extension.

Some examples of this feature are:

- Refresh the group policy upon VPN connection.
- Mount a network drive upon a VPN connection.
- Unmount a network drive upon a VPN disconnection.

To enable scripts, check the **Enable Scripting** option in the VPN profile. By default, the client does not launch scripts. The client does not require the script to be written in a specific language. It requires an application that can run the script to be installed on the client computer. For the client to launch the script, the script must run from the command line.

Secure Client can only launch scripts after the user logs in and establishes a VPN session. You cannot launch the OnConnect script from the Start Before Logon (SBL) GUI. You must check the **Enable Post SBL On Connect Script** option in the VPN profile to trigger the scripts once the user logs in. Secure Client is a 32-bit application. When the scripts run on a 64-bit Windows version, they use the 32-bit version of cmd.exe.

How to Add Customized Scripts for Secure Client

Before you begin

1. Configure a remote access VPN.
2. Enable scripting in the VPN profile.
3. Add the VPN profile to the remote access VPN group policy.

Procedure

Step 1 Create OnConnect and OnDisconnect scripts for a platform.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Scripts**.
e) From the **Platform** drop-down list, choose a platform.
f) Select one of the following:

- **On Connect**: To select an OnConnect script.

- **On Disconnect**: To select an OnDisconnect script.

g) Click **Browse** and select the script you want to execute on the endpoint.

Step 3 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Localization**.
d) Click **+** to select the translation file.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

Verify the Secure Client customizations. For more information, see Verify Secure Client Customizations, on page 1878.

Deploy Custom Applications Using Cisco Secure Client APIs

For Windows, Linux, or MacOs machines, you can create and deploy a custom client that uses the Secure Client APIs. You can use this client binary file to replace the Secure Client GUI or CLI binary files.

Your executable can call any resource files such as logo images that you import to the management center. When you deploy your own executable, you can use any filenames for your resource files.

The following table lists the filenames of the client executable files for the different operating systems:

Table 109: Filenames of the Secure Client Executable Files

Client OS	Client GUI File	Client CLI File
Windows	vpnui.exe	vpncli.exe
Linux	vpnui	vpn
MacOS	Not supported by the management center deployment. However, you can deploy an executable for the macOS that replaces the client GUI using other means, such as Altiris Agent.	vpn

How to Deploy Custom Applications Using Cisco Secure Client API

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create the custom application using the Cisco Secure Client APIs.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Binary**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the custom application.

Step 3 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Binaries**.
d) Click **+** to select the translation file.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customize the Secure Client Installer

You can customize the Secure Client GUI by creating a custom transform that deploys with the client installer program. You can import the transform to the management center and deploy it to the threat defense device. The threat defense deploys this transform to the endpoint using the client installer program.

Note This customization is available only for Windows.

Localize the Client Installer

You can translate the messages displayed by the Cisco Secure Client installer. The management center uses a transform to translate the messages displayed by the installer. The transform alters the installation but leaves the original security-signed MSI intact. These transforms only translate the installer screens and do not translate the client GUI screens.

Every release of Cisco Secure Client includes a localized transform that administrators can upload to the management center whenever they upload Cisco Secure Client packages with new software. If you use our localization transform, ensure that you update them with the latest release from Cisco.com whenever you upload a new Cisco Secure Client package.

How to Customize or Localize the Client Installer

Before you begin

Configure one or more remote access VPN policies.

Procedure

Step 1 Create a customized or localized transform.

Step 2 Create a new Secure Client Customization object.

a) Choose **Objects** > **Object Management** > **VPN** > **Secure Client Customization**.
b) Click **Add Secure Client Customization**.
c) Enter the name and description for the customization.
d) From the **Customization Type** drop-down list, choose **Customized Installer Transform** or **Localized Installer Transform**.
e) From the **Platform** drop-down list, choose a platform.
f) Click **Browse** and select the transform.

Step 3 Add the customization to the remote access VPN policy.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click the edit icon of the remote access VPN policy.
c) Click **Advanced > Secure Client Customizations > Custom Installer Transforms** or **Localized Installer Transforms**.
d) Click **+** to select the transform.
e) Click **Add**.
f) Click **OK**.

Step 4 Click **Save**.

Step 5 Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Verify Secure Client Customizations

Validate the Deployment

After the deployment is complete, validate the deployment in the management center. Click the **Transcript Details** ( )) icon to verify the commands generated for the customizations.

Examples

1. The example below shows the transcript details of a GUI text and messages customization: Secure Client en_us localization with customized prompts.

```
import webvpn translation-table AnyConnect language en-us disk0:/AnyConnect_en-us.po
```

2. The example below shows the transcript details of customized icons and images: customization of the Secure Client logo to ABC logo.

```
import webvpn AnyConnect-customization type resource platform win name company_logo.png
 disk0:/company_logo.png
```

3. The example below shows the transcript details of the customized OnConnect and OnDisconnect scripts. The On connect script mounts the network drive and the On disconnect script unmounts the network drive.

```
import webvpn AnyConnect-customization type binary platform win name
  scripts_OnConnect_mount.bat disk0:/mount.bat
import webvpn AnyConnect-customization type binary platform win name
  scripts_OnDisconnect_unmount.bat disk0:/unmount.bat
```

Verify Customizations Using Threat Defense Commands

Use the following commands on the threat defense to verify the customizations:

- **show import webvpn translation-table detailed**: Shows the available translation tables.

```
HQ-FTD# show import webvpn translation-table detailed
 Translation Tables' Templates:
   AnyConnect           ia4DaAXNSvl5pZboQRGJcs9KMXY=
   customization
 Translation Tables:
   fr                   customization        BWWodsOt1PbvDvYOp8hLb3W7a64=
   ja                   customization        lNvUk1+qTLNZyNrBcApMQPHnm1M=
   ru                   customization        UqyKyUAcjR+xTGUtdiIFnoIiW5U=
```

- **show import webvpn AnyConnect-customization detailed**: Shows the details of the Secure Client customizations.

```
HQ-FTD# show import webvpn AnyConnect-customization detailed
OEM resources for AnyConnect client:
  linux-64/binary/scripts_OnConnect_conn.sh           w6+n7z80D/8AR+ul2f7DvTmcDTw=
  linux-64/binary/scripts_OnDisconnect_discon.sh      jx5LJC2XBEmEkGeww59CAkszvnI=
  linux-64/resource/company-logo.png                  GsfBDroqGSQEEwuBDS/3DJNVv88=
  win/binary/scripts_OnConnect_mount.bat              dzjfsLYYft/XMlPlzskKl+Wv1bw=
  win/binary/scripts_OnDisconnect_unmount.bat         k6xlKhF1l2IRyJu08+sdYXgKNgM=
  win/resource/company_logo.png                       cmEvxwqvtaS+Pz/6sb9n3NZudS4=
```

Verify Customizations in Secure Client

- In Secure Client, click the **Message History** tab to verify that the customizations are downloaded.

  Use the DART tool to view the client-side diagnostics.

Table 110: Verifying the Customizations in Secure Client

Customization	Verification
GUI text and message customizations	• Verify if Secure Client has the language localization or customized files in the following locations: • Windows: %ProgramData%\Cisco\Cisco AnyConnect Secure Mobility Client\l10n\<language-code>\LC_MESSAGES (AnyConnect versions 4.9 and earlier) • Windows: %ProgramData%\Cisco\Cisco Secure Client\l10n\<language-code>\LC_MESSAGES (Secure Client versions 5.0 and later) • For Mac OS and Linux: /opt/cisco/anyconnect/l10n/<LANGUAGE-CODE>/LC_MESSAGES /opt/cisco/secureclient/l10n/<LANGUAGE-CODE>/LC_MESSAGES • Verify the contents of the localized or customized file and confirm if they have the customized or localized strings. For example: AnyConnect.mo
Image and icon customizations	• Verify if Secure Client has the customized files in the following locations: • Windows: %PROGRAMFILES%\ Cisco\Cisco AnyConnect Secure Mobility Client\res\ (AnyConnect versions 4.10 and earlier) • Windows: %PROGRAMFILES%\ Cisco\Cisco Secure Client\UI\res (Cisco Secure Client 5.0 and above) • Linux: /opt/cisco/anyconnect/resources or /opt/cisco/secureclient/resources • Verify the content of the customized icon or image file.
Customized OnConnect and OnDisconnect scripts	• Verify if the customized scripts are in the following locations: • Windows: %ProgramData%\Cisco\Cisco Secure Client\Script (Cisco Secure Client 5.0 and above) • Windows: %ProgramData%\Cisco\ Cisco AnyConnect Secure Mobility Client\Script (AnyConnect versions 4.9 and earlier) • Mac OS and Linux: /opt/cisco/anyconnect/script or /opt/cisco/secureclient/vpn/script • Verify the script.

Configure Secure Client Management VPN Tunnel

A management VPN tunnel provides connectivity to the corporate network whenever a client system is powered up, without the VPN users having to connect to the VPN. This helps organizations keep their endpoints up-to-date with software patches and updates. Management tunnel disconnects when the user-initiated VPN tunnel is established.

This section provides information about configuring Secure Client management VPN tunnel on Firewall Threat Defense. Configuring the Secure Client management tunnel on Firewall Threat Defense using the Cloud-Delivered Firewall Management Center web interface requires the following settings:

- A **Connection profile** with certificate-based authentication and a group URL.
- **Secure Client management VPN profile file**, configured a server with group URL and backup servers if required.
- A **Group policy** with the management VPN profile, split tunneling with explicitly included networks, client bypass protocol, and no banner.

For detailed instructions on configuring the Secure Client Management VPN tunnel, see Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense, on page 1882.

Requirements and Prerequisites for Secure Client Management VPN Tunnel

Software and Configuration Requirements

Ensure that you have the following before you configure the Secure Client Management tunnel on using the Firewall Threat Defense using the Cloud-Delivered Firewall Management Center web interface:

- Ensure that you are using Firewall Threat Defense and Cloud-Delivered Firewall Management Center versions 6.7.0 or above.
- Download the Secure ClientSecure Client VPN Webdeploy package 4.7 or above and upload it to Firewall Threat Defense remote access VPN.
- Ensure that the certificate authentication is configured in the connection profile.
- Ensure that no banner is configured in the group policy.
- Check the split tunneling configuration in the management tunnel-group policy.

Certificate Requirements

- Firewall Threat Defense must have a valid identity certificate for remote access VPN and the root certificate from the local certifying authority (CA) must be present on the Firewall Threat Defense.
- Endpoints connecting to the management VPN tunnel must have a valid identity certificate.
- CA certificate for Firewall Threat Defense's identity certificate must be installed on the endpoints and the CA certificate for the endpoints must be installed on the Firewall Threat Defense.
- The identity certificate issued by the same local CA must be present in the Machine store.

  Certificate Store (For Windows) and/or in System Keychain (For macOS).

Limitations of Secure Client Management VPN Tunnel

- Secure Client Management VPN Tunnel supports only certificate authentication, it does not support AAA-based authentication.
- Public or private proxy settings are not supported.
- Secure Client upgrade and AnyConnect module download are not supported when the management VPN tunnel is connected.

Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense

Procedure

Step 1 **Create a remote access VPN policy configuration using the wizard**:

For information about configuring a remote access VPN, see Configuring a New Remote Access VPN Connection, on page 1821.

Step 2 **Configure connection profile settings for management VPN tunnel**:

Note
It is advisable to create a new connection profile to be used only for Secure Client management VPN tunnel.

a) Edit the remote access VPN policy you have created.
b) Select and edit the connection profile that will be used for management VPN tunnel.
c) From **AAA** drop-down menu, choose **Authentication Method** and click **Client Certificate Only**. Configure the authorization and accounting settings as required.
d) Click the **Aliases** tab of the connection profile.
e) Click **Add (+)** under URL Aliases and **URL Alias** for the connection profile.
f) Click **Enabled** to enable the URL.
g) Click **OK** and then click **Save** to save the connection profile settings.

For more information about connection profile settings, see Configure Connection Profile Settings, on page 1832.

Step 3 **Create a management tunnel profile using the Secure Client profile editor**:

a) Download the Secure Client **VPN Management Tunnel Standalone Profile Editor** from Cisco Software Download Center if you have not done already.
b) Create a management tunnel profile with the required settings for your VPN users and save the file.
c) Configure a server in the Server List with the group URL you have configured in the connection profile.

For information about creating a management profile using the Profile Editor, see the *Cisco Secure Client (including AnyConnect) Administrator Guide*.

Step 4 **Create a management tunnel object**:

a) On your Cloud-Delivered Firewall Management Center web interface, navigate to **Objects** > **Object Management** > **VPN** > **Secure Client File**
b) Click **Add Secure Client File**.
c) Specify the **Name** for the Secure Client file.

d) Click **Browse** and select the management tunnel profile file you have saved.
e) Click the **File Type** drop-down and select **Secure Client Management VPN Profile**.
f) Click **Save**.

Note
You an also create the management tunnel object when you create or update Secure Client settings for a group policy. See Group policy options for Secure Client, on page 3065.

Step 5 **Associate a management profile with a group policy and configure group policy settings**:

You must add the management VPN profile to the group policy associated with the connection profile used for the management tunnel VPN connection. When the user connects, the management VPN profile is downloaded along with the user VPN profile already mapped to the group policy, enabling the management VPN tunnel feature.

Caution
No Banner: Check and ensure that no banner is configured in the group policy settings. You can check the banner settings under **Group Policy** > **General Settings** > **Banner**.

a) Edit the connect profile you have created for management VPN tunnel.
b) Click **Edit Group Policy** > **Secure Client** > **Management Profile Edit Group Policy** and choose **AnyConnect Secure Client**, then click **Management Profile**.
c) Click the **Management VPN Profile** drop-down and select the management profile file object you have created.

Note
You can also click + and add a new Secure Client Management VPN Profile object.

d) Click **Save**.

Step 6 **Configure split tunneling in group policy**:

a) Click **Edit Group Policy** and then choose **General**, then click **Split Tunneling**.
b) From the IPv4 or IPv6 split tunneling drop-down, select **Tunnel networks specified below**.
c) Select the Split Tunnel Network List Type: **Standard Access List** or **Extended Access List**, and then select the required access list to allow the traffic over the management VPN tunnel.
d) Click **Save** to save the split tunnel settings.

Secure Client Custom Attribute

Secure Client Management VPN tunnel requires split include tunneling configuration by default. If you are configuring Secure Client custom attribute in the group policy to deploy the management VPN tunnel with split tunneling to tunnel all, you can do so using FlexConfig because Cloud-Delivered Firewall Management Center 6.7 web interface does not support Secure Client custom attribute .

The following is an example command for Secure Client custom attribute:

```
webvpn
 anyconnect-custom-attr ManagementTunnelAllAllowed description ManagementTunnelAllAllowed
anyconnect-custom-data ManagementTunnelAllAllowed true true
group-policy MGMT_Tunnel attributes
 anyconnect-custom ManagementTunnelAllAllowed value true
```

Step 7 **Deploy, verify, and monitor the remote access VPN policy**:

a) Deploy the management VPN tunnel configuration to Firewall Threat Defense.

Note

Client systems must connect to the Firewall Threat Defense remote access VPN once to download the management tunnel VPN profile to the client machines.

b) You can verify the Secure Client management VPN tunnel at **AnyConnect Secure Mobility ClientSecure Mobility Client** and choose **VPN**, then click **Statistics**.

You can also check the management VPN session details on the Firewall Threat Defense command prompt using the **show vpn-sessiondb anyconnect** command.

c) On your Cloud-Delivered Firewall Management Center web interface, click **Analysis** to view the management tunnel session information.

Related Topics

Configure Connection Profile Settings, on page 1832
Firewall Threat Defense group policy objects, on page 3061

Multiple Certificate Authentication

Multiple certificate based authentication gives the ability to have the Firewall Threat Defense validate the machine or device certificate, to ensure the device is a corporate-issued device, in addition to authenticating the user's identity certificate to allow VPN access using the Secure Client during SSL or IKEv2 EAP phase.

The multiple certificates option allows certificate authentication of both the machine and user via certificates. Without this option, you could only do certificate authentication of either machine or the user, but not both.

Guidelines and Limitations of Multiple Certificate Authentication

Note When you configure multiple certificate authentication, ensure that you set the value of **AutomaticCertSelection** to true in the Cisco Secure Client Profile settings.

- Multiple certificate authentication currently limits the number of certificates to two.
- Secure Client must indicate support for multiple certificate authentication. If that is not the case then the gateway uses one of the legacy authentication methods or fails the connection. Secure Client version 4.4.04030 or later supports Multi-Certificate based authentication.
- Secure Client supports only RSA-based certificates.
- Only SHA256, SHA384, and SHA512 based certificate are supported during the Secure Client aggregate authentication.
- Certificate authentication cannot be combined with SAML authentication.

Configuring Multiple Certificate Authentication

Before you begin

Before you configure multiple certificate authentication, ensure that you have configured the certificate enrollment object that is used to obtain the identity certificate for each Firewall Threat Defense device. For more information, see Certificate map objects, on page 3058.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select the remote access VPN policy and click **Edit**.

Note
If you have not configured a remote access VPN, click **Add** to create a new remote access VPN policy.

Step 3 Select and **Edit** a connection profile to configure multiple certificate authentication.

Step 4 Click **AAA** settings and select **Authentication Method** > **Client Certificate Only** or **Client Certificate & AAA**.

Note
Select the **Authentication Server** if you have selected the Client Certificate & AAA authentication method

Step 5 Select the **Enable multiple certificate authentication** checkbox.

Step 6 Choose one of the certificates to **Map username from client certificate**:

- **First Certificate**— Select this option to map the username from the machine certificate sent from the VPN client.
- **Second Certificate**— Select this option to map the username from the user certificate sent from the client.

The username sent from the client is used as the VPN session username when certificate only authentication is enabled. When AAA and certificate authentication is enabled, VPN session username will be based on prefill option.

Note
If you select the **Map specific field** option, which includes the username from the client certificate, the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively.

If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile DN rules are used for enhanced certificate authentication.

If you have selected the Client Certificate & AAA authentication, select the **Prefill username from certificate on user login window** option to prefill the secondary username from the client certificate when the user connects via AnyConnect VPN module of Cisco Secure Client.

- **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.

Step 7 Configure the required AAA settings and connection profile settings for the remote access VPN.

Step 8 Save the connection profile and remote access VPN configuration and deploy it on your Firewall Threat Defense device.

Manage VPN Access of Remote Users Based on Geolocation

You can manage the remote access VPN connections of users based on their geolocations. By configuring rules such that they allow or deny VPN connections from specific countries or regions, you can meet compliance requirements and enhance security. Connections that don't meet these location-based criteria are blocked before authentication and the details are logged in the Cloud-Delivered Firewall Management Center (**Devices** > **Troubleshoot** > **Troubleshooting Logs**).

This feature supports all versions of Secure Client.

Prerequisites

Firewall Threat Defense device must be Version 7.7.0 or later.

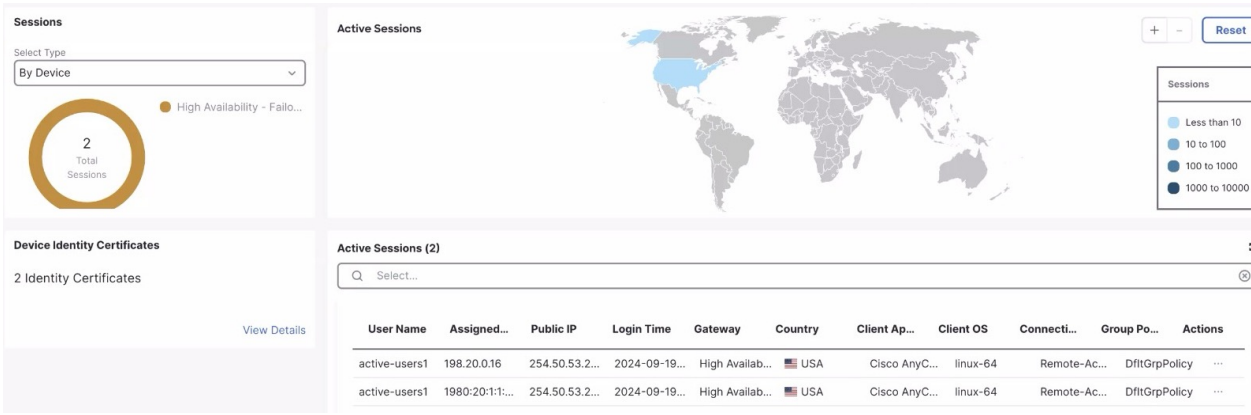
Workflow to Manage VPN Access of Remote Users Based on Geolocation

Step	Task	More Information
1	Define a policy to allow geolocation-based access control for your remote clients.	Configure a service access object, on page 2952
2	Update the remote access VPN configuration with the policy.	Configure Access Interfaces for Remote Access VPN, on page 1851
3	Deploy the configurations on the devices.	—
4	After clients connect to the Firewall Threat Defense device: **1.** Verify the active remote access VPN sessions in the **Remote Access VPN** dashboard. **2.** Verify the logs for the denied remote access VPN sessions at **Devices** > **Troubleshoot** > **Troubleshooting Logs**.	Monitor and Troubleshoot Service Access Policies, on page 1887

Guidelines and Limitations for Managing Remote Access VPN Users Based on Geolocation

Guidelines

- In a service access object, if you use a geolocation object (country, continent, or geolocation object), use it only in one rule.
- Configure the service access rules in the correct order because you cannot reorder these rules.



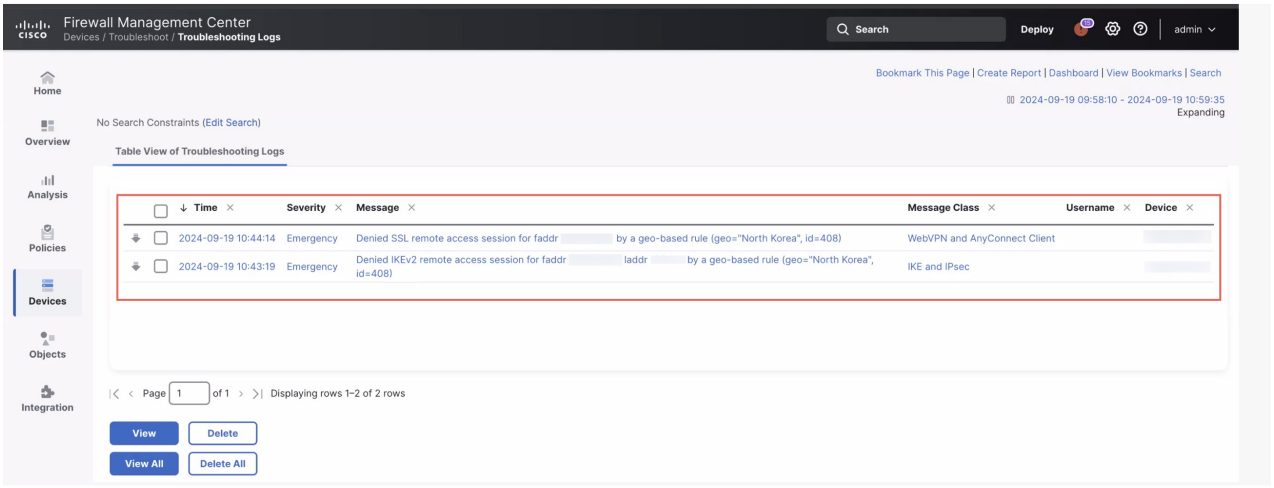
Limitations

- Clustering is not supported.
- Geolocation-based unclassified IP addresses are not categorized according to their geographic origin. For such unclassified IP addresses, the Cloud-Delivered Firewall Management Center enforces the default service access policy action.
- Connections from IETF RFC1918 addresses are allowed for geolocation-based remote access VPN regardless of service-access policy settings.

Monitor and Troubleshoot Service Access Policies

Monitor Active Remote Access VPN Sessions in Remote Access VPN Dashboard

Choose **Overview** > **Dashboards** > **Remote Access VPN**.



Monitor Denied Remote Access VPN Sessions

Monitor the denied remote access VPN sessions at **Devices** > **Troubleshoot** > **Troubleshooting Logs**. To view the denied remote access VPN sessions, you must configure the syslog settings in the Firewall Threat Defense:

1. Choose **Devices** > **Platform Settings** and create or edit a threat defense policy.
2. In the left pane, click **Syslog**.
3. Click the **Logging Setup** tab.
4. Check the **Enable Logging** check box.
5. Click the **VPN Logs** radio button.
6. From the **Logging Level** drop-down list, choose **6 - informational**.
7. Click **Save**.

Note You cannot view the denied remote access VPN sessions if the **All Logs** option is configured with a **Logging Level** between 0 and 2.

Verify Service Access Policies

From the Firewall Threat Defense device CLI, run the following commands:

- **show running-config service-access**: Displays the user-defined service access policies.

```
firepower#show running-config service-access
   service-access deny geolocation OBJGRP_Asia1
   service-access permit interface outside ra-ssl-client geolocation OBJGRP_India
   service-access deny ra-ikev2 geolocation any
```

- **show service-access**: Displays details of the user-defined service access policies.

```
firepower# show service-access
1 outside          : ra-ikev2 ra-ssl-client (permit) hits = 8288
  Last hit time    : 10:58:10.038 IST Tue Jul 16 2024
  object-group     : FMC_INTERNAL_XXY
2 any              : ra-ikev2 ra-ssl-client (deny) hits = 123
  Last hit time    : 11:23:12.032 IST Tue Jul 17 2024
  object-group     : any

firepower# show service-access detail
1 outside          : ra-ikev2 ra-ssl-client (permit) hits = 8288
  Last hit time    : 10:58:10.038 IST Tue Jul 16 2024
  object-group     : FMC_INTERNAL_XXY
  geolocation      : Egypt(818) Jordan(400)
                     Iran (Islamic Republic of)(364)
                     Saudi Arabia(682)
```

- **show geodb**: Displays details of the geolocation table.

  show geodb { **ipv4** | **ipv6** | **counters** | **context** } [**location** *country_name* | **lookup** *ip_address*] [**detail**]

  - **show geodb** { **ipv4** | **ipv6** } : Displays the total number of IPv4 or IPv6 address mappings.

```
firepower# show geodb ipv4
 Geolocation Table - IPv4
 Total number of mappings available: 532507
 Last geolocation data read time:  17:02:13.000 IST Thu Jul 18 2024
```

```
Running geolocation update version: 2024-02-15-019
```

- **show geodb** { **ipv4** | **ipv6** } **location** *country_name* **detail**: Displays the details of the IPv4 or IPv6 address mappings.

```
firepower# show geodb ipv4 location Antarctica detail
Geolocation Table - IPv4
id=0x00007fff82c284e0, geo_id=10, hits=0
        range_lower=77.70.176.176, range_upper=77.70.176.183
id=0x00007fff82cca360, geo_id:10, hits=0
     range_lower=79.110.169.69, range_upper=79.110.169.69
Total number of mappings available: 28
```

- **show geodb counters**: Displays the details of active, permitted, and denied sessions.

```
firepower# show geodb counters
current   - ongoing sessions
permitted - cumulative permitted sessions
denied    - cumulative denied sessions
Location                current          permitted      denied
Egypt                     0                  0             5
India                     45                 1345         45
```

- **show geodb** { **ipv4** | **ipv6lookup** *ip_address*: Displays the geolocation of a specific IPv4 or IPv6 address.

```
firepower# show geodb ipv4 lookup 223.223.128.24
Geolocation of 223.223.128.24 is "India" (356) with id=0x000015114d0aa330
Matching network range: 223.223.128.0 - 223.223.159.255
```

Troubleshoot Service Access Policies

- **Syslogs**

  Enable remote access VPN service access syslogs:

  1. Choose **Devices** > **Platform Settings**.
  2. Create or edit a platform settings policy.
  3. In the left pane, click **Syslog**.
  4. Click the **Logging Setup** tab and check the **Enable Logging** check box.
  5. Click the **Syslog Settings** tab and enable the syslogs for service access syslog 751031 and 716166.

- **Commands**
  - Use the **show running-config service-access**, and **show service-access** commands to view details of user-defined service access policies.
  - Use the **show geodb** command to view details of the geolocation table.
  - Use the **debug geolocation <debug-level>** command to capture debug logs related to geolocation. The debug levels can be 1 (Error), 2 (Warning), 3 and 4 (Info), 5 (Debug), or 255 (Debug all).

- Use the **clear geodb counters** command to clear the geolocation table counters such as the hit counts of the service access policies. However, you cannot clear the actual permitted and denied counters for locations using this command; you can clear these counters only after you reboot the device.

Customizing Remote Access VPN AAA Settings

This section provides information about customizing your AAA preferences for remote access VPNs. For more information, see Configure AAA Settings for Remote Access VPN, on page 1835.

Authenticate VPN Users via Client Certificates

You can configure remote access VPN authentication using client certificate when you create a new remote access VPN policy using the wizard or by editing the policy later.

Before you begin

Configure the certificate enrollment object that is used to obtain the identity certificate for each Firewall Threat Defense device that acts as a VPN gateway.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.

Step 3 For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

Step 4 Click **AAA** > **Authentication Method** > **Client Certificate Only**.

With this authentication method, the user is authenticated using a client certificate. You must configure the client certificate on VPN client endpoints. By default, the user name is derived from client certificate fields CN and OU respectively. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display the following default values, respectively: **CN (Common Name)** and **OU (Organisational Unit)**. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields, that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

- Primary and Secondary fields pertaining to the **Map specific field** option contain these common values:
  - C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier
  - EA (Email Address)

- GENQ (Generational Qualifier)
- GN (Given Name)
- I (Initial)
- L (Locality)
- N (Name)
- O (Organisation)
- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1835.

Step 5 Save your changes.

Related Topics

Configure VPN User Authentication via Client Certificate and AAA Server

When you configure remote access VPN authentication to use both client certificate and authentication server, VPN client authentication is done using both the client certificate validation and AAA server.

Before you begin

- Configure the certificate enrollment object that you use to obtain the identity certificate for each Firewall Threat Defense device that acts as a VPN gateway.
- Configure the RADIUS server group object and any AD or LDAP realms to use in the remote access VPN policy configuration.
- Ensure that the AAA Server is reachable from the Secure Firewall Threat Defense device for the remote access VPN configuration to work.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy for which you want to update the authentication or click **Add** to create new one.

Step 3 If you choose to create new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

Step 4 Go to **AAA** and from the **Authentication Method** drop-down, choose **Client Certificate & AAA**.

- When you select the **Authentication Method** as:

  Client Certificate & AAA—Both types of authentication are done.

  - **AAA**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
  - **Client Certificate**—Authenticates the user with client certificate. You must configure client certificate on the VPN client endpoints. By default, the username is derived from client certificate fields CN & OU respectively. If you use any other field in the client profile to specify the username, use **Primary Field** and **Secondary Field** to map appropriate fields.

    If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

    Primary and Secondary fields pertaining to the **Map specific field** option contains these common values:

    - C (Country)
    - CN (Common Name)
    - DNQ (DN Qualifier
    - EA (Email Address)
    - GENQ (Generational Qualifier)
    - GN (Given Name)
    - I (Initial)
    - L (Locality)
    - N (Name)
    - O (Organisation)

- OU (Organisational Unit)
- SER (Serial Number)
- SN (Surname)
- SP (State Province)
- T (Title)
- UID (User ID)
- UPN (User Principal Name)

- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1835.

Step 5 Save your changes.

Manage Password Changes over VPN Sessions

Password management allows remote access VPN policy administrator to configure the notification settings for the remote access VPN users on their password expiry. Password management is available in AAA settings with authentication methods AAA Only and Client Certificate & AAA. For more information, see Configure AAA Settings for Remote Access VPN, on page 1835.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access VPN policy that you want to update.

Step 3 Click **Edit** on the connection profile that includes AAA settings.

Step 4 Choose **AAA** > **Advanced Settings** > **Password Management**.

Step 5 Check the **Enable Password Management** check-box and select one of the following:

- Notify User - days ahead of password expiry and specify the number of days in the box.
- Notify user on the day of password expiration.

Step 6 Save your changes.

Related Topics

Configure Connection Profile Settings, on page 1832

Send Accounting Records to the RADIUS Server

Accounting records in remote access VPN help the VPN administrator track the services that users access and the amount of network resources that they consume. Accounting information includes when user session start and stop, username, the number of bytes that pass through the device for each session, the service used, and the duration of each session.

You can use accounting alone or together with authentication and authorization. When you activate AAA accounting, the network access server reports the user activity to the configured accounting server. You can configure a RADIUS server as the accounting server so that the Cloud-Delivered Firewall Management Center sends all the user activity information to the RADIUS server.

Note You can use the same RADIUS server or separate RADIUS servers for authentication, authorization, and accounting in remote access VPN AAA settings.

Before you begin

- Configure a RADIUS group object with RADIUS servers to receive authentication requests or accounting records. For more information, see RADIUS server group configuration options, on page 2944.
- Ensure that the RADIUS server is reachable from the Firewall Threat Defense device. Configure routing on your Cloud-Delivered Firewall Management Center at **Devices** > **Device Management**, and click **Edit** ( ). Then, click the **Routing** tab to ensure connectivity to the RADIUS server.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** on the remote access policy for which you want to configure RADIUS server, or create new remote access VPN policy.

Step 3 Click **Edit** on the connection profile that includes AAA settings and choose **AAA**.

Step 4 Select the RADIUS server from the **Accounting Server** drop-down.

Step 5 Save your changes.

Related Topics

Configure Connection Profile Settings, on page 1832

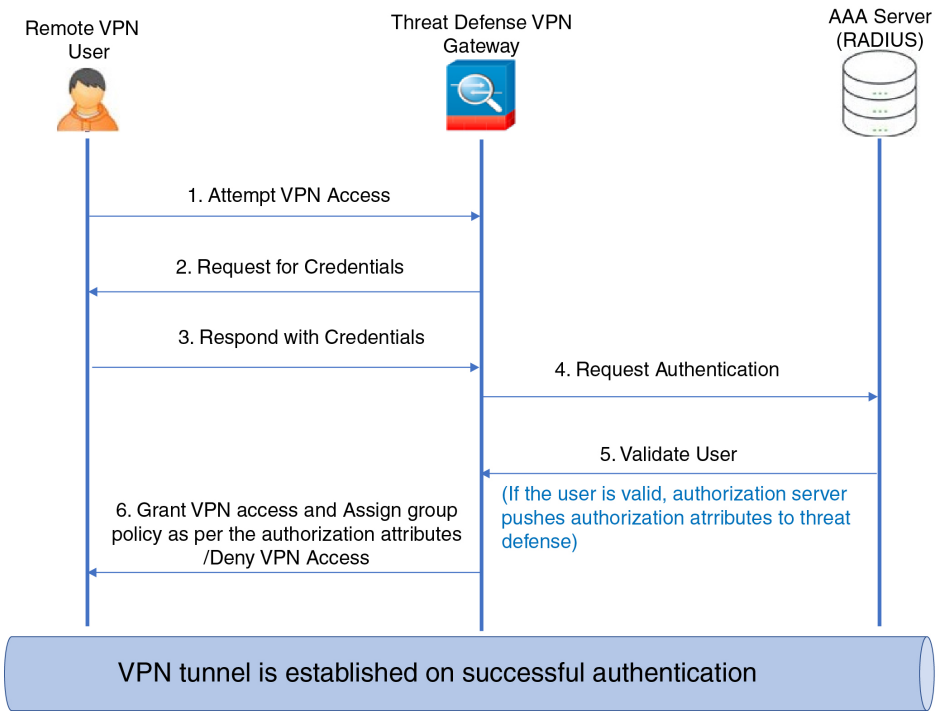
Delegating Group Policy Selection to Authorization Server



The group policy applied to a user is determined when the VPN tunnel is being established. You can select a group policy for a connection profile while creating a remote access VPN policy using the wizard or update the connection policy for connection profiles later. However, you can configure the AAA (RADIUS) server to assign the group policy or it is obtained from the current connection profile. If the Firewall Threat Defense

device receives attributes from the external AAA server that conflicts with those configured on the connection profile, then attributes from the AAA server always take the precedence.

You can configure ISE or the RADIUS Server to set the Authorization Profile for a user or user-group by sending IETF RADIUS Attribute 25 and map to the corresponding group policy name. You can configure specific group policy to a user or user group to push a Downloadable ACL, set a banner, Restrict VLAN, and configure the advanced option of applying an SGT to the session. These attributes are applied to all users that are part of that group when the VPN connection is established.

For more information, see the Configure Standard Authorization Policies section of Cisco Identity Services Engine Administrator Guide and RADIUS Server Attributes for Secure Firewall Threat Defense, on page 1841.

Figure 374: Remote Access VPN Group Policy Selection by AAA Server

Related Topics

Configure a group policy object, on page 3062
Configure Connection Profile Settings, on page 1832

Override the Selection of Group Policy or Other Attributes by the Authorization Server

When a remote access VPN user connects to the VPN, the group policy and other attributes configured in the connection profile are assigned to the user. However, the remote access VPN system administrator can delegate the selection of group policy and other attributes to the authorization server by configuring ISE or the RADIUS Server to set the Authorization Profile for a user or user-group. Once users are authenticated, these specific authorization attributes are pushed to the Firewall Threat Defense device.

Before you begin

Ensure that you configure a remote access VPN policy with RADIUS as the authentication server.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**.

Step 3 Select RADIUS or ISE as the authorization server if not configured already.

Step 4 Select **Advanced** > **Group Policies** and add the required group policy. For detailed information about a group policy object, see Configure a group policy object, on page 3062.

You can map only one group policy to a connection profile; but you can create multiple group policies in a remote access VPN policy. These group policies can be referenced in ISE or the RADIUS server and configured to override the group policy configured in the connection profile by assigning the authorization attributes in the authorization server.

Step 5 Deploy the configuration on the target Firewall Threat Defense device.

Step 6 On the authorization server, create an Authorization Profile with RADIUS attributes for IP address and downloadable ACLs.

When the group policy is configured in the authorization server selected for remote access VPN, the group policy overrides the group policy configured in the connection profile for the remote access VPN user after the user is authenticated.

Related Topics

Configure a group policy object, on page 3062

Deny VPN Access to a User Group

When you do not want an authenticated user or user group to be able to use VPN, you can configure a group policy to deny VPN access. You can configure a group policy in a remote access VPN policy and reference it in the ISE or RADIUS server configuration for authorization.

Before you begin

Ensure that you have configured remote access VPN using the Remote Access Policy wizard and configured authentication settings for the remote access VPN policy.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**.

Step 3 Select **AdvancedGroup Policies**.

Step 4 Select a group policy and click **Edit** or add a new group policy.

Step 5 Select **AdvancedSession Settings** and set **Simultaneous Login Per User** to 0 (zero).
This stops the user or user group from connecting to the VPN even once.

Step 6 Click **Save** to save the group policy and then save the remote access VPN configuration.

Step 7 Configure ISE or the RADIUS server to set the Authorization Profile for that user/user-group to send IETF RADIUS Attribute 25 and map to the corresponding group policy name.

Step 8 Configure the ISE or RADIUS server as the authorization server in the remote access VPN policy.

Step 9 Save and deploy the remote access VPN policy.

Related Topics

Configure Connection Profile Settings, on page 1832

Restrict Connection Profile Selection for a User Group

When you want to enforce a single connection profile on a user or user group, you can choose to disable the connection profile so that the group alias or URLs are not available for the users to select when they connect using the AnyConnect VPN module of Cisco Secure Client.

For example, if your organization wants to use specific configurations for different VPN user groups such as mobile users, corporate-issued laptop users, or personal laptop users, you can configure connection a profile specific to each of these user groups and apply the appropriate connection profile when the user connects to the VPN.

The AnyConnect VPN module of Cisco Secure Client, by default, shows a list of the connection profiles (by connection profile name, alias, or alias URL) configured in Cloud-Delivered Firewall Management Center and deployed on Firewall Threat Defense. If custom connection profiles are not configured, AnyConnect VPN module of Cisco Secure Client shows the *DefaultWEBVPNGroup* connection profile. Use the following procedure to enforce a single connection profile for a user group.

Before you begin

- On your Cloud-Delivered Firewall Management Center web interface, configure remote access VPN using the remote access VPN policy wizard with Authentication Method as 'Client Certificate Only' or 'Client Certificate + AAA'. Choose the username fields from the certificate.
- Configure ISE or RADIUS server for authorization and associate the group policy with the authorization server.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access policy and click **Edit**.

Step 3 Select **Access Interfaces** and disable **Allow users to select connection profile while logging in**.

Step 4 Click **Advanced Certificate Maps**.

Step 5 Select **Use the configured rules to match a certificate to a Connection Profile**.

Step 6 Select the **Certificate Map Name** or click the **Add** icon to add a certificate rule.

Step 7 Select the **Connection Profile**, and click **Ok**.

With this configuration, when a user connects from the AnyConnect VPN module of Cisco Secure Client, the user will have the mapped connection profile and will be authenticated to use the VPN.

Update the Secure Client Profile for Remote Access VPN Clients

Secure Client Profile is an XML file that contains an administrator-defined end user requirements and authentication policies to be deployed on a VPN client system as part of Secure Client. It makes the preconfigured network profiles available to end users.

You can use the GUI-based Secure Client Profile Editor, an independent configuration tool, to create them. The standalone profile editor can be used to create a new or modify existing Secure Client profile. You can download the profile editor from Cisco Software Download Center.

See the Secure Client Profile Editor chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) Administrator Guide for details.

Before you begin

- Ensure that you have configured remote access VPN using the Remote Access Policy wizard and deployed the configuration on Firewall Threat Defense device. See Create a New Remote Access VPN Policy, on page 1822.
- On your Cloud-Delivered Firewall Management Center web interface, go to **Objects** > **Object Management** > **VPN** > **Secure Client File** and add the new Secure Client image.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.

Step 2 Select a remote access VPN policy and click **Edit**.

Step 3 Select the connection profile that includes the client profile to be edited, and click **Edit**.

Step 4 Click **Edit Group Policy** > **Secure Client** > **Profiles**.

Step 5 Select the client profile XML file from the list or click **Add** to add a new client profile.

Step 6 Save the group policy, connection profile, and then the remote access VPN policy.

Step 7 Deploy the changes.
Changes to the client profile will be updated on the VPN clients when they connect to the remote access VPN gateway.

RADIUS Dynamic Authorization

Secure Firewall Threat Defense has the capability to use RADIUS servers for user authorization of VPN remote access and firewall cut-through-proxy sessions using dynamic access control lists (ACLs) or ACL names per user. To implement dynamic ACLs for dynamic authorization or RADIUS Change of Authorization (RADIUS CoA), you must configure the RADIUS server to support them. When the user tries to authenticate, the RADIUS server sends a downloadable ACL or ACL name to the Firewall Threat Defense. Access to a given service is either permitted or denied by the ACL. Secure Firewall Threat Defense deletes the ACL when the authentication session expires.

RADIUS Server Attributes for Secure Firewall Threat Defense, on page 1841

Configuring RADIUS Dynamic Authorization

Before you begin:

- Only one interface can be configured in the security zone or interface group if it is referred in a RADIUS Server.
- A dynamic authorization enabled RADIUS server requires Secure Firewall Threat Defense 6.3 or later for the dynamic authorization to work.
- Interface selection in RADIUS server is not supported on Secure Firewall Threat Defense 6.2.3 or earlier versions. The interface option will be ignored during deployment.
- Firewall Threat Defense posture VPN does not support group policy change through dynamic authorization or RADIUS change of authorization (CoA).

Step 7	Deploy the configuration changes.	Deploy configuration changes, on page 202

Two-Factor Authentication

You can configure two-factor authentication for the remote access VPN. With two-factor authentication, the user must supply a username and static password, plus an additional item such as an RSA token or a passcode. Two-factor authentication differs from using a second authentication source in that two-factor is configured on a single authentication source, with the relationship to the RSA server tied to the primary authentication source.

Secure Firewall Threat Defense supports RSA tokens and Duo Push authentication requests to Duo Mobile for the second factor in conjunction with any RADIUS or AD server as the first factor in the two-factor authentication process.

Configuring RSA Two-Factor Authentication

About this task:

You can configure the RADIUS or AD server as the authentication agent in the RSA server, and use the server in Cloud-Delivered Firewall Management Center as the primary authentication source in the remote access VPN.

When using this approach, the user must authenticate using a username that is configured in the RADIUS or AD server, and concatenate the password with the one-time temporary RSA token, separating the password and token with a comma: *password*,*token*.

In this configuration, it is typical to use a separate RADIUS server (such as one supplied in Cisco ISE) to provide authorization services. You would configure the second RADIUS server as the authorization and, optionally, accounting server.

Before you begin:

Ensure that the following configurations are complete before configuring RADIUS two-factor authentication on Secure Firewall Threat Defense:

On the RSA Server

- Configure RADIUS or Active Directory server as an authentication agent.
- Generate and download the configuration (*sdconf.rec*) file.
- Create a token profile, assign the token to the user, and distribute the token to the user. Download and install the token on the remote access VPN client system.

For more information, see RSA SecureID Suite documentation.

On the ISE Server

- Import the configuration (*sdconf.rec*) file generated on the RSA server.
- Add the RSA server as the external identity source and specify the shared secret.

Table 112: Procedure

	Do This	More Info
Step 1	Log on to your Cloud-Delivered Firewall Management Center web interface.	
Step 2	Create a RADIUS server group.	RADIUS server group configuration options, on page 2944
Step 3	Create a RADIUS Server object within the new RADIUS server group, with RADIUS or AD server as the host and with a timeout of 60 seconds or more.	RADIUS server group configuration options, on page 2944 **Note** The RADIUS or AD server must be the same server that is configured as the authentication agent in RSA server. For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the Secure Client Profile XML file as well.
Step 4	Configure a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.	Create a New Remote Access VPN Policy, on page 1822
Step 5	Select RADIUS as the authentication server and then select the newly-created RADIUS server group as the authentication server.	Configure AAA Settings for Remote Access VPN, on page 1835
Step 7	Deploy the configuration changes.	Deploy configuration changes, on page 202

Configuring Duo Two-Factor Authentication

About this task:

You can configure the Duo RADIUS server as the primary authentication source. This approach uses the Duo RADIUS Authentication Proxy. (You cannot use a direct connection with the Duo Cloud Service over LDAPS.)

For the detailed steps to configure Duo, see https://duo.com/docs/cisco-firepower.

You would then configure Duo to forward authentication requests directed to the proxy server to use another RADIUS server, or an AD server, as the first authentication factor, and the Duo Cloud Service as the second factor.

When using this approach, the user must authenticate using a username that is configured on both the Duo Cloud or web server, and the associated RADIUS server. The user must enter the password configured in the RADIUS server, followed by one of the following Duo codes:

- **Duo-passcode**. For example, *my-password*,123456.
- **push**. For example, *my-password*,**push**. Use push to tell Duo to send a push authentication to the Duo Mobile app, which the user must have already installed and registered.
- **sms**. For example, *my-password*,**sms**. Use **sms** to tell Duo to send an SMS message with a new batch of passcodes to the user's mobile device. The user's authentication attempt will fail when using **sms**. The user must then re-authenticate and enter the new passcode as the secondary factor.
- **phone**. For example, *my-password*,**phone**. Use **phone** to authenticate using phone callback.

For more information on login options with examples, see https://guide.duo.com/anyconnect.

Before you begin:

Before configuring two-factor authentication with Duo Authentication Proxy on Firewall Threat Defense, ensure that you complete the following configurations:

- Configure a working primary authentication (RADIUS or AD) for your remote access VPN users before you begin to deploy Duo.
- Install Duo proxy service on a Windows or Linux machine within your network to integrate Duo with Secure Firewall Threat Defense remote access VPN. This Duo proxy server also acts as a RADIUS server.

  Download and install the most recent Duo authentication proxy from the following location:

  - **Windows**: https://dl.duosecurity.com/duoauthproxy-latest.exe
  - **Linux**: https://dl.duosecurity.com/duoauthproxy-latest-src.tgz
  - Verify the checksum at https://duo.com/docs/checksums#duo-authentication-proxy.

- Configure Duo authentication file `authproxy.cfg`. Follow instructions on the https://duo.com/docs/cisco-firepower#configure-the-proxy page to configure the authentication configuration settings.

  The `authproxy.cfg` configuration file must contain the details for RADIUS or ISE server, Firewall Threat Defense device, Duo proxy server details, Integration Key, Secret key, and API host details.
- Ensure that you have the right API host information in the `authproxy.cfg` file.
- Configure other required settings such as secondary authentication factor in the newly installed Duo proxy server at **Duo Security Server** > **Duo Admin Panel** > **Applications** > **CISCO RADIUS VPN**.

Table 113: Procedure

	Do This	More Info
Step 1	Log on to your Cloud-Delivered Firewall Management Center web interface.	
Step 2	Create a RADIUS server group.	RADIUS server group configuration options, on page 2944

	Do This	More Info
Step 3	Create a RADIUS Server object within the new RADIUS server group with Duo proxy server as the host with a timeout of 60 seconds or more.	Configure RADIUS server options, on page 2945 **Note** For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the Secure Client Profile XML file as well.
Step 4	Configure a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.	Create a New Remote Access VPN Policy, on page 1822
Step 5	Select RADIUS as the authentication server and then select the RADIUS server group created with the Duo proxy server as the authentication server.	Configure AAA Settings for Remote Access VPN, on page 1835
Step 7	Deploy the configuration changes.	Deploy configuration changes, on page 202

Secondary Authentication

Secondary authentication or double authentication in Secure Firewall Threat Defense adds an additional layer of security to remote access VPN connections by using two different authentication servers. With secondary authentication enabled, the Secure Client VPN users must provide two sets of credentials to login to the VPN gateway.

Secure Firewall Threat Defense remote access VPN supports secondary authentication in AAA Only and Client Certificate & AAA authentication methods.

Figure 375: Remote Access VPN Secondary or Double Authentication

Related Topics

Configure Remote Access VPN Secondary Authentication, on page 1904

Configure Remote Access VPN Secondary Authentication

When remote access VPN authentication is configured to use both client certificate and authentication sever, VPN client authentication is done using both the client certificate validation and AAA server.

Before you begin

- Configure two authentication (AAA) servers— the primary and secondary authentication servers, and required identity certificates. The authentication servers can be RADIUS server, and AD or LDAP realms.
- Ensure that the AAA servers are reachable from the Secure Firewall Threat Defense device for the remote access VPN configuration to work. Configure routing (at **Devices** > **Device Management**, click **Edit** (). Then, click **Device > Routing**) to ensure connectivity to the AAA servers.

Procedure

Step 1 On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access** .

Step 2 Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.

Step 3 For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.

Step 4 Click **AAA** > **Authentication Method**, **AAA** or **Client Certificate & AAA**.

- When you select the **Authentication Method** as:

  Client Certificate & AAA—Authentication is done using both client certificate and AAA server.

  - **AAA**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
  - Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

- **Use secondary authentication** — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

  Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the Secure Client login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

  You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

  Note
  By default, secondary authentication is not required.

  Authentication Server— Secondary authentication server to provide secondary username and password for VPN users.

  Select the following under **Username for secondary authentication**:

  - **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.
  - **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.
  - **Map username from client certificate**: Prefills the secondary username from the client certificate.
    - If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

      See **Authentication Method** descriptions for more information about primary and secondary field mapping.
    - **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via Secure Client.
      - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.

- **Use secondary username for VPN session**: The secondary username is used for reporting user activity during a VPN session.

For more information, see Configure AAA Settings for Remote Access VPN, on page 1835.

Single Sign-On Authentication with SAML 2.0

About SAML Single Sign-On Authentication

Security Assertion Markup Language (SAML) is an open standard for logging users into applications using their sessions in another context. Organizations already know the identity of users when users log in to their Active Directory (AD) domain or the intranet. They use this identity information to log in users to other applications, such as web-based applications using SAML. Individual applications do not need to store credentials and users do not have to remember and manage different sets of credentials for individual applications. SAML single sign-on (SSO) works by transferring the user's identity from one place (the identity provider) to another (the service provider).

SAML Single Sign-On with Secure Firewall Threat Defense

The Secure Firewall Threat Defense device supports SAML 2.0 single sign-on (SSO) authentication for remote access VPN connections using the Secure Client. You need the following to configure SAML 2.0 SSO on Secure Firewall Threat Defense:

- **Identity Provider (IdP)**—The Duo Access Gateway acts as the identity provider to perform user authentication and issues assertions.
- **Service Provider (SP)**—The Firewall Threat Defense device acts as the service provider and obtains the authentication assertion from the identity provider.
- **VPN Client**—The Secure Client performs SAML 2.0 authentication via the embedded browser.

Guidelines and Limitations for SAML 2.0

- Firewall Threat Defense supports the following signatures for SAML authentication:
  - SHA1 with RSA and HMAC
  - SHA2 with RSA and HMAC
- Firewall Threat Defense supports SAML 2.0 Redirect-POST binding , which is supported by all SAML IdPs.
- The Firewall Threat Defense functions as a SAML SP only. It cannot act as an Identity Provider in gateway mode or peer mode.
- You can enforce an access policy on a SAML-authenticated user if you have an associated identity policy with an AD realm matching the SAML domain. However, it does not work for Azure AD SAML because it requires additional mapping from the tenant ID of the Azure AD to an associated realm ID on the threat defense device.

- Having SAML authentication attributes available in DAP evaluation (similar to RADIUS attributes sent in RADIUS auth response from AAA server) is not supported. Firewall Threat Defense supports SAML enabled group policy on DAP policy; however, you cannot check the username attribute while using SAML authentication, because the username attribute is masked by the SAML Identity provider.
- Firewall Threat Defense administrators need to ensure clock synchronization between the Firewall Threat Defense and the SAML IdP for proper handling of authentication assertions and proper timeout behavior.
- Firewall Threat Defense administrators have the responsibility to maintain a valid signing certificate on both Firewall Threat Defense and IdP considering the following:
  - The IdP signing certificate is mandatory when configuring an IdP on the Firewall Threat Defense.
  - The Firewall Threat Defense does not do a revocation check on the signing certificate received from the IdP.
- In SAML assertions, there are NotBefore and NotOnOrAfter conditions. The Firewall Threat Defense SAML configured timeout interacts with these conditions as follows:
  - Timeout overrides NotOnOrAfter if the sum of NotBefore and timeout is earlier than NotOnOrAfter.
  - If NotBefore + timeout is later than NotOnOrAfter, then NotOnOrAfter takes effect.
  - If the NotBefore attribute is absent, the Firewall Threat Defense denies the login request. If the NotOnOrAfter attribute is absent and SAML timeout is not set, Firewall Threat Defense denies the login request.
- Firewall Threat Defense does not work with Duo in a deployment using an internal SAML, which forces the Firewall Threat Defense to proxy for the client to authenticate, due to the FQDN change that occurs during challenge/response for Two-factor authentication (push, code, password).
- When using SAML with Secure Client, follow these guidelines:
  - Untrusted server certificates are not allowed in the embedded browser.
  - The embedded browser SAML integration is not supported in CLI or SBL modes.
  - SAML authentication established in a web browser is not shared with Secure Client and vice versa.
  - Depending on the configuration, various methods are used when connecting to the headend with the embedded browser. For example, while Secure Client might prefer an IPv4 connection over an IPv6 connection, the embedded browser might prefer IPv6, or vice versa. Similarly, Secure Client may fall back to no proxy after trying proxy and getting a failure, while the embedded browser may stop navigation after trying proxy and getting a failure.
  - You must synchronize your Firewall Threat Defense's Network Time Protocol (NTP) server with the IdP NTP server in order to use the SAML feature.
  - You cannot access internal servers with SSO after logging in using an internal IdP.
  - The SAML IdP NameID attribute determines the user's username and is used for authorization, accounting, and VPN session database.
- SAML does not support Start Before Logon (SBL).
- Multiple attributes received with a SAML assertion are not supported.

- A firewall uses the Identity Provider Entity ID as the SAML object name from the single sign-on server object created in the Cloud-Delivered Firewall Management Center (**Objects** > **Object Management** > **AAA Server** > **Single Sign-on Server**). Hence, you cannot use multiple SAML objects with the same Identity Provider Entity ID on a single firewall.

Configuring a SAML Single Sign-On Authentication

Before you begin

Ensure that you have done the following before you configure SAML single sign-on with Firewall Threat Defense remote access VPN:

- Create an account with Duo.
- Download and install the Duo Access Gateway.
- Obtain the following from your SAML identity provider (Duo).
  - Identity Provider Entity ID URL
  - Sign-in URL
  - Sign-out URL
  - Identity provider certificate
- Create a SAML single sign-on server object. For more information, see Add a single sign-on server, on page 2946.

Note You can create a single sign-on server object in the **Connection Profile** settings when you create a new policy using the Remote Access VPN policy Wizard.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** next to the remote access VPN policy for which you want to configure SAML authentication. If you want to create a new policy, click **Add**.

Step 3 Click **Edit** on the connection profile that you want to modify.

Step 4 Choose **AAA** settings and select **SAML** from the **Authentication Method** drop-down.

Step 5 Choose the required SAML single sign-on server as the **Authentication Server**.

Step 6 Configure the required settings for the remote access VPN.

Step 7 Save and deploy the remote access VPN policy on your Firewall Threat Defense device.

Configuring SAML Authorization

About SAML Authorization

SAML authorization supports user attributes delivered in SAML assertions within the AAA and Dynamic Access Policy (DAP) frameworks. You can configure the SAML assertion attributes on the Identity Provider as name-value pairs which then parses as strings. The attributes received are made available to DAP so that they can be used when defining selection criteria within a DAP record. The SAML assertion *cisco_group_policy* is used to determine the Group Policy to be applied to the VPN session.

Dynamic Access Policy Attribute Representation

In the DAP table, the DAP attributes are represented in the following format:

```
aaa.saml.name = "value”
```

Example, *aaa.saml.department = ”finance"*

This attribute can be used in DAP selection as follows:

```
<attr>
<name>aaa.saml.department</name>
<value>finance</value>
<operation>EQ</operation>
</attr>
```

Multi-Valued Attributes

Multi-valued attributes are also supported in DAP and the DAP table is indexed :

```
aaa.saml.name.1 = "value”
aaa.saml.name.2 = "value"
```

Active Directory memberOf Attributes

The Active Directory (AD) memberOf attribute receives a special processing that is consistent with the way it is handled through an LDAP query.

Group names are represented by the CN attribute of the DN.

Example Attributes received from the authorization server:

```
memberOf = "CN=FTD-VPN-Group,OU=Users,OU=TechspotUsers,DC=techspot,DC=us"
 memberOf = "CN=Domain Admins,OU=Users,DC=techspot,DC=us”
```

Dynamic Access Policy attributes:

```
aaa.saml.memberOf.1 = "FTD-VPN-Group”
aaa.saml.memberOf.2 = "Domain Admins"
```

Interpretation of the cisco_group_policy Attribute

A group-policy can be specified by a SAML assertion attribute. When an attribute "cisco_group_policy" is received by the Firewall Threat Defense, the corresponding value is used to select the connection group-policy

Configure SAML Authorization

Before you begin

Ensure that you have configured a single sign-on server like DUO and completed the required Identity Provider (IdP) and Service Provider (SP) settings.

For more information, see Single Sign-On Authentication with SAML 2.0, on page 1906.

Procedure

Step 1 Configure a single sign-on server object if not configured already.

a) Choose **Objects** > **Object Management** > **AAA Server** > **Single Sign-on Server**.
b) Click **Add Single Sign-on Server**.
c) Enter the single sign-on server details and click **Save**.

For more information, see Add a single sign-on server, on page 2946.

Step 2 Configure SAML authentication in the remote access VPN connection profile.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Click **Edit** on the remote access VPN policy for which you want to configure SAML authorization or create a new policy.
c) Edit the required connection profile and select **AAA**.
d) Select the single sign-on server object from the **Authentication Server** drop-down.
e) Save the remote access VPN configuration.

Step 3 Match a SAML criteria in DAP policy.

a) Select **Devices** > **VPN** > **Dynamic Access Policy**.
b) Create a new DAP or edit an existing one.
c) Create a DAP record or edit and existing record.
d) Click **AAA Criteria** > **SAML Criteria** > **Add SAML Criteria**.
e) Create a SAML criteria based on the SAML assertions returned by the SSO server.

Step 4 Deploy the remote access VPN configuration.

Advanced Secure Client Configurations

Configure Secure Client Modules on a Firewall Threat Defense

Secure Client can integrate with various Cisco endpoint security solutions and offer enhanced security using different Secure Client modules.

You can use the managed headend Firewall Threat Defense to distribute and manage Secure Client modules to the endpoints. When a user connects to the Firewall Threat Defense, it downloads and installs Secure Client and the required modules on the endpoint.

In version 6.7 and later, you can use the headend Firewall Threat Defense, managed by a Cloud-Delivered Firewall Management Center, to distribute and manage Secure Client modules to the endpoints. These modules then integrate with the corresponding Cisco endpoint security solution.

In versions 6.4 to 6.6, you can enable these modules and profiles on a Firewall Threat Defense using FlexConfig. For more information, see Configure AnyConnect Modules and Profiles Using FlexConfig.

Benefits

If you use a Firewall Threat Defense to distribute and manage Secure Client modules to the endpoints, you can easily perform the following tasks:

- Distribute and manage Secure Client modules and profiles on each endpoint.
- Upgrade Secure Client on each endpoint.

Types of Secure Client Modules

AMP Enabler

Use this module to deploy Secure Endpoint, on endpoints. The module pushes Secure Endpoint to endpoints from a server hosted locally within the enterprise. This module provides an additional security agent that detects potential malware threats in the network, removes these threats, and protects the enterprise.

In Cisco Secure Client 5.0, AMP Enabler is only for macOS. Cisco Secure Client for Windows offers full integration with Cisco Secure Endpoint.

ISE Posture

Use this module to perform endpoint posture checks such as antivirus, antispyware, operating system and so on using Cisco Identity Services Engine (ISE) and assess the endpoint's compliance. ISE provides next generation identity and access control policy. ISE Posture performs a client-side evaluation. The client receives the posture requirement policy from the headend, performs the posture data collection, compares the results against the policy, and sends the assessment results back to the headend.

Network Visibility

Use this module to monitor the endpoint application usage using the Network visibility module. You can uncover potential behavior anomalies and make informed network design decisions. It enhances the enterprise administrator's ability to do capacity and service planning, auditing, compliance, and security analytics. You can share the usage data with NetFlow analysis tools such as Cisco Stealthwatch.

Umbrella Roaming Security

Use this module for a DNS-layer security using the Cisco Umbrella Roaming Security service. Cisco Umbrella provides content filtering, multiple policies, robust reporting, active directory integration, and much more.

Web Security

Use this module to enable Cisco Secure Web Appliance (SWA), powered by Cisco Talos. This module protects the endpoint by blocking risky sites and testing unknown sites before allowing users to access them. It can deploy web security either through the on-prem WSA or the cloud-based Cisco Cloud Web Security. This module is not part of the AnyConnect package from release 4.5 and in Secure Client 5.0.

Network Access Manager

This module provides a secure layer 2 network and performs device authentication to access wired and wireless networks. Network Access Manager manages user and device identity and the network access protocols required for secure access.

Network Access Manager is not supported on macOS or Linux.

Start Before Login

Start Before Login (SBL) allows users to establish their VPN connection to the enterprise infrastructure before logging onto Windows. After the SBL module installation, you must enable SBL in the Secure Client VPN profile and add it to the remote access VPN group policy.

DART

Diagnostics and Reporting Tool (DART) collates system logs and other diagnostic information to troubleshoot AnyConnect installation and connection problems. You can send this data to Cisco TAC for troubleshooting.

By default, DART is not enabled in new RA VPN group policies for 6.7 and later versions. In 6.6 and earlier versions, DART is enabled by default.

Feedback

The customer experience feedback (CEF) module provides information about which features and modules you use and have enabled. This information gives an insight into the user experience so that Cisco can continue to improve the quality, reliability, performance, and user experience of the Cisco Secure Client. Secure Client does not download the Feedback module to the endpoint. The feedback data is sent to the Cisco Feedback Server.

Prerequisites for Configuring Secure Client Modules

- Configure the associated products depending on the module that you are going to use.
- Download the following Secure Client-related packages from Cisco Software Download Center to your local host.
  - Cisco Secure Client Headend Deployment Package for the required platforms.

    This package is for the headend and contains all the Secure Client modules. For Windows, the filename is cisco-secure-client-win-5.0.03076-webdeploy-k9.pkg.
  - Profile Editor: Create profiles for the modules that require profiles.

    Secure Client needs a Secure Client profile for some of the modules. A profile contains configurations to enable the modules and connect to the corresponding security services. The profile editor supports only Windows.

    The following table lists if the modules require a client profile:

Secure Client Module	Requires a Client Profile
AMP Enabler	Yes
ISE Posture	Yes
Network Access Manager	Yes
Network Visibility Module	Yes
Umbrella Roaming Secure Module	Yes
Feedback	Yes
Web Security	Yes
DART	No
Start Before Login	No

- Licensing
  - You need one of the following Secure Client licenses: Secure Client Premier, Secure Client Advantage, or Secure Client VPN Only
  - Your Cloud-Delivered Firewall Management Center Essentials license must allow export-controlled functionality.

    Choose **System** (⚙) > **Licenses** > **Smart Licenses** to verify this functionality in the management center.

Guidelines for Configuring Secure Client Modules

- All Secure Client modules are supported from AnyConnect 4.8 and later, and Secure Client 5.0.
- Different modules support profiles with different file extensions. The following table lists the modules and the supported file extensions of their profiles:

Table 114: Supported File Extensions of Profiles

Module	File Extension
AMP Enabler	*.xml, *.asp
Feedback	*.xml
ISE Posture	*.xml, *.isp
Network Access Manager	*.xml, *.nsp
Network Visibility	*.xml, *.nvmsp
Umbrella Roaming Security	*.xml, *.json
Web Security	*.xml, *.wsp, *.wso

- You can add only one entry per client module. You can edit or delete an entry for a module.
- If you plan to use ISE posture and Network Access Manager modules on a Windows OS, you must install Network Access Manager before you use the ISE Posture module.
- If you enable the Umbrella Roaming Security module, ensure that you disable the **Always send DNS requests over tunnel** option under split tunnelling in the VPN group policy.
- If you want to use SBL, then you must enable SBL in the Secure Client VPN profile.

Install Secure Client Modules using a Firewall Threat Defense

Before you begin

Ensure that you review the Prerequisites for Configuring Secure Client Modules, on page 1912 and Guidelines for Configuring Secure Client Modules, on page 1913 topics.

Procedure

Step 1 The administrator creates profiles, if needed, for the required Secure Client modules.

Step 2 The administrator uses the Cloud-Delivered Firewall Management Center to:

a) Configure the modules and add the profiles in the remote access VPN group policy.

b) Deploy the configuration on the Firewall Threat Defense.

Step 3 The user uses Secure Client to initiate a VPN connection to the Firewall Threat Defense.

Step 4 The Firewall Threat Defense authenticates the user.

Step 5 The Secure Client checks for updates.

Step 6 The Firewall Threat Defense distributes the Secure Client modules and the profiles on the endpoint.

What to do next

Configure a Remote Access VPN Group Policy with Secure Client Modules, on page 1914.

Configure a Remote Access VPN Group Policy with Secure Client Modules

To install and update the Secure Client modules on the endpoint using a Firewall Threat Defense managed by a Cloud-Delivered Firewall Management Center, you must update the remote access VPN group policy with the Secure Client module configurations.

Before you begin

Ensure that you have configured a remote access VPN policy in the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.
Step 2 Select a remote access VPN policy and click **Edit**.
Step 3 Select a connection profile and click **Edit**.
Step 4 Click **Edit Group Policy**.
Step 5 Click the **Secure Client** tab.
Step 6 Click **Client Modules**.
Step 7 Click +.
Step 8 Choose a module from the **Client Module** drop-down list.
Step 9 Choose a profile for the module from the **Profile to download** drop-down list or click + to add a profile.
Step 10 Check the **Enable module download** check box to download the module on the endpoint.
Step 11 Click **Add**.
Step 12 Repeat steps 7 to 11 if you want to add more modules.
Step 13 Click **Save**.

What to do next

1. Deploy the configuration on the threat defense.
2. Launch the Secure Client, select the VPN profile, and connect to the VPN. Secure Client installs the configured modules on it.
3. Verify the configuration. For more information, see Verify Secure Client Modules Configuration, on page 1915.

Verify Secure Client Modules Configuration

On the Firewall Threat Defense

Use the following commands on the Firewall Threat Defense to view the profiles and the Secure Client modules configuration:

- **show disk0:**- View the profiles and their configuration.
- **show run webvpn** - View details of the Secure Client configurations.
- **show run group-policy <ravpn_group_policy_name>** - View details of the RA VPN group policy for Secure Client.
- **show vpn-sessiondb anyconnect** - View details of the active Secure Client VPN sessions.

On the Endpoint

1. Use the Secure Client to establish a VPN connection to the Firewall Threat Defense.

2. Verify if the configured modules are downloaded and installed as part of the Secure Client.
3. Verify if the configured profiles, if any, are available in the locations documented in Profile Locations for all Operating Systems.

On the Cloud-Delivered Firewall Management Center

You can monitor remote access VPN active sessions on the Cloud-Delivered Firewall Management Center using the Remote Access VPN dashboard (**Overview** > **Dashboards** > **Remote Access VPN**). You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices

When you use Secure Client to establish a VPN connection from a mobile device, all the traffic including the traffic from personal applications is routed through the VPN.

For mobile devices that run on Android or iOS, you can restrict the applications that use the VPN tunnel. This application-based remote access VPN is called Per App VPN. To use Per App VPN, you must install and configure a third-party Mobile Device Manager (MDM) application. You must define the list of approved applications that can be used over the VPN tunnel in the MDM. You can enable Per App VPN on the Firewall Threat Defense headend so that your MDM can apply your policies on mobile devices.

Benefits

Benefits of restricting the remote access VPN to approved applications include:

- Performance—Limits VPN traffic over the corporate network and frees up resources of the VPN headend.
- Protection—Protects the corporate VPN tunnel from unapproved malicious applications on the mobile device.

Prerequisites and Licensing for Configuring Per App VPN Tunnels

Prerequisites

- Install and configure a third-party Mobile Device Manager (MDM).

  You must configure the applications that will be allowed in the VPN in the MDM itself, not on the Firewall Threat Defense headend device.
- Download the Cisco AnyConnect Enterprise Application Selector from Cisco Software Download Center.

  You need this tool to define the Per App VPN policy.

Licensing

- Secure Client Premier, or Secure Client Advantage.
- Essentials license must allow export-controlled functionality.

  To verify this functionality in the Cloud-Delivered Firewall Management Center, choose **System** (⚙) > **Licenses** > **Specific Licenses**.

Determine the Application IDs for Mobile Applications

Before configuring the Firewall Threat Defense headend to allow application-based VPN from mobile devices, you must determine which applications should be allowed in the tunnel.

We strongly recommend that you configure the per-app policy in the MDM on the user's mobile device. This simplifies the headend configuration. If you decide to configure the list of allowed applications on the headend, you must determine the application IDs for each application on each type of endpoint.

The application ID, called the bundle ID in iOS, is a reverse DNS name. You can use an asterisk as a wildcard. For example, ***.*** indicates all applications, com.cisco.* indicates all Cisco applications.

To determine the application IDs:

- **Android**—Go to Google Play in a web browser and select the Apps category. Click (or hover over) an application that you want to allow, then look at the URL. The app id is in the URL, on the **id=** parameter. For example, the following URL is for Facebook Messenger, so the app id is com.facebook.orca.

  https://play.google.com/store/apps/details?id=com.facebook.orca

  For applications that are not available through Google Play, such as your own applications, download a package name viewer application to extract the app ID. There are many of these applications available, one of them should provide what you need, but Cisco does not endorse any of them.

- **iOS**—There is no straight-forward way to get the bundle ID. Following is one way to find it:

  1. Use a desktop web browser such as Chrome to search for the application name.
  2. In the search results, look for the link to download the app from the Apple App Store. For example, Facebook Messager would be similar to:

     https://apps.apple.com/us/app/messenger/id454638411
  3. Copy the number after the **id** string. In this example, **454638411**.
  4. Open a new browser window, and add the number to the end of the following URL:

     https://itunes.apple.com/lookup?id=

     For this example: https://itunes.apple.com/lookup?id=454638411
  5. You will be prompted to download a text file, usually named 1.txt. Download the file.
  6. Open the file in a text editor such as WordPad, and search for bundleId. For example:

     "bundleId":"com.facebook.Messenger",

     In this example, the bundle ID is com.facebook.Messenger. Use this as the app ID.

Once you have your list of application IDs, you can configure the policy as explained in .

Configure Application-Based VPN Tunnels

After you install and configure your MDM software, you can enable Per App VPN on the Firewall Threat Defense headend device. Once enabled on the headend, your MDM software will control which applications are tunneled over the VPN to the corporate network.

Before you begin

- Ensure that you have a remote access VPN policy in the Cloud-Delivered Firewall Management Center.

- Configure Per App VPN using MDM and enroll each device to the MDM server.
- Download the Cisco AnyConnect Enterprise Application Selector.

Procedure

Step 1 Use the Cisco AnyConnect Enterprise Application Selector to define the Per App VPN policy.

We recommend that you create a simple **Allow All** policy, and define the allowed applications in the MDM. However, you can specify a list of applications to allow and control the list from the headend. If you want to include specific applications, create a separate rule for each application, using a unique name and the application's app ID. For more information on getting the app IDs, see Determine the Application IDs for Mobile Apps.

To create an **Allow All** policy that supports both Android and iOS platforms using the AnyConnect Enterprise Application Selector:

a) Choose **Android** from the drop-down list as the platform type and configure the following options:

- **Friendly Name**—Enter a name for the policy. For example, Allow_All.
- **App ID**—Enter *.* to match all possible applications.
- Leave the other options.

b) Choose **iOS** from the drop-down list as the platform type and configure the following options:

- **Friendly Name**—Enter a name for the policy. For example, Allow_All.
- **App ID**—Enter *.* to match all possible applications.
- Leave the other options.

c) Choose **Policy > View Policy** to get the base64 encoded string for the policy.

This string contains an encrypted XML file that allows the Firewall Threat Defense to see the policies. Copy this value. You need this string when you configure Per App VPN on the Firewall Threat Defense.

Step 2 Use the Cloud-Delivered Firewall Management Center to enable the Per App on the Firewall Threat Defense headend device.

a) Choose **Devices** > **VPN** > **Remote Access**.
b) Select a remote access VPN policy and click **Edit**.
c) Select a connection profile and click **Edit**.
d) Click **Edit Group Policy**.
e) Click the **Secure Client** tab.
f) Click **Custom Attributes** and click **+**.
g) Choose **Per App VPN** from the **Secure Client Attribute** drop-down list.
h) Choose an object from the **Custom Attribute Object** drop-down list or click **+** to add an object.

When you add a new custom attribute object for Per App VPN, enter the name, description, and the base64 encoded policy string from the Cisco AnyConnect Enterprise Application Selector.

i) Click **Save**.

j) Click **Add** and click **Save**.

Step 3 Deploy your changes on the Cloud-Delivered Firewall Management Center.

What to do next

1. Launch the Secure Client, select the VPN profile, and connect to the VPN.
2. Verify the configuration. For more information, see Verify Per App Configuration, on page 1919.

Verify Per App Configuration

On the Firewall Threat Defense

Use the following commands on the Firewall Threat Defense to view the Per App configuration:

- **show run webvpn**
- **show run group-policy <ravpn_group_policy_name>**
- **show run anyconnect-custom-data**

On the Endpoint

After the endpoint establishes a VPN connection with the Firewall Threat Defense:

1. Click the **Statistics** icon of the Secure Client.
2. **Tunnel Mode** will be “Application Tunnel” instead of “Tunnel All Traffic.”
3. **Tunneled Apps** will list the applications you enabled for tunneling in the MDM.

Remote Access VPN Examples

How to Limit Secure Client Bandwidth Per User

This section provides instructions to limit the maximum bandwidth that the VPN users consume when they connect using the Secure Client to Secure Firewall Threat Defense remote access VPN gateway. You can limit the maximum bandwidth by using a Quality of service (QoS) policy in Firewall Threat Defense, to ensure that a single user or group or users do not take over the entire resource. This configuration lets you give priority to critical traffic, prevent bandwidth hogging, and manage the network. If a When traffic exceeds the maximum rate, the Firewall Threat Defense drops the excess traffic.

Step	Do This	More Info
1	Create and set up a realm.	Create an LDAP realm or an Active Directory realm and realm directory, on page 2325

Step	Do This	More Info
2	Create a QoS policy and QoS rule for the user or group available in the newly created realm.	• See Create a QoS policy, on page 1696 to create a QoS policy. • See Configuring QoS rules, on page 1698 to create a QoS rule.
3	Configure remote access VPN policy and select the newly created realm for user authentication.	Create a New Remote Access VPN Policy, on page 1822
4	Deploy the remote access VPN policy.	Deploy configuration changes, on page 202

How to Use VPN Identity for User-Id Based Access Control Rules

Step	Do This	More Info
1	Create and set up a realm.	Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
2	Create an identity policy and add an identity rule.	• See Create an identity policy, on page 2507 to create an identity policy. • See Create an identity rule, on page 2515 to create an identity rule.
3	Associate the identity policy with an access control policy.	Associate prefilter, decryption, and identity policies with an access control, on page 2016
4	Configure remote access VPN policy and select the newly created realm for user authentication.	Create a New Remote Access VPN Policy, on page 1822
5	Deploy the remote access VPN policy.	Deploy configuration changes, on page 202

Configure Firewall Threat Defense Multiple Certificate Authentication

Multiple Certificate-based Authentication

Multiple certificate-based authentication allows the Firewall Threat Defense to validate the machine or device certificate. Multiple certificates can be enabled for certificate-based authentication in the remote access VPN connection profile. It can be combined with AAA authentication. The multiple certificates option in the remote access VPN connection profile allows certificate authentication of both the machine and user via certificates. This ensures that the device is a corporate-issued device, in addition to authenticating the user's identity certificate to allow RA VPN access. The administrator can choose if the username for the session should be taken from the machine certificate or user certificate.

When multiple certificate-based authentication is configured, two certificates are obtained from the VPN client:

- **First Certificate** —Machine certificate to authenticate the endpoint.
- **Second Certificate**—User certificate to authenticate the VPN user.

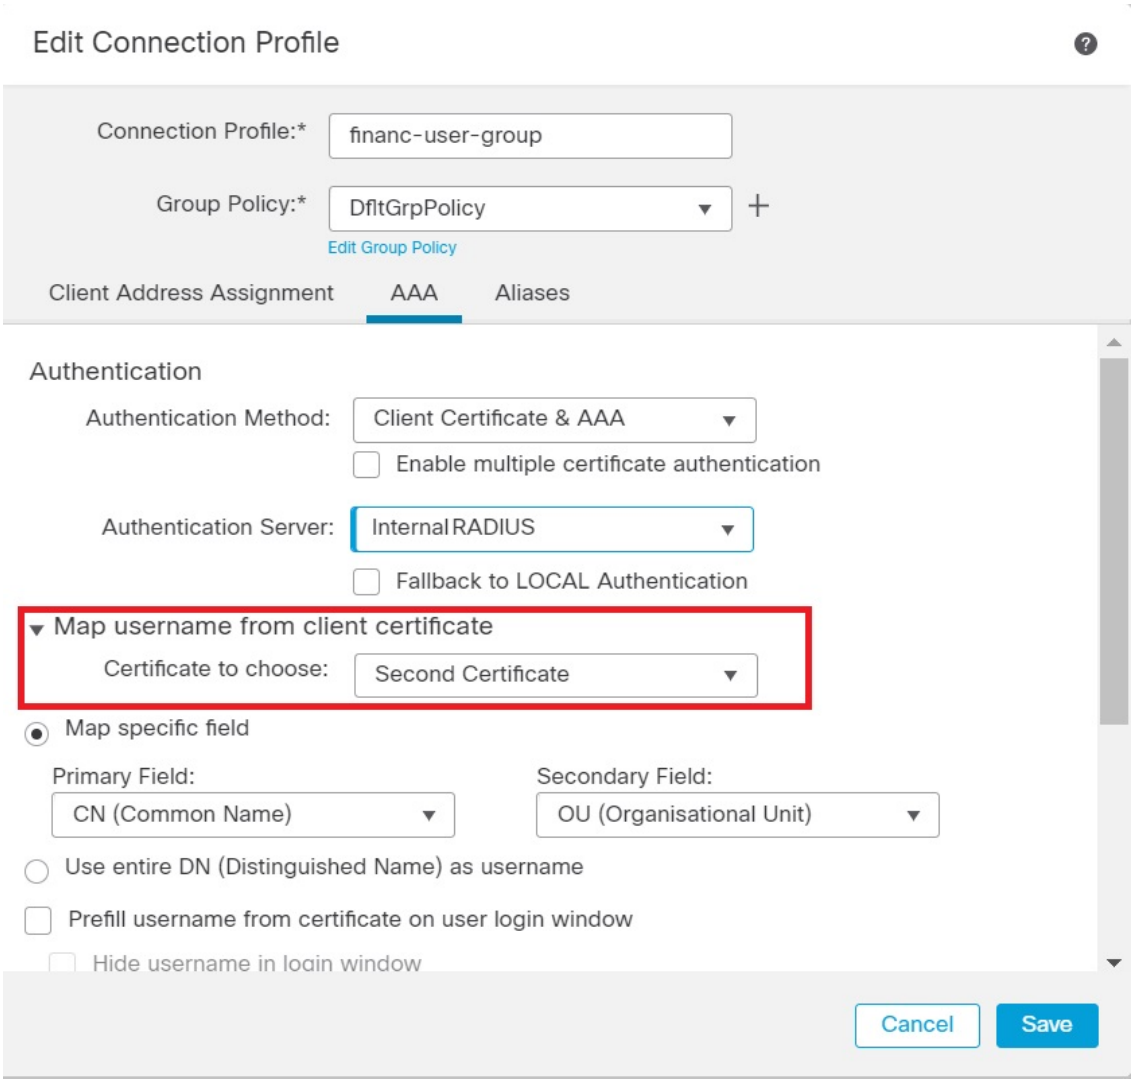
For detailed information about Firewall Threat Defense certificates, see Manage Firewall Threat Defense certificates, on page 3080.

Limitations

- Multiple certificate authentication currently limits the number of certificates to two.
- Secure Client supports only RSA-based certificates.
- Only SHA256, SHA384, and SHA512 based certificates are supported during the Secure Client aggregate authentication.
- Certificate authentication cannot be combined with SAML authentication.

Pre-fill Username from Certificate

The Pre-fill username option allows a field from the certificates to be parsed and used for subsequent AAA authentication (primary and secondary). When two certificates are used for authentication, the Administrator can choose the certificate from which the username should be derived for the prefill functionality. By default, username for prefill is retrieved from the User certificate (second certificate received from Secure Client). The prefilled username is used as the VPN session username when the Certificate Only authentication method is enabled. When AAA and certificate authentication is enabled, VPN session username will be based on the pre-fill option.



Configure Multiple Certificate Authentication for Remote Access VPN

1. On your Cloud-Delivered Firewall Management Center web interface, choose **Devices** > **VPN** > **Remote Access**.
2. Edit an existing remote access policy, or create a new one and then edit.

   See Create a New Remote Access VPN Policy, on page 1822.
3. Select the connection profile to configure multiple certificate authentication, and click **Edit**.

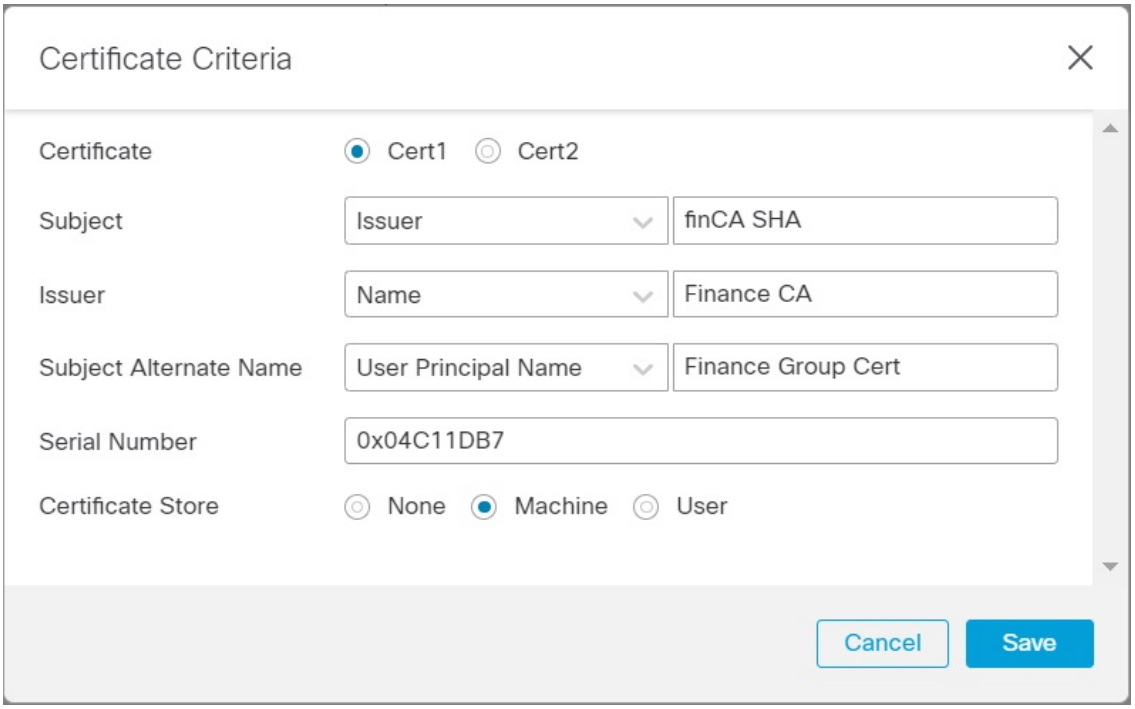
   See Configure Connection Profile Settings, on page 1832.
4. Choose **AAA**, and then select an **Authentication Method**:

Figure 376:

- **Client Certificate Only**—User is authenticated using client certificate. Client certificate must be configured on VPN client endpoints. By default, the username is derived from client certificate fields CN & OU respectively. In case, the username is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.
- **Client Certificate & AAA**—User is authenticated using both the types of authentication, AAA and client certificate.

5. Select **Enable multiple certificate authentication**.
6. Select **Map username from client certificate** and select a certificate from the **Certificate to choose** drop-down to choose the username for the VPN session from the machine certificate or user certificate.
   - **First Certificate** —Map the username from the Machine Certificate.
   - **Second Certificate**—Map the username from the User certificate to authenticate the VPN user.

7. Configure the required connection profile settings and remote access VPN settings.
8. Save the connection profile and remote access VPN policy. Deploy the remote access VPN on Firewall Threat Defense.



For information about remote access VPN AAA settings, see Configure AAA Settings for Remote Access VPN, on page 1835.

Certificate Configuration in DAP

You can also configure certificate criteria attributes in a DAP record. The user and machine certificate received from the VPN client during multiple-certificate authentication is loaded into dynamic access policy (DAP) to allow policies to be configured based on the field of the certificate. You can make policy decisions based on the fields of a certificate used to authenticate that connection attempt.

1. Choose **Devices** > **VPN** > **Dynamic Access Policy**.
2. Edit an existing DAP policy or create a new one and then edit the policy.
3. Choose an existing DAP record, or create a new one and then edit the record.
4. Select **Endpoint Criteria** > **Certificate**.
5. Select the Match Criteria **All** or **Any**.
6. Click **Add** to add certificate attributes.

Figure 377:

7. Select the certificate, **Cert1** or **Cert2**.
8. Select the **Subject** and specify the certificate subject value.

9. Select the **Issuer** and specify the certificate issuer name.
10. Select the **Subject Alternate Name** and specify the alternate name for the subject.
11. Specify the **Serial Number**.
12. Select the **Certificate Store**: None, Machine, or User.

    This option adds a condition to check for the store from which the certificate is picked on the endpoint.
13. Click **Save** to complete the certificate criteria settings.

    Configure the required DAP record settings and then associate the DAP with the remote access VPN.

For more information about DAP, see Dynamic Access Policies , on page 1927.

Monitor Remote Access VPNs

Remote Access VPN Dashboard

Remote Access Virtual Private Network (RA VPN) allows remote users to securely connect to your network. The RA VPN dashboard allows you to monitor real-time data from active RA VPN sessions on the devices. You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

RA VPN dashboard (**Overview** > **Dashboards** > **Remote Access VPN**) provides a snapshot of the active RA VPN sessions on the threat defense devices managed by the Cloud-Delivered Firewall Management Center.

The dashboard provides:

- Visualization of active user sessions based on their location.
- Detailed information about the active user sessions.
- Mitigation of user session problems by terminating sessions, if required.
- Distribution of active user sessions per device, encryption type, Secure Client version, operating system, and connection profile.
- Device identity certificate expiration details of the devices.

The dashboard has the following widgets:

- Active Sessions (Tabular View)
- Active Sessions (Map view)
- Sessions
- Device Identity Certificates

Active Sessions (Tabular View)

This widget provides a tabular view of the active RA VPN users connected. You can view details of the active RA VPN sessions such as username, assigned IP, public IP, login time, VPN gateway (threat defense device), client application, client operating system, connection profile, and group policy. You can use the filter to

narrow down your search based on the different criteria. You can also perform the following actions on the individual sessions:

- Terminate a session of a specific user.
- Terminate all sessions of a specific user connected to a specific VPN gateway.
- Terminate all sessions that are connected to a specific VPN gateway.

If a client device supports dual address stack and the RA VPN configuration on the Firewall Threat Defense device allows IPv4 and IPv6 address pools, when a client establishes an RA VPN session with the headend device, it assigns an IPv4 and an IPv6 address to the client's tunnel interface. The RA VPN session has two IP addresses, an IPv4 and an IPv6 address on the threat defense device. The Cloud-Delivered Firewall Management Center shows two sessions for the same user, one with an IPv4 address and another with an IPv6 address, and the session count is two.

Hence, even when there is only a single RA VPN session from a user as per **show vpn-sessiondb l2l filter ipaddress** command on the device, the Cloud-Delivered Firewall Management Center shows two different sessions.

Active Sessions (Map View)

This widget shows an interactive heat map to visualize the location of the users connected through RA VPN sessions on the devices.

- Countries that have user sessions appear in shades of blue.
- Legend of the map provides a scale that indicates the correlation between the number of sessions in a country and the shade of blue for the country.
- Hover the mouse pointer over the map to view the country name and the total number of active user sessions.
- Zoom in, zoom out, and reset options are available.

Sessions

This widget allows you to monitor real-time data from active RA VPN sessions on the devices. You can filter and view the distribution of active RA VPN sessions according to:

- Device: Displays the number of sessions per device.
- Encryption Type: Displays the number of Secure Client SSL or IPsec sessions.
- Secure Client Version: Displays the sessions per Secure Client version.
- Operating System: Displays the sessions per operating systems. For example, Windows, Linux, Mac, Mobile OS, and so on.
- Connection Profile: Displays the sessions per connection profile.

Device Identity Certificates

This widget provides information about the identity certificate expiry of the RA VPN gateways. You can view expired certificates and certificates that are due for expiry within a month. Click **View Details** to view the certificates in the **Devices** > **Certificates** page.

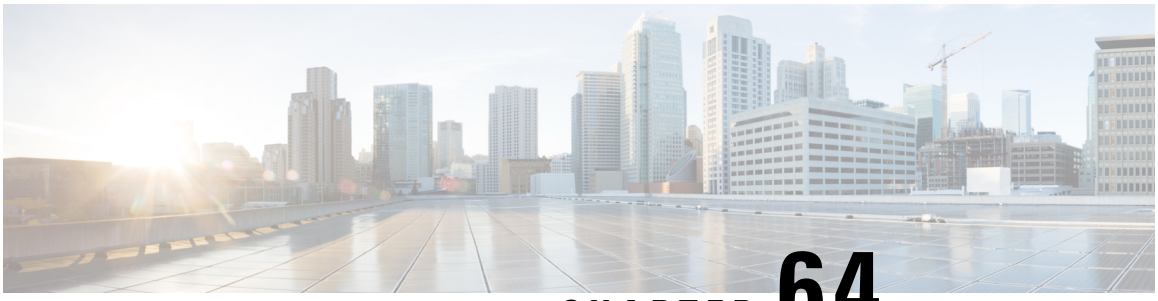
VPN Session and User Information

The system generates events that communicate the details of user activity on your network, including VPN-related activity. The system monitoring capabilities enable you to determine quickly whether remote access VPN problems exist and where they exist. You can then apply this knowledge and use your network management tools to reduce or eliminate problems for your network and users. Optionally, you can log out remote access VPN users as needed.

Viewing Remote Access VPN Active Sessions

Analysis > **Users heading** > **Active Sessions**

Lets you view the currently logged-in VPN users at any given point in time with supporting information such as the user name, login duration, authentication type, assigned/public IP address, device details, client version, endpoint information, throughput, bandwidth consumed group policy, tunnel group and so on. The system allows you to filter current user information, log users out, and delete users from the summary list.



Note If you configure your VPN in a high-availability deployment, the device name displayed against active VPN sessions can be the primary or secondary device that identified the user session.

Viewing Remote Access VPN User Activity

Analysis > **Users heading** > **User Activity**

Lets you view the details of user activity on your network. The system logs historical events and includes VPN-related information such as connection profile information, IP address, geolocation information, connection duration, throughput, and device information.

CHAPTER 64

Dynamic Access Policies

Dynamic access policies (DAP) enable you to configure authorization that addresses the dynamics of VPN environments. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group membership and endpoint security.

- Firewall Threat Defense dynamic access policies, on page 1927
- Prerequisites for dynamic access policy, on page 1929
- Guidelines and limitations for dynamic access policies, on page 1929
- Configure a Dynamic Access Policy (DAP), on page 1930
- Associate dynamic access policy with remote access VPN, on page 1941

Firewall Threat Defense dynamic access policies

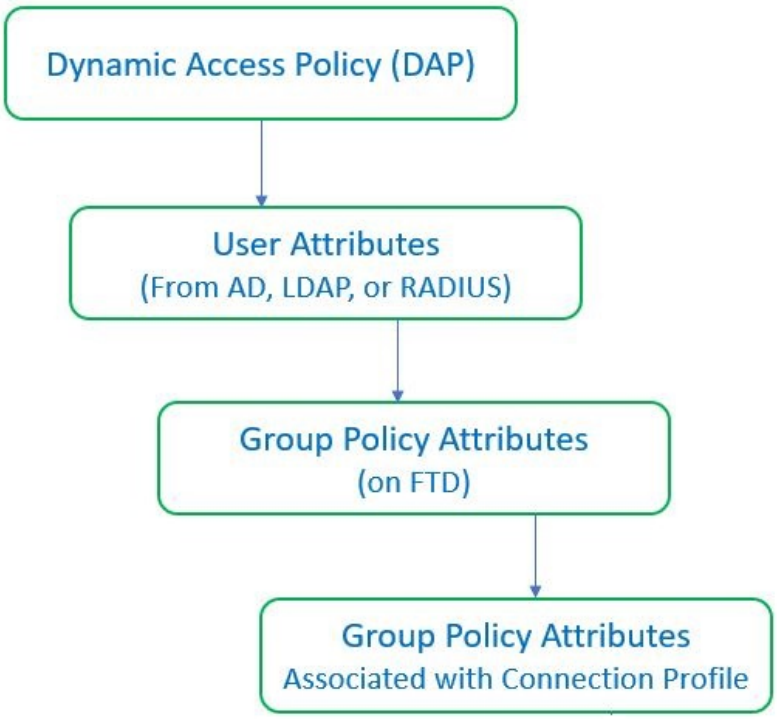
A Secure Firewall Threat Defense dynamic access policy is a collection of access control attributes that

- addresses issues of multiple group memberships and endpoint security in VPN environments
- grants access to particular users for particular sessions according to defined policies, and
- adapts to dynamic environments with multiple variables affecting each VPN connection.

Dynamic access policy operation

VPN gateways operate in dynamic environments. Multiple variables can affect each VPN connection. For example, intranet configurations that frequently change, the various roles each user inhabits within an organization, and log in attempts from remote access sites with different configurations and levels of security. The task of authorizing users is much more complicated in a VPN environment than it is in a network with a static configuration.

You can create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. The Firewall Threat Defense device generates a DAP during user authentication by selecting or aggregating attributes from one or more DAP records. The device then selects these DAP records based on the endpoint security information of the remote device and AAA authorization information for the authenticated user. Then the device applies the DAP record to the user tunnel or session.



Hierarchy of policy enforcement of permissions and attributes in a Firewall Threat Defense device

The Firewall Threat Defense device supports applying user authorization attributes, also called user entitlements or permissions, to VPN connections. The attributes are applied from a DAP on the Firewall Threat Defense, external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the Firewall Threat Defense device.

If the Firewall Threat Defense device receives attributes from all sources, the device evaluates, merges, and applies the attributes to the user policy. If there are conflicts between attributes coming from the DAP, the AAA server, or the group policy, the attributes from the DAP always take precedence.

The Firewall Threat Defense device applies attributes in this order:

Figure 378: Policy enforcement flow

1. **DAP attributes on the FTD**—The DAP attributes take precedence over all others.
2. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
3. **Group policy configured on the FTD**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the Firewall Threat Defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.

4. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy that is applied to the user before authentication.

Note The Firewall Threat Defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. For the user session, the device uses the attributes on the group policy that you assign to the connection profile, unless the user attributes or the group policy from the AAA server overrides them.

Prerequisites for dynamic access policy

This reference provides the licensing prerequisites that must be met before configuring Dynamic Access Policy features.

Licensing prerequisites

- Firewall Threat Defense must have at least one of these Secure Client licenses:
  - Secure Client Premier
  - Secure Client Advantage
  - Secure Client VPN Only
- The Firewall Threat Defense Essentials license must allow export-controlled functionality.

General prerequisite

Ensure that you have the Secure Firewall Posture package before you configure the dynamic access policy. You can add the Secure Firewall Posture file at **Objects** > **Object Management** > **VPN** > **Secure Client File**.

Guidelines and limitations for dynamic access policies

Consider these guidelines and limitations when implementing Dynamic Access Policies:

- Matching of AAA attributes in a DAP will work only if a AAA server is configured to return the correct attributes when authenticating or authorizing a remote access VPN session.
- Minimum Secure Client and Secure Firewall Posture package version supported for DAP is 4.6. But it is highly recommended to use the latest version of Secure Client.
- DAP does not support clustering or multi-instance mode.
- DAP condition with an assigned IPv4 or IPv6 address does not work for local authentication.

Configure a Dynamic Access Policy (DAP)

Create a dynamic access policy

Create a dynamic access policy to enable conditional access control for VPN users based on their endpoint security posture and compliance status.

Dynamic access policies evaluate endpoint attributes and security posture to determine appropriate access permissions for VPN users. These policies work in conjunction with posture assessment packages to enforce security compliance.

Before you begin

Ensure that you have the Secure Firewall Posture package before you configure the dynamic access policy. You can add the Secure Firewall Posture file at **Objects** > **Object Management** > **VPN** > **Secure Client File**.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**, and click **Create Dynamic Access Policy**.

Step 2 Specify the **Name** for the DAP policy and an optional **Description**.

Step 3 Choose the **HostScan Package** from the drop-down list.

Step 4 Click **Save**.

What to do next

To configure DAP record, see Create Dynamic Access Policy Record

Create a dynamic access policy record

A dynamic access policy (DAP) can contain multiple DAP records, where you configure user and endpoint attributes. You can prioritize the DAP records within a DAP so that the Firewall Threat Defense device can select and sequence the required criteria when a user attempts VPN connection.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Edit an existing dynamic access policy or click **Create Dynamic Access Policy** to create a new one and then edit the policy.

Step 3 Click **Create DAP Record**.

Step 4 Click the **General** tab.

Step 5 Specify the **Name** for the DAP record.

Step 6 Enter the **Priority** for the DAP record.

The lower the number, the higher the priority.

Step 7 Select one of these actions to take when a DAP record matches:

- **Continue**—Applies access policy attributes to the session. If any, the next DAP record (next policy line with less priority) is then evaluated.
- **Terminate**—Terminates the session.
- **Quarantine**—Quarantines the connection.

Step 8 Check the **Display User Message on Criterion Match** check-box and add the user message.

The Firewall Threat Defense displays this message to the user when the DAP record matches.

Step 9 Check the **Apply a Network ACL on Traffic** check box and select the access control list from the drop-down.

Step 10 Check the **Apply one or more Secure Client Custom Attributes** check box and select the custom attributes object from the drop-down.

Step 11 Click **Save**.

Configure posture assessment criteria

For a DAP policy, you can configure file, process, or registry endpoint attributes with unique endpoint IDs. These IDs can be used as endpoint criteria in Lua scripts to configure a DAP record.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Click **Create Dynamic Access Policy** to create a new DAP policy. and then edit the policy.

Step 3 Click the edit icon adjacent to the DAP policy.

Step 4 Click **Add Posture Assessment Criteria**.

Step 5 Do one of these:

- Configure a file endpoint attribute:
  - **a.** Click the **File** radio button.
  - **b.** In the **Endpoint ID** field, enter a unique ID for the file. It can be a string or a number.
  - **c.** In the **File Path** field, specify the file path.
- Configure a registry endpoint attribute:
  - **a.** Click the **Registry** radio button.
  - **b.** In the **Endpoint ID** field, enter a unique ID for the registry. It can be a string or a number.
  - **c.** In the **Entry Path** field, specify the file path.

- Configure a process endpoint attribute:
  a. Click the **Process** radio button.
  b. In the **Endpoint ID** field, enter a unique ID for the process. It can be a string or a number.
  c. In the **Process Name** field, specify the process name.

Note
You cannot edit an Endpoint ID once it is saved.

Step 6 Click **Save**.

What to do next

You can use the endpoint IDs to configure advanced posture assessment criteria using Lua scripts. For more information, see Configure advanced settings for DAP, on page 1941.

Configure AAA criteria settings for a DAP record

Configure AAA criteria settings to specify the conditions under which DAP records are selected and applied to user sessions based on AAA authorization and posture assessment information.

DAP complements AAA services by providing a limited set of authorization attributes that can override the attributes that AAA provides. The Firewall Threat Defense device selects DAP records based on the AAA authorization information for the user and posture assessment information for the session. The Firewall Threat Defense device can choose multiple DAP records depending on this information, which it then aggregates to create DAP authorization attributes.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.
Step 2 Edit an existing DAP policy or create a new one and then edit the policy.
Step 3 Select a DAP record or create a new one, and edit the DAP record.
Step 4 Click **AAA Criteria**.
Step 5 Select one of the **Match criteria between sections**.

- Any—Matches any of the criteria.
- All—Matches all the criteria.
- None—Matches none of the set criteria.

Step 6 Click **Add** to add the required **Cisco VPN Criteria**.

Cisco VPN criteria include attributes for group policy, assigned IPv4 address, assigned IPv6 address, connection profile, username, username 2, and SCEP required.

a) Select an attribute and specify the **Value**.

b) Click **Add another criteria** to add more criteria.
c) Click **Save**.

Step 7 Select **LDAP Criteria**, **RADIUS Criteria**, or **SAML Criteria** and specify the **Attribute ID** and **Value**.

Step 8 Click **Save**.

Configure endpoint attribute selection criteria in DAP

Endpoint attributes contain information about the endpoint system environment, posture assessment results, and applications. A Firewall Threat Defense device dynamically generates a collection of endpoint attributes during session establishment and stores these attributes in a database that is associated with the session. Each DAP record specifies the endpoint selection attributes that must be satisfied for the Firewall Threat Defense device to choose it for a session. The Firewall Threat Defense device selects only DAP records that satisfy every condition configured.

Note When using remote Access VPN with DAP or Secure Firewall Posture (formerly HostScan) and change of authorization (CoA), endpoint attribute checks differ between initial authentication and CoA-triggered authorization.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**, and click **Create Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click **Endpoint Criteria** and configure attributes such as anti-malware, device, Secure Client, NAC, application, personal firewall, operating system, process, registry, file, and certificate authentication.

Note
You can create multiple instances of each type of endpoint attribute. There is no limit for the number of endpoint attributes for each DAP record.

Step 4 Click **Save**.

Add an anti-malware endpoint attribute to a DAP record

Add anti-malware endpoint attributes to a DAP to control access based on the presence and configuration of anti-malware software on client devices.

Anti-malware endpoint attributes allow you to create access policies that verify client devices have appropriate anti-malware protection before granting network access.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Anti-Malware**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add the anti-malware attributes.

In the **Anti-Malware** dialog box, configure these parameters:

a) Check the **Installed** check box to indicate whether the selected endpoint attribute and its accompanying qualifiers are installed or not installed.
b) In **Real Time Scanning**, choose **Enabled** or **Disabled** to activate or deactivate real-time malware scanning.
c) Choose the anti-malware vendor from the **Vendor** drop-down list.
d) Choose the anti-malware description from the **Product Description** drop-down list.
e) Choose the **Version** of the anti-malware product.
f) Specify the number of days since the **Last Update**.

You can indicate that an anti-malware update must occur in less than (<) or more than (>) the number of days you specify.

g) Click **Save**.

Add a device endpoint attribute to a DAP record

Add device endpoint attributes to a DAP to control access based on specific device characteristics such as hostname, MAC address, BIOS serial number, or port configuration.

Device endpoint attributes allow you to create policies that evaluate device-specific criteria to determine access permissions. These attributes help enforce security policies based on device identity and configuration.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Device**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add application attributes.

In the **Device** dialog box, configure these parameters:

Select the **=** or **≠** operator to check the attribute to be equal to or not equal to the value you enter for these attributes:

- **Host Name**—Hostname of the device. Use the computer's host name only, not the fully qualified domain name (FQDN).

- **MAC Address**—MAC address of the network interface card you are testing for. The address must be in the format xxxx.xxxx.xxxx where x is a hexadecimal character.
- **BIOS Serial Number**—BIOS serial number value of the device you are testing for. The number format is manufacturer-specific.
- **Port Number**—Listening port number of the device.
- **Secure Desktop Version**—Version of the Secure Firewall Posture image running on the endpoint.
- **OPSWAT Version**—The OPSWAT client version.
- **Privacy Protection**—None, Cache cleaner, Secure Desktop.
- **TCP/UDP Port Number**—TCP or UDP port in the listening state.

Step 6 Click **Save**.

Add Secure Client endpoint attributes to a DAP record

Add specific endpoint attributes to a Dynamic Access Policy (DAP) record to control client access based on Secure Client characteristics such as client version, platform, and device identifiers.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Secure Client**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add the attributes.

In the **Secure Client** dialog box, configure these parameters:

Select the = or ≠ operator to check the attribute to be equal to or not equal to the value you enter.

a) Specify the **Client Version**.
b) Choose the platform from the **Platform** drop-down list.
c) Choose the platform version from the **Platform Version** drop-down list.
d) Specify the **Device Type** and **Device Unique ID**.
e) Add the **MAC Addresses**.

Note
The MAC Address must be in the format XX-XX-XX-XX-XX-XX, where each X is a hexadecimal character. You can click **Add another MAC Address** to add more addresses.

f) Click **Save**.

Add NAC endpoint attributes to a DAP record

You can configure Network Access Control (NAC) endpoint attributes within a DAP (Dynamic Access Policy) record to evaluate endpoint posture status based on a defined criteria.

NAC endpoint attributes in DAP records help determine access permissions based on endpoint posture compliance. You can specify whether endpoints must match all criteria or any criteria, and define specific posture token strings for evaluation.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **NAC**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add NAC attributes.

Step 6 In the **NAC** dialog box, set the operator to be equal to **=** or not equal to **≠** the posture status.

Step 7 Choose one of these options from the **Posture Status** drop-down list:

- Compliant
- Non-Compliant
- Unknown

Step 8 Click **Save**.

Add an application attribute to a DAP record

This task allows you to define application-specific criteria within a DAP record to control access based on the type of remote access client.

Application attributes in DAP records help determine access policies by evaluating the client application type used for remote connections. You can configure these attributes to match all or any specified criteria.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Application**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add application attributes.

Step 6 In the **Application** dialog box, choose equals (**=**) or does not equal (**≠**) and specify the **Client Type** to indicate the type of remote access connection. Choose from one of these options:

- Clientless

- Cut-Through-Proxy
- Secure Client
- IPsec
- L2TP
- IPsec-IKEv2-Generic-RA

Step 7 Click **Save**.

Add a personal firewall endpoint attribute to a DAP record

Adding personal firewall endpoint attributes to a DAP allows you to control network access based on whether client devices have specific firewall software installed, enabled, and meeting version requirements.

Personal firewall endpoint attributes help enforce security policies by ensuring that connecting devices meet firewall protection standards before granting network access.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Personal Firewall**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add personal firewall attributes.

In the **Personal Firewall** dialog box, configure these parameters:

a) Click **Installed** to indicate whether the personal firewall endpoint attribute and its accompanying qualifiers (fields below the Name/Operation/Value column) are installed or not installed.
b) Select **Enabled** or **Disabled** to activate or deactivate firewall protection.
c) Choose the name of the firewall vendor from the **Vendor** drop-down list.
d) Choose the firewall description from the **Product Description** drop-down list.
e) Select the equals (**=**) or does not equal (**≠**) operator and choose the **Version** of the personal firewall product.
f) Click **Save**.

Add an operating system endpoint attribute to a DAP record

Operating system endpoint attributes help create granular access policies by identifying and filtering client devices based on their operating system characteristics. This is useful for implementing different access levels or restrictions based on device types.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Operating System**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add endpoint attributes.

In the **Operating System** dialog box, configure these parameters:

a) Select the equals (**=**) or does not equal (**≠**) operator and then choose the operating system from the **Operating System** drop-down list.
b) Select the equals (**=**) or does not equal (**≠**) operator and then specify the operating system version in the **Version** field.
c) Click **Save**.

Add a process endpoint attribute to a DAP

Configure process endpoint attributes to define specific criteria for device access policy enforcement based on running processes.

Process endpoint attributes allow you to create device access policies based on specific processes running on endpoints. This helps ensure that only devices with approved processes can access network resources.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Process**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click **+** to add process attributes.

In the **Process** dialog box, configure these parameters:

a) Select **Exists** or **Does not exist**.
b) Specify the **Process Name**.
c) From the **Endpoint ID** drop-down list, choose the process ID or click **+** to configure a posture assessment criteria for the process. For more information, see Configure posture assessment criteria, on page 1931.
d) For **Process Name**, click **Exists** or **Does not exist** and specify the process name.
e) Click **Save**.

Add a registry endpoint attribute to a DAP record

Registry endpoint attributes allow you to define specific registry keys that the system scans during posture assessment to determine endpoint compliance status.

Scanning for registry endpoint attributes applies to Windows operating systems only.

Before you begin

Before configuring a registry endpoint attribute, define the registry key for which you want to scan in the Secure Firewall Posture window for Cisco Secure Desktop.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **Registry**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add registry attributes.

In the **Registry** dialog box, configure these parameters:

a) Select the **Entry Path** for the registry and specify the path.
b) From the **Endpoint ID** drop-down list, choose the ID for the registry or click + to configure a posture assessment criteria for the registry. For more information, see Configure posture assessment criteria, on page 1931.
c) Choose the existence of the registry, **Exists** or **Does not exist**.
d) Select the registry **Type** from the list.
e) Select the equals (=) or does not equal (≠) operator and enter the **Value** of the registry key.
f) Select **Case insensitive** to disregard the case of the registry entry while scanning.
g) Click **Save**.

Add a file endpoint attribute to a DAP record

You can configure file endpoint criteria within a DAP (Device Access Policy) record to specify file attributes used for posture assessment and device authorization.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP policy and a DAP record.

Step 3 Click the **Endpoint Criteria** tab and click **File**.

Step 4 Select the **Match criteria** as **All** or **Any**.

Step 5 Click + to add file attributes.

In the **File** dialog box, configure these parameters:

a) From the **Endpoint ID** drop-down list, choose the ID for the file or click **+** to configure a posture assessment criteria for the file. For more information, see Configure posture assessment criteria, on page 1931.
b) Specify the **File Path**.
c) Select **Exists** or **Does not exist** to indicate the presence of the file.
d) Select less than (<) or greater than (>) and specify the **Last Modified** days for the file.
e) Select the equal to (=) or not equal to ≠ operator and enter the **Checksum**.
f) Click **Save**.

Add certificate authentication attributes to a DAP record

Adding certificate authentication attributes to a DAP allows you to control access based on specific certificate fields such as subject, issuer, and serial number.

You can index each certificate to allow referencing to any of the received certificates, by the configured rules. Based on these certificate fields, you can configure DAP rules to allow or disallow connection attempts.

Note This configuration is applicable only for certificates used with multiple certificate authentication. It does not apply for single client certificate authentication.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.
Step 2 Create or edit a DAP record.
Step 3 Click the **Endpoint Criteria** tab and click **Multiple Certificate Authentication**.
Step 4 Select the **Match criteria** as **All** or **Any**.
Step 5 Click **+** to add certification authentication criteria.

In the **Multiple Certificate Authentication Criteria** dialog box, configure these parameters:

a) Select **Cert1** or **Cert2** certificate.
b) Select the **Subject** and specify the subject value.
c) Select the **Issuer** and specify the issuer value.
d) Select the **Subject Alternate Name** and specify the subject value.
e) Specify the **Serial Number**.
f) Choose the **Certificate Store** as **None**, **Machine**, or **User**.

The VPN client sends the certificate store information.

g) Click **Save**.

Configure advanced settings for DAP

This task allows you to configure selection criteria for DAP records using Lua scripts when the standard AAA AND endpoint attribute areas are insufficient for your requirements.

You can use the **Advanced** tab for adding selection criteria other than what is possible in the AAA AND endpoint attribute areas. For example, while you can configure the Firewall Threat Defense to use AAA attributes that satisfy any, all, OR none of the specified criteria, the endpoint attributes are cumulative, AND must satisfy all. To let the security appliance employ one endpoint attribute OR another, you must create appropriate logical expressions in Lua AND enter them here.

Procedure

Step 1 Choose **Devices** > **VPN** > **Dynamic Access Policy**.

Step 2 Create or edit a DAP record.

Step 3 Click the **Advanced** tab.

Step 4 Select **AND** OR **OR** as the match criteria to use in the DAP configuration.

Step 5 Add the Lua script in the **Lua script for advanced attribute matching** field.

Step 6 To use the endpoint criteria ID in your Lua script:

a. Place the cursor at the point where you want to insert the endpoint criteria ID.

b. From the **Endpoint Criteria** drop-down list, choose the criteria a

c. Choose the corresponding ID from the adjacent drop-down list.

Example:

In this example, DAPTESTFILE, LIBAGENT, vpnagent, AND DUOAGENT were inserted in the Lua script:

```
EVAL(endpoint.file["DAPTESTFILE"].exists,"EQ","true") or
EVAL(endpoint.file["LIBAGENT"].exists,"EQ","true") and
EVAL(endpoint.process[""vpnagent""].exists,"EQ","true") and
EVAL(endpoint.registry[""DUOAGENT""].exists,"EQ","true")
```

Step 7 Click **Save**.

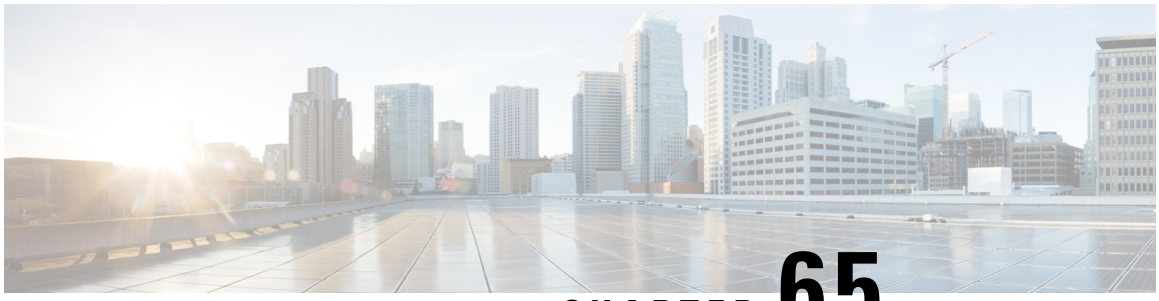
Associate dynamic access policy with remote access VPN

You can associate Dynamic Access Policy (DAP) with remote access VPN policy for the dynamic access policy attributes to match during VPN session authentication and authorization. You can then deploy the remote access VPN on the Firewall Threat Defense.

Procedure

Step 1 Choose **Devices** > **VPN** > **Remote Access**.

Step 2 Click **Edit** next to the remote access VPN policy to which you want to associate dynamic access policy.



Step 3 Click the link in remote access VPN to select the dynamic access policy.

Step 4 Select the policy from the **Dynamic Access Policy** drop-down or click **Create a new Dynamic Access Policy** to configure a new dynamic access policy.

Step 5 Click **OK**.

Step 6 Click **Save** to save the remote access VPN policy.

When the remote access VPN user tries to connect, the VPN checks the configured dynamic access policy records and attributes. VPN creates a dynamic access policy based on the matching dynamic access policy records and takes appropriate action on the VPN session.

CHAPTER 65

VPN Monitoring and Troubleshooting in Security Cloud Control

- Monitor site-to-site VPNs using Site-to-Site VPN summary page, on page 1943
- Monitor Remote Access VPN Sessions, on page 1943
- SD-WAN summary dashboard, on page 1943

Monitor site-to-site VPNs using Site-to-Site VPN summary page

You can view a summary of your site-to-site VPN topologies in the **Site-to-Site VPN Summary** page. For each topology, you can view details such as VPN type, network topology, VPN interfaces, VPN devices, and tunnel statuses.

You can edit or delete the topology using the edit and delete buttons. For SASE topology VPNs, you have options to deploy, edit and delete any topology.

Monitor Remote Access VPN Sessions

The Security Cloud Control Remote Access Monitoring dashboard can be used to view consolidated information about RA VPN users, including the current status of users, device types, client applications, user geolocation information, and duration of connections. You can also disconnect RA VPN sessions as needed.

See Monitor Remote Access Virtual Private Network Sessions for more information.

SD-WAN summary dashboard

The SD-WAN Summary dashboard (**Overview** > **Dashboards** > **SD-WAN SummaryAnalysis** > **SD-WAN Summary**) provides a snapshot of your WAN devices and their interfaces. This dashboard helps you to:

- Identify issues with the underlay and overlay (VPN) topologies.
- Troubleshoot VPN issues using the existing **Health Monitoring**, **Device Management**, and **Site-to-Site Monitoring** pages.
- Monitor application performance metrics of WAN interfaces. The threat defense steers application traffic based on these metrics.

For clusters, this dashboard displays application performance metrics of only the control node and not the data nodes.

WAN device criteria

A WAN device must meet one of these criteria:

- The device must be a VPN peer.
- The device must have WAN interface.

WAN interface criteria

A WAN interface must meet one of these criteria:

- The interface has IP address-based path monitoring enabled on it.
- The interface has a Policy Based Routing (PBR) policy with at least one application configured to monitor it.

For more information about PBR policy and path monitoring, see Policy-Based Routing, on page 1541.

Uplink decisions

Click **Uplink Decisions** to view the **VPN Troubleshooting** page. You can view syslogs with ID: 880001. These syslogs show the threat defense interfaces through which it steers traffic based on the configured PBR policy.

To view the above syslogs and to view the data on this dashboard, ensure that you review Prerequisites for using SD-WAN summary dashboard, on page 1806.

Prerequisites for using SD-WAN summary dashboard

Ensure that you review these prerequisites before using the SD-WAN summary dashboard.

General prerequisites

- You must be an Admin, Security Analyst, or Maintenance user to view this dashboard. See Secure Firewall Management Center and Cloud-delivered Firewall Management Center User Role Mapping for more information.
- Threat Defense devices must be Version 7.2 or later.
- Enable IP-based path monitoring and HTTP-based application monitoring on the WAN interfaces.

  To do this:

  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click the edit icon adjacent to the interface that you want to edit.
  4. Click the **Path Monitoring** tab.
  5. Check the **Enable IP based Monitoring** check box.

6. Check the **Enable HTTP based Application Monitoring** check box.
7. Click **OK**.

- Configure a PBR policy with at least one application configured to monitor it:
  1. Choose **Devices** > **Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click **Routing**.
  4. In the left pane, click **Policy Based Routing**.
  5. Click **Add**.
  6. From the **Ingress Interface** drop-down list, choose an interface.
  7. Click **Add** to configure a forwarding action.
  8. Configure the parameters.
  9. Click **Save**.
- To view syslogs when you click **Uplink Decisions**, you must:
  - Choose **Devices** > **Platform Settings** and create or edit a threat defense policy.
  - In the left pane, click **Syslog**.
  - Click the **Logging Setup** tab.
  - Check the **Enable Logging** check box to turn on the data plane system logging for the threat defense device.
  - Click the **All Logs** radio button to enable logging of all the troubleshooting syslog messages.

    or

    Click the **VPN Logs** radio button to enable logging of only the VPN troubleshooting messages.
  - Click **Save**.

Monitor WAN devices and interfaces using the SD-WAN summary dashboard

The SD-WAN Summary dashboard has these widgets :

- WAN connectivity, on page 1946
- VPN topology, on page 1946
- interface throughput, on page 1946
- Device inventory, on page 1946
- WAN device health, on page 1946

WAN connectivity

This widget provides a summary of the WAN interfaces statuses. It shows the number of WAN interfaces that are in the **Online**, **Offline** or **No Data** states. Note that you cannot monitor subinterfaces using this widget.

Click **View All Interfaces** to view more details about the interfaces in the health monitor page.

If a WAN interface is in the **Offline** or **No Data** state, you can troubleshoot it from the health monitor page:

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click the **Interface** tab to view the interface status and aggregate traffic statistics for a specific time.

   Alternatively, you can click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

VPN topology

This widget provides a summary of the site-to-site VPN tunnel statuses. It shows the number of **Active**, **Inactive**, and **No Active Data** VPN tunnels.

Click **View All Connections** to view the VPN tunnel details in the **Site-to-site VPN Monitoring** dashboard.

If the tunnels are in the **Inactive** or **No Active Data** state, you can troubleshoot using the **Site-to-site VPN Monitoring** dashboard. In the **Tunnel Status** widget, hover your cursor over a topology, click **View** ( ) and do one of these actions:

- Click the **CLI Details** tab to view the details of the VPN tunnels.
- Click the **Packet Tracer** tab to use the packet tracer tool for the topology.

interface throughput

This widget monitors the average throughput of the WAN interfaces during the chosen time period.

The interface throughput is classified into four bands. These details aid in cost planning and resourcing. You can choose a time range for the widget data from the **Show Last** drop-down list. The range is from 15 minutes to two weeks.

Click **View Health Monitoring** to view more details about the interface in the health monitor page.

Device inventory

This widget lists all the managed WAN devices and groups them according to the model.

Click **View Device Management** to view more details about the device in the **Device Management** page.

WAN device health

This widget displays the device count according to the health of the WAN devices. You can view the number of devices with errors, warnings, or those that are in **Disabled** state.

Click **View Health Monitoring** to view the alarms, and quickly identify, isolate, and resolve issues.

If the health of a device is affected, you can troubleshoot it from the health monitor page.

1. In the **Monitoring** pane, expand **Devices**.

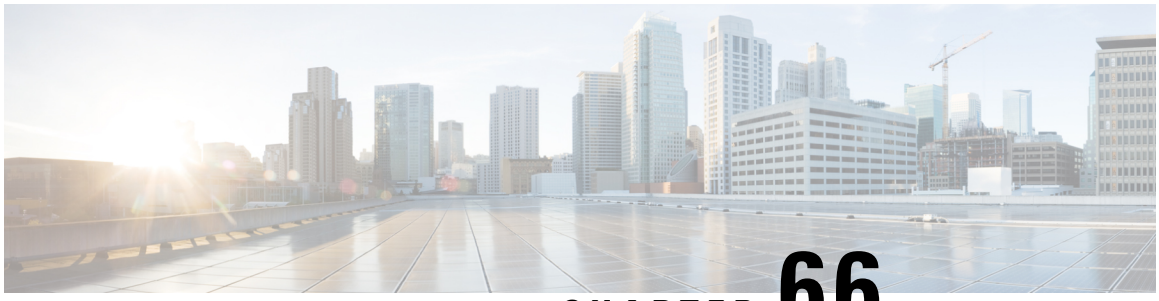
2. Click the corresponding WAN device to view the device-specific health details.
3. Click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

A device can be in **Disabled** state for multiple reasons, including these:

- Management interface is disabled.
- Device is powered off.
- Device is being upgraded.

Monitor application performance metrics of WAN interfaces using SD-WAN summary dashboard

You can monitor application performance metrics of WAN interfaces using the **Application Monitoring** tab of the SD-WAN Summary dashboard. These metrics include Jitter, Round Trip Time (RTT), Mean Opinion Score (MOS), and Packet Loss.



By default, the metrics data is refreshed every 5 minutes. You can change the refresh time; the range is from 5 to 30 minutes. You can view the metrics in tabular and graphical formats. For each WAN interface, the latest metric value appears in the table. For graphical data, you can choose a time interval of up to 24 hours to view the metrics data for the corresponding WAN interfaces.

PART XVI

Zero Trust Network Access

- Zero Trust Network Access Overview, on page 1951
- Clientless Zero Trust Network Access, on page 1955
- Universal Zero Trust Network Access, on page 1975

CHAPTER 66

Zero Trust Network Access Overview

- Clientless and universal zero trust network access, on page 1951
- Zero trust network access, on page 1952
- Comparison of clientless and universal ZTNA, on page 1952
- History for zero trust network access, on page 1953

Clientless and universal zero trust network access

Zero Trust Access or Zero Trust Network Access (ZTNA) is a security process that protects internal resources using identity-based access, including user trust and posture. The process verifies the user, device, and request context before allowing access to internal resources and applications. It grants the least privilege access only after verifying the user, understanding the request context, and assessing any risks.

ZTNA deployment models

You can choose between two ZTNA deployment models.

- Clientless Zero Trust Network Access
- Universal Zero Trust Network Access

Clientless zero trust network access

Clientless Zero Trust Network Access (Clientless ZTNA) authenticates and authorizes access to protected web-based resources and applications from inside (on-premises) or outside (remote) the network. Clientless ZTNA accomplishes this authentication using an external identity provider (IdP) with Security Assertion Markup Language (SAML) authentication. No client software is needed on the user's device.

Clientless ZTNA is ideal for remote users accessing web applications and unmanaged devices.

Universal zero trust network access

Universal Zero Trust Network Access (Universal ZTNA) is a client-based solution that provides identity-based access to all internal resources regardless of user location. It enforces strong authentication, posture validation, and traffic inspection for each application and user.

Universal ZTNA supports both remote and on-premises users. On-premises users access a trusted network using a Secure Firewall Threat Defense device. Remote users access a trusted network through the cloud-based Secure Access service, which evaluates policies and proxies the user traffic securely in the cloud.

Zero trust network access

Zero Trust Network Access (ZTNA) provides secure, segmented application access by requiring explicit authorization for every connection. This approach reduces the attack surface and simplifies secure migrations without adding devices.

Key characteristics

ZTNA uses your existing Threat Defense deployment as an enforcement point for application access, enabling segmented and per-application authorization. ZTNA establishes individual tunnels for both remote and on-premises users.

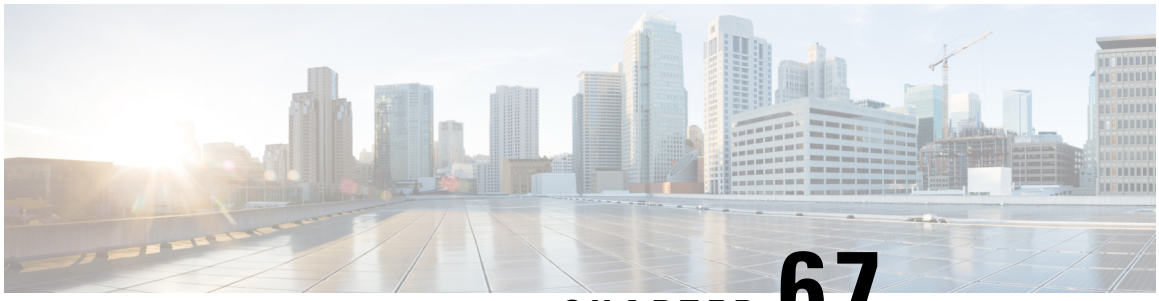
ZTNA hides the network from users and ensures that they can only access applications for which they have been explicitly authorized. Authorization for one application does not provide implicit access to other applications, which significantly reduces the attack surface. In other words, every access to an application or a resource must be explicitly authorized.

You can adopt a more secure access model by adding zero trust access functionality to Threat Defense. This eliminates the need to install or manage additional devices in the network.

Comparison of clientless and universal ZTNA

This comparison outlines the key technical and operational differences between clientless ZTNA and universal ZTNA deployment models. Clientless ZTNA uses a browser-based approach, which is ideal for guest users or unmanaged devices that require access to web applications. Universal ZTNA uses an agent-based solution that supports all protocols. It continuously monitors device posture in managed corporate environments. Consider factors such as application support, security inspection capabilities, and licensing requirements to choose the best strategy for securing your remote and on-premises workforce.

Factor	Clientless ZTNA	Universal ZTNA
Client required	No client is required(browser-based)	Yes, Secure Client is required
Application support	Supports web applications only	Supports all protocols and applications
Device posture	Device posture monitoring is limited (available through agents such as Duo Desktop)	Provides comprehensive and continuous device posture monitoring
Best for	Guest users, contractors, unmanaged devices	Employees, managed devices
Components involved	Third-party identity provider (IdP) configured with application access using Security Assertion Markup Language (SAML) authentication	• Secure Access • Secure Client software • Identity provider (depending on users' location)
Security policies	Deep inspection (Snort, IPS, File)	Deep inspection (Snort, IPS, File)



Factor	Clientless ZTNA	Universal ZTNA
User location	Remote and on-premises	Remote and on-premises
Licenses	Export-controlled license for Firewall Management Center	Licenses for Secure Access, Secure Client software, and Security Cloud Control Firewall Management (formerly Cisco Defense Orchestrator)

History for zero trust network access

This reference provides the minimum Firewall Management Center and Threat Defense versions needed to support zero trust application policies and monitoring.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Universal Zero Trust Network Access (universal ZTNA).	7.7.10	7.7.10	Universal Zero Trust Network Access (universal ZTNA) is a comprehensive solution that provides secure access to internal network resources based on user identity, trust, and posture. It ensures that access to one application does not implicitly grant access to the entire network, as with remote access VPN. New/modified screens: **Policies** > **Zero Trust Application** Requires Cisco Secure Access and Security Cloud Control. Deployment restrictions: Not supported with clustered devices, container instances, or transparent mode. Supported platforms: Secure Firewall 1150, 3100, 4100, 4200, and Firewall Threat Defense Virtual.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Clientless zero-trust access.	20230929	7.4.0 with Snort 3	Zero Trust Access allows you to authenticate and authorize access to protected web based resources, applications, or data from inside (on-premises) or outside (remote) the network using an external SAML Identity Provider (IdP) policy. The configuration consists of a Zero Trust Application Policy (ZTAP), Application Group, and Applications. New/modified screens: **Policies** > **Zero Trust Application** New/modified CLI commands: • **show running-config zero-trust application** • **show running-config zero-trust application-group** • **show zero-trust sessions** • **show zero-trust statistics** • **show cluster zero-trust statistics** • **clear zero-trust sessions application** • **clear zero-trust sessions user** • **clear zero-trust statistics**

CHAPTER 67

Clientless Zero Trust Network Access

Clientless Zero Trust Network Access enables users to access protected TLS web applications through their browser using SAML identity providers, eliminating the need to install a client on the endpoint. This solution leverages Zero Trust Application Policies, Application Groups, and applications. This document describes how to configure these features, outlines their limitations, and provides information on deployment, monitoring, and troubleshooting.

- Zero Trust Access, on page 1955

- How threat defense works with zero trust access, on page 1958
- Prerequisites for zero trust application policy, on page 1960
- Limitations for Clientless Zero Trust Network Access, on page 1960
- Create a zero trust application policy, on page 1961
- Create an application group, on page 1963
- Create an application, on page 1965
- Create an ungrouped application, on page 1967
- Set targeted devices for zero trust access policy, on page 1968
- Edit a zero trust application policy, on page 1969
- Manage zero trust application policies, on page 1970
- Monitor zero trust sessions, on page 1971

Zero Trust Access

Clientless Zero Trust Network Access is based on Zero Trust Access principles. Zero Trust Access is a zero trust security model that eliminates implicit trust. The model grants the least privilege access after verifying the user, the context of the request, and after analyzing the risk if access is granted.

Clientless Zero Trust Network Access enables you to authenticate and authorize access to protected web-based resources and applications from inside (on-premises) or outside (remote) the network using an external Security Assertion Markup Language (SAML) identity provider (IdP) policy.

Key features

The solution includes these capabilities.

- Supports multiple SAML-based identity providers such as Duo, Azure Active Directory (Azure AD), Okta, and other identity providers.
- Client applications such as Cisco Secure Client are not required on the endpoint (client devices) for secure access.
- Access and authentication are performed through the browser.
- Supports only TLS web applications.
- Agents such as Duo Health support client device posture. These agents evaluate the posture against a policy in Duo and provide access based on this evaluation. Third-party identity providers such as Okta or PingID perform this same functionality with their agents that support posture evaluation.
- Supports HTTP-Redirect SAML binding.
- Supports application groups that make it easier to enable protection on a set of applications.
- Leverages threat defense intrusion and malware protection on zero trust application traffic.

You can use the Secure Firewall Management Center web interface to create a Zero Trust Application Policy that allows you to define private applications and assign threat policies to them. The policy is application specific where the administrator decides the inspection levels based on the threat perception for that application.

Components of a Clientless Zero Trust Network Access configuration

A new configuration of Clientless Zero Trust Network Access consists of a Zero Trust Application Policy, Application Group, and Applications.

Configuration components

The configuration includes these main components:

- **Zero Trust Application Policy**— consists of application groups, and grouped or ungrouped applications. Settings for Security Zones and Security Controls associate at a global level with all ungrouped applications and application groups.

  A global port pool is assigned to the policy, by default. A unique port is automatically assigned from this pool to each private application that is configured.

  Zero Trust Application policy consists of application groups, and grouped or ungrouped applications.

- **Application Groups**—Consists of a logical group of applications that share SAML authentication settings and can optionally share Security Zones and Security Controls settings.

  Application Groups inherit the Security Zones and Security Controls settings from the global policy and can override the values.

  When you create an Application Group, you can use the same SAML IDP configuration to authenticate multiple applications. Applications that are part of an Application Group inherit the Application Group's SAML configuration. This eliminates the need to configure the SAML settings for each application. After the Application Group is created, new applications can be added to it without configuring the IDP for it.

When an end user tries to access an Application that is part of group, the user is authenticated to the Application Group for the first time. When the user tries to access other applications that are part of the same Application Group, the user is provided access without being redirected again to the IDP for authentication. This prevents overloading the IDP with requests for application access and optimizes the usage of the IDP if a limit is enabled.

- **Applications**—There are two types:
  - **Ungrouped Applications**— Are standalone applications. SAML settings must be configured for every application. The applications inherit the Security Zones and Security Controls settings from the global policy and can be overridden by the application.
  - **Grouped Applications**— Are multiple applications that are grouped under an Application Group. The SAML settings are inherited from the Application Group and cannot be overridden. However, the Security Zones and Security Controls settings can be overridden for each application.

These certificates are required for the configuration.

- **Identity Certificate**—This certificate is used by Firewall Threat Defense to masquerade as the applications.Firewall Threat Defense behaves as a SAML Service Provider (SP). This certificate must be a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of the private applications. It is a common certificate for all applications protected by Firewall Threat Defense.
- **IDP Certificate**—The IDP provides a certificate for each defined Application or Application Group. This certificate must be configured so that Firewall Threat Defense can verify the IDP's signature on incoming SAML assertions.

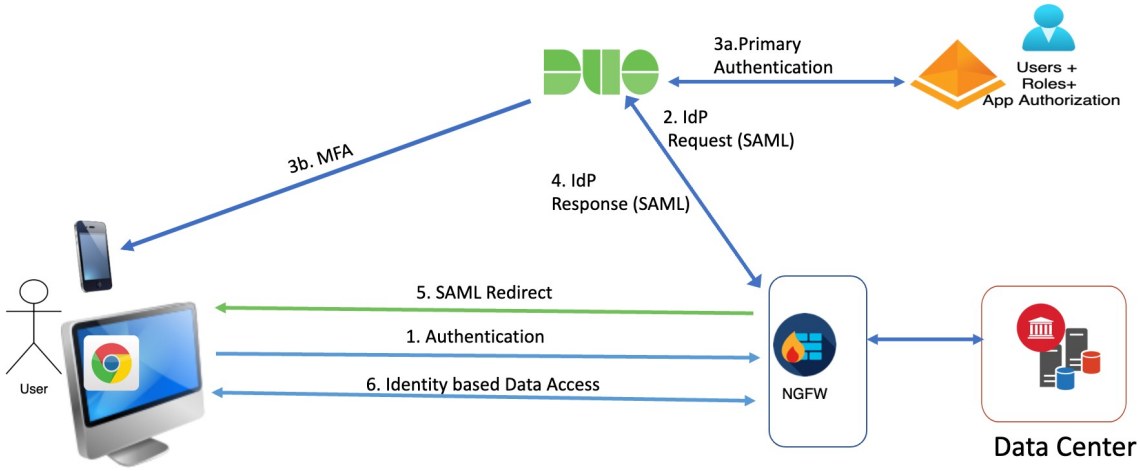
Note IDP certificates are commonly included within the metadata file; otherwise, users are required to have the IDP certificate readily available during the configuration of applications.

- **Application Certificate**—The encrypted traffic from user to the application is decrypted by Firewall Threat Defense using this certificate for the purpose of inspection.

Note This certificate is required to verify the cookies in the header to authorize connections, even if you are not conducting an IPS or Malware inspection.

How Clientless Zero Trust Network Access works

Summary



The key components involved in the Zero Trust Access clientless workflow are:

- User: Initiates access requests through a browser and provides authentication credentials.
- Identity Provider (IdP): Handles user authentication including primary and multi-factor authentication challenges.

- Threat Defense: Validates HTTPS requests, processes SAML responses, and controls application access.
- Application: The target resource that users access after successful authentication and authorization.

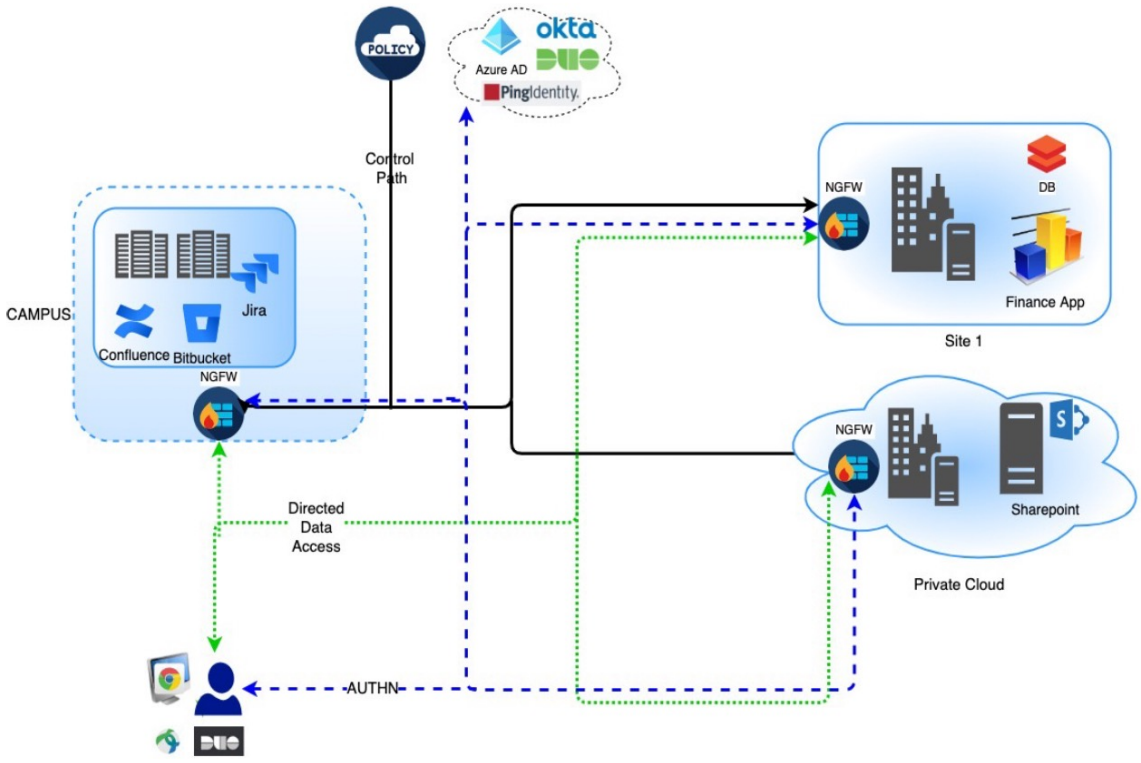
Workflow

Figure 379: Clientless zero trust network access workflow

These stages describe how the clientless zero trust network access workflow processes user requests:

1. User types the application URL in the browser and threat defense validates the HTTPS request.
   - If the HTTPS request is valid, the user is redirected to the mapped port.
   - If the HTTPS request is invalid, the user is sent for authentication per application.
2. The user is redirected to the configured identity provider (IdP).
3. The IdP performs authentication challenges for the user.
   - The user is redirected to the configured primary authentication source.
   - The user is challenged with the configured secondary multi-factor authentication, if any.
4. The IdP sends a SAML response to threat defense. The user ID and other necessary parameters are retrieved from the SAML response through the browser.
5. The user is redirected to the application.
6. The user is allowed access to the application after validation is successful.

How threat defense works with zero trust access



Summary

The key components involved in the Threat Defense Zero Trust Access process are:

- Remote or on-premises user: Initiates HTTPS requests from an endpoint using a browser to connect to applications.
- Threat Defense firewall: Intercepts user requests and redirects them to the identity provider for authentication and authorization.
- Identity Provider (IdP): Handles the authentication and authorization process for users attempting to access protected applications.
- Protected web applications: Applications secured behind the firewall that users can access after successful authentication.

Workflow

Figure 380: Threat defense deployment

These stages describe how Threat Defense works with Zero Trust Access:

1. Using a browser, a remote or on-prem user sends a HTTPS request to connect to an application from an endpoint.
2. The HTTPS request is intercepted by the firewall that protects the application.
3. The firewall redirects the user to application's configured IdP for authentication.

Note In the figure, each firewall protects a set of web applications. The user can directly access the applications behind the firewall after authentication and authorization.

4. After the authentication and authorization process is complete, the firewall allows the user to access the application.

Prerequisites for zero trust application policy

Licensing requirements

Ensure you have the necessary licensing before configuring Zero Trust Application Policy.

- Smart license account with export-controlled features
- (Optional) IPS and Threat licenses—You need these licenses if you use security controls.

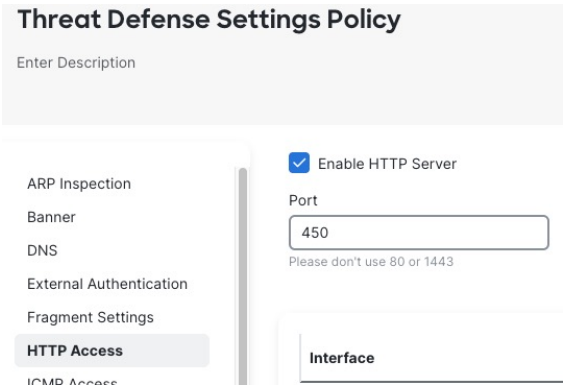
Configuration requirements

Complete the required configurations for Zero Trust Application Policy implementation.

- Create a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of private applications. For more information, see Add certificate enrollment objects, on page 2999.
- Create a security zone through which you can regulate access to private applications. For more information, see Create security zone and interface group objects, on page 1002.

Limitations for Clientless Zero Trust Network Access

Be aware of the following limitations when using Clientless Zero Trust Network Access:



- Supports only TLS-enabled web applications. All traffic must be decrypted.
- Supports only SAML identity providers.
- IPv6 is not supported.

  NAT66, NAT64, and NAT46 scenarios are not supported.
- Supports IPv6; however, you can use only homogeneous network address translations (NAT) scenarios such as NAT66 and NAT44.

  NAT64, and NAT46 scenarios are not supported.
- Clientless zero trust network access is available on Firewall Threat Defense only if Snort 3 is enabled.
- By default, the Firewall Threat Defense device uses port 443 for secure communications. Because this is the same port used by TLS-enabled applications likely to be configured for zero trust network access, you must change the device's HTTP server port.

Go to **Devices** > **Platform Settings**, then edit the Threat Defense Settings policy for the device, click **HTTP Access**, select the **Enable HTTP Server** check box, and enter a port other than 443 in the field. When you're finished, click **Save** in the upper right corner of the page.

The following figure shows an example.

- All hyperlinks in protected web applications must have a relative path and are not supported on individual mode clusters.
- Protected web applications running on a virtual host or behind internal load balancers must use the same external and internal URL.
- Not supported on applications with strict HTTP Host Header validation enabled.
- If the application server hosts multiple applications and serves content based on the Server Name Indication (SNI) header in the TLS Client Hello, the external URL of the zero trust application configuration must match the SNI of that specific application.

Create a zero trust application policy

This task creates a Zero Trust Application Policy that enables secure access to private applications through authentication and authorization controls.

Before you begin

Ensure that you complete all the prerequisites listed in Prerequisites for zero trust application policy, on page 1960.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**.

Step 2 Click **Add Policy**.

Step 3 In the **General** section, enter the policy name in the **Name** field. The description field is optional.

Step 4 Enter a domain name in the **Domain Name** field.

Ensure that the domain name is added to the DNS. The domain name resolves to the Firewall Threat Defense gateway interface from where the application is accessed. The domain name is used to generate the ACS URL for all private applications in an Application Group.

If you select an ACME certificate as the policy's identity certificate in the next step, the domain name must match the common name (CN) of the ACME certificate.

Note
When you change the domain name, the SAML Service Provider (SP) metadata gets updated. You must reconfigure these settings:

- IdP with the new SAML SP metadata
- DNS server with new domain name

When a deployment takes place after the domain name change, all the applications will be removed and readded, interrupting application access.

Step 5 Choose an existing certificate from the **Identity Certificate** drop-down list.

Click the **Add** (+) icon to configure a certificate enrollment object. For more information, see Add certificate enrollment objects, on page 2999.

You can choose an ACME certificate for authenticating the Firewall Threat Defense device as a SAML SP for a Zero Trust Application policy. ACME certificates automate the lifecycle management of SSL and TLS certificates, including their auto-renewal.

Step 6 Choose a security zone from the **Security Zones** drop-down list.

Click the **Add** (+) icon to add a new security zone.

To add security zones, see Create security zone and interface group objects, on page 1002.

Step 7 The **Global Port Pool** section sisplays a default port range. Modify it, if required. Port values range from 1024 to 65535. A unique port from this pool is assigned to each private application.

Note
- This port range should not conflict with the existing NAT range.
- Ensure that any intermediary or third-party firewall devices in your network are configured to allow traffic across the entire range defined in the **Global Port Pool**. Blocking these ports prevents application access after SAML authentication and authorization.

Step 8 (Optional) In the **Security Controls** section, you can add an Intrusion or Malware and File policy:

- **Intrusion Policy**—Choose a default policy from the drop-down list or click the **Add** (+) icon to create a new custom intrusion policy. For more information, see Creating a Custom Snort 3 Intrusion Policy topic in the latest version of the Cisco Secure Firewall Management Center Snort 3 Configuration Guide.
- **Variable Set**—Choose a default variable set from the drop-down list or click the **Add** (+) icon to create a new variable set. For more information, see Create a variable set, on page 3053.

  Note
  To use variable sets, you must have the Secure Firewall Threat Defense IPS license for your managed devices.

- **Malware and File Policy**—Choose an existing policy from the drop-down list. Click the **Add** (+) icon to create a new malware and file policy. For more information, see Manage file policies, on page 2601.

Step 9 Click **Save** to save the policy.

What to do next

1. Create an Application Group. See Create an application group, on page 1963.
2. Create an Application. See Create an application, on page 1965.
3. Associate a Zero Trust Application Policy with a device. See Set targeted devices for zero trust access policy, on page 1968
4. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an application group

Create an application group to enable SAML-based authentication and manage zero trust network access applications with centralized security controls.

Application groups allow you to organize and manage multiple applications under a single SAML configuration, providing centralized authentication and security policy enforcement for zero trust network access.

Before you begin

Create a zero trust application policy, on page 1961

Procedure

Step 1 Click **Add Application Group**.

Step 2 In the **Application Group** section, type the name in the **Name** field and click **Next**.

Step 3 In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the values of the **Entity ID** and **Assertion Consumer Service (ACS) URL** fields or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

Step 4 In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

- **XML File Upload**—Choose a file or drag and drop the XML file.

  The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

- **Manual Configuration**—Perform these steps:
  - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
  - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
  - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add certificate enrollment, on page 1964.

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

Step 5 In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**.

The re-authentication interval allows you to provide a value that determines when a user must authenticate again.

Step 6 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy. You can override these settings. Click **Next**.

Step 7 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 8 Click **Save**.

The Application Group is created and is displayed on the Zero Trust Application page.

What to do next

1. Create an application, on page 1965.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Add certificate enrollment

This task allows you to add certificate enrollment by configuring the certificate name and installing the IdP certificate in PEM format.

Certificate enrollment is required to establish secure authentication. You need to provide certificate information in the correct format to ensure proper system configuration.

Procedure

Step 1 Enter the **Name**.

Step 2 Paste the certificate information in the **IdP Certificate** field in PEM format.

Note
If the certificate is dependent on a root or intermediate certificate, you must install the dependant certificates. See Certificates, on page 3079.

Step 3 Click **Save**.

Create an application

This task creates a Grouped or Ungrouped Application to establish secure access controls for private applications within your Zero Trust Access policy framework.

Before you begin

1. Create a zero trust application policy, on page 1961.
2. Create an application group, on page 1963 (required only for Grouped Applications).

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Add Application**.

Step 4 In the **Application Settings** section, complete the following fields.

- **Application Name**—Enter the application name.
- **External URL**—Enter the URL that is used by the user to access the application.
- **Application URL**—By default, the external URL is used as the Application URL. Uncheck the **Use External URL as Application URL** check box to specify a different URL.

  If Threat Defense uses an internal DNS, the Application URL must match an entry within that DNS to ensure it resolves to the application. In addition, if you enter a fully qualified domain name (FQDN) that could have either an IPv4 or IPv6 address, the FQDN must resolve to both IPv4 and IPv6. Threat Defense does not translate between these types of addresses.

- **Application Certificate**—Choose the certificate for the private application. Click the **Add** (+) icon to configure an internal certificate object. For more information, see Add internal certificate objects, on page 2997.
- **Source Network Address Translation**—Source Network Address Translation (source NAT) translates the source IP address in a packet to an address from a specified range.

  Enable **Source Network Address Translation** to specify an IP address range. The source IP address of an incoming request is translated to an IP address from the specified range. Source NAT works for both IPv4 and IPv6 addresses.

  - **IPv4**—Choose the source network for NAT from the list. Click **Add** (+) to create a network object. For more information, see Networks, on page 2982.
  - **IPv6**—Choose the source network for NAT from the list. Click **Add** (+) to create a network object. For more information, see Networks, on page 2982.

  Source NAT translates the source IP address of an incoming request to a routable IP address specified in the network object or the object group.

  Note

Only object or object groups of type Host or Range are supported.

- **Application Group**—Choose the Application Group from the drop-down list. See Create an application group, on page 1963.

  Note
  This field is not applicable for an ungrouped application.

Step 5 Click **Next**.

Step 6 Depending on the type of application:

- For a Grouped Application, the **SAML Service Provider (SP) Metadata**, **SAML Identity Provider (IdP) Metadata**, and **Re-authentication Interval** are inherited from the Application Group and do not need to be configured by the user.
- For an Ungrouped Application, perform these steps:

  a. In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the **Entity ID**, **Assertion Consumer Service (ACS) URL** of the IdP, or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

  b. In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

  - **XML File Upload**—Choose a file or drag and drop the XML file.

    The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

  - **Manual Configuration**—Perform these steps:

    - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
    - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.
    - **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

      Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see Add certificate enrollment, on page 1964.

  - **Configure Later**—If you do not have the IdP metadata, you can configure it later.

  Click **Next**.

  c. In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**. The reauthentication interval allows you to provide a value that determines when a user must authenticate again.

Step 7 In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy or application group. You can override these settings. Click **Next**.

Step 8 Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

Step 9 Click **Save**.

The application is listed on the Zero Trust Application page and enabled by default.

What to do next

1. Set targeted devices for zero trust access policy, on page 1968.
2. Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Create an ungrouped application

This task creates a standalone application for zero trust application access.

Before you begin

Create a zero trust application policy, on page 1961

Procedure

Step 1 Choose **Policies** > **Access Control** > **Zero Trust Application**

Step 2 Select the policy and click **Add Application**.

Step 3 In the **Application Settings** section, complete the following fields.

- **Application Name**—Enter the application name.
- **Application Group**—This field is not applicable for a standalone application.
- **External URL**—Enter the URL that is used by the user to access the application.
- **Internal URL (FQDN or Network IP)**—Enter the URL where the application is hosted on the internal server.
- **Application Certificate**—Enter the certificate for the private application.

Click **Next**.

Step 4 In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the Entity ID or ACS URL of the IdP or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

Step 5 In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using either one of the methods:

- **XML File Upload**—Select a file or drag and drop the XML file.
- **Manual Configuration**—Complete the following fields:
  - **Entitv ID**—The URL that is defined in the SAML IdP to identify a service provider uniquely.
  - **Single Sign-On URL**—The URL for signing into the SAML identity provider server.
  - **Certificate**—Certificate of the IdP enrolled into the threat defense to verify the messages signed by the IdP.

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

Step 6 In the **Re-authentication Interval** section, enter the value in the **Interval** field and click **Next**.

Step 7 In the **Interface Access and Security Controls** section, the interface objects and threat settings are inherited from the parent policy. You can override these settings.

Step 8 Review the settings and click **Finish**.

Step 9 Click **Save**.

The Application is displayed on the policy page under **Ungrouped Applications**.

What to do next

Set targeted devices for zero trust access policy, on page 1968

Set targeted devices for zero trust access policy

Set the specific devices where a Zero Trust Application policy will be deployed to control application access and enforce security policies.

Each Zero Trust Application policy can target multiple devices; each device can have one deployed policy at a time.

Before you begin

1. Create a zero trust application policy, on page 1961.
2. Create an application group, on page 1963.
3. Create an application, on page 1965.

Follow these steps to set targeted devices for Zero Trust Access Policy:

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the policy.

Step 3 Click **Targeted Devices**.

Step 4 Choose the devices where you want to deploy the policy using any one of the methods:

- Choose a device in the **Available Devices** list and click >> or the **Add** (⊕) icon.
- To remove a device from the **Selected Devices** list, choose a device and click << or the **Delete** (🗑) icon.

Step 5 Click **Apply** to save policy assignments.

Step 6 Click **Save** to save the policy.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Edit a zero trust application policy

Edit the settings of a Zero Trust Application Policy to modify policy configurations, application groups, or individual applications according to your security requirements.

Follow these steps to edit the settings of a Zero Trust Application Policy.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Click **Edit** (✎) next to the Zero Trust Application Policy you want to edit.

Step 3 Edit your Zero Trust Application Policy.

You can change these settings or perform these actions:

- Name and Description—Click **Edit** (✎) next to the policy name, make your changes, and click **Apply**.
- To modify the policy settings:
  - Click **Settings**
  - Modify the settings as required.

    Important
    Editing the domain name for the SAML ACS URL interrupts application access.

  - Click **Save**.
- To modify the Application Group settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application Group you want to edit.
  - In each section, click **Edit** to modify the settings, as required

    Important
    Editing the Application Group name interrupts application access.

  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.

- To modify the Application settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application you want to edit.
  - In each section, click **Edit** to modify the settings, as required.

    Important
    Editing the Application name interrupts application access.

  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.
- To enable, disable, or delete multiple Applications, choose the Applications, click the required bulk action, and click **Save**.

  Note
  These actions are also available in the right-click menu.

  - To enable all Applications, click **Bulk Actions** > **Enable**.
  - To disable all Applications, click **Bulk Actions** > **Disable**.
  - To delete all Applications, click **Bulk Actions** > **Delete**.
- Click **Return to Zero Trust Application** to return to the policy page.

The Zero Trust Application Policy settings are updated with your changes.

What to do next

Deploy configuration changes. See Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Manage zero trust application policies

This task allows you to manage zero trust application policies to control access and security for applications in your network.

Procedure

Step 1 Choose **Policies** > **Zero Trust Application**

Step 2 Choose the appropriate action for the zero trust application policies.

- Create—Click **New Policy**. See Create a zero trust application policy, on page 1961

- Edit—Click **Edit** ( ). See Edit a zero trust application policy, on page 1969
- Report—Click **Report** ( ).
- Delete—Click **Delete** ( ).

Step 3 Click **Save**.

What to do next

Ensure that there are no warnings before you deploy the configuration to threat defense. To deploy configuration changes, see Deploy Configuration Changes in the Cisco Secure Firewall Management Center Administration Guide.

Monitor zero trust sessions

This task enables administrators to effectively monitor Zero Trust Application Policy sessions through multiple methods including connection events, dashboard visualization, CLI commands, and diagnostic troubleshooting tools.

After a Zero Trust Application Policy is deployed, additional monitoring capabilities become available to track session activity, user behavior, and system performance. To monitor the zero trust sessions, do these steps.

Procedure

Step 1 Add Zero Trust fields to the connection events table view.

a. Choose **Analysis** > **Connections** > **Events**.

b. Click the **Table View of Connection Events** tab.

c. In the table view of events, multiple fields are hidden by default. To change the fields that are displayed, click the **x** icon in any column name to display a field selector.

d. Select these fields:

- **Authentication Source**
- **Zero Trust Application**
- **Zero Trust Application Group**
- **Zero Trust Application Policy**
- **Zero Trust Application Host**
- **Zero Trust Origin User**
- **Zero Trust Proxy**

- **Zero Trust Rule**
- **Zero Trust Status**
- **Zero Trust Tunnel ID**

e. Click **Apply**.

See Connection and Security-Related Connection Events in the Secure Firewall Management Center Administration Guide for more information on the connection events.

Step 2 Access the Zero Trust dashboard to monitor real-time session data.

The Zero Trust dashboard provides a summary of the top zero trust applications and zero trust users that are managed by the management center.

Choose **Overview** > **Dashboards heading** > **Dashboard**, and click the **Zero Trust** tab to access the dashboard.

The dashboard has the following widgets:

- Top Zero Trust Applications
- Top Zero Trust Users

Step 3 Use CLI commands to monitor and troubleshoot Zero Trust configurations.

Log in to the device CLI and use the following commands:

CLI Command	Description
show running-config zero-trust	View the running configuration for a zero trust configuration.
show running-config zero-trust-hybrid	View the running configuration for a universal zero trust configuration.
show zero-trust	Display the run-time zero trust statistics and session information.
show cluster zero-trust	Display the summary of zero trust statistics across nodes in a cluster.
clear zero-trust	Clear zero trust sessions and statistics.
show counters protocol zero_trust	View the counters that are hit for zero trust flow.
