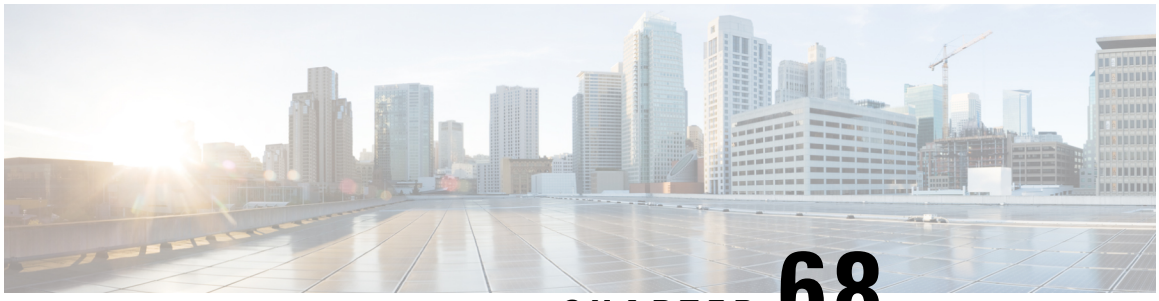
Step 4 Run diagnostic tools to troubleshoot Zero Trust configuration issues.

The diagnostics tool facilitates the troubleshooting process by detecting possible issues with zero trust configurations. The diagnostics can be classified into two types:

- **Application-specific diagnostics** are used to detect issues such as:
  - DNS-related issues
  - Misconfigurations such as socket not open, and issues with classification and NAT rules.
  - Issues with deployment of zero trust policy or SSL rules

    - Issues with source NAT issues and exhaustion of PAT pool



- **General diagnostics** are used to detect issues such as:
    - Strong cipher license not enabled
    - Invalid application certificate
    - SAML-related issues
    - Home agent and cluster bulk sync issues

a. Click Diagnostics ( ) next to the zero trust application that you want to troubleshoot. The **Diagnostics** dialog box appears.

b. Choose the device from the **Select Device** drop-down list and click **Run**. A report is generated in the **Reports** tab after the diagnostic process is complete.

c. To view, copy, or download the logs, click the **Logs** tab.

You have successfully configured comprehensive monitoring for Zero Trust sessions. The connection events table now displays Zero Trust-specific fields, the dashboard provides real-time visualization of top applications and users, CLI commands are available for detailed system monitoring, and diagnostic tools can identify and troubleshoot configuration issues.

CHAPTER 68

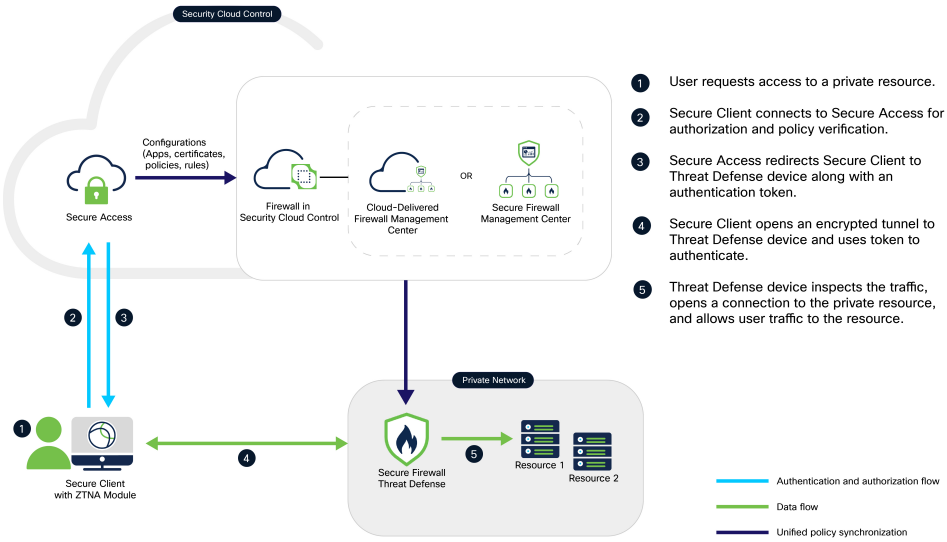
Universal Zero Trust Network Access

Universal Zero Trust Network Access (ZTNA) secures internal resources by validating user identity and device posture instead of granting full network access. The solution integrates Security Cloud Control, Secure Access, and Firewall Threat Defense devices to enforce granular, context-aware security policies. Administrators configure these components within the Security Cloud Control platform to protect applications and prevent lateral movement across hybrid environments.

- Universal Zero Trust Network Access, on page 1975
- Threat Defense with Universal ZTNA, on page 1976
- Prerequisites for Universal Zero Trust Network Access, on page 1977
- Restrictions for Universal Zero Trust Network Access, on page 1978
- Enable Cloud-Delivered Firewall Management Center in security cloud control, on page 1979
- Configure Security Devices, on page 1979
- Configure network connections, on page 1985
- Related documentation, on page 1993

Universal Zero Trust Network Access

Universal Zero Trust Network Access (universal ZTNA) is a client-based ZTNA solution that enables users to securely access internal resources and applications regardless of their location, whether remote or on-premises. It enables administrators to specifically allow access to internal network resources according to user identity including user trust and posture, without granting access to the entire network as with Remote Access VPN.



Because universal ZTNA does not assume that access granted to one application implicitly authorizes access to other applications, the network attack surface is reduced.

Universal ZTNA ensures least-privileged, per-application, per-user access with strong authentication, posture validation, and comprehensive traffic inspection. It secures applications effectively across hybrid environments.

Components of Universal ZTNA

A new configuration of universal ZTNA consists of Security Cloud Control Firewall Management (formerly called Cisco Defense Orchestrator), and Secure Access, both provisioned on the Security Cloud Control platform. Security Cloud Control Firewall Management manages the Firewall Threat Defense devices through the Secure Firewall Management Center.

Figure 381: Components of universal ZTNA

- **Security Cloud Control Firewall Management**: Manages the configuration and deployment of universal ZTNA policies to the Firewall Threat Defense devices. The Threat Defense devices protect on-premises resources by enforcing universal ZTNA policies. Threat Defense inspects traffic and enforces intrusion prevention system (IPS), file, and malware policies on the traffic.
- **Secure Access**: Secure Access defines the access policies, posture, and security profiles for the user. It enforces the policies for user traffic through the cloud.
- **Security Cloud Control platform**: Security Cloud Control provides a unified secure management plane for both Secure Access and Firewall, simplifying the administration of universal ZTNA policies across them.
- **Secure Client**: The Secure Client is installed on the end user's device. It acts as the enforcement point that intercepts connection requests to protected internal resources, enabling secure, identity-based access.

The following sections describe how to enable universal ZTNA on a Threat Defense device. For the complete configuration of universal ZTNA, refer to the *Universal Zero Trust Network Access Configuration Guide*.

Threat Defense with Universal ZTNA

A universal ZTNA-enabled Firewall Threat Defense device is a critical enforcement point that protects private resources by integrating zero trust principles with firewall capabilities. Here's how it operates to secure private resources:

- Enforces access and validates policy: A Threat Defense device intercepts all access requests to private resources. It enforces granular, context-aware access policies that verify user identity, device posture, and contextual factors before granting access. Only requests that meet the least-privilege criteria are allowed, blocking the unauthorized attempts to access resources.
- Establishes a secure tunnel to the resource: After validating the access policy, the Threat Defense device establishes a secure, encrypted tunnel between the user's device and the private resource. This tunnel ensures that private resources are isolated from direct network exposure.

- Inspects traffic: Threat Defense device continuously inspects the traffic and blocks threats before they reach the resources. The device applies the intrusion prevention system, file, and malware detection capabilities to detect and block the threats.
- Microsegments and prevents lateral movement: The device enforces microsegmentation by restricting traffic flows to only the authorized resources. This containment prevents lateral movement within the network, limiting the impact of any potential breach.

Prerequisites for Universal Zero Trust Network Access

This topic discusses requirements and guidelines for Universal Zero Trust Network Access (universal ZTNA).

Licensing requirements

- Secure Firewall Management Center requires a smart license account with export-controlled features. It does not function in evaluation mode for universal ZTNA.

  Secure Firewall Threat Defense devices require an IPS license if Intrusion policy is configured. If Malware policies are configured, the devices require IPS and Malware Defense licenses. For more information, refer to the "Licenses" section in the *Cisco Secure Firewall Management Center Administration Guide*.
- Secure Access requires a subscription of Cisco Secure Private Access Essentials or Advantage.

Device requirements

- All Cloud-Delivered Firewall Management Center and Secure Firewall Threat Defense devices must be running Version 7.7.10 or later.
- All Secure Firewall Threat Defense devices must be configured for routed mode; transparent mode is not supported.
- In Security Cloud Control, when you are configuring universal zero trust access for a device, ensure that the Enrollment Type for the device identity certificate is an object that is created using the PKCS12 file format. No other certificate type is supported. If necessary, you can also create a new certificate object from Security Cloud Control, which supports the PKCS12 format. See Configure Security Devices.
- Configure the Domain Name System (DNS) to resolve Fully Qualified Domain Name (FQDN) of private resources. Use the Platform Settings menu on the Secure Firewall to configure the DNS. See Interface and Device Settings.
- High Availability (HA) devices *are* supported; they are displayed as one entity.
- Secure Client (with ZTNA module enabled) Version 5.1.10 and later is supported.

  The client must be running in a platform that supports Trusted Platform Module (TPM), such as Windows 11.

Guidelines on certificate types

- **User Identity Certificate**: Secure Client, which is zero trust access enabled, presents the user identity certificate during the Mutual Transport Layer Security (mTLS) session with Secure Access and Firewall Threat Defense to request access to private resources.

- **Firewall Threat Defense Device Certificate**: Threat Defense devices that are universal ZTNA-enabled use device certificates to establish secure mTLS connections with the Secure Client and Secure Access. Ensure that the device identity certificate is of type PKCS12.

  If you have already enrolled a manual certificate for the device, first export it to the PKCS12 format using the **Devices** > **Certificates** > **Export Certificate** menu on Firewall Management Center. Use the exported PKCS12 file to create a new PKCS12 certificate enrollment object.

- **Decryption Certificate**: (Optional) To decrypt the traffic that is sent to private resources, enable **Decryption** for the resources in Secure Access and provide the server certificate and key. We recommend that you use a certificate that is signed by a publicly recognized certificate authority (CA).

Supported devices

Both on-premises Firewall Management Center and Cloud-Delivered Firewall Management Center can be configured to manage the devices.

Only devices that have 16 cores or more are supported. Such models of Secure Firewall Threat Defense

- 1150
- 3105, 3110, 3120, 3130, 3140
- 4115, 4125, 4145, 4112
- 4215, 4225, 4245
- FTDv

Note You can configure universal ZTNA on a 16 core FTDv. No other deployment configuration of FTDv supports universal ZTNA.

Restrictions for Universal Zero Trust Network Access

Be aware that Universal ZTNA has several operational limitations that may affect deployment and functionality.

- Universal ZTNA does not support IPv6.
- Universal ZTNA-enabled devices do not enforce policies for traffic over a site-to-site tunnel.
- Universal ZTNA does not support clustered devices.
- Universal ZTNA does not support devices in multi-instance mode.
- Universal ZTNA sessions do not support jumbo frames.
- Universal ZTNA supports only global VRF.
- Universal ZTNA does not support protocols such as FTP or TFP, where the data or secondary connection originates from a server.

For example, an active FTP connection uses a persistent control connection for commands and creates temporary data connections for file transfers. Universal ZTNA does not support such data connections that originate from the server.

Enable Cloud-Delivered Firewall Management Center in security cloud control

Enable the Cloud-Delivered Firewall Management Center to configure universal ZTNA and manage associated Secure Firewall Threat Defense devices.

To configure universal ZTNA, first enable the Cloud-Delivered Firewall Management Center in Cisco Security Cloud Control. After you enable it, configure the associated Secure Firewall Threat Defense devices. The devices can then use the networks, private resources, and policies needed to configure and manage universal ZTNA.

Procedure

Step 1 From the Security Cloud Control menu, click **Administration** > **Integrations** > **Firewall Management Center**.

Step 2 Click **Enable Cloud-Delivered FMC**.

Security Cloud Control starts provisioning the instance. This process takes a few minutes to complete. You can track the progress in the **Status** column of **Cloud-Delivered FMC**.

After the provisioning is complete, the status changes to **Active**.

Onboard the Firewall Threat Defense devices to the Cloud-Delivered Firewall Management Center. To learn how to onboard a Threat Defense device, see Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center

The Cloud-Delivered Firewall Management Center is enabled and active in Security Cloud Control, ready for Secure Firewall Threat Defense device configuration.

Configure Security Devices

All Firewall Threat Defense devices associated with the Cloud-Delivered Firewall Management Center that you onboarded to Security Cloud Control are *security devices* to which you can:

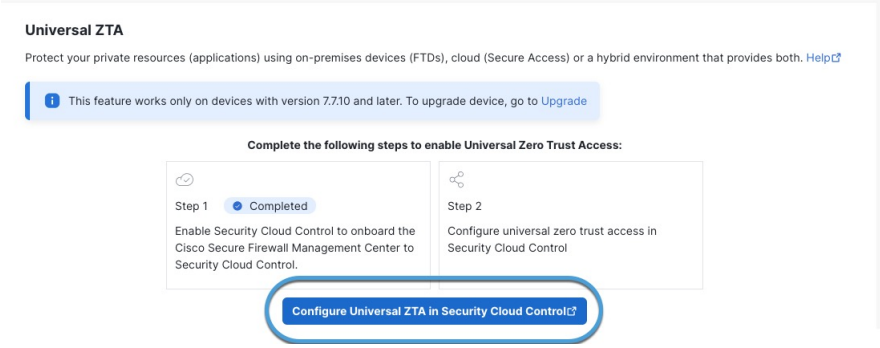
- Associate private resources, which are internal applications you want to protect with identity-based access control, IPS, malware, and other protections.
- Deploy Secure Access access rules. Security devices are responsible for enforcing access rules for on-premises users, remote users, or both.

Perform these steps to enable **universal zero trust network access settings** on the Threat Defense devices. These steps include configuring the device FQDN, inside interface, outside interface, and PKCS12 certificate to enable universal ZTNA on the devices.

Before you begin

You must know the name of each device's internal and external network interfaces:

- The internal interface (also referred to as the *DMZ* interface) is used to apply access rules to on-premises users.
- The external interface is used to apply access rules to remote users.



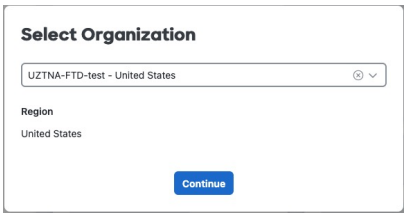
You can choose internal, external, or both types of interfaces for each security device.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, click **Policies** > **Zero Trust Application**.

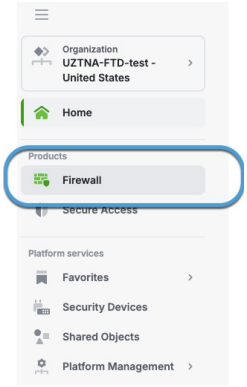
Step 2 Click **Configure Universal ZTA in Security Cloud Control**.

This figure shows an example.



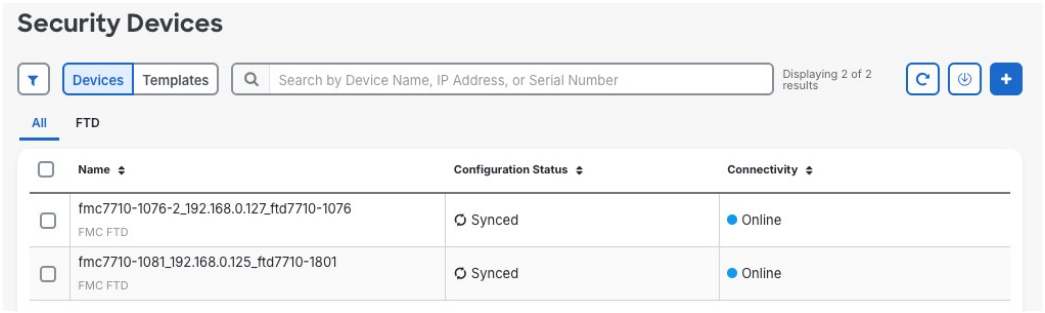
Step 3 When prompted, log in to Security Cloud Control.

Step 4 When prompted, select your organization from the drop-down list and click **Continue**.



Select an organization that has both Secure Access and Secure Firewall micro applications configured.

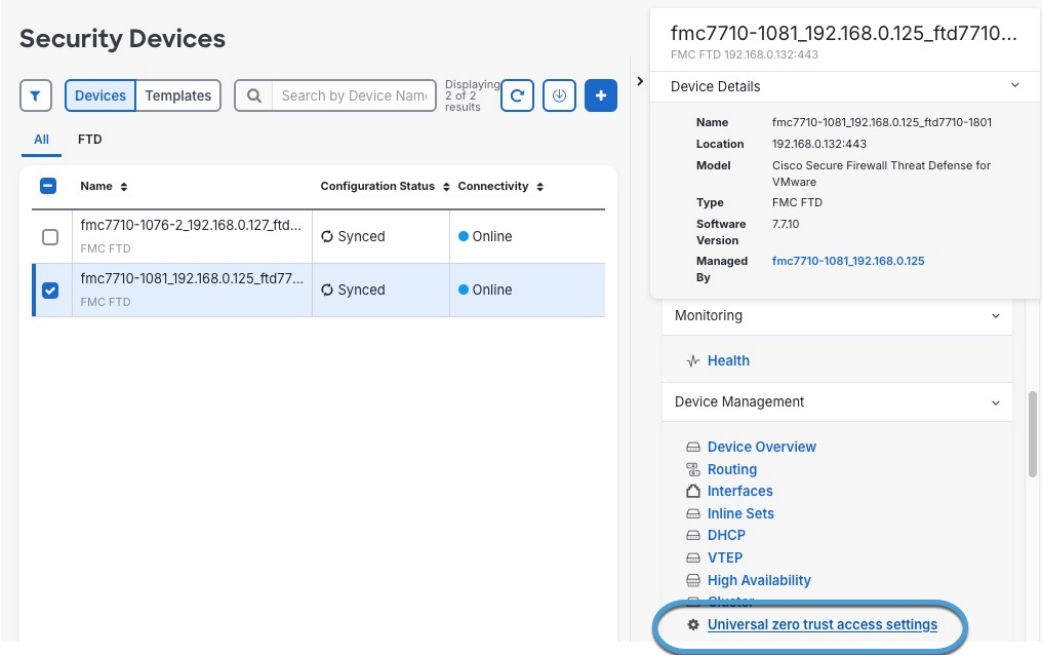
This figure shows an example.



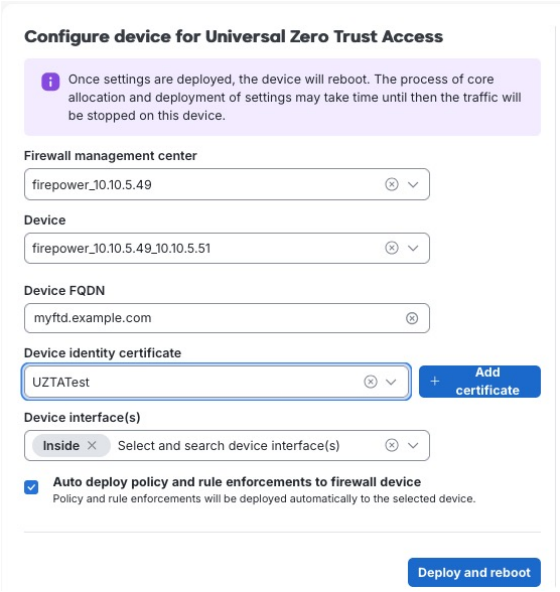
Step 5 In Security Cloud Control, in the Products section, click **Firewall**.

This figure shows an example.

Step 6 In the Manage section, click **Security Devices**.



The **Security Devices** page displays the available security devices.



Step 7 Select the check box next to a device to add to the universal zero trust network access configuration.

Step 8 In the right pane, click **Device Management** > **Universal zero trust access settings**.

This figure shows an example.

Step 9 Enter or edit the following information on the **Configure device for Universal Zero Trust Access** page.

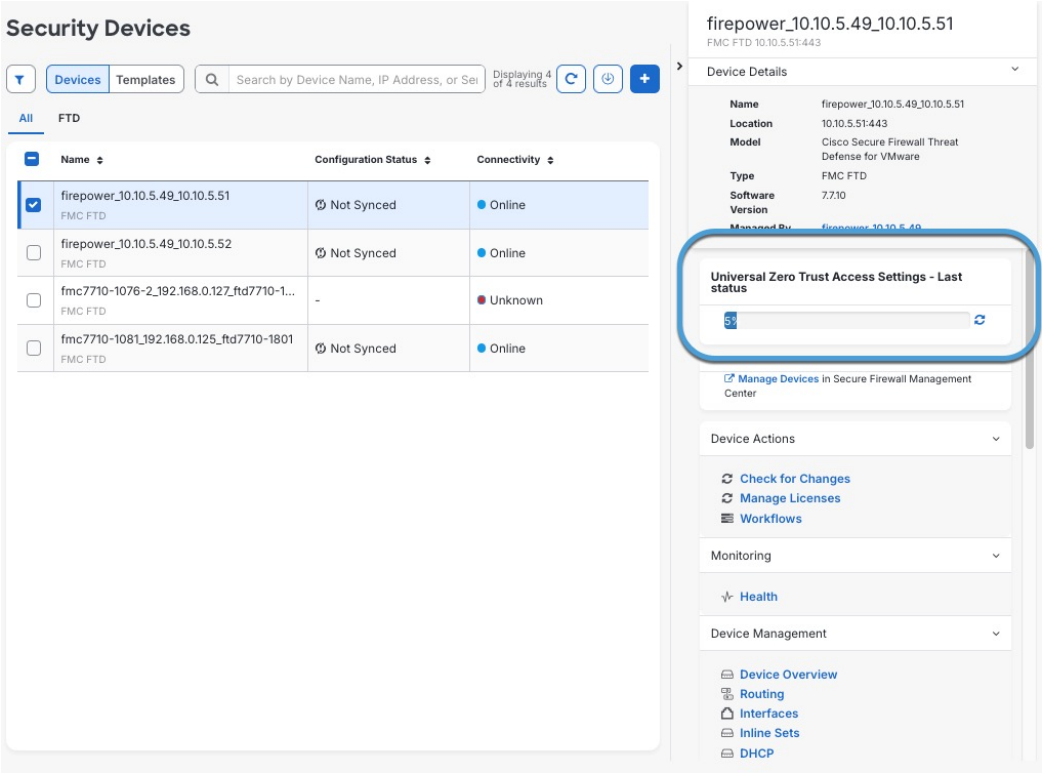
This table describes the configurations to enable universal ZTNA on the device.

Item	Description
Firewall management center	From the drop-down list, click the name of a Cloud-Delivered Firewall Management Center to use for policy deployment, monitoring, and other tasks.
Device	From the drop-down list, click the name of a device to use for rule deployment and enforcement.

Item	Description
Device FQDN	Enter the security device's fully qualified domain name (FQDN). The FQDN is also referred to as the TLS/SSL certificate's Common Name. Secure Access redirects the clients to the resource that is represented by this FQDN. Ensure that the device FQDN *exactly matches* the Common Name (CN) of the device identity certificate and must also match a Subject Alternative Name (SAN) in the certificate.
Device identity certificate	The **Device identity certificate** must have a Common Name that: • *Exactly matches* the value you enter in the **Device FQDN** field. • Matches a Subject Alternative Name (SAN) in the certificate. From the drop-down list, click the name of an existing identity certificate from the list. Click **Add certificate** and add an identity certificate in **.p12** format (also referred to as PKCS#12; see this article on ssl.com). **Note** Universal ZTNA supports only the PKCS#12 format of certificate enrollment. In the provided fields, enter a **Name** to identify the certificate. Then copy/paste, drag/drop, or upload the certificate and private key. If the certificate is encrypted, enter its password in the provided field. You can optionally use a wildcard certificate as discussed in What is a Wildcard Certificate? on ssl.com.
Device Interface(s)	From the drop-down list, select the check box next to any of the following types of interfaces. • Internal network interface (or DMZ): deploys access rules for on-premises users only. • External network interface: deploys access rules for remote users only. • Both types of interfaces: deploys access rules for either on-premises or remote users.
Auto deploy policy and rule enforcements to firewall device	Select the check box to automatically deploy access rules to the device after they are updated on Secure Access. On the device, the Auto deploy feature selectively deploys only the Universal ZTNA access policy. It does not impact other changes or configurations on the Firewall Management Center. **Note** If there are other interdependent policies on the device (which are interlinked with the Universal ZTNA access policy), the Firewall configuration status displays an error message. The deployment then stops. In such cases, you should manually deploy the Universal ZTNA access policy from the Firewall Management Center.

Step 10 Click **Deploy and Reboot**.

The device reboots to reallocate the system resources for universal ZTNA components.



Note
The device takes several minutes to reboot, during which time all traffic handled by the device is disrupted.

If you deploy a High Availability (HA) pair of devices, both devices reboot simultaneously.

This behavior is applicable to only 10.0 version.

Step 11 On the **Security Devices** page, select the check box next to the device to which you just deployed the Universal ZTNA configuration.

The right pane displays the deployment status, as shown in the figure.

For additional information, click **Device Actions** > **Workflows** in the right pane.

After the deployment completes, you can view the completion status in the **Universal Zero trust Access Settings - Last status** tab for the device.

Universal ZTNA-enabled Firewall Threat Defense device is connected to Secure Access.

What to do next:

Check the availability of the Threat Defense device under Secure Access by clicking **Security Cloud Control** > **Secure Access** > **Connect** > **Network Connections** > **FTD**.

Configure network connections

Configure private resources and the devices that protect these resources to complete the Universal ZTNA configuration.

The final step in configuring Universal ZTNA is to configure private resources and the devices that are responsible for protecting the resources.

Before you begin

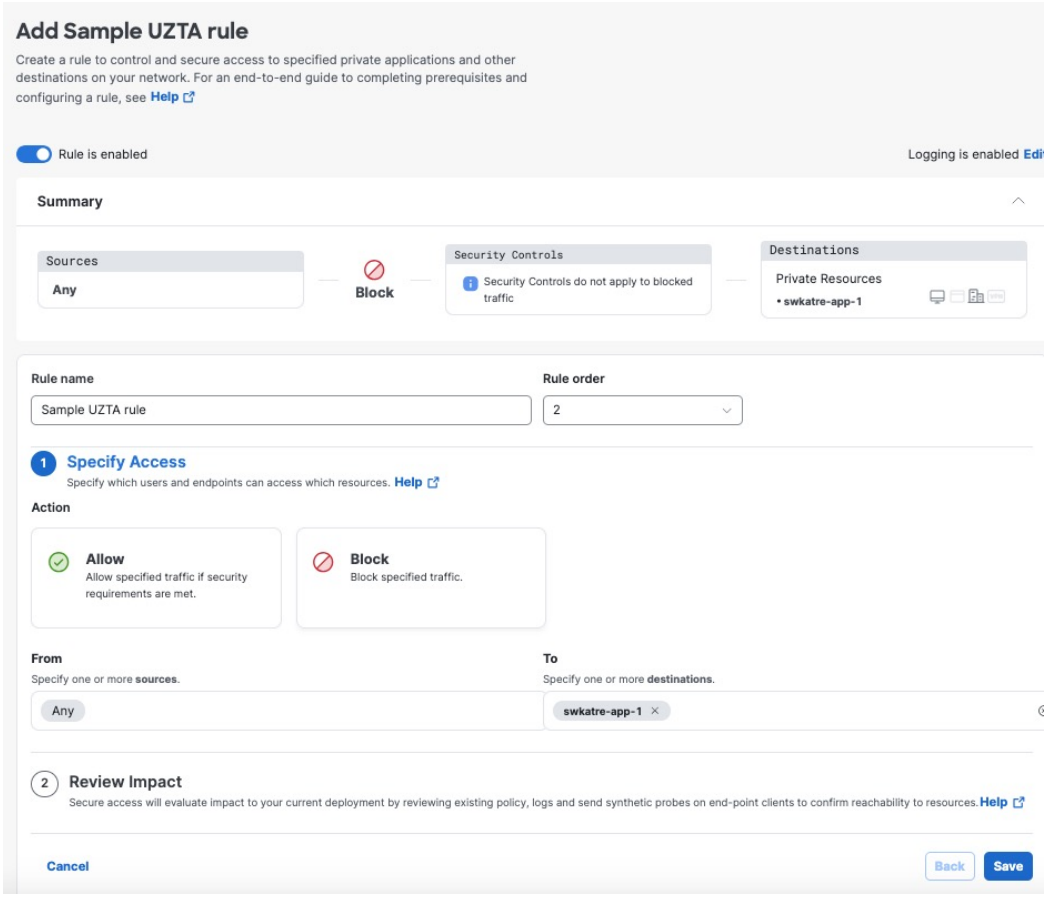
Complete the tasks discussed in Configure Security Devices, on page 1979.

Procedure

Step 1 In Security Cloud Control, click **Products** > **Secure Access**.

The Secure Access product menu appears in the left navigation bar.

Step 2 Click **Resources** > **Destinations** > **Private Resources**.

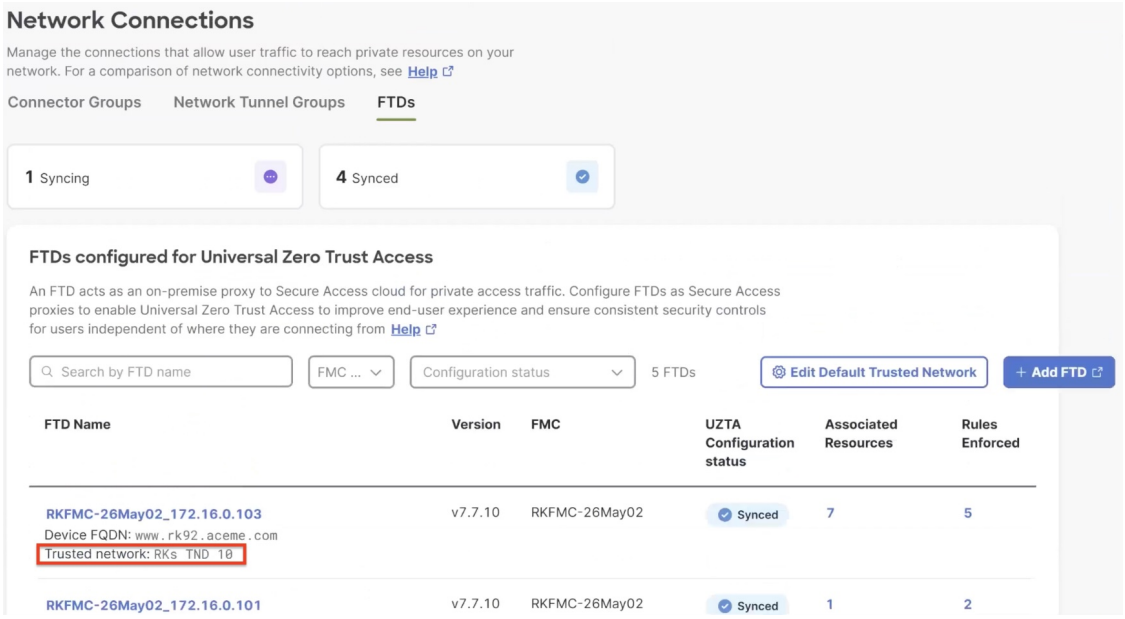


Add private resources. For guidance, refer to Manage Private Resources.

Note
When you add a private resource, select the zero-trust connections method of endpoint connections. This selection enables client-based zero trust access for the private resource.

Step 3 Click **Secure** > **Access Policy**.

Add or edit access rules. For more information, refer to Manage the Access Policy.



This sample access rule blocks access to a destination named **swatw-app-1**:

Step 4 Click **Connect** > **Network Connections**.

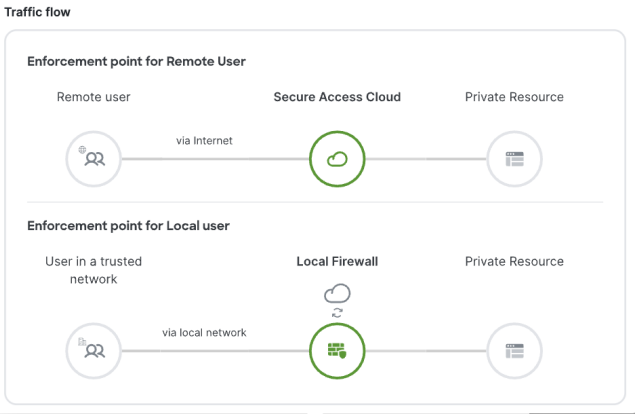
Step 5 Click the **FTDs** tab.

The page displays the available Secure Firewall Threat Defense devices configured for universal zero trust network access.

Before proceeding to the next step, ensure that the device is associated with a trusted network. This association enforces policies on traffic originating from the trusted network.

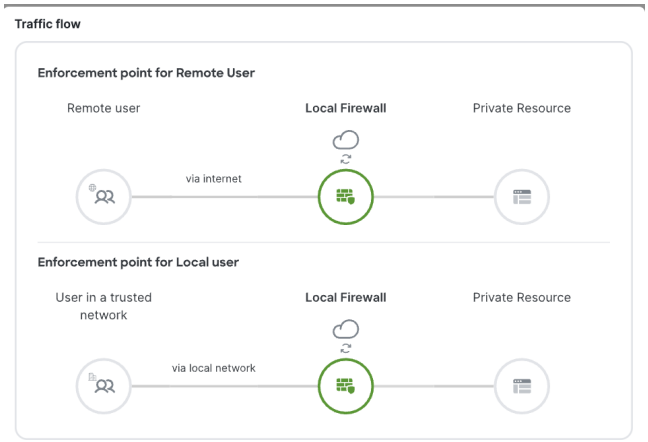
After onboarding a Threat Defense device, it is automatically associated with a default trusted network if one exists. If not, you must create a trusted network and associate it with the Threat Defense device.

Step 6 Click the name of a Threat Defense device to configure.



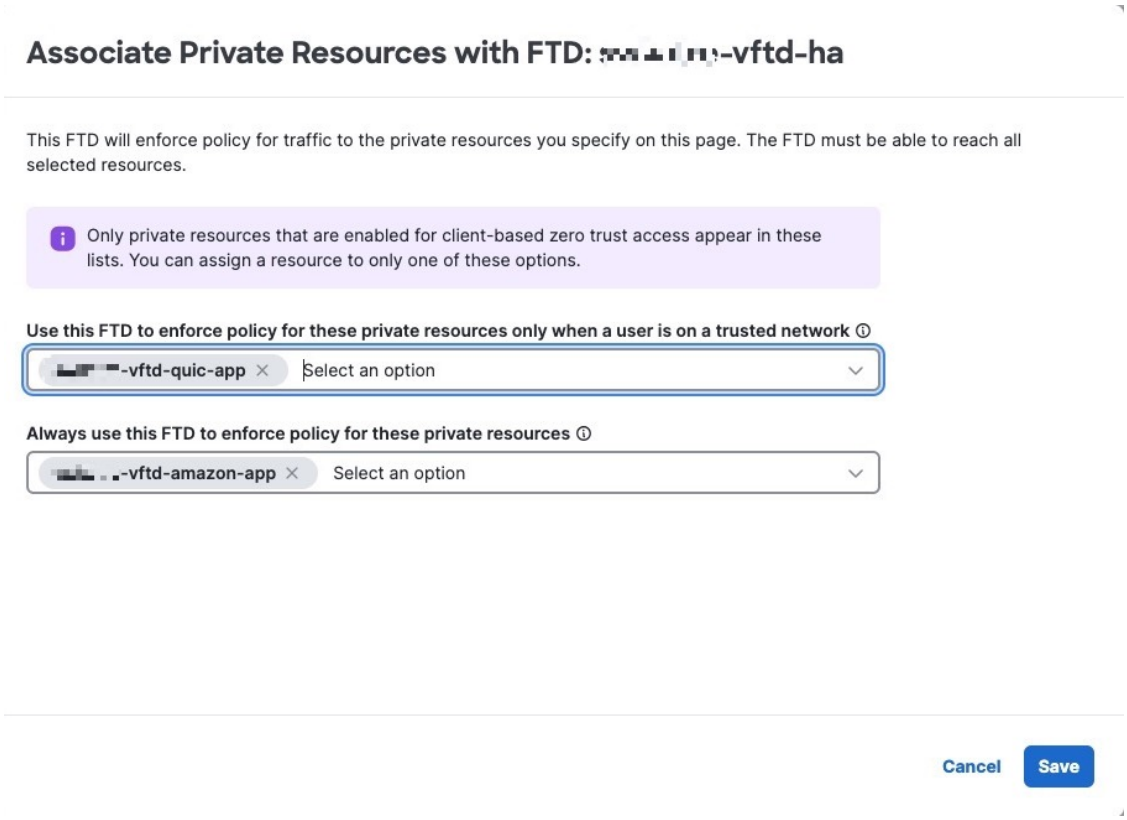
Step 7 In the right pane, click **Associate Resources**.

Note



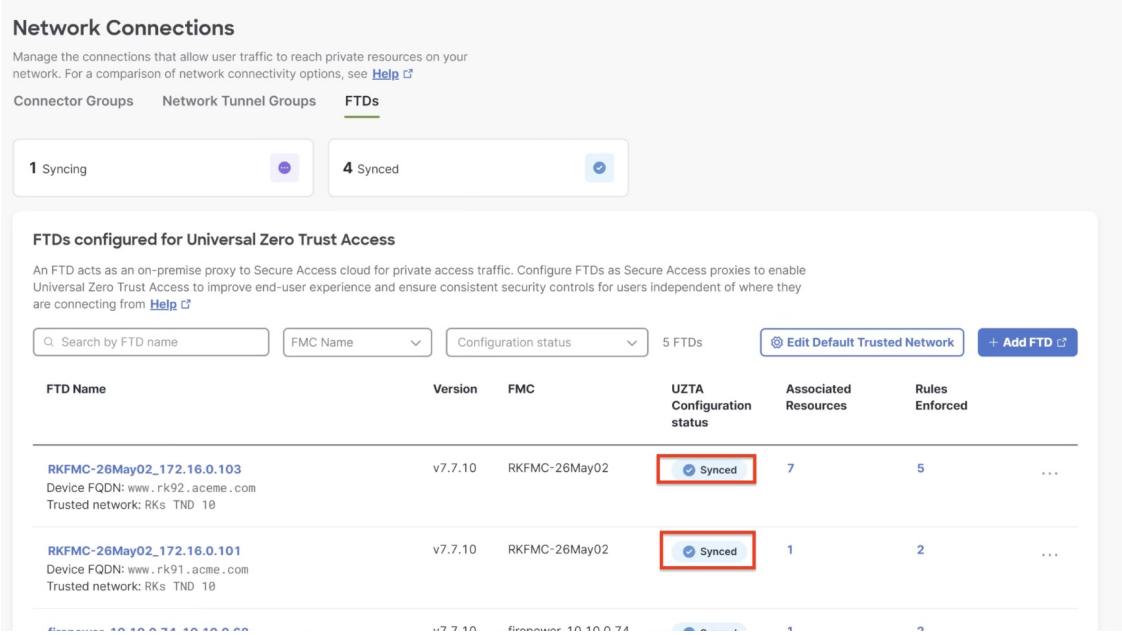
- Only those resources that are enabled for zero trust access can be associated with a Threat Defense device.
- A Threat Defense device must have connectivity to the associated private resources.
- Resources associated with a Threat Defense device are shared with other devices that have the same FQDN.

Step 8 In the **Associate Private Resources** dialog box, make the following selections to specify the access policy enforcement and traffic flow for a user:



- **Use Threat Defense device to enforce policy only for on-premises users**: From the **Use this FTD to enforce policy** drop-down list, select the private resources that a user should access only from an on-premises location.

- **Use Threat Defense device to enforce policy for both on-premises and remote users**: From the **Always use this FTD to enforce policy** drop-down list, select the private resources for which the selected Threat Defense device always enforces policy, regardless of whether the user is on-premises or remote.

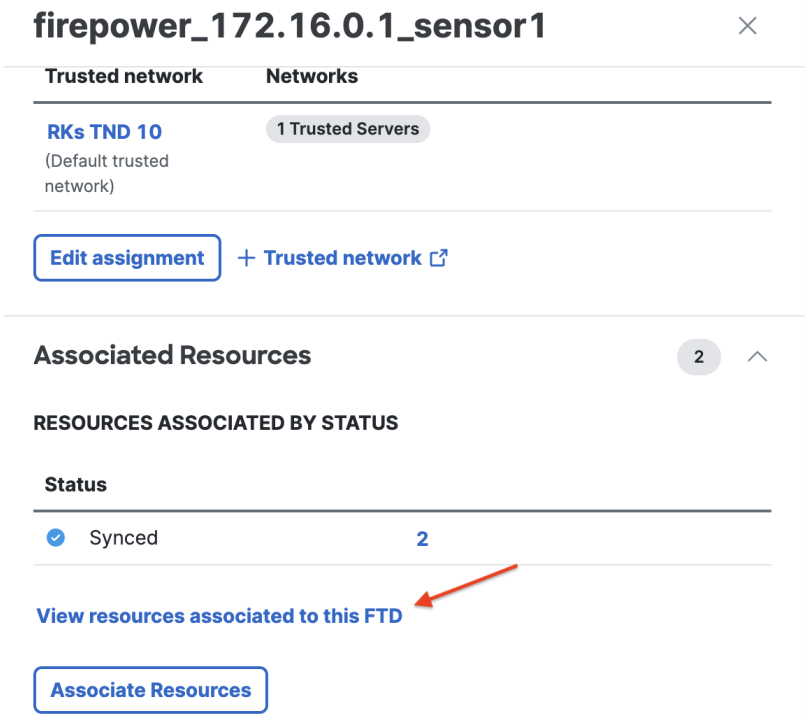


The following figure shows an example of using a Threat Defense device to enforce access rules for the **vftd-quic-app** for on-premises users and **vftd-amazon-app** for all users, whether on-premises or remote.

Step 9 Click **Save**.

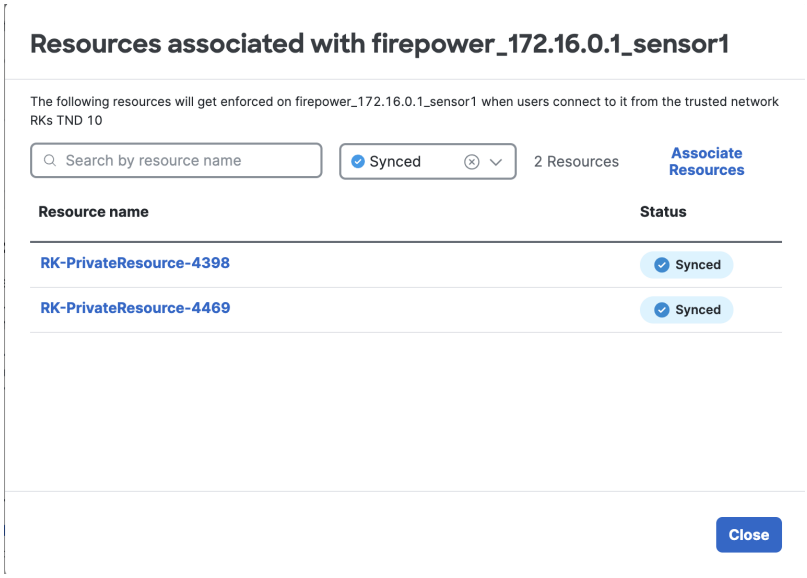
The configurations are applied to the device, and the **UZTA Configuration status** column for the device displays **Synced**.

The following figure shows an example.



Configuration status can also be:

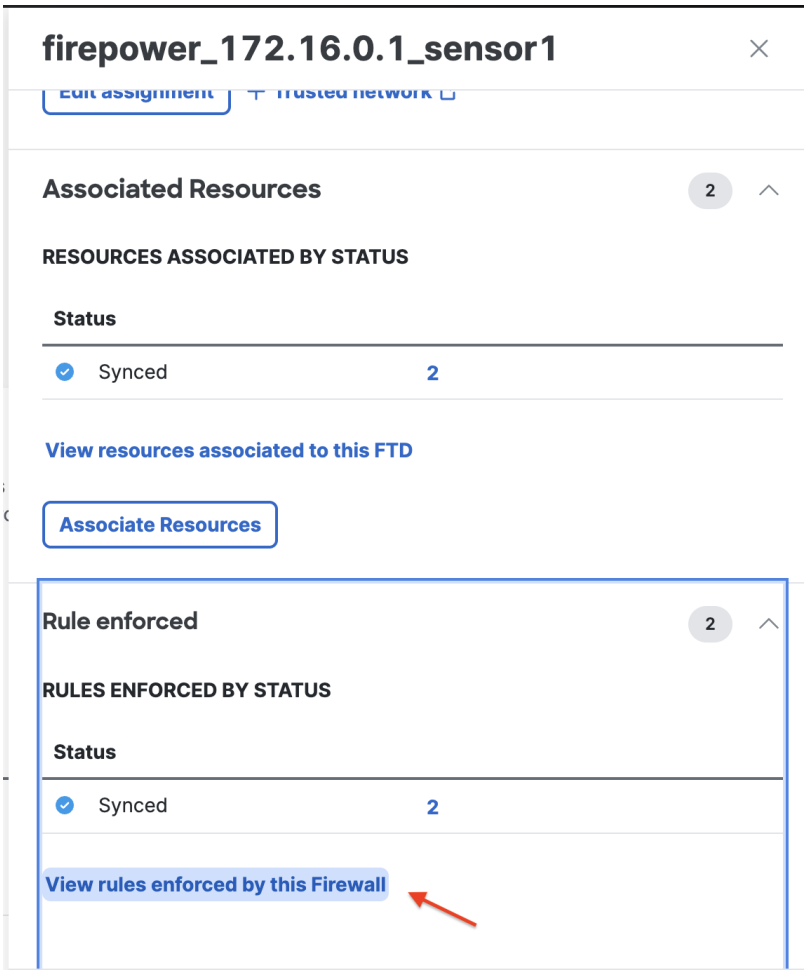
- Syncing—updates to the Threat Defense device are ongoing.
- Out of sync—modifications to Secure Access configurations are pending update to the Threat Defense device.
- Failed to sync—configurations were not updated on the Threat Defense device.



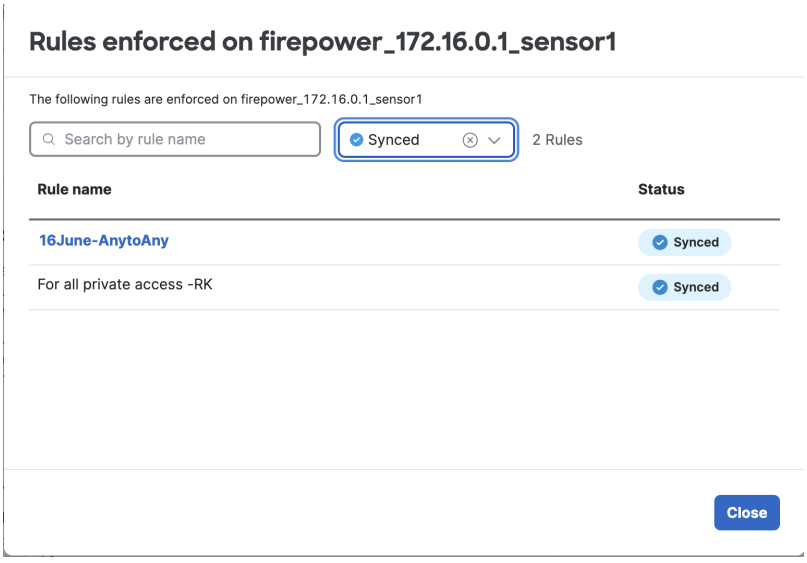
To view a detailed status for each resource and rule associated with a Threat Defense device, complete these actions:

a) Click the numeral in the **Associated Resources** column.

In the slide-in pane, under the **Associated Resources** section, click **View resources associated with this FTD**.



The configuration status of each resource is displayed.



b) To check the configuration status of each rule enforced by the Threat Defense device, click the numeral in the **Rules Enforced** column.

In the slide-in pane, under the **Rules Enforced** section, click **View rules enforced by this Firewall**.

The configuration status of each rule that is enforced is displayed.

Universal ZTNA is now set up, allowing your clients to access private resources in your network securely.

Network connections are configured, and Universal ZTNA is set up to allow secure access to private resources.

PART XVII

Access Control Policy Basics

- Access Control Policies, on page 1997
- Security Intelligence, on page 2027
- Access Control Rules, on page 2041
- URL Filtering Rules, on page 2085

CHAPTER 69

Access Control Policies

These topics describe how to work with access control policies:

- Access control policies, on page 1997
- Requirements and prerequisites for access control policies, on page 2002
- Manage access control policies, on page 2002
- History for access control policies, on page 2023

Access control policies

An access control policy is a hierarchical policy that allows you to specify, inspect, and log network traffic. You can use the characteristics of each connection to allow, trust, block, or monitor the connection.

Each managed device can be assigned to one access control policy. The data that the policy's assigned (also known as targeted) devices collect about your network traffic can be used to filter and control that traffic based on:

- simple, easily determined transport and network layer characteristics: source and destination, port, protocol, and so on
- the latest contextual information on the traffic, including characteristics such as reputation, risk, business relevance, application used, or URL visited
- realm, user, user group, or ISE attribute
- custom Security Group Tag (SGT)
- characteristics of encrypted traffic; you can also decrypt this traffic for further analysis
- whether unencrypted or decrypted traffic contains a prohibited file, detected malware, or intrusion attempt
- time and day (on supported devices)

Each type of traffic inspection and control occurs where it makes the most sense for maximum flexibility and performance. For example, reputation-based blocking uses simple source and destination data, so it can block prohibited traffic early in the process. In contrast, detecting and blocking intrusions and exploits is a last-line of defense.

Access control policy components

This list describes the main components of an access control policy.

- Name and description: Each access control policy must have a unique name. A description is optional.
- Inheritance settings: Policy inheritance allows you to create a hierarchy of access control policies. A parent (or base) policy defines and enforces default settings for its descendants. A policy's inheritance settings allow you to select its base policy. You can also lock settings in the current policy to force any descendants to inherit them. Descendant policies can override unlocked settings.
- Policy assignment: Every access control policy identifies which devices use it. Each device can use only one access control policy. You can also assign the policy to device templates.
- Rules: Access control rules provide a granular method of handling network traffic. Rules are numbered, starting at 1, including rules inherited from ancestor policies. The system matches traffic to rules from the top down, ascending by rule number.

  Traffic is handled by the first rule for which all conditions match. Conditions can be simple or complex, and often depend on licensing.
- Default action: The default action determines how the system handles and logs traffic that is not handled by any other access control configuration. It can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.
- Security Intelligence: This feature acts as the first line of defense against malicious internet content. It enables blocking of connections based on IP address, URL, and domain name reputation intelligence. To ensure continual access to vital resources, you can override block list entries with custom do not block list entries.
- HTTP responses: When a user's website request is blocked, you can display either a generic response page or a custom page. Alternatively, you can warn users but allow them to proceed to the requested site.
- Logging: Logging settings enable configuration of default syslog destinations for the policy. These settings apply to the policy and all included decryption, prefilter, and intrusion policies unless overridden in individual rules or policies.
- Advanced access control options: Advanced policy settings typically require little modification, and defaults are often suitable. Modifiable options include traffic preprocessing, decryption, identity, and various performance configurations.

Access control policy default actions

The default action is the access control policy configuration that determines how the system handles and logs traffic that is not handled by any other access control configuration. The default action can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data.

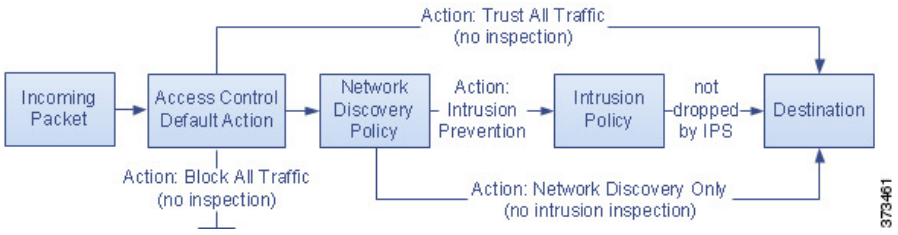
In a simple access control policy, the default action specifies how a device handles all traffic. In a more complex policy, the default action handles traffic that:

- is not fast pathed by the prefilter policy
- is not on a Security Intelligence block list

- is not blocked by the decryption policy (encrypted traffic only)
- matches none of the rules in the policy (except monitor rules, which match and log—but do not handle or inspect—traffic)

Note You cannot perform file or malware inspection on traffic handled by the default action. Logging of connections handled by the default action is initially disabled but can be enabled.

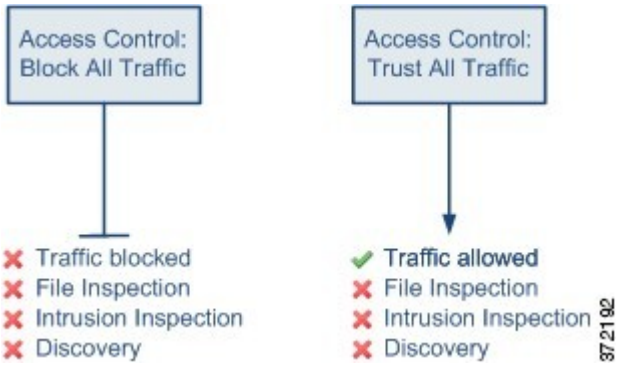
If you are using policy inheritance, the default action for the lowest-level descendant determines how traffic is handled. An access control policy can inherit its default action from the base policy, but this inheritance is not enforced.



This table describes the types of inspection you can perform on traffic handled by each default action.

Table 115: Types of default actions and inspection options

Default action	Effect on traffic	Inspection type and policy
Access Control: Block All Traffic	Block without further inspection.	None.
Access Control: Trust All Traffic	Trust (allow to its final destination without further inspection).	None.
Intrusion Prevention	Allow, as long as it is passed by the intrusion policy you specify.	Intrusion, using the specified intrusion policy and associated variable set. Discovery, using the network discovery policy.
Network Discovery Only	Allow.	Discovery only, using the network discovery policy.
Inherit from base policy	Defined in base policy.	Defined in base policy.



This diagram illustrates the table.

Figure 382: Default action configuration options

This diagram illustrates the **Block All Traffic** and **Trust All Traffic** default actions.

Figure 383: Block all traffic and trust all traffic default actions

This diagram illustrates the **Intrusion Prevention** and **Network Discovery Only** default actions.

Figure 384: Intrusion prevention and network discovery only default actions

Note The purpose of **Network Discovery Only** is to improve performance in a discovery-only deployment. Different configurations can disable discovery if you are only interested in intrusion detection and prevention.

Access control policy inheritance

Access control policy inheritance is a hierarchical policy-based implementation that allows child policies to inherit rules and settings from ancestor or base policies. This structure ensures that mandatory rules defined in parent policies are consistently enforced, while providing the flexibility for child policies to selectively override default configurations.

Access control policy hierarchy structure

You can nest access control policies, where each policy inherits the rules and settings from an ancestor policy. You can enforce this inheritance, or allow lower-level policies to override their ancestors.

Just as you create a domain hierarchy, you can create a corresponding hierarchy of access control policies. A descendant, or child, access control policy inherits rules and settings from its direct parent, or base, policy. That base policy may have its own parent policy from which it inherits rules and settings, and so on.

An access control policy's rules are nested between its parent policy's Mandatory and Default rule sections. This implementation enforces Mandatory rules from ancestor policies, but allows the current policy to write rules that preempt Default rules from ancestor policies.

You can lock these settings to enforce them in all descendant policies:

- Security Intelligence—Connections that are allowed or blocked based on the latest reputation intelligence for IP addresses, URLs, and domain names.
- HTTP response pages—Displaying a custom or system-provided response page when you block a user's website request.
- Advanced settings—Specifying associated subpolicies, network analysis settings, performance settings, and other general options.

When using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

Rule and other policy warnings

Policy and rule editors use icons to mark configurations that could adversely affect traffic analysis and flow. Depending on the issue, the system may warn you when you deploy or prevent you from deploying entirely.

Note Move your pointer over an icon to read the warning, error, or informational text.

Table 116: Policy error icons

Icon	Description	Example
Errors ( )	If a rule or configuration has an error, you cannot deploy until you correct the issue, even if you disable any affected rules.	A rule that performs category and reputation-based URL filtering is valid until you assign a device that does not have a URL Filtering license. At that point, an error icon appears next to the rule, and you cannot deploy until you edit or delete the rule, unassign the device, or enable the license.
Warning ( )	You can deploy a policy that displays rule or other warnings. However, misconfigurations marked with warnings have no effect. If you disable a rule with a warning, the warning icon disappears. It reappears if you enable the rule without correcting the underlying issue.	Preempted rules or rules that cannot match traffic due to misconfiguration have no effect. This includes conditions using empty object groups, application filters that match no applications, excluded LDAP users, invalid ports, and so on. However, if a warning icon marks a licensing error or model mismatch, you cannot deploy until you correct the issue.

Icon	Description	Example
Information ()	Information icons convey helpful information about configurations that may affect the flow of traffic. These issues do not prevent you from deploying.	The system might skip matching the first few packets of a connection against some rules, until the system identifies the application or web traffic in that connection. This allows connections to be established so that applications and HTTP requests can be identified.
Rule Conflict ()	When you enable rule conflict analysis, this icon appears in the rule table for rules that have conflicts.	Conflicts include redundant rules, redundant objects, and shadowed rules. Redundant and shadowed rules do not match traffic because previous rules would already match the criteria. Redundant objects make your rules unnecessarily complex.

Requirements and prerequisites for access control policies

Ensure that your environment meets these requirements before configuring access control policies.

- You must have **Administrator**, **Network Admin**, or **Access Admin** privileges to configure access control policies.
- Custom roles: You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.
  - **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for network analysis and intrusion policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.
  - **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Manage access control policies

Configure and manage access control policies by editing system-provided policies and creating custom access control policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

At the top of the page, there are convenient links to some related features: Object management, Intrusion policies, Network Analysis policies, DNS policies, and policy Import/Export.

Step 2 These actions help you to manage your policy:

- Create—Click **Create Policy**; see Creating a basic access control policy, on page 2004.
- Edit—Click **Edit** ( ); see Editing an access control policy, on page 2004
- Delete—Click **Delete** ( ). You must remove any device assignments before deleting a policy.

  To delete more than one policy at a time, select the check boxes for the policies, then select **Delete Policies** above the table.
- Copy—Select **Clone** from the **More** ( ) menu. Device assignments are not retained in the copy.
- Lock or unlock a policy—See Lock an access control policy, on page 2006.

Step 3 These options help you to analyze, monitor, and customize your policies:

- Analyze policy—Select one or more policy and then click **Analyze Policies** to evaluate access control policies for anomalies such as redundant or shadowed rules, and take action to fix discovered anomalies. The analysis job is sent to the cloud and takes time to complete. See Identify and fix anomalies with policy analyzer & optimizer, on page 2017.

  The Anomalies column shows the results of the analysis. Click the **% Optimizable** link to see the anomalies, or **Re-Analyze** to run the analysis again. The Last Analyzed column shows when Policy Analyzer & Optimizer was last run.

  After completing analysis and optimization, you can download the reports by selecting the following options from the **More** ( ) menu: **Download Last Policy Analysis**, **Remediation History**.

  Note
  To use the policy analysis feature, you must be using a Cloud-Delivered Firewall Management Center or an On-Prem Firewall Management Center connected to Security Cloud Control (Security Cloud Control). If your setup does not meet requirements, the explanatory dialog that opens when you click this button includes an **Integrate** button to help get you started. Policy Analyzer & Optimizer operates in the cloud only.
- Columns—Click the **Show/Hide Columns** icon above the list of rules to select which information to show in the table. Click **Show All/Hide All** to quickly add or remove all listed columns, excepting name and actions. Click **Default** to undo all of your customizations.
- Inheritance—Vertical lines indicate inheritance relationships between policies.
- Report—Select **Generate Report** from the **More** ( ) menu. The report is generated as a background process. Go to the message/notifications center and look in the tasks list. When the report is finished, you can download it from the notification.
- View the audit log—Click **View Audit Log** from the **More** ( ).

Creating a basic access control policy

When you create a new access control policy, it contains default actions and settings. After creating the policy, you are immediately placed in an edit session so that you can adjust the policy to suit your requirements.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Create Policy**.

Step 3 Enter a unique **Name** and, optionally, a **Description**.

Step 4 Optionally, choose a base policy.

If an access control policy is enforced on your domain, this step is not optional. You must choose the enforced policy or one of its descendants as the base policy.

If you select a base policy, the base policy defines the default action and you cannot select a new one in this dialog box. Logging for connections handled by the default action depends on the base policy.

Step 5 When you do not select a base policy, specify the initial **Default Action**:

- **Block all traffic** creates a policy with the **Access Control: Block All Traffic** default action.
- **Intrusion Prevention** creates a policy with the **Intrusion Prevention: Balanced Security and Connectivity** default action, associated with the default intrusion variable set.
- **Network Discovery** creates a policy with the **Network Discovery Only** default action.

When you select a default action, logging of connections handled by the default action is initially disabled. You can enable it later when you edit the policy.

Note
If you want to trust all traffic by default, or if you chose a base policy and do not want to inherit the default action, you can change the default action later.

Step 6 Optionally, choose the devices to assign to the policy. To narrow the devices that appear, enter a search string. The list includes both devices and device templates.

If you want to deploy this policy immediately, you must perform this step.

Step 7 Click **Save**.

The new policy opens for edit. You can add rules to it and make other changes as needed. See Editing an access control policy, on page 2004.

Editing an access control policy

When you edit an access control policy, you should lock it to ensure that your changes do not get overridden by another person who might edit it simultaneously.

You can only edit access control policies that were created in the current domain. Also, you cannot edit settings that are locked by an ancestor access control policy.

To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Note When you edit a policy and do not lock it, a banner message might indicate that other users are currently editing the policy. When one of these users saves changes, you will be prompted to either merge or discard your changes. You should immediately decide what to do. For more information, see Merge concurrent edits to an access control policy, on page 2008 .

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** .

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Edit your access control policy.

Note
You can operate on multiple rules at one time by selecting their checkboxes in the left column, then selecting the action you want to perform from the **Select Bulk Rule Actions** drop-down list next to the search box. Bulk editing is available for enabling and disabling, copying, moving, deleting, and editing rules, or viewing hit counts or related events. You can also remove object overlaps in the selected rules.

You can change the following settings or perform these actions:

- Name and description—Click **Edit** ( ) next to the name, make your changes, and click **Save** .
- Default action and settings—Choose a value from the **Default Action** drop-down list, then click **Cog** ( ) , make your changes to the settings, and click **OK** . For detailed information, see Configure the access control default action, on page 2010 .
- Associated policies—To edit or change policies in the packet flow, click the policy type in the packet flow representation below the policy name. You can select the **Prefilter Rules** , **Decryption** , **Security Intelligence** , and **Identity** policies. When necessary, click **Access Control** to return to the access control rules.
- Policy assignment—To identify the managed devices targeted by this policy, or enforce this policy in a subdomain, click the **Assigned: x devices** link. You can assign the policy to devices or device templates.
- Rules—To manage access control rules, and to inspect and block malicious traffic using intrusion and file policies, click **Add Rule** , or right-click an existing rule and select **Edit** or another appropriate action. The actions are also available from the **More** ( ) button for each rule. See Create and edit access control rules, on page 2066 .

- Layout—Use the **Grid/Table View** icon above the list of rules to change the layout. Grid view provides color-coded objects in an easy-to-see layout. Table view provides a summary list so that you can see more rules at once. You can freely switch views without impacting the rules.
- Columns (table view only)—Click the **Show/Hide Columns** icon above the list of rules to select which information to show in the table. Click **Show/Hide Empty Columns** to quickly add, or remove, all columns that have no information, that is, you are not using those conditions in any rule. Click **Revert to Default** to undo all of your customizations.
- Analyze rule logic—You can select the following options from the **Analyze** menu to examine the logic of your rules:
  - **Manage Rule Hit Counts** —To view statistics on how many connections matched each rule. See View rule hit counts, on page 2018 .
  - **Enable/Disable Rule Conflicts** —Select whether you want to see information on whether rules interfere with each other. You can then view the results using the following commands. See Analyzing rule conflicts and warnings, on page 2020
    - **Show Warnings and Errors** —See whether there are rules with configuration issues that you need to address.
    - **Show Policy Warnings** —See whether there are configuration issues with the policy.
    - **Show Rule Conflicts** —See whether you have redundant or shadowed rules. These conflicts could prevent certain rules from ever being matched by connections, meaning either that you need to fix the match criteria, move the rule, or simply delete the rule.

Step 4 To change additional settings for the policy, select one of these options from the **More** drop-down arrow at the end of the packet flow line.

- **Encrypted Visibility Engine** —Whether to enable and configure the encrypted visibility engine. See Configure EVE, on page 2242 .
- **Advanced Settings** —To set preprocessing, decryption, identity, performance, and other advanced options. See Configure advanced settings for the access control policy, on page 2688 .
- **HTTP Responses** —To specify what the user sees in a browser when the system blocks a website request. See Choose HTTP response pages, on page 2105 .
- **Inheritance Settings** —To change the base access control policy for this policy, and to enforce this policy's settings in its descendant policies. See Choose a base access control policy, on page 2011 and Lock settings in descendant access control policies, on page 2012 .
- **Logging** —To set the default logging options for the policy.

Step 5 Click **Save** .

Lock an access control policy

Lock an access control policy to prevent other administrators from editing it, ensuring that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes.

If you do not lock a policy, you might have to merge your changes if another user edits the policy simultaneously and saves changes first. For more information, see Merge concurrent edits to an access control policy, on page 2008.

The lock is for the access control policy itself. The lock does not apply to objects used in the policy. For example, another user can edit a network object that is used in a locked access control policy. Your lock remains in place until you explicitly unlock the policy, so you can log out and come back to your edits later.

When locked, other administrators have read-only access to the policy. However, other administrators can assign a locked policy to a managed device.

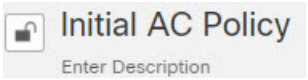
Before you begin

Any user role that has permission to modify the access control policy has permission to lock it, and to unlock a policy that was locked by another user.

However, the ability to unlock a policy that was locked by another administrator is controlled by the following permission: **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Override Access Control Policy Lock**.

If you are using custom roles, your organization might have limited your unlocking abilities by not assigning this permission. Without this permission, only the administrator who locks a policy can unlock it.

Procedure



Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy you want to lock or unlock.

In the access control policy list:

- The **Lock Status** column shows whether a policy is already locked, and if so, who locked it. An empty cell indicates that the policy is not locked.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. Or, it is locked by another user.

Step 3 Click the lock icon next to the policy name to lock or unlock the policy.

If the policy inherits settings from a parent policy, you must choose one of these options when you click the lock icon.

- **Lock/Unlock this policy**—The locking or unlocking is for this policy only.
- **Lock/Unlock all policies in hierarchy**—This policy and all parent policies are locked or unlocked. If a parent policy is already locked by another administrator, you will see a message and you will not be able to lock that parent policy. When unlocking policies, if you have the Override Access Control Policy Lock permission, all parent policies are unlocked even if they were locked by other users.

Merge concurrent edits to an access control policy

Handle conflicts when multiple users make changes to the same access control policy simultaneously, ensuring no critical changes are lost while maintaining policy integrity.

When you allow multiple users to edit an access control policy, you have two choices:

- Have users lock the policy when editing it. This ensures that a single user at a time can make changes. Using locking, you never have to worry about lost or conflicting changes. However, it limits your ability to respond quickly to unexpected events, especially if a user leaves the policy locked while out of the office. For more information about locking policies, see Lock an access control policy, on page 2006.
- Allow users to simultaneously edit the policy. If more than one user has made unsaved edits at a given time, the first user who saves the policy gets all of their changes saved. Other users are immediately notified of the save, and must then merge their changes. The rest of this topic explains this approach.

Note If you are using change management, where edits are done within the scope of a ticket, the ticket locks the policy and concurrent editing is not possible.

Before you begin

To limit the amount of merging you have to do, save the policy early and often.

Procedure

Step 1 Determine if other users are also editing the policy.

When you edit an access control policy, look for this message banner at the top of the page:

```
User name is currently editing this policy.
```

This message indicates that the named user (there might be more than one) currently have the policy open for edit.

Step 2 Watch for notifications that another user saved changes and take action.

This banner message indicates another user saved changes and you need to take immediate action:

```
User name modified this policy and saved changes. Merge Discard.
```

Click one of these links:

- **Merge**—Open a merge window where you can make decisions about which of your changes to keep or to discard, and to identify changes that cannot be merged. See the next step when taking this option.
- **Discard**—Discard all of your changes immediately and start over. If you select this option, the page is refreshed with the latest changes from the other user.

Step 3 Merge changes.

When you click the **Merge** option, a merge window opens with a summary of the total number of observed differences between your edits and the last user's saved edits. No other user's unsaved edits are included. Observations include direct conflicts and informational notifications.

Note
You must complete all merge decisions before you close the window. You cannot wait until later once you click the **Merge** option.

a) Evaluate each conflict and make a decision for each.

When evaluating the change list, consider these points:

- Initially, all observations are shown, but you can select/deselect the filtering options for **Conflict** and **Info** to limit the displayed information. Conflicts arise when users edit the same rule or setting. Informational items are for edits to different rules or settings.
- If there are no conflicts, your cache is immediately updated with the last saved changes and you can proceed. For example, if you are editing rule 1, and the other user saved changes to rule 2, it is unlikely that there are any conflicts.
- For each conflict (other than rule name), the window shows the version of the element saved by the other user (**Version on Firewall Management Center**), and your changes (**Modified Version**). Changes are color-coded for new (e.g. an option that was not previously defined), edited, or deleted policy elements. You must select either to **Discard** your change, or to **Accept Mine** and overwrite the other user's change. When discarding a change, the rule is refreshed with the other user's saved change and yours is removed.
- Rule conflicts are considered at the rule level, not per element within the rule. For example, if you edit destination networks, and the saved changes are for source networks, either your changes or the other user's changes are retained, not both.
- If the conflict involves the name of a rule, the system tries to create a unique name by adding an underscore and number to the name, such as Rule_1. You can alternatively enter a new name in the edit box provided and click **Save**. If you click **Discard**, the generated rule name is used.
- You cannot skip any conflict. For each conflict, you must make a decision to discard or keep your change.
- If the user who saved changes deleted a rule that you edited, the rule is deleted and you do not have the option to keep the rule.
- If the user who saved changes updated a rule, and your change is to delete the rule, the rule is retained: you cannot merge your deletion.
- For these options, if your change conflicts with the saved changes, your change is discarded and merging the change is not an option:
  - Other policy assignments: prefilter, Security Intelligence, identity, decryption
  - Changes to advanced settings, policy logging, EVE, HTTP response pages.
  - Policy default action.
  - Inheritance settings.

b) Click **Close**.

Step 4 Once the merger is complete, you can either save the policy immediately or continue editing it. Saving the policy might reduce the impact of future merges.

Configure the access control default action

Configure the default action for an access control policy when connections do not match specific access control rules.

The default action for an access control policy is applied to any connection that:

- is not fast pathed by the prefilter policy
- is not on a Security Intelligence block list
- is not blocked by the decryption policy (encrypted traffic only)
- matches none of the rules in the policy (except monitor rules, which match and log—but do not handle or inspect—traffic)

Procedure

Step 1 Edit the access control policy whose inheritance settings you want to change; see Editing an access control policy, on page 2004.

Step 2 Select the **Default Action** at the bottom of the rules list.

For detailed information on what each option does, see Access control policy default actions, on page 1998.

Step 3 Click **Cog** (⚙) to configure the default action settings.

You can configure the following options. Click **OK** when finished.

- Logging options—Whether to log the connection. You can **Log at beginning of connection**, **Log at end of connection**, or both. If you select block as the default action, you can log at the beginning of the connection only.
- **Send connection events to**—If you select one of the logging options, select whether to send events to any combination of the following:
  - **Firewall Management Center**—Send events to the manager.
  - **Syslog server**—Send events to the default syslog server configured for the policy. You can configure overrides to specify a different severity level or syslog server destination.

  (Splunk or SIEM syslog server integration) If you have configured Cloud-Delivered Firewall Management Center as the source of connection events in Splunk configuration, choose **Firewall Management Center** under **Send Connection Events to** options. If you have configured Firewall Threat Defense as the connection event source, select at least one syslog destination. For Splunk or any SIEM syslog configuration procedure, see the *Cisco Secure Firewall Management Center Administration Guide*.
- **SNMP trap**—If you enable logging, you can send SNMP traps to an SNMP server. Select an SNMP configuration, or click + to configure a new one.

- **Default action variable set**—If you selected one of the intrusion prevention default actions, select the variable set that should be used with the intrusion policy you selected.

Step 4 Click **Save**.

Manage access control policy inheritance

Inheritance relates to using another policy as a base policy for an access control policy. This allows you to use one policy to define some baseline characteristics that can be applied to multiple policies. To understand how inheritance works, refer to Access control policy inheritance, on page 2000.

Procedure

Step 1 Edit the access control policy whose inheritance settings you want to change; see Editing an access control policy, on page 2004.

Step 2 Manage policy inheritance:

- Change base policy — To change the base access control policy for this policy, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in Choose a base access control policy, on page 2011.
- Lock settings in descendants — To enforce this policy's settings in its descendant policies, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in Lock settings in descendant access control policies, on page 2012.
- Inherit settings from base policy — To inherit settings from a base access control policy, proceed as directed in Inherit access control policy settings from the base policy, on page 2012.
- Required in domains — To enforce this policy in a subdomain, click the **Assigned: x devices** link and proceed as described in Enforce an access control policy in a domain, on page 2013.

Choose a base access control policy

Choose a base access control policy to establish policy inheritance, allowing a child policy to inherit rules and settings from its parent while maintaining the ability to modify unlocked configurations.

When you change the base policy for the current access control policy, the system updates the current policy with any locked settings from the new base policy.

Procedure

Step 1 In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 Choose a policy from the **Select Base Policy** drop-down list.

To remove inheritance, select **None**.

Step 3 Click **OK**.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes.

Lock settings in descendant access control policies

Lock a setting in an access control policy to enforce the setting in all descendant policies.

Descendant policies can override unlocked settings. When you lock settings, the system saves overrides already made in descendant polices so that the overrides can be restored if you unlock settings again.

Procedure

Step 1 In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 In the Child Policy Inheritance Settings area, check the settings you want to lock.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.

Step 3 Click **OK** to save the inheritance settings.

Step 4 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes.

Inherit access control policy settings from the base policy

Configure a child access control policy to inherit settings from a base policy or override them with custom configurations.

Child access control policies inherit many settings from their base policy by default. If these settings are unlocked in the base policy, you can override them.

If you later reinherit the settings from the base policy, the Cloud-Delivered Firewall Management Center displays the base policy's settings and dims the controls. However, it saves the overrides you made and restores them if you disable inheritance again.

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**, or select **HTTP Responses**, **Logging**, **Encrypted Visibility Engine**, or **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line

Step 2 Check the **Inherit from (*base policy*)** check box for each setting you want to inherit.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.

Step 3 Click **Save**.

What to do next

- Deploy configuration changes.

Enforce an access control policy in a domain

Require that every device in a domain use the same base access control policy or one of its descendant policies.

This procedure is relevant in a multi-domain deployment only.

Procedure

Step 1 In the access control policy editor, click the **Assigned: x devices** link.

Step 2 Click **Required on Domains**.

Step 3 Build your domain list:

- Add — Select the domains where you want to enforce the current access control policy, then click **Add** or drag and drop into the list of selected domains.
- Delete — Click **Delete** ( ) next to a leaf domain, or right-click an ancestor domain and choose **Delete Selected**.
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Step 4 Click **OK** to save the domain enforcement settings.

Step 5 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes.

Assign access control policy to devices

An access control policy specifies the devices that use it. Each device can be assigned to only one access control policy. You can also assign the policy to device templates. Templates are included in the list of available and selected devices.

Procedure

Step 1 In the access control policy editor, click the **Assigned to x devices** link.

Step 2 Build your target list:

- Add — Select one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete — Click **Delete** ( ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Under **Impacted Devices**, the system lists the devices whose assigned access control policies are children of the current policy. Any change to the current policy affects these devices.

Step 3 Assign the access control policy to devices:

- Add — Select one or more **available devices**, then click the **Right Arrow** ( ) icon or drag and drop into the list of **assigned devices**.
- Delete — Click the **Delete** ( ) next to a device, or select multiple devices, and then click the Left Arrow .
- Search — Type a search string in the search field. Click **Clear** ( ) to clear the search.

Step 4 Click **OKApply** to save your assigned device settings.

Step 5 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes.

Logging settings for access control policies

Logging settings for access control policies are configuration option that allow you to configure default syslog destinations for the current access control policy. The settings are applicable to the access control policy and all the included decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

To configure logging settings for an access control policy, select **Logging** from the **More** drop-down arrow at the end of the packet flow line.

You can configure default syslog destinations and syslog alert for the access control policy. The settings are applicable to the access control policy and all the included decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

Logging for connections handled by the default action is initially disabled.

Intrusion settings and file and malware settings are effective only after you have selected an option at the top of the page for sending syslog messages generally.

Default syslog settings

Default syslog settings provide two destination options:

- **Destination** > ***Specific Syslog alert object***: Events are sent based on the selected syslog alert as configured using the instructions in *Creating a Syslog alert Response* in the *Cisco Secure Firewall Management Center Administration Guide*. You can select the syslog alert from the list or add one by specifying the name, logging host, port, facility, and severity.

  When using this option, the system sends syslog messages to the server using the Management interface. Ensure there is a route from the Management interface to the syslog server, or messages will not arrive at the server.

- **Destination** > **Use FTD Platform Settings**: Connection or intrusion events are sent with the selected severity to syslog collectors configured in Platform Settings. Using this option, you can unify the syslog configuration by configuring it in platform settings and reusing the settings in access control policy. Severity selected in this section is applied to all connection and intrusion events. The default severity is alert.

Intrusion settings

Intrusion settings include these options:

- **Send syslog messages for intrusion events**: Send intrusion events as syslog messages. The defaults set above are used unless you override them.
- **Show overrides** or **Hide overrides**: If you want to use the default syslog destination and severity, leave these options empty. Otherwise, you can set a different syslog server destination for intrusion events, and change the severity of the events.

File and malware settings

File and malware settings include these options:

- **Send syslog messages for file and malware events**: Send file and malware events as syslog messages. The defaults set above are used unless you override them.
- **Show overrides** or **Hide overrides**: If you want to use the default syslog destination and severity, leave these options empty. Otherwise, you can set a different syslog server destination for file and malware events, and change the severity of the events.

AI defense settings

Associate prefilter, decryption, and identity policies with an access control

Associate subpolicies with an access control policy to create a comprehensive security framework that handles different aspects of network traffic processing.

The easiest way to associate subpolicies to an access control policy is by clicking the policy's link in the packet flow shown at the top of an access control policy. Alternatively, you can use the policy's advanced settings to associate the subpolicy, as described in this topic. The subpolicies that you can associate with access control policy are:

- Prefilter policy—Performs early traffic handling using limited network (layer 4) outer-header criteria.
- Decryption policy—Monitors, decrypts, blocks, or allows application layer protocol traffic encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS).
- Identity policy—Performs user identification based on the realm and authentication method associated with the traffic.

Before you begin

Before associating a decryption policy with an access control policy, review the information about TLS server identity discovery in TLS server identity discovery, on page 2692.

Procedure

Step 1 In the access control policy editor, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 2 Locate the policy settings area for prefilter, decryption, or identity policies.

Step 3 Click **Edit** ( ) in the corresponding policy settings area.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Choose a policy from the drop-down list.

If you choose a user-created policy, you can click the edit icon that appears to edit the policy.

Step 5 Click **OK**.

Step 6 Click **Save** to save the access control policy.

What to do next

- Deploy configuration changes.

Identify and fix anomalies with policy analyzer & optimizer

Use the Policy Analyzer & Optimizer to evaluate access control policies for anomalies such as redundant or shadowed rules, and take action to fix discovered anomalies.

The Policy Analyzer & Optimizer is hosted in the cloud and is different from the rule analysis available when you are not integrated with the cloud. The non-cloud policy analysis is not available once you integrate with the cloud.

The system automatically performs policy analysis on a daily basis (every 24 hours). You can also manually start an analysis. When you initially enable the service, the system starts an analysis of all existing access control policies.

Note Before optimizing a policy, create a copy of the policy. If you are then dissatisfied with the results of optimization, you can easily reassign the managed devices to the copy and return the system to its starting state.

Before you begin

- If you have enabled change management, Policy Analyzer & Optimizer automatically creates a ticket for the changes, and submits the ticket. The approver must approve the ticket before the changes can be deployed.
- If you are using domains, you cannot click the link in the Anomaly column to see the report. Instead, log into Security Cloud Control and use the feature from that application.
- Policy Analyzer & Optimizer adds rule comments on rules that are updated, disabled, or merged. You can later search on these comments to find optimized rules.
- Changes implemented by Policy Analyzer & Optimizer are reflected in the audit log as API calls under the default name internaladmin.
- After enabling Policy Analyzer & Optimizer, the system evaluates changes every time a rule is added or edited. Users are notified when applying a rule edit if the change will create anomalies such as redundant or shadowed rules.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

If you have already run an analysis, the Anomaly column shows the number of issues with the policy and the percentage the policy can be optimized, and the state of the policy analysis, such as Error or Completed. Last Analyzed shows the date/time when the analysis was run.

Step 2 Select one or more policy, then click **Analyze Policy**.

The analysis runs as a background process in the cloud. When the analysis is complete, the results appear in the Anomaly column.

Notes:

- You can also start an analysis when editing the policy by selecting **Analyze** > **Policy**. Other options from that menu allow you to show hit counts and warnings.
- If you have not connected to the cloud yet, the explanatory dialog that opens when you click this button includes an **Integrate** button to help get you started. Policy Analyzer & Optimizer operates in the cloud only.

Step 3 When the analysis is complete, click the **% Optimizable** link in the Anomaly column to launch Policy Analyzer & Optimizer in the cloud.

When you have done all the actions you want to take, click **Apply Remediations** (in the cloud). You are shown a confirmation of what will be done. Click **Proceed** to implement the changes.

If the initial analysis ended in an error, you could instead click **Re-analyze** to restart the process.

Step 4 Deploy the policy to complete the changes.

If you have change management enabled, the approver must first approved the ticket that contains the remediations before you can deploy them.

View rule hit counts

Hit count indicates the number of times a policy rule or default action has been matched to a connection. The hit count is incremented only for the first packet of a connection that matches a rule. You can use this information to identify the efficacy of your rules. Hit count information is available only for access control and prefilter rules applied to Firewall Threat Defense devices.

Note

- The count persists through reboots and upgrades.
- Counts are maintained by each unit in an HA pair or cluster separately.
- You will not be able to derive the hit count information from a device when deployment or a task is in progress on the device.
- You can also see rule hit count information in the device CLI using the **show rule hits** command.
- If you have accessed the Hit Count page from the Access Control Policy page, you will not be able to view or edit prefilter rules and vice-versa.
- Hit counts are not available for rules that use the Monitor action.

Before you begin

If you use custom user roles, ensure that the roles include these privileges:

- View Device, to see the hit counts.
- Modify Device, to refresh the hit counts.

Follow these steps to view rule hit counts:

Procedure

Step 1 In the access control policy or prefilter policy editor, click **Analyze** > **Manage Rule Hit Counts** on the top-right of the page.

Step 2 On the Hit Count page, select the device from the **Select a device** drop-down list.

If it is not the first time that you are generating hit counts for this device, the last fetched hit count information appears next to the drop-down box. Also, verify the **Last Deployed** time to confirm recent policy changes.

Select **All** to see an aggregate of hit counts across all devices assigned to the policy.

Step 3 If necessary, click **Refresh** ( ) to obtain current hit count data from the selected device.

In the prefilter policy, you might need to click **Fetch Current Hit Count** to get initial hit count data.

You cannot refresh the hit count while deployment to the device is in progress.

Step 4 View and analyze the data.

You can do these actions:

- Click **Prefilter** or **Access Control** to switch between the hit counts for these policies.
- Search for a specific rule by entering a search string in the **Filter** box.
- Broadly limit the list to **Hit Rules** or **Never Hit Rules** by selecting these options in the **Filter by** field. When viewing hit rules, you can further limit the list by selecting a time range in the **In Last** field (for example, in the last 1 day).
- (When viewed from the access control policy.) Clear the hit counts for one or more rule by selecting the checkbox for the rule, then clicking **Clear Hit Counts**. When confirming the action, choose **Clear and Reload** to refresh the hit count data. You can clear hit counts for up to 500 rules at a time. You cannot undo clearing hit counts.

  Note
  Click the checkbox in the table header to select all rules visible in the list. To select a range of rules, select the first rule's checkbox, then **`Shift+click`** the last rule's checkbox; all rules in between are also selected.

- (When viewed from the access control policy.) You can do these actions with individual rules:
  - Edit the rule by clicking **Edit** from the **More** ( ) menu.
  - Delete the rule from the policy by clicking **Delete** from the **More** ( ) menu.
  - Enable or disable the rule by clicking **Enable Rule** or **Disable Rule** from the **More** ( ) menu.
  - Clear the hit count (reset it to zero) for the rule by clicking **Clear Hit Count** from the **More** ( ) menu. You cannot undo this action.
- (When viewed from the access control policy.) You can do these actions with individual rules:
  - Edit the rule by clicking **Edit** ( ).

- Delete the rule from the policy by clicking **Delete** ( ).
- Enable or disable the rule by clicking the **Slider** ( ).
- Clear the hit count (reset it to zero) for the rule by clicking the **X** for the rule. You cannot undo this action.

- Change the displayed columns by clicking and selecting the columns to show. When viewed from the prefilter policy, use the **Cog** ( ) to select the columns to display.
- (When viewed from the prefilter policy.) Click on a rule name to edit it, or click **View** ( ) in the last column to view the rule details. Clicking on the rule name highlights it in the policy page where you can edit it.
- (When viewed from the prefilter policy.) Clear the hit count information (reset it to zero) for a rule by right-clicking the rule and selecting **Clear Hit Count**. You can select multiple rules by using Ctrl+click. You cannot undo this action.

Step 5 Optionally, you can generate a comma-separated values report of the details on the page by clicking **Generate CSV** on the bottom-left of the page.

Step 6 Click **Close** to return to the policy page.

Analyzing rule conflicts and warnings

View warnings and information about rule conflicts to examine the logic of your access control policy and to identify rules that need changes.

Note The feature described in this topic is available only if you do not integrate with the Cisco Security Clound. When you integrate with the cloud, the more powerful Policy Analyzer & Optimizer replaces this feature. See Identify and fix anomalies with policy analyzer & optimizer, on page 2017.

When rules overlap, you can end up with unnecessary rules in the policy, and these rules will never be matched to traffic. The analysis can help you delete unnecessary rules, or identify rules that should be moved or modified so they enforce the desired policy.

Policy warnings and errors point out things that you should understand and perhaps address to ensure that your rules provide the desired services.

Rule conflict analysis identifies these problems:

- Object overlap—An element in a field of a rule is a subset of one or more elements in the same field of the rule. For example, the source field might include a network object for 10.1.1.0/24, and another object for the host 10.1.1.1. Because 10.1.1.1 is within the network covered by 10.1.1.0/24, the object for 10.1.1.1 is redundant and can be deleted, simplifying the rule and saving device memory.
- Redundant rule—Two rules apply the same action to the same type of traffic and removing the base rule would not change the ultimate result. For example, if a rule permitting FTP traffic for a particular network

were followed by a rule allowing IP traffic for that same network, and there were no rules in between denying access, then the first rule is redundant and you can delete it.

- Shadowed rule—This is the reverse of a redundant rule. In this case, one rule will match the same traffic as another rule such that the second rule will never be applied to any traffic because it comes later in the access list. If the action for both rules is the same, you can delete the shadowed rule. If the two rules specify different actions for traffic, you might need to move the shadowed rule or edit one of the two rules to implement your desired policy. For example, the base rule might deny IP traffic, and the shadowed rule might permit FTP traffic, for a given source or destination.

Before you begin

When doing the analysis:

- Only the first conflict for a given rule is identified. Once you fix the problem, the rule might be identified as having a conflict with another rule in the table. However, a rule might have multiple warnings or errors.
- Rule conflict analysis considers source/destination security zone, network, VLAN, and service/port match conditions and action only. It does not consider other match criteria, so an apparently redundant rule might not be completely redundant.
- FQDN network objects cannot be analyzed for conflict, because the IP address of an FQDN cannot be known prior to DNS lookup.
- Disabled rules are ignored.
- Time range attributes are ignored. Rules for different time periods might be marked as redundant when they are not actually redundant for the time ranges.
- Icons for warnings and errors, and rule conflicts when you enable the feature, are shown in the rules table. For a reference to the icons, see Rule and other policy warnings, on page 2001.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** and edit an access control policy.

Step 2 Do one of these to open the rule conflicts and warnings dialog box:

- To view rule conflicts, click the **Analyze** drop-down and click **Show Rule Conflicts** from the menu.

  You must re-enable rule conflict detection each time you open the policy or make a change and save the policy.

- To view rule warnings and errors, click **Analyze** > **Show Rule Warnings and Errors**.

  After you make a change to the policy, you can refresh the results by clicking **Re-Analyze** next to the **Analyze** button.

- To view policy warnings, click **Analyze** > **Show Policy Warnings**.

Step 3 In the rule conflicts and warnings dialog box:

- Rule warnings and errors are shown on a separate tab from rule conflicts. There is also a separate tab for policy warnings.

- Each tab contains sub-tabs to let you examine individual types of problems, such as redundant vs. shadowed or warnings vs. errors. You can also search for an item.
- **More** (⋮) next to each rule name provides shortcuts to edit, disable, or delete the rule.

Step 4 Click **Close** when finished.

Search for rules

Use search to help you find rules, especially when you have a large number of them.

Procedure

Step 1 When editing an access control policy, build the search string by clicking in the **Search** box.

- For a simple text string search, type the string. The search returns rules that have that string in any column. You cannot do a string search in conjunction with a tag search, such as combining a string search with a source networks search.
- To search on a specific column, start typing the name of the column until the system prompts you with the full name, such as Source Networks, or select the name from the list of searchable fields. When you select the search tag, you can then enter the search string for that tag. For example, **Source Networks 10.1.1.1**.
- When searching for IP addresses within the source/destination columns (but not as a simple text search), you can use the **Seach Inside Subnets and Ranges** option to control whether you eactly match the IP address (unchecked) or match any subnet or range that includes the searched address (checked). For example, with the option checked, searching for 10.1.1.1 will include rules for 10.1.1.0/24.
- Searches in the port field return exact match only.
- When entering mulitple values, separate the values with commas.
- When building a search string with multiple tags, do not include spaces between the tags.
- When you select a tag, you are prompted with values that appear in those columns. Select the values you want to search for.
- You can quickly filter based on some common features by clicking the filter icon to the left of the search box and selecting to show rules with any combination of the following: Allow, Block, Monitor, Intrusion Policy, Time Range, expired rules, , rules that include objects whose definitions overlap..
- To see the rules that apply to a specific device or set of devices, click the filter icon and select the devices. Rules apply to a device if they use security zones that contain at least one interface on the device, or if they do not include security zones.

Step 2 With your cursor at the end of the search string in the search box, press Enter.

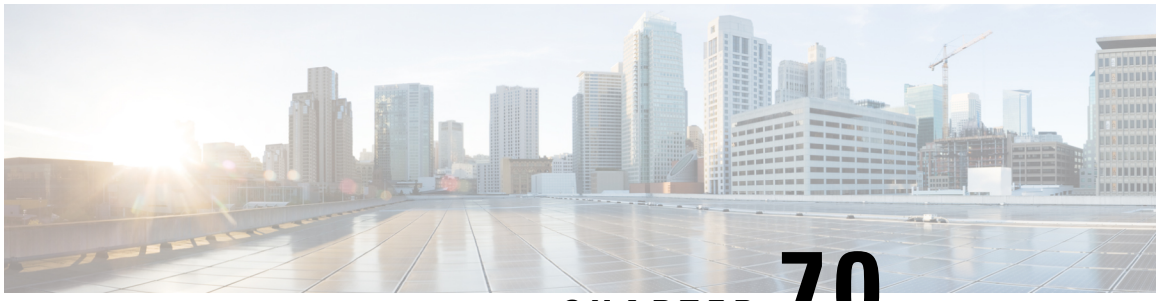
The rules that satisfy the search string are highlighted and non-matching rules are hidden. You can deselect **Show Only Matching Rules** to see the entire table, with the highlighted rules within the table. This lets you see the surrounding rules.

Beside the Show Only Matching Rules checkbox is a summary of the total number of rules in the policy compared to the number that match the search string.

Step 3 After your first search, clicking in the search box prompts you with recent searches and tags. You can quickly repeat a search by selecting it, or build similar searches by selecting previous searches or tags and building on them.

Step 4 To close the search and return to the unfiltered and unhighlighted table, click the **X** at the right of the search box. You can also put your cursor at the end of the search string and press the Esc key.

History for access control policies



This history table provides a comprehensive history of feature changes for access control policies in Cisco Secure Firewall Management Center across releases.

Table 117: Access control policy feature history by release

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Simultaneous editing of access control policies by multiple users.	10.0.0	Any	In previous releases, if two or more users simultaneously edited an access control policy, the first user who saved would retain their changes, and all other users would immediately lose all of their edits. Now, these users have the ability to selectively merge their changes, and changes that do not conflict with the first user's saved changes will automatically be accepted. This improves collaboration between users and reduces the need to lock the policy during edits.
Object group search performance enhancements.	7.6.0	7.6.0	Object group search is now faster and uses fewer CPU resources. New CLI commands: **clear asp table network-object**, **show asp table network-object**, **debug acl ogs** Modified CLI comments (enhanced output): , **packet-tracer**, **show access-list**, **show object-group** See: Device Settings and *Cisco Secure Firewall Threat Defense Command Reference*

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Granular permissions for modifying access control policies and rules.	7.4.0	Any	You can define custom user roles to differentiate between the intrusion configuration in access control policies and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. When defining user roles, you can select the **Policies** > **Access Control** > **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** option to allow the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. You can use the **Modify Remaining Access Control Policy Configuration** to control the ability to edit all other aspects of the policy. The existing pre-defined user roles that included the Modify Access Control Policy permission continue to support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.
New access control policy user interface and rule conflict analysis.	7.3.0	Any	The access control policy user interface introduced in 7.2 is now the default interface. You can also enable rule conflict analysis to help identify redundant rules and objects, and shadowed rules that cannot be matched due to previous rules in the policy.
Access control policy locking.	7.2.0	Any	You can lock an access control policy to prevent other administrators from editing it. Locking the policy ensures that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes. Any user who has permission to modify the access control policy has permission to lock it. We added an icon to lock or unlock a policy next to the policy name while editing the policy. In addition, there is a new permission to allow users to unlock policies locked by other administrators: Override Access Control Policy Lock. This permission is enabled by default in the Administrator, Access Admin, and Network Admin roles.
Rule hit counts persist over reboot.	7.2.0	Any	Rebooting a managed device no longer resets access control rule hit counts to zero. Hit counts are reset only if you actively clear the counters. In addition, counts are maintained by each unit in an HA pair or cluster separately. You can use the **show rule hits** command to see cumulative counters across the HA pair or cluster, or see the counts per node. We modified the device CLI command: **show rule hits**.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Usability improvements for the access control policy.	7.2.0	Any	There is a new user interface available for the access control policy. You can continue to use the legacy user interface, or you can try out the new user interface. The new interface has both a table and a grid view for the rules list, the ability to show or hide columns, enhanced search, infinite scroll, a clearer view of the packet flow related to policies associated with the access control policy, and a simplified add/edit dialog box for creating rules. You can freely switch back and forth between the legacy and new user interfaces while editing an access control policy.
DNS filtering	7.0.0 6.7.0 (experimental)	Any	If URL filtering is enabled and configured, a new option to enhance category and reputation filtering efficacy is enabled by default for each new access control policy. For more information, see DNS filtering, on page 2099 and subtopics. The Advanced tab of access control policy has a new option under General Settings: **Enable reputation enforcement on DNS traffic**.
TLS server identity discovery	6.7.0	Any	Enable access control policies to evaluate URL and application conditions when a client connects to a TLS 1.3-enabled server. TLS server identity discovery enables these conditions to be evaluated without decrypting traffic. Enabling this feature can impact device performance, depending on model. The Advanced tab page of access control policy has new options: • Warning is displayed on the Advanced tab; moving the slider to the right enables TLS server identity discovery. • New option on the Advanced tab page: **TLS Server Identity Discovery**.
New Security Intelligence categories	—	Any	These categories were introduced at about the time of the 6.6 release, but are not specific to 6.6: • banking_fraud • high_risk • ioc • link_sharing • malicious • newly_seen • spyware

CHAPTER 70

Security Intelligence

The following topics provide an overview of Security Intelligence, including use of lists for blocking and allowing traffic and basic configuration.

- Security intelligence, on page 2027
- License requirements for security intelligence, on page 2028
- Requirements and prerequisites for security intelligence, on page 2028
- Best practices for security intelligence, on page 2028
- Guidelines and limitations for security intelligence, on page 2029
- Security intelligence sources, on page 2029
- Configure security intelligence, on page 2030
- Security intelligence monitoring, on page 2037
- Override security intelligence blocking, on page 2038
- Troubleshooting security intelligence, on page 2039

Security intelligence

Security Intelligence is an early line of defense mechanism that

- uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domain names
- operates as the first phase of access control, before the system performs more resource-intensive evaluation, and
- improves performance by quickly excluding traffic that does not require inspection through Security Intelligence block listing.

Security intelligence features and limitations

Security Intelligence provides access to regularly updated intelligence feeds from Cisco. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations.

You can refine Security Intelligence Block listing with Do Not Block lists and monitor-only Block lists. These mechanisms exempt traffic from being blocked by a Block list, but do **not** automatically trust or fastpath matching traffic. Traffic added to a Do Not Block list or monitored at the Security Intelligence stage is intentionally subject to further analysis with the rest of access control.

Note You cannot use a Block list to block fastpathed traffic. Prefilter evaluation occurs before Security Intelligence filtering. Fastpathed traffic bypasses all further evaluation, including Security Intelligence.

Important You must apply the Network Discovery policy on the device for a successful application of the SI policy.

Best practices for security intelligence

Configure your access control policies to block threats detected by Cisco-provided Security Intelligence feeds. See Configuration example: Security intelligence blocking, on page 2036.

If you want to supplement the Cisco-provided Security Intelligence feeds with custom threat data, or manually block emerging threats:

- For IP addresses, use custom Security Intelligence lists and feeds, or Network objects. To create these, see Security intelligence, on page 3021 and Networks, on page 2982, and their subtopics. To use them for Security Intelligence, see Configure security intelligence, on page 2030. Network objects used in Security Intelligence policy require an IPS license.
- For URLs and domains, use custom Security Intelligence lists and feeds, *not* objects or groups. See details at Manual URL filtering options, on page 2102.
- You can also add entries to a Block list from events. See Global and domain security intelligence lists, on page 3023.

To test new feeds, or for passive deployments, set the action from block to monitor only. See Security intelligence monitoring, on page 2037.

If you need to exclude specific sites or addresses from Security Intelligence blocking, see Override security intelligence blocking, on page 2038.

If your Firepower deployment is integrated with Cisco XDR and you use custom Security Intelligence lists and feeds, be sure to update Security Services Exchange with these lists and feeds. For details, see instructions for configuring auto-promotion of events in the Security Services Exchange online help.

System-provided Security Intelligence categories may change over time and without notification; you should plan to check periodically for changes, and modify your policies accordingly.

You should also configure URL filtering, a separate feature with separate licensing requirements, for further protection against malicious sites. See URL Filtering Rules, on page 2085.

To reduce latency and CPU overhead, avoid referencing a single, massive SI feed object across your entire security policy. Instead, utilize customized objects to create smaller, targeted subsets of your intelligence data.

Using URL/Domain feeds instead of IP blocklists can reduce CPU overhead because domain filtering is generally more efficient and less resource-intensive than managing massive IP blocklists.

Excluding trusted IPs by adding known good or essential partner IP addresses to an "Do Not Block" list in Security Intelligence (SI) feeds helps reduce CPU overhead as the firewall or security device bypasses unnecessary scanning and deeper inspection for these IPs.

Guidelines and limitations for security intelligence

Be aware of these limitations when configuring and using Security Intelligence:

- The Security Intelligence configuration that includes detection signatures or malware URLs might lead to false threat alerts when the Firewall Threat Defense troubleshoot files are scanned.
- If a TCP connection attempt is initiated from an IP address that is blocked due to its poor reputation, a TCP reset (RST) packet is sent. This causes the connection to be terminated instantly, preventing the establishment of the TCP session and signalling the rejection to the sender.

Security intelligence sources

Security Intelligence sources are data providers that

- supply regularly updated intelligence feeds for domains, URLs and IP addresses

- enable custom blocking and allow lists for specific sites or addresses, and
- provide global lists for immediate event-based blocking and allowing.

Types of security intelligence sources

Security Intelligence uses these source types:

- **System-provided feeds**: Cisco provides access to regularly updated intelligence feeds for domains, URLs and IP addresses. For more information, see Security intelligence, on page 3021.
- **Third-party feeds**: Optionally, supplement Cisco-provided feeds with third-party reputation feeds, which are dynamic lists that the Cloud-Delivered Firewall Management Center downloads from the internet on a regular basis. See Custom security intelligence feeds, on page 3029.
- **Custom Block lists or feeds (or objects)**: Block specific IP addresses, URLs, or domain names using a manually-created list or feed (for IP addresses, you can also use network objects.)

  For example, if you become aware of malicious sites or addresses that are not yet blocked by a feed, add these sites to a custom Security Intelligence list and add this custom list to the Block list in the Security Intelligence tab of your access control policy, as described in Custom Security Intelligence lists, on page 3031 and Configure security intelligence, on page 2030.

  For IP addresses, you can optionally use network objects rather than lists or feeds for this purpose; for information, see Networks, on page 2982. (For URLs, using lists and feeds is strongly recommended over other methods.)
- **Custom Do Not Block lists or feeds**: Override Security Intelligence blocking for specific sites or addresses. See Override security intelligence blocking, on page 2038.
- **Global Block lists (one each for Network, URL and DNS)**: While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Block List so that Security Intelligence will handle future traffic from that source. See Global and domain security intelligence lists, on page 3023.
- **Global Do Not Block lists (one each for Network, URL and DNS)**: While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Do Not Block List if you do not want Security Intelligence to block future traffic from that source. See Global and domain security intelligence lists, on page 3023.

Configure security intelligence

Configure Security Intelligence filtering to automatically block or monitor traffic based on threat intelligence feeds and custom block or allow lists. This provides an additional layer of security by filtering known malicious IP addresses, URLs, and domains before they reach your network resources.

Each access control policy has Security Intelligence options. You can add network objects, URL objects and lists, and Security Intelligence feeds and lists to a Block list or Do Not Block list, and constrain any of these by security zone. You can also associate a DNS policy with your access control policy, and add domain names to a Block or Do Not Block list.

The number of objects in the Do Not Block lists plus the number in the Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

Before you begin

- Tip: For guidance on minimum configuration recommendations, see also Configuration example: Security intelligence blocking, on page 2036.
- To ensure that ALL options are available to select, add at least one managed device to your management center.
- In passive deployments, or if you want to set Security Intelligence filtering to monitor-only, enable logging
- Configure a DNS policy to take Security Intelligence action for domains. For more information, see DNS Policies for Security Intelligence, on page 2557.

Follow these steps to configure Security Intelligence filtering in an access control policy:

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Choose the type of objects to configure.

- Click **Networks** to add network objects (IP addresses).

  Note
  Network objects used in a Security Intelligence policy require a IPS license.

- Click **URLs** to add URL objects.

Step 3 Find the **Available Objects** you want to add to the Block or Do Not Block list.

- Search the available objects by typing in the **Search by name or value** field. Clear the search string by clicking **Reload** ( ) or **Clear** ( ).
- If no existing list or feed meets your needs, click **Add** ( ), select **New Network List** or **New URL List**, and proceed as described in Create custom security intelligence feeds, on page 3030 or Upload new custom security intelligence lists to the Cloud-Delivered Firewall Management Center, on page 3032.
- If no existing object meets your needs, click **Add** ( ), select **New Network Object** or **New URL Object**, and proceed as described in Create a network object, on page 2985.

Security Intelligence ignores IP address blocks using a `/0` netmask.

Step 4 Choose one or more **Available Objects** to add.

Step 5 (Optional) Choose an **Available Zone** to constrain the selected objects by zone.

You cannot constrain system-provided Security Intelligence lists by zone.

Note

The **Any** zone for an SI list applies only to interfaces that are part of a security zone. However, an exception is that if a device does not have any interfaces associated with a security zone, then the **Any** zone will match any interface.

For example, if you have five interfaces on a device and none of them are associated with a security zone, any SI list that is assigned to the **Any** zone will be inspected against traffic on ALL interfaces on the device. If you add one interface to a security zone on that device, it effectively would remove SI inspection on the other four interfaces, where the zone is set to **Any** for an SI list. If you add the other four interfaces to a security zone, they will be evaluated by the SI list attached to the **Any** zone.

Step 6 Click **Add to Do Not Block list** or **Add to Block list**, or click and drag the selected objects to either list.

To remove an object from a Block or Do Not Block list, click **Delete** ( ) To remove multiple objects, choose the objects and right-click to **Delete Selected**.

Step 7 (Optional) Set objects on the Block list to monitor-only by right-clicking the object under **Block List**, then choosing **Monitor-only (do not block)**.

You cannot set system-provided global Security Intelligence lists to monitor only.

Step 8 Choose a DNS policy from the **DNS Policy** drop-down list.

Step 9 Click **Save**.

Security Intelligence filtering is now configured for your access control policy. The system will automatically block or monitor traffic based on the configured Block and Do Not Block lists, providing enhanced protection against known threats.

What to do next

- Deploy configuration changes.

Related Topics

Security intelligence, on page 3021
Snort restart scenarios, on page 194

Security intelligence options

Use the Security Intelligence tab in the access control policy editor to configure network (IP address) and URL Security Intelligence, and to associate the access control policy with a DNS policy in which you have configured Security Intelligence for domains.

Available objects

Available objects include:

- Security Intelligence categories populated by the system-provided feed.

  For details, see Security intelligence categories, on page 2034.

- System-provided Global Block and Do Not Block lists.

  For descriptions, see Security intelligence sources, on page 2029.

- Security Intelligence lists and feeds that you create under Object > Object Management > Security Intelligence.

  For descriptions, see Security intelligence sources, on page 2029.

- Network and URL objects that are configured on the respective pages under Object > Object Management. These are different from the Security Intelligence objects in the previous bullet.

  For details about network objects, see Networks, on page 2982. (For URLs, use Security Intelligence lists or feeds rather than objects.)

  Note that range and group network object types are not supported in Security Intelligence policy.

Available zones

Except for the system-provided Global lists, you can constrain Security Intelligence filtering by zone.

For example, to improve performance, you might want to target enforcement to specific zones rather than all interfaces. As a more specific example, you can block spam only for a security zone that handles email traffic.

To enforce Security Intelligence filtering for an object on multiple zones, you must add the object to the Block or Do Not Block list separately for each zone.

Note that range and group network object types are not supported in Security Intelligence policy.

DNS policy

In order to match DNS traffic using Security Intelligence, you must select a DNS policy for your Security Intelligence configuration.

Using Block or Do Not Block lists, or monitoring traffic based on a DNS list or feed, also requires that you:

- Configure DNS Security Intelligence lists and feeds. See Security intelligence, on page 3021.
- Create a DNS policy. See Create basic DNS policies, on page 2561 for more information.
- Configure DNS rules that reference your DNS lists or feeds. See Create and edit DNS rules, on page 2563 for more information.
- Because you deploy the DNS policy as part of your access control policy, you must associate both policies. See Requirement: deploy DNS policy configuration changes, on page 2575 for more information.

Do not block list

See Override security intelligence blocking, on page 2038.

To select all objects in the list, right-click an object.

Block list

See Configuration example: Security intelligence blocking, on page 2036 and other topics in this chapter.

For explanations of the visual indicators in the Block list, see Block list icons, on page 2036.

To select all objects in the list, right-click an object.

Logging

Security Intelligence logging, enabled by default, logs all blocked and monitored connections handled by an access control policy's assigned devices. However, the system does not log Do Not Block list matches; logging of connections on the Do Not Block list depends on their eventual disposition. Logging must be enabled for connections on the Block list before you can set objects on that list to monitor-only.

To enable, disable, or view logging settings, right-click an object in the Block list.

Related Topics

Global and domain security intelligence lists, on page 3023
Security intelligence lists and multitenancy, on page 3024

Security intelligence categories

Security Intelligence categories are determined by the system-provided feeds described in Security intelligence, on page 3021.

These categories are used in the following locations:

- The Networks sub-tab on the Security Intelligence tab of an access control policy
- The URLs sub-tab beside the Networks tab on the Security Intelligence tab of an access control policy
- In a DNS policy on the DNS tab in the DNS rule configuration page
- In events generated when traffic matches Block or Monitor configurations in the above locations

Note If your organization is using Secure Firewall Threat Intelligence Director: When viewing events, you may see categories that indicate that the action was taken by TID, such as `TID URL Block`.

Categories are updated by Talos from the cloud, and this list may change independently of Firepower releases.

Table 118:

Security Intelligence Category	Description
Attackers	Active scanners and hosts known for outbound malicious activity
Banking_fraud	Sites that engage in fraudulent activities that relate to electronic banking
Bogon	Bogon networks and unallocated IP addresses
Bots	Sites that host binary malware droppers
CnC	Sites that host command-and-control servers for botnets
Cryptomining	Hosts providing remote access to pools and wallets for the purpose of mining cryptocurrency

Security Intelligence Category	Description
Dga	Malware algorithms used to generate a large number of domain names acting as rendezvous points with their command-and-control servers
Exploitkit	Software kits designed to identify software vulnerabilities in clients
High_risk	Domains and hostnames that match against the OpenDNS predictive security algorithms from security graph
Ioc	Hosts that have been observed to engage in Indicators of Compromise (IOC)
Link_sharing	Websites that share copyrighted files without permission
Malicious	Sites exhibiting malicious behavior that do not necessarily fit into another, more granular, threat category
Malware	Sites that host malware binaries or exploit kits
Newly_seen	Domains that have recently been registered, or not yet seen via telemetry. **Attention** Currently, this category does not have any active feed and is reserved for future use.
Open_proxy	Open proxies that allow anonymous web browsing
Open_relay	Open mail relays that are known to be used for spam
Phishing	Sites that host phishing pages
Response	IP addresses and URLs that are actively participating in malicious or suspicious activity
Spam	Mail hosts that are known for sending spam
Spyware	Sites that are known to contain, serve, or support spyware and adware activities
Suspicious	Files that appear to be suspicious and have characteristics that resemble known malware
Tor_exit_node	Hosts known to offer exit node services for the Tor Anonymizer network

Block list icons

The visual indicators may appear in the Block list on the Security Intelligence tab in an access control policy.

Icon or Visual Indicator	Description
Block ( )	The object is set to block.
Monitor ( )	The object is set to monitor-only. See Security intelligence monitoring, on page 2037
An object is displayed in strikethrough text	The same object is also on the Do Not Block list, which overrides the block.

Configuration example: Security intelligence blocking

Configure Security Intelligence blocking to protect your network from known malicious IP addresses, URLs, and domains using regularly updated threat intelligence feeds.

Configure your access control policy to block all threats detectable by the system's regularly updated Security Intelligence feeds.

The number of objects in the Block lists plus the number in the Do Not Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

Before you begin

- To ensure that all options are available to select, add at least one managed device to your management center.
- Configure a DNS policy to block all Security Intelligence threat categories for domains. For more information, see DNS Policies for Security Intelligence, on page 2557.
- If you have, or will have, custom lists of entities to block, create a Security Intelligence object of each type (URLs, DNS, Networks.) See Security intelligence, on page 3021.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control**.

Step 2 Create a new access control policy or edit an existing policy.

Step 3 In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Click **Networks** to add blocking criteria for IP addresses.

a) Scroll down in the Networks list and select all of the threat categories listed below the Global lists.
b) If applicable, select the security zones for which you want to block these threats.
c) Click **Add to Block List**.

d) If you have created custom lists or feeds with addresses to block, add those to the Block List using the same steps as above.

Step 5 Click **URLs** to add blocking criteria for URLs, and repeat the steps you followed for Networks.

Step 6 Choose a DNS policy from the **DNS Policy** drop-down list; see DNS policies, on page 2557.

Step 7 Click **Save**.

Your access control policy now blocks malicious IP addresses, URLs, and domains based on Security Intelligence threat feeds, providing enhanced protection against known threats.

What to do next

- Enable logging for these connections
- Deploy configuration changes.
- For additional protection, configure URL filtering to block malicious URLs. See URL Filtering Rules, on page 2085.

Security intelligence monitoring

Security Intelligence monitoring is a security feature that

- logs connection events for traffic that would have been blocked by Security Intelligence, but does not block the traffic,
- enables testing of feeds before implementation, and
- optimizes performance in passive deployments.

Use cases for security intelligence monitoring

Monitoring is especially useful for:

- Testing feeds before you implement them.

  Consider a scenario where you want to test a third-party feed before you implement blocking using that feed. When you set the feed to monitor-only, the system allows connections that would have been blocked to be further analyzed by the system, but also logs a record of each of those connections for your evaluation.

- Passive deployments, to optimize performance.

  Managed devices that are deployed passively cannot affect traffic flow; there is no advantage to configuring the system to block traffic. Additionally, because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Note If configured, Secure Firewall Threat Intelligence Director may impact the action taken (Monitor or Block.)

To configure Security Intelligence monitoring:

After you configure Security Intelligence blocking following the instructions in Configuration example: Security intelligence blocking, on page 2036, right-click each applicable object in the Block list and choose **Monitor-only**. You cannot set system-provided Security Intelligence lists to monitor only.

Override security intelligence blocking

Use Do Not Block lists to exempt specific domains, URLs, or IP addresses from being blocked by Security Intelligence lists or feeds.

You can use Do Not Block lists for various purposes:

- Override the occasional false-positive block in a reputable Security Intelligence feed
- Inspect specific traffic in depth instead of blocking it early based on reputation
- Exempt otherwise-restricted transactions based on zone from Security Intelligence blocking

  For example, you can add an improperly classified URL to a Do Not Block list, but then restrict the Do Not Block list object using a security zone used by those in your organization who need to access those URLs. That way, only those with a business need can access the URLs on the Do Not Block list.

Note Entries on a Do Not Block list are simply exemptions from the block list. Any connection that passes the Security Intelligence policy is subject to the access control rules. Thus, an entry in the Do Not Block list can subsequently be blocked by an access control rule or intrusion policy. Your Do Not Block entries should always be exemptions from your block lists.

Procedure

Step 1 Option 1: Add an IP address, URL, or domain from an event to the Global Do Not Block List. See Global and domain security intelligence lists, on page 3023.

Step 2 Option 2: Use a custom Security Intelligence list or feed.

a) Create the custom Security Intelligence list or feed. See Custom Security Intelligence lists, on page 3031 or Create custom security intelligence feeds, on page 3030.

b) For IP addresses (Networks) and URLs: Edit your access control policy, click the Security Intelligence tab, then click the custom list or feed in the Networks or URLs sub-tab, then click **Add to Do Not Block List**.

c) Save your changes.

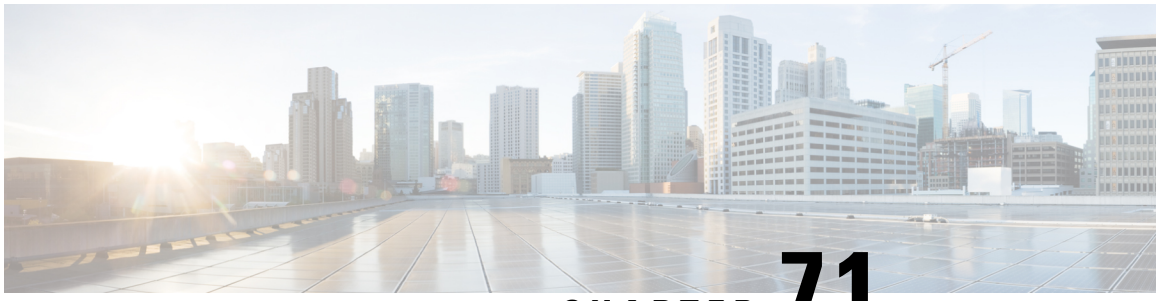
d) For domains (DNS): See the "DNS Policy" section in the Security intelligence options, on page 2032 topic.

e) Deploy your changes.

The specified domains, URLs, or IP addresses are now exempted from Security Intelligence blocking and will be subject to access control rules instead.

Troubleshooting security intelligence

See the following topics for troubleshooting Security Intelligence.



Security intelligence categories missing from the Available Options List

Security Intelligence categories (such as CnC or Exploitkit) display in the Networks tab under Available Options only after you add at least one managed device to your management center.

You must add a device in order to pull all TALOS feeds that provide the Security Intelligence categories.

If the expected category does not appear in Security Intelligence, verify that it is not a URL filtering category, which uses a different set of categories.

To see URL filtering categories, look at the **URLs** tab in an access control rule.

CHAPTER 71

Access Control Rules

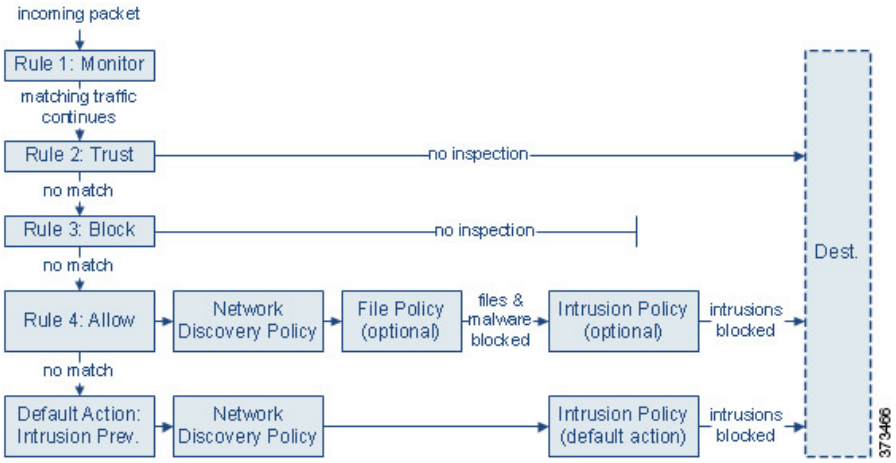
The following topics describe how to configure access control rules.

- Access control rules, on page 2041
- Requirements and prerequisites for access control rules, on page 2052
- Guidelines and limitations for access control rules, on page 2053
- Best practices for application control, on page 2054
- Best practices for access control rules, on page 2058
- Access control rule management, on page 2062
- Examples for access control rules, on page 2080

Access control rules

Within an access control policy, access control rules provide a granular method that

- handles network traffic across multiple managed devices within an access control policy
- provides conditions that match traffic in a specified order, and
- determines actions to monitor, trust, block, or allow matching traffic.



Rule evaluation and traffic handling

The system matches traffic to access control rules in the order you specify. In most cases, the system handles network traffic according to the first access control rule where all the rule's conditions match the traffic.

Each rule also has an action, which determines whether you monitor, trust, block, or allow matching traffic. When you allow traffic, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Note Security Intelligence filtering, decryption, user identification, and some decoding and preprocessing occur before access control rules evaluate network traffic.

This scenario summarizes the ways that traffic can be evaluated by access control rules in an inline, intrusion prevention deployment.

In this scenario, traffic is evaluated as follows:

- **Rule 1: Monitor** evaluates traffic first. Monitor rules track and log network traffic. The system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at Access control rule monitor action, on page 2046.)
- **Rule 2: Trust** evaluates traffic next. Matching traffic is allowed to pass to its destination without further inspection, though it is still subject to identity requirements and rate limiting. Traffic that does not match continues to the next rule.
- **Rule 3: Block** evaluates traffic third. Matching traffic is blocked without further inspection. Traffic that does not match continues to the final rule.
- **Rule 4: Allow** is the final rule. For this rule, matching traffic is allowed; however, prohibited files, malware, intrusions, and exploits within that traffic are detected and blocked. Remaining non-prohibited, non-malicious traffic is allowed to its destination, though it is still subject to identity requirements and rate limiting. You can configure Allow rules that perform only file inspection, or only intrusion inspection, or neither.
- **Default Action** handles all traffic that does not match any of the rules. In this scenario, the default action performs intrusion prevention before allowing non-malicious traffic to pass. In a different deployment, you might have a default action that trusts or blocks all traffic, without further inspection. (You cannot perform file or malware inspection on traffic handled by the default action.)

Traffic you allow, whether with an access control rule or the default action, is automatically eligible for inspection for host, application, and user data by the network discovery policy. You do not explicitly enable discovery, although you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

Note that access control rules handle encrypted traffic when your decryption configuration allows it to pass, or if you do not configure decryption. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Access control rule management

The rules table of the access control policy editor allows you to add, edit, categorize, search, filter, move, enable, disable, delete, and otherwise manage access control rules in the current policy.

Properly creating and ordering access control rules is a complex task, but one that is essential to building an effective deployment. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations.

Use the search bar to filter the list of access control policy rules. You can deselect the **Show Only Matching Rules** option to see all rules. Matched rules are highlighted.

For each access control rule, the policy editor displays its name, a summary of its conditions, the rule action, and icons that communicate the rule's inspection options or status.

The system provides specific icons to communicate the inspection options or status of each rule:

- **Time Range Option** ( )
- **Intrusion policy** ( )
- **File policy** ( )
- **Logging** ( )
- **Warning** ( )
- **Errors** ( )
- **Rule Conflict** ( )

Disabled rules are dimmed and marked (disabled) after the rule name.

To create or edit a rule, refer to Create and edit access control rules, on page 2066 .

Tip A right-click menu provides shortcuts to many rule management options, including editing, deleting, moving, enabling, and disabling.

Access control rule components

In addition to its unique name, each access control rule has basic components that determine how the system processes and handles network traffic.

State

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Position

Rules in an access control policy are numbered, starting at 1. If you are using policy inheritance, rule 1 is the first rule in the outermost policy. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

Rules can also belong to a section and a category, which are organizational only and do not affect rule position. Rule position goes across sections and categories.

Section and category

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize access control rules, you can create custom rule categories inside the Mandatory and Default sections.

If you are using policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default sections.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can be simple or complex; their use often depends on license.

Traffic must meet all of the conditions specified in a rule. For example, if the Application condition specifies HTTP but not HTTPS, the URL category and reputation conditions will not apply to HTTPS traffic.

Applicable time

You can set rules to operate during specified days and times

Action

A rule's action determines how the system handles matching traffic. You can monitor, trust, block, or allow (with or without further inspection) matching traffic. The system does not perform deep inspection on trusted, blocked, or encrypted traffic.

Inspection

Deep inspection options govern how the system inspects and blocks malicious traffic you would otherwise allow. When you allow traffic with a rule, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

Logging

Logging settings govern records that the system keeps for handled traffic. You can log sessions at connection start, end, or both; log connections to databases, syslog, or SNMP trap servers. You can log connections to the database, as well as to a syslog or an SNMP trap server.

Comments

Each time you save changes to an access control rule, you can add comments.

Access control rule order

Access control rule order is a traffic processing method that

- numbers rules in an access control policy starting at 1
- matches traffic to access control rules in top-down order by ascending rule number, and
- handles network traffic according to the first access control rule where all the rule's conditions match the traffic.

In most cases, except for Monitor rules, the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule.

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize, you can create custom rule categories inside the Mandatory or Default sections. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

If you use policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default rule sections. Rule 1 is the first rule in the outermost policy, not the current policy, and the system assigns rule numbers across policies, sections, and categories.

Any predefined user role that allows you to modify access control policies also allows you to move and modify access control rules within and among rules categories. You can, however, create custom roles that restrict users from moving and modifying rules. Any user who is allowed to modify access control policies can add rules to custom categories and modify rules in them without restriction.

Caution Failure to set up your access control rules properly can have unexpected results, including traffic being allowed that should be blocked. In general, application control rules should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

Note Proper access control rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs. For more information, refer to Best practices for ordering rules, on page 2059.

Access control rule actions

An access control rule action is a configuration setting that determines how the system handles and logs matching traffic, with options to monitor, trust, block, or allow traffic with or without further inspection.

Default action behavior

The access control policy's *default action* handles traffic that does not meet the conditions of any access control rule with an action other than Monitor.

Access control rule monitor action

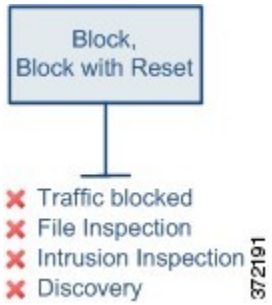
The **Monitor** action is an access control rule action that forces connection logging regardless of how matching traffic is eventually handled. It does not affect traffic flow by permitting or denying traffic immediately, and allows traffic to be matched against additional rules to determine the final action.

When a connection matches a monitor rule, the next non-monitor rule that the connection matches determines traffic handling and any further inspection. If there are no additional matching rules, the Firewall Threat Defense device uses the default action.

There is an exception: If a monitor rule contains layer 7 conditions, such as an application condition, the system allows early packets to pass and the connection to be established (or the SSL handshake to complete), even if a subsequent rule would block the connection. Early packets are not evaluated against subsequent rules, so to prevent uninspected traffic, you can specify an intrusion policy for these packets in the access control policy's advanced settings. For more information, refer to Inspection of packets that pass before traffic is identified, on page 2918. After the system completes its layer 7 identification, it applies the appropriate action to the remaining session traffic.

Access control rule trust action

The **Trust** action is the access control rule action that allows traffic to pass without deep inspection or network discovery, still subjects trusted traffic to identity requirements and rate limiting, and bypasses additional inspection services while maintaining basic security controls.



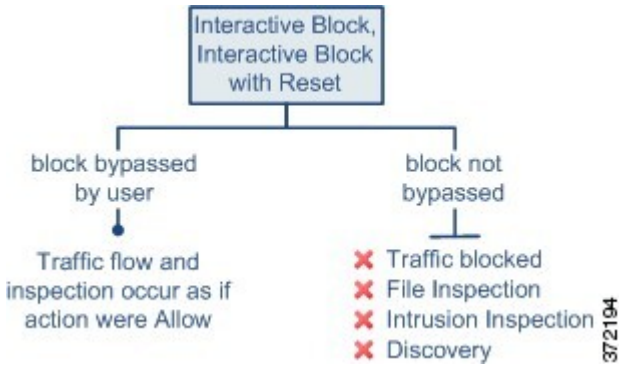
Note

- Some protocols, such as FTP and SIP, use secondary channels, which the system opens through the process of inspection. In some cases, trusted traffic can bypass all inspection, and these secondary channels cannot be opened properly. If you run into this problem, change the trust rule to **Allow**.
- For trust rules with logging options disabled, end-of-flow events are still generated in the system. However, the events are not visible on the event pages.
- Because access control rules are evaluated after other policies, such as decryption, trusting a connection does not necessarily mean it will be fast-pathed with no inspection. For example, if a connection matches both a decryption rule that requires decryption, and a trust access control rule, the connection is decrypted and inspected as needed, prior to being allowed by the trust rule. Trust simply means no additional inspection, such as intrusion inspection, will be applied. If your intention is to allow a connection uninspected, either use the prefilter policy to fast path the connection, or ensure that no other policy applies inspection services to the connection.

Access control rule blocking actions

A block action is an access control rule action that denies network traffic without further inspection and prevents the use of file, intrusion, or network discovery policies for blocked traffic.

Block and **Block with reset** actions immediately stop traffic from entering the network. Block with reset rules reset the connection except for web requests met with an HTTP response page. The HTTP response page is used to notify users when their web request is blocked, but it cannot be displayed if the connection is immediately reset.



For more information, refer to HTTP response pages, on page 2103.

Related Topics

HTTP response pages, on page 2103

Access control rule interactive blocking actions

The **Interactive Block** and **Interactive Block with reset** actions are access control rule actions that give web users a choice to continue to their intended destinations.

If a user bypasses the block, the rule mimics an allow rule. Therefore, you can associate interactive block rules with file and intrusion policies, and matching traffic is also eligible for network discovery.

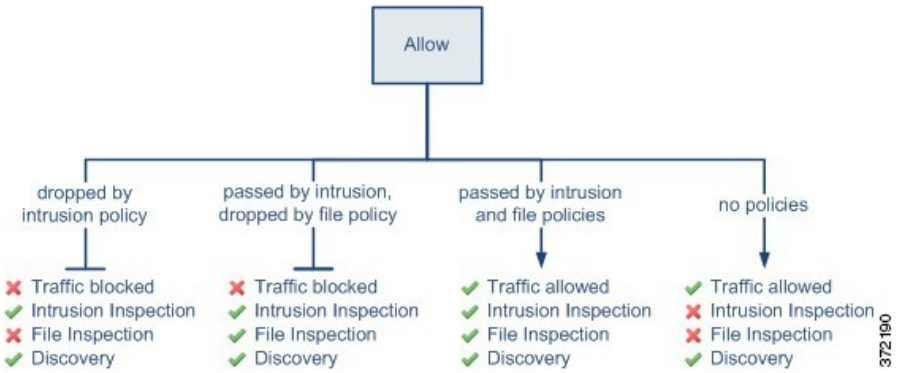
If a user does not (or cannot) bypass the block, the rule mimics a block rule. Matching traffic is denied without further inspection.

Note If you enable interactive blocking, you cannot reset all blocked connections. This is because the response page cannot display if the connection is immediately reset. Use the **Interactive Block with reset** action to (non-interactively) block-with-reset all non-web traffic, while still enabling interactive blocking for web requests.

For more information, refer to HTTP response pages, on page 2103.

Related Topics

Decryption rule blocking actions, on page 2222



Access control rule allow action

An access control rule allow action is a rule action that allows matching traffic to pass. However, traffic is still subject to identity requirements and rate limiting.

Optionally, you can use deep inspection to further inspect and block unencrypted or decrypted traffic before it reaches its destination:

- You can use an intrusion policy to analyze network traffic according to intrusion detection and prevention configurations, and drop offending packets depending on the configuration.
- You can perform file control using a file policy. File control allows you to detect and block your users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols.
- You can perform network-based advanced malware protection (AMP), also using a file policy. malware defense can inspect files for malware, and block detected malware depending on the configuration.

This diagram illustrates the types of inspection performed on traffic that meets the conditions of an Allow rule (or a user-bypassed Interactive Block rule). Notice that file inspection occurs before intrusion inspection; blocked files are not inspected for intrusion-related exploits.

For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with an access control rule. You can, however, configure one without the other. Without a file policy, traffic flow is determined by the intrusion policy; without an intrusion policy, traffic flow is determined by the file policy.

Regardless of whether the traffic is inspected or dropped by an intrusion or file policy, the system can inspect it using network discovery. However, permitting traffic does not guarantee that discovery inspection occurs. The system only performs discovery for connections involving IP addresses explicitly monitored by your network discovery policy. Also, application discovery is limited for encrypted sessions.

Deep inspection using file and intrusion policies

Deep inspection is a security mechanism that uses intrusion and file policies as the last line of defense before traffic is allowed to its destination.

Policy types and capabilities

Deep inspection uses two types of policies to analyze traffic:

- *Intrusion policies* govern the system's intrusion prevention capabilities.
- *File policies* govern the system's file control and malware defense capabilities.

Access control occurs before deep inspection; access control rules and the access control default action determine which traffic is inspected by intrusion and file policies.

By associating an intrusion or file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy, a file policy, or both.

In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.

Note By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

To associate intrusion and file policies with an access control rule, see:

- Access Control Rules: Intrusion Policy Selection
- Configure an access control rule to perform malware protection, on page 2592

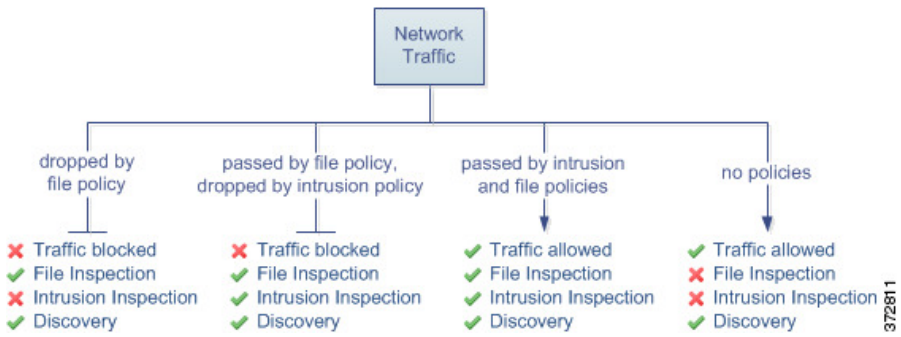
For more information about intrusion policies, refer to Network Analysis and Intrusion Policy Basics.

For more information about file policies, refer to File Policies for Network Malware Protection, on page 2583.

File and intrusion inspection order

File and intrusion inspection order defines the traffic processing sequence that performs file inspection before intrusion inspection for any single connection handled by an access control rule, preventing files blocked by a file policy from being inspected for intrusions while prioritizing simple file blocking by type over malware inspection.

For a connection matching an Allow or Interactive Block rule, the system determines traffic flow based on the following configurations:



- Without a file policy, traffic flow is determined by the intrusion policy.
- Without an intrusion policy, traffic flow is determined by the file policy.
- Without either, allowed traffic is inspected by network discovery only.

In your access control policy, you can associate multiple Allow and Interactive Block rules with different intrusion and file policies to match inspection profiles to various types of traffic.

Note The system does not perform any kind of inspection on trusted traffic. Although configuring an Allow rule with neither an intrusion nor file policy passes traffic like a Trust rule, Allow rules let you perform discovery on matching traffic.

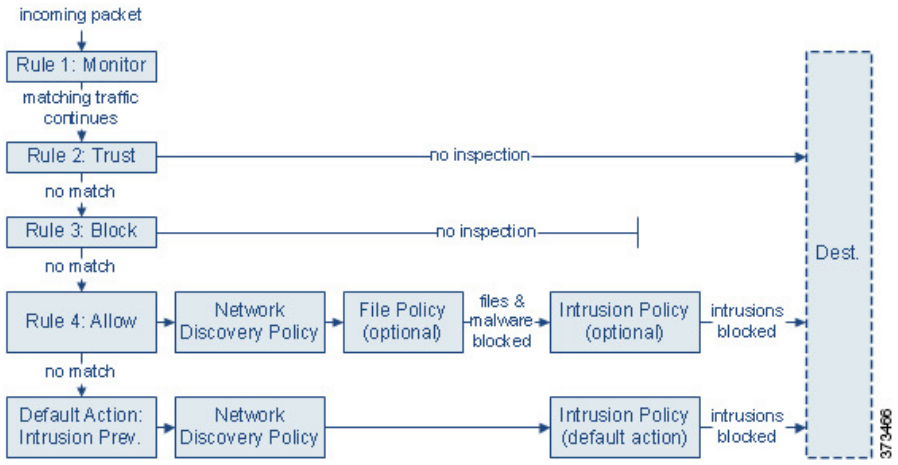
The diagram below illustrates the types of inspection you can perform on traffic that meets the conditions of either an Allow or user-bypassed Interactive Block access control rule. For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with a single access control rule.

Figure 385: Traffic inspection flowchart

For any single connection handled by an access control rule, file inspection occurs before intrusion inspection. That is, the system does not inspect files blocked by a file policy for intrusions. Within file inspection, simple blocking by type takes precedence over malware inspection and blocking.

For example, consider a scenario where you normally want to allow certain network traffic as defined in an access control rule. However, as a precaution, you want to block the download of executable files, examine downloaded PDFs for malware and block any instances you find, and perform intrusion inspection on the traffic.

You create an access control policy with a rule that matches the characteristics of the traffic you want to provisionally allow, and associate it with both an intrusion policy and a file policy. The file policy blocks the download of all executables, and also inspects and blocks PDFs containing malware:



- First, the system blocks the download of all executables, based on simple type matching specified in the file policy. Because they are immediately blocked, these files are subject to neither malware nor intrusion inspection.
- Next, the system performs malware cloud lookups for PDFs downloaded to a host on your network. Any PDFs with a malware disposition are blocked, and are not subject to intrusion inspection.
- Finally, the system uses the intrusion policy associated with the access control rule to inspect any remaining traffic, including files not blocked by the file policy.

Note Until a file is detected and blocked in a session, packets from the session might be subject to intrusion inspection.

How access control traffic handling works with intrusion and file policies

Summary

This diagram shows the flow of traffic in an inline intrusion prevention and malware defense deployment, as governed by an access control policy that contains four different types of access control rules and a default action.

Workflow

In the scenario above, the first three access control rules in the policy—Monitor, Trust, and Block—cannot inspect matching traffic. Monitor rules track and log but do not inspect network traffic, so the system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important

exception and caveat at Access control rule monitor action, on page 2046.) Trust and Block rules handle matching traffic without further inspection of any kind, while traffic that does not match continues to the next access control rule.

The fourth and final rule in the policy, an Allow rule, invokes various other policies to inspect and handle matching traffic, in the following order:

1. Discovery: Network Discovery Policy—First, the network discovery policy inspects traffic for discovery data. Discovery is passive analysis and does not affect the flow of traffic. Although you do not explicitly enable discovery, you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy.
2. malware defense and File Control: File Policy—After traffic is inspected by discovery, the system can inspect it for prohibited files and malware. malware defense detects and optionally blocks malware in many types of files, including PDFs, Microsoft Office documents, and others. If your organization wants to block not only the transmission of malware files, but all files of a specific type (regardless of whether the files contain malware), file control allows you to monitor network traffic for transmissions of specific file types, then either block or allow the file.
3. Intrusion Prevention: Intrusion Policy—After file inspection, the system can inspect traffic for intrusions and exploits. An intrusion policy examines decoded packets for attacks based on patterns, and can block or alter malicious traffic. Intrusion policies are paired with variable sets, which allow you to use named values to accurately reflect your network environment.
4. Destination—Traffic that passes all the checks described above passes to its destination.

An Interactive Block rule (not shown in the diagram) has the same inspection options as an Allow rule. This is so you can inspect traffic for malicious content when a user bypasses a blocked website by clicking through a warning page.

Traffic that does not match any access control rules in the policy with an action other than Monitor is handled by the default action. In this scenario, the default action is an Intrusion Prevention action, which allows traffic to its final destination as long as it is passed by the intrusion policy you specify. In a different deployment, you might have a default action that trusts or blocks all traffic without further inspection. Note that the system can inspect traffic allowed by the default action for discovery data and intrusions, but not prohibited files or malware. You cannot associate a file policy with the access control default action.

Note Sometimes, when a connection is analyzed by an access control policy, the system must process the first few packets in that connection, allowing them to pass, before it can decide which access control rule (if any) will handle the traffic. However, so these packets do not reach their destination uninspected, you can specify an intrusion policy (in the advanced settings for the access control policy) to inspect these packets and generate intrusion events.

Requirements and prerequisites for access control rules

Ensure that your deployment meets these requirements before you configure access control rules.

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.
  - **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Guidelines and limitations for access control rules

Consider these limitations when you configure rules in the access control policy:

- There is a limit of 1000 rules that can be shown at a time on the current page. Thus, if you have a very large number of rules, such as 3000 rules within a single category, actions like selecting all rules in a category and deleting them does not delete all of the rules. You might need to select/delete rules again to delete all the rules that you are targeting.
- If you edit an access control rule that is actively in use, the changes do not apply to established connections at deploy-time. The updated rule is used to match against future connections. However, if the system is actively inspecting a connection (for example, with an intrusion policy), it will apply changed matching or action criteria to existing connections.

  For Firewall Threat Defense, you can ensure that your changes apply to all current connections by using the Firewall Threat Defense **clear conn** CLI command to end established connections. Note that you should only do this if it is acceptable to end those connections, on the assumption that the sources for the connections will then attempt to reestablish the connection and thus be matched appropriately against the new rule.

- VLAN tags in access rules only apply to inline sets; they cannot be used in access rules applied to firewall interfaces.
- To use fully-qualified domain name (FQDN) network objects as source or destination criteria, you must also configure DNS for the data interfaces in the platform settings policy. The system does not use the management DNS server setting to do lookups for FQDN objects used in access control rules.

  Note that controlling access by FQDN is a best-effort mechanism. Consider the following points:

  - Whenever possible, use Security Intelligence or URL filtering instead of FQDN rules.
  - Because DNS replies can be spoofed, only use fully trusted DNS servers.
  - Some FQDNs, especially for very popular servers, can have hundreds if not thousands of IP addresses, and these can frequently change. Because the system uses cached DNS lookup results, users might get addresses that are not yet in the cache, and their connections will not match the FQDN rule. Rules that use FQDN network objects function effectively only for names that resolve to fewer than 100 addresses.

    We recommend that you do not create network object rules for an FQDN that resolves to more than 100 addresses, as the likelihood of the address in a connection being one that has been resolved and available in the DNS cache on the device is low. For these cases, use a URL-based rule instead of an FQDN network object rule.
  - For popular FQDNs, different DNS servers can return a different set of IP addresses. Thus, if your users use a different DNS server than the one you configure, FQDN-based access control rules might not apply to all IP addresses for the site that are used by your clients, and you will not get the intended results for your rules.
  - Some FQDN DNS entries have very short time to live (TTL) values. This can result in frequent recompilation of the lookup table, which can impact overall system performance.
  - If more than 8 FQDNs resolve to the same IP address, the system cannot reliably match traffic to the rules for those FQDN. At most 8 FQDNs per IP address can be handled.
- The maximum objects per match criteria per access control rule is 200. For example, you can have up to 200 network objects in a single access control rule.
- Block with reset can be CPU-intensive for rules that drop a high rate of TCP traffic. When the system drops TCP traffic with this action, it also generates TCP reset packets, which can affect device performance during high-volume drops. For access control rules that are expected to drop large amounts of TCP traffic, use **Block** instead of **Block with reset**, unless TCP reset behavior is required.

  If TCP reset behavior is required for denied inbound TCP traffic, you can also evaluate using a regular **Block** rule with the **service resetinbound** command through FlexConfig for the applicable interface.

Best practices for application control

These topics discuss our recommended best practices for controlling applications with access control rules.

Recommendations for application control

Ensure that adaptive profiling is enabled

If adaptive profiling is not enabled (its default state), access control rules cannot perform application control.

Enable application detectors automatically

If no detector is enabled for an application you want to detect, the system automatically enables all system-provided detectors for the application. If none exist, the system enables the most recently modified user-defined detector for the application.

Configure your policy to examine the packets that must pass before an application is identified

The system cannot perform application control before *both* of these conditions occur:

- A monitored connection is established between a client and server
- The system identifies the application in the session

This identification should occur in 3 to 5 packets, or after the server certificate exchange in the SSL handshake if the traffic is encrypted. If you configure the access control rule to use application default ports, the application rule can be enforced without allowing initial packets to pass.

If early traffic matches all other criteria but application identification is incomplete, the system allows the packet to pass and the connection to be established (or the SSL handshake to complete). After the system completes its identification, the system applies the appropriate action to the remaining session traffic.

To ensure that your system examines these initial packets, select an intrusion policy in the **Intrusion Policy used before Access Control rule is determined** options in the access control policy advanced settings.

Understand limitations to identifying applications

A server must adhere to the protocol requirements of an application for the system to be able to recognize it. For example, if you have a server that sends a keep-alive packet rather than an ACK when an ACK is expected, that application might not be identified, and the connection will not match the application-based rule. Instead, it will be handled by another matching rule or the default action. This might mean that connections you want to allow can be denied instead. If you run into this problem, and you cannot fix the server to follow the protocol standards, you need to write a non-application-based rule to cover traffic for that server, for example, by matching the IP address and port number.

Create separate rules for URL and application filtering

Create separate rules for URL and application filtering whenever possible, because combining application and URL criteria can lead to unexpected results, especially for encrypted traffic.

Rules that include both application and URL criteria should come after application-only or URL-only rules, unless the application+URL rule is acting as an exception to a more general application-only or URL-only rule.

Place URL rules before application and other rules

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of these criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

Handling application traffic packets without payloads

When performing access control, the system applies the default policy action to packets that do not have a payload in a connection where an application is identified.

Handling referred application traffic

To handle traffic referred by a web server, such as advertisement traffic, match the referred application rather than the referring application.

Controlling application traffic that uses multiple protocols

Some applications use multiple protocols. To control their traffic, make sure your access control policy covers all relevant options. These applications typically include the application name in each aspect that you can control. Also see Application-specific requirements for filtering, on page 2057.

Controlling evasive application traffic

See Application-specific requirements for filtering, on page 2057.

Best practice for choosing between application matching and port matching

In traditional firewalls, you can match traffic based on OSI layers 3 (protocol) and 4 (transport), such as IP or TCP/80. All traffic on a given port (or a whole protocol) is then either allowed or blocked based on that rule's action.

Application criteria, on the other hand, are OSI layer 7. Different applications can use the same TCP/UDP port. By using application criteria, you can selectively allow or block different applications on the same port without allowing or blocking all applications on that port.

Whether you use port-based or application-based criteria in your rule can impact rule performance. Because TCP/UDP ports are quickly identifiable in packets, the system can match the correct rule on the first packet. With application-layer criteria, it can take 3-5 packets to identify the specific application (if you do not also specify ports).

Consider these best practices:

- If you want to handle all of the traffic on a given TCP/UDP port in the same way for the specified interfaces and networks, use port-based matching. For example, to handle all SSH traffic the same way, select the SSH port (TCP/22) on the Ports tab.
- If you want to narrowly match a specific application that uses the same port as other applications, select the application on the Applications tab. This is how you can handle web applications, which all use TCP/80 or 443, so that you can selectively block or allow certain web applications without blocking or allowing all web applications.
- If you want to control application use by a user group, select the user group on the Users tab and the application on the Application tab. For example, you could block the Gaming applications category for members of the Contractor user group.
- For rules that go from a less secure network (such as the internet) to a more secure network (such as an internal protected network), use the Ports tab whenever possible. For example, you can allow/block ICMP traffic from the internet to an internal network.
- Avoid mixing Port tab and Applications tab specifications in a single rule. Instead, when you select an application, leave the Port tab empty, and instead specify the port as **Application Default** on the Applications tab. This will target the rule to the right ports (per application) and enhance how quickly the right application can be matched to the rule.

- If you do have a mix of port-based and application-based rules, place the port-based rules higher in the rules list, so that connections can be matched to those rules first. Protocol and port can be more quickly identified than applications.

Application-specific requirements for filtering

Office 365 admin portal

If the access policy has logging enabled at the beginning as well as at the end of a connection, the first packet will be detected as Office 365 and the end of connection will be detected as Office 365 Admin Portal. This should not affect blocking.

Skype

To control Skype traffic, choose the **Skype** tag from the **Application Filters** list rather than selecting individual applications. This ensures that the system can detect and control all Skype traffic the same way.

GoToMeeting

In order to fully detect GoToMeeting, your rule must include all of these applications:

- GoToMeeting
- Citrix Online
- Citrix GoToMeeting Platform
- LogMeIn
- STUN

Zoho mail

To control Zoho mail, choose *both* **Zoho** and **Zoho mail** from the Available Application list.

Evasive application detection considerations

For evasive applications such as Bittorrent, Tor, Psiphon, and Ultrasurf, only the highest-confidence scenarios are detected by default. If you need to take action on this traffic (such as block or implement QoS), it may be necessary to configure more aggressive detection with better effectiveness. To do this, contact TAC to review your configurations as these changes may result in false positives.

WeChat

It is not possible to selectively block WeChat Media if you allow WeChat.

RDP file transfer

If allowing the RDP (Remote Desktop Protocol) application does not allow file transfers, ensure that the rule for RDP includes both the TCP and UDP port 3389. RDP file transfer uses UDP.

Best practices for access control rules

Configuring and ordering access control rules properly is essential to protect your network. Consider these best practices to achieve optimal results:

- Always evaluate device compatibility of access control rules before deployment.
- Ensure resources, such as physical memory and processors, can handle expanded rule criteria.

Note Ensure the system evaluates all rules together and creates a set of criteria for devices when you deploy configuration changes. You cannot deploy to a device if these criteria exceed its resources.

General best practice for access control

General best practices

- Use a prefilter policy to provide early blocking for unwanted traffic, and to fastpath traffic that does not benefit from access control inspection. For more information, refer to Best practices for fastpath prefiltering, on page 2542.
- Access control rules are deployed as access control entries (ACE) on the device. To minimize the number of access control entries created per access control rule, and improve overall performance, enable object group search for each device. Object group search is a device setting, not an access control policy setting, so you must edit each device to ensure the feature is enabled. For more information, refer to Configure object group search, on page 1190.
- Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.
- Certain features, including URL filtering, application detection, and rate limiting, must allow some packets to pass in order for the system to identify the traffic.
- If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.

Licensing and feature support

- Although you can configure the system without licensing your deployment, many features require that you enable the appropriate licenses before you deploy.
- Some features are only available on certain device models. Warning icons and confirmation dialog boxes designate unsupported features.

Deployment considerations

- When you deploy an access control policy, its rules are not applied to existing connections. Traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the policy rules effectively applied, clear the existing connection sessions, and then deploy the policy.
- For the system to affect traffic, you must deploy relevant configurations to managed devices using routed, switched, or transparent interfaces, or inline interface pairs.
- The system might prevent you from deploying inline configurations to passively deployed devices, including inline devices in tap mode. In other cases, the policy might deploy successfully, but attempts to block or alter traffic can produce unexpected results because passive devices do not enforce traffic actions. For example, the system might report multiple beginning-of-connection events for a connection that the policy attempts to block.

Best practices for creating, ordering, and implementing access control rules are detailed in Best practices for access control rules, on page 2058 and subtopics.

Best practices for ordering rules

Access control rules are matched top down, first match wins. Thus, to get the results you expect, you must pay careful attention to proper sequencing.

- In general, place top-priority rules that must apply to all traffic near the top of the policy. Always order rules to suit your organization's needs.
- Specific rules should come before general rules, especially when the specific rules are exceptions to general rules. Otherwise, traffic will match the general rule first and never hit the applicable specific rule.
- Rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number) should come as early as possible. Rules based on these criteria do not require inspection to identify matching connections.
- Whenever possible, put specific drop rules near the top of the policy. This ensures the earliest possible decision on undesirable traffic.
- URL filtering, application-based, and geolocation-based rules and others that require inspection should come after rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number), but before rules that specify file and intrusion policies.
- For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:
  - They include application conditions.
  - The traffic to be inspected is encrypted.
- Put URL filtering rules above application rules, and follow application rules with micro-application rules and Common Industrial Protocol (CIP) sub-classification application filtering rules.
- In general, rules with application conditions should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example. For more information, see Best practice for choosing between application matching and port matching, on page 2056 and Recommendations for application control, on page 2054.

- Rules that specify file policies and intrusion policies should come at the bottom of the rule order. These rules require resource-intensive deep inspection, and you should eliminate as many threats as possible using less-intensive methods first, for performance reasons, in order to minimize the number of potential threats that require deep inspection.

Application rule order

Place rules with application conditions lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this Wikipedia article.

For more information, refer to Best practice for choosing between application matching and port matching, on page 2056 and Recommendations for application control, on page 2054.

Rule preemption

Rule preemption is a policy evaluation condition that occurs when a rule will never match traffic because a rule earlier in the evaluation order matches the traffic first. A rule's conditions govern whether it preempts other rules.

Rule preemption scenarios

Any type of rule condition can preempt a subsequent rule. This table shows common preemption scenarios:

Table 119: Rule preemption examples

Rule 1 (preempting)	Rule 2 (preempted)	Rule preemption scenario
Allow Admin users	Block Admin users	The second rule cannot block Admin traffic because the first rule allows it.
Allow Source Network VLAN 22-33	Block Source Network VLAN 27	The VLAN range in the first rule includes the VLAN in the second rule, so the first rule preempts the second. To block VLAN 27, you must move that rule above the one that allows VLAN 22-33.
Allow Source Network 10.4.0.0/16	Allow Source Network 10.4.0.0/16, VLAN 2	The VLAN range in the first rule includes the VLAN in the second rule, so the first rule preempts the second. To block VLAN 27, you must move that rule above the one that allows VLAN 22-33.
Allow Source Network 10.10.10.0/24 to URL www.netflix.com	Allow Source Network 10.10.10.0/24 to URL www.netflix.com	A rule also preempts an identical subsequent rule where all configured conditions are the same.

Best practice for rule actions and rule order

A rule's action determines how the system handles matching traffic. Improve performance by placing rules that do not perform or ensure further traffic handling before the resource-intensive rules that do. Then, the system can divert traffic that it might otherwise have inspected.

The following examples show how you might order rules in various policies, given a set of rules where none is more critical and preemption is not an issue.

If your rules include application conditions, also refer to Best practice for choosing between application matching and port matching, on page 2056.

Optimum order for access control rules

Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Place access control rules that invoke deep inspection last.

1. Monitor—Rules that log matching connections, but take no other action on traffic. (However, see the important exception and caveat at Access control rule monitor action, on page 2046.)
2. Trust, Block, Block with reset—Rules that handle traffic without further inspection.
3. Allow, Interactive Block (no deep inspection)—Rules that do not inspect traffic further, but allow discovery.
4. Allow, Interactive Block (deep inspection)—Rules associated with file or intrusion policies that perform deep inspection for prohibited files, malware, and exploits.

Best practices for simplifying and focusing rules

Follow these best practices to simplify configuration and ensure optimal device performance and rule clarity:

Simplify rule conditions

Minimize individual rule criteria. Use as few elements in rule conditions as possible. For example, use IP address blocks rather than individual IP addresses when defining network conditions.

Avoid redundant conditions

If a single condition is enough to match the traffic you want to handle, do not add more. Redundant conditions can make configuration unnecessarily complex and may negatively impact device performance, especially during cluster or high-availability unit re-join.

For example:

- Use security zones that represent multiple interfaces carefully. If you specify source and destination networks as conditions, and these are enough to match the traffic you are targeting, then specifying a security zone is not required.
- If you want to match a set of internal interfaces to any destination on the Internet (for example), then simply use a source security zone that includes your internal interfaces. No network or destination interface criteria are needed.

Combine elements for organization, not performance

The use of network objects containing many individual IP addresses offers organizational benefits only. It does not improve device performance compared to listing those IP addresses individually.

For recommendations related to application detection, refer to Best practice for choosing between application matching and port matching, on page 2056.

Narrowly constrain resource-intensive rules, especially by interface

As much as possible, use rule conditions to narrowly define the traffic handled by resource-intensive rules. Focused rules are also important because rules with broad conditions can match many different types of traffic, and can preempt later, more specific rules. Examples of resource-intensive rules include:

- TLS/SSL rules that decrypt traffic—Not only the decryption, but further analysis of the decrypted traffic, requires resources. Narrow focus, and where possible, block or choose not to decrypt encrypted traffic.
- Access control rules that invoke deep inspection—Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Make sure you only invoke deep inspection where required.
- If you specify security zones in a rule, the rule is deployed only to devices that have interfaces in the specified zone. So, if you want to focus a rule on only some devices that are assigned to the policy, ensure that you select a security zone that applies to the appropriate subset of devices. This ensures that unnecessary rules are not deployed to a device.

Maximum number of access control rules and intrusion policies

The maximum number of access control rules or intrusion policies that are supported by a device depends on many factors, including policy complexity, physical memory, and the number of processors on the device.

If you exceed the maximum supported by a device, you cannot deploy the access control policy and you must reevaluate.

Guidelines for intrusion policies

Consider these guidelines when configuring intrusion policies:

- In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.
- You may want to consolidate intrusion policies or variable sets so you can associate a single intrusion policy-variable set pair with multiple access control rules. On some devices you may find you can use only a single variable set for all your intrusion policies, or even a single intrusion policy-variable set pair for the whole device.

Access control rule management

Access control rule management is a security administration process that involves procedures for creating, modifying, and maintaining access control rules.

These topics explain how to manage access control rules.

Add an access control rule category

Categories help organize rules into logical groups so you can understand and manage your policy more easily.

You can divide an access control policy's **Mandatory** and **Default** rule sections into custom categories. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The Firewall Management Center assigns rule numbers across sections and categories.

Procedure

Step 1 In the access control policy editor, click **Add Category**.

If your policy already contains rules, you can click a blank area in the row for an existing rule to set the position of the new category before you add it. You can also right-click an existing rule and select **Insert new category**.

Step 2 Enter a **Name**.

Step 3 From the **Insert** drop-down list, choose where you want to add the category:

- To insert a category below all existing categories in a section, choose **into Mandatory** or **into Default**.
- To insert a category above an existing category, choose **above category**, then choose a category.
- To insert a category above or below an access control rule, choose **above rule** or **below rule**, then enter an existing rule number.

Step 4 Click **Apply**.

Step 5 Click **Save** to save the policy.

What to do next

You can now:

- Drag and drop rules into, or out of, the category.
- When creating a rule, select a category it should be part of.
- When editing a rule, reposition the rule to be in the category, or to move it out of the category.

Introduction to real-time Policy Analyzer and Optimizer

The real-time Policy Analyzer and Optimizer feature enhances access control rule management by providing immediate, real-time feedback on potential rule conflicts during configuration. Traditionally, users would add or modify access control rules without visibility into whether these new rules are shadowed or are made redundant by the existing rules in the access control policy.

While the on-demand Policy Analyzer and Optimizer within Security Cloud Control post-deployment analysis, the new real-time anomaly detection capability integrates proactive anomaly detection directly into the rule creation and editing workflow. This offers instant insights even as users create or update rules in Cloud-Delivered Firewall Management Center.

Benefits of real-time Policy Analyzer and Optimizer

The real-time Policy Analyzer and Optimizer feature addresses the common challenge of undetected rule anomalies, such as shadowing or redundancy, prior to deployment. These anomalies result in inefficient, cluttered rule sets having unnecessary or duplicate entries. By identifying conflicts even as rules are being added or modified, real-time anomaly detection helps administrators to:

- **Reduce rules set complexity**: Streamlines policies by highlighting and enabling the removal of redundant or shadowed rules.
- **Improve efficiency**: Eliminates the need for time-consuming post-deployment analysis, saving effort and accelerating policy deployment.
- **Maintain policy integrity**: Ensures that potential conflicts are identified and presented to users before they impact network security or performance.

How real-time Policy Analyzer and Optimizer works

Anomalies are detected and reported exclusively on the rule currently being created or edited, ensuring that existing rules are not independently flagged unless changes are made on them.

When you add or edit a rule, Cloud-Delivered Firewall Management Center checks for conflicts (shadowed or redundancy) based on the position of that rule:

- **Adding a rule after existing rules**: A new rule can be shadowed by rules that are already placed above it in the policy.
- **Adding a rule in the middle**: A new rule can be shadowed by the rules above it and may also make the rules positioned below it redundant.
- **Adding a rule at the beginning**: A new rule can make the rules positioned below it redundant.

Note When editing a rule, if changes introduce new anomalies, they will be reported, and the conflict type will be determined based on the edited rule's position.

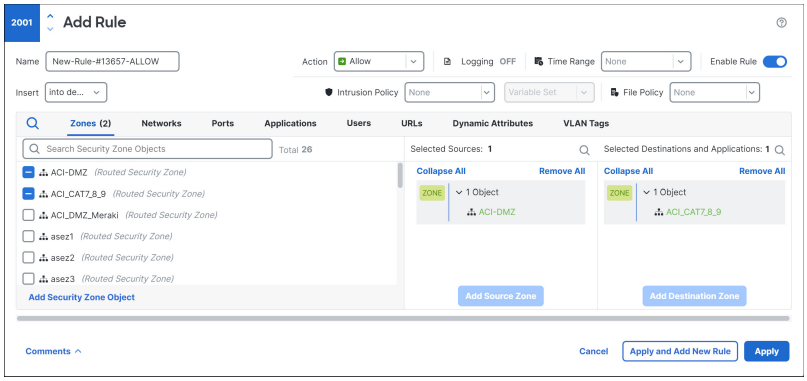
Prerequisites for using real-time Policy Analyzer and Optimizer

To use the real-time Policy Analyzer and Optimizer, enable AgenticOps Insights in Security Cloud Control. For more information, see Enable AgenticOpsInsights.

Once AgenticOps Insights is enabled, the real-time Policy Analyzer and Optimizer will be enabled automatically. To view and manage the settings, navigate to **Insights & Reports** > **AgenticOps Insights** > **Settings** > **Policy Analyzer & Optimizer**.

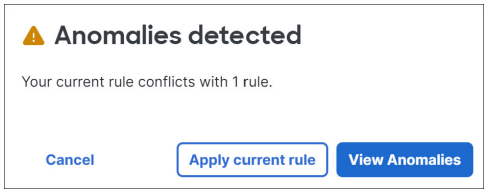
Note You can choose to opt out of real-time Policy Analyzer and Optimizer if you no longer want to use this feature. Click the real-time Policy Analyzer and Optimizer toggle button and then click **Submit** to disable the feature.

Limitations of real-time Policy Analyzer and Optimizer



These are the limitations to consider when using the real-time Policy Analyzer and Optimizer feature:

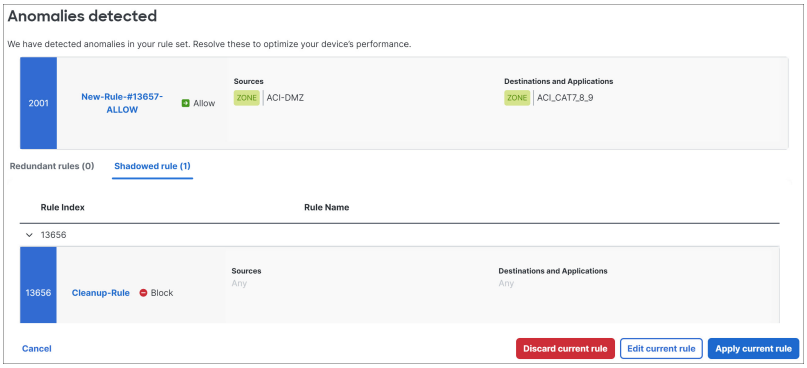
- **Bulk operations**: Adding rules in bulk using APIs is not supported.
- **Rule type specificity**: Conflict detection is available only for access control rule types.
- **Workflow enabled**: Real-time Policy Analyzer and Optimizer is skipped if a workflow is enabled for rule management.
- **Stale policy cache**: Anomaly detection is skipped if another user has uncommitted changes. To proceed with real-time anomaly detection, users must first deploy or cancel pending changes, if any.
- **Device overrides**: Conflict detection considers only the primary value assigned to all object types when adding or modifying rules, and does not consider object overrides.
- **Disabled rules**: Disabled rules are excluded from conflict detection and do not appear as conflicts for other rules.



Manage rule anomalies

This section explains how the real-time Policy Analyzer and Optimizer feature in Cloud-Delivered Firewall Management Center automatically detects anomalies when you create a new rule or edit a rule. It also describes the options available in the interface for reviewing and resolving the detected anomalies. The same behavior applies when modifying an existing rule.

When you create a new rule, the following rule configuration dialog box is displayed:



After defining the rule details and clicking **Apply**, the feature performs an automatic anomaly check on the new rule. If conflicts with existing rules are found, the **Anomalies detected** warning dialog box is displayed.

You can click one of the following options to:

- **Cancel**: Returns you to the rule editing interface to update the current rule.
- **Apply Current Rule**: Saves the rule despite the detected anomalies.
- **View Anomalies**: Opens a dialog box to display detailed information about the conflicts detected.

On clicking **View Anomalies**, the **Anomalies detected** dialog box is displayed, showing all the anomalies that have been detected in the context of to the current rule.

You can click one of the following options to:

- **Cancel**: Closes the anomalies dialog box.
- **Discard current rule**: Prompts a confirmation dialog box to discard the rule.
  - **Discard current rule**: The rule is discarded, and both the anomalies dialog box and the add rule dialog box are closed.
  - **Cancel**: The confirmation dialog box closes, returning you to the anomalies dialog box.
- **Edit current rule**: Closes the anomalies dialog box and returns you to the add rule dialog box to modify the rule details.
- **Apply current rule**: A dialog box is displayed prompting you to save the rule despite potential anomalies.
  - **Proceed**: The rule will be saved.
  - **Cancel**: The confirmation dialog box will close, returning you to the anomalies dialog box or the initial warning dialog box, depending on which is applicable.

Create and edit access control rules

Use access control rules to apply actions to specific traffic classes. Rules allow you to selectively allow desirable traffic and drop unwanted traffic.

Before you begin

If you have enabled the Policy Analyzer & Optimizer tool, your edits are evaluated as you make them. If anomalies are detected, you are notified during the edit and prompted to make changes when you click **Apply** to save the rule. You can view the anomalies, such as redundant and shadowed rules, and choose to edit or delete the rule. You can also proceed with saving the rule as is, to deal with the issue later.

Procedure

Step 1 In the access control policy editor, you have the following options:

- To add a new rule, click **Add Rule**.

- To edit an existing rule, click **Edit** ( ).
- To start with a copy of an existing rule, choose one of the following commands from the **More** ( ) menu.
  - **Copy Rule**, to copy the rule to the clipboard, so you can use the **Paste Above/Below** commands to place it anywhere in the same policy.
  - **Copy Rule to Different Policy**, to copy the rule to another access control policy. A dialog box opens so that you can select the policy and chose the rule placement.
  - **Clone Rule**, to create the copy immediately below the duplicated rule.
- To edit multiple rules, use the checkboxes to select multiple rules, then select **Edit** or another action from the **Select Action/Bulk Rule Actions** list next to the search box.
- To do inline editing, where you change the configuration of an object in a rule condition, right-click the value and choose **Edit**. You can also use the right-click menu to remove a item, add it to the filter, or copy the text or value.

If **View** ( ) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

Step 2 If this is a new rule, enter a **Name**.

Step 3 Configure the rule components.

If you are bulk-editing multiple rules, only a subset of options are available.

Table 120: Access control rule components

Rule component	Configuration description
Position	Specify the rule position (**Insert** for new rules, the **Reposition** icon next to the rule name for existing rules); see Access control rule order, on page 2045.
Action	Choose a rule **Action**; see Access control rule actions, on page 2046.
Advanced Logging	Click **Advanced Logging** and choose the protocols for application-aware and protocol-aware event logs. See *About Application-Aware Event Logging* in the *Cisco Secure Firewall Management Center Administration Guide* for more information. **Note** The **Advanced Logging** option is available when the feature is enabled in the access control policy's advanced settings. See *Enable Application-Aware Event Logging* in the *Cisco Secure Firewall Management Center Administration Guide*.
Logging	Click **Logging** to specify options for connection logging and SNMP traps. .
Time Range	(Optional.) For Firewall Threat Defense devices, choose the days and times when the rule is applicable. If you do not choose an option, the rule is always active. For details, see Create a time range object, on page 3036.
Enable Rule	Whether the rule is active. Disabled rules are not applied to connections. You can disable rules to temporarily turn them off, for example, during troubleshooting.

Rule component	Configuration description
Security Protections (Deep inspection)	(Optional.) For Allow and Interactive Block rules, select options for **Intrusion Policy**, **Variable Set**, and **File Policy**. You can apply intrusion and file policies independently; you do not need to configure both.
Conditions	Select the objects you want to add to either source or destination, then click either **Add to Sources** or **Add to Destinations and Applications** to add matching conditions for connections. You can click a tab to restrict the list of available objects, for example, to Networks, Security Zones, Applications, and so forth. However, the sources and destination column always show all selected objects regardless of the tab you are on. See Access control rule conditions, on page 2068 for more information.
Comments	Open the comments list at the bottom of the dialog box, enter your comment, and click **Add Comment/Post** to add a comment.

Step 4 Click **Add** or **Apply** to save the rule.

Step 5 Click **Save** to save the policy.

What to do next

If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure a time zone for a device, on page 1304.

Deploy configuration changes.

Best practices for access control rules, on page 2058

Access control rule conditions

Access control rule conditions are traffic matching criteria that define the characteristics of the connections you want to target with each rule. Use the conditions precisely to fine-tune the rule to apply to all, and only, the traffic that should be handled by the rule. The following topics explain the match conditions that you can use.

Security/tunnel zone rule conditions

Security/tunnel zone rule conditions are traffic matching mechanisms that

- use security zones and tunnel zones to select traffic for a rule
- segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices
- allow you to identify tunneled traffic, such as GRE, that should be handled as a tunnel rather than apply access control rules to the encapsulated connections within the tunnel.

You can use security zones to control traffic by its source and destination interfaces. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones for it to match the rule. Just as all interfaces in a security zone must be of the same type (all inline, passive, switched, or routed), all zones used

in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

When using tunnel zones, ensure that you have matching rules in the prefilter policy to associate tunneled traffic with the zone. Then, you can select the tunnel zone as a source zone in a rule; tunnel zones cannot be destinations. If you do not have prefilter rules to rezone the tunnels into the tunnel zone, an access control rule for the tunnel will never apply to any connections. You can specify destination security zones to target tunnels that leave the device through specific interfaces.

Security zone considerations

Consider the following when deciding on security zone criteria:

- Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.
- Access control rules generate ACL entries (ACEs) in the device configuration to provide early processing and drops whenever possible. If you specify security zones in rules, ACEs are created for each interface in the zone, which can greatly increase the size of the ACL. Excessively large ACLs generated from access control rules can impact system performance.

Network rule conditions

Network rule conditions are the network objects or geographical locations that define the network addresses or locations of the traffic.

Network criteria selection

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from these tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.

  Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.

  You can use objects that define the address using the fully-qualified domain name (FQDN); the address is determined through a DNS lookup. However, FQDN objects are not supported in these sections in access control policies: original client networks, SGT/ISE attributes, network analysis and intrusion policy, Security Intelligence, threat detection, elephant flow settings.

- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

Note To ensure that you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).

Traffic matching configuration:

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

Original client in network conditions (filtering proxied traffic)

For some rules, you can handle proxied traffic based on the originating client. Use a source network condition to specify proxy servers, then add an original client constraint to specify original client IP addresses. The system uses a packet's X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header field to determine original client IP.

Traffic matches the rule if the proxy's IP address matches the rule's source network constraint, and the original client's IP address matches the rule's original client constraint. For example, to allow traffic from a specific original client address, but only if it uses a specific proxy, create three access control rules:

Access Control Rule 1: Blocks proxied traffic from a specific IP address (209.165.201.1)

Source Networks: 209.165.201.1
Original Client Networks: none/any
Action: Block

Access Control Rule 2: Allows proxied traffic from the same IP address, but only if the proxy server for that traffic is one you choose (209.165.200.225 or 209.165.200.238)

Source Networks: 209.165.200.225 and 209.165.200.238
Original Client Networks: 209.165.201.1
Action: Allow

Access Control Rule 3: Blocks proxied traffic from the same IP address if it uses any other proxy server.

Source Networks: any
Original Client Networks: 209.165.201.1
Action: Block

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on whether the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

User rule condition example

Configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 121: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.

Characteristic	Description	Example
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Configure application conditions and filters

To build an application condition or filter, choose the applications whose traffic you want to control from a list of available applications. It is recommended that you constrain the available applications using filters. You can use filters and individually specified applications in the same condition.

Before you begin

- Adaptive profiling must be enabled (its default state) in the access control policy's advanced settings for access control rules to perform application control.

Follow these steps to configure application conditions and filters:

Procedure

Step 1 In the access policy rule editor, click **Applications**.

Step 2 Find and choose the applications you want to add from the **Available Applications** list.

To constrain the applications displayed in **Available Applications**, choose one or more **Application Filters** or search for individual applications.

Tip

Click **Information** ( ) next to an application to display summary information and internet search links. A **lock** icon marks applications that the system can identify only in decrypted traffic.

When you choose filters, singly or in combination, the Available Applications list updates to display only the applications that meet your criteria. You can choose system-provided filters in combination, but not user-defined filters.

- Multiple filters for the same characteristic (risk, business relevance, and so on)—Application traffic must match only one of the filters. For example, if you choose both the medium and high-risk filters, the Available Applications list displays all medium and high-risk applications.
- Filters for different application characteristics—Application traffic must match both filter types. For example, if you choose both the high-risk and low business relevance filters, the Available Applications list displays only applications that meet both criteria.

Step 3 Click **Add Application** or **Add to Rule**, or drag and drop.

Tip
Before you add more filters and applications, click **Clear Filters/Selection** to clear your current choices.

Step 4 If destination ports are not specified on the Ports tab, select the **Port** for the applications.

The **Port** specification applies to all the applications in the list; it does not apply to any filters. You cannot specify different port options for each application. If you already specified destination ports on the Ports tab, that selection is reflected in the application list, and you cannot make the selection.

If you have not already specified destination ports for the rule, choose one of the following:

- **Application Default**—The system looks at the default port only when evaluating traffic for an application match. Click the info button (i) to see what is considered the default for each application.

  When editing a rule, if the rule already has source ports, and you add an application that has an incompatible port and select Application Default port, you are warned. If you elect to use the application default port, the incompatible source port is removed.

- **Any**—The system does not restrict the application identification based on the port used in the connection. If there are source ports specified on the Port tab, you might need to select this option to be able to save the rule.

Regardless of the option you select, if you subsequently configure any destination value on the Ports tab, the ports specified on the Ports tab override your selection here, and change the application port to Any. If you want to limit the rule to one, multiple, or a range of ports that are not the application default port, use the Ports tab.

This option does not apply to custom detectors.

Note
If the access control policy is assigned to devices running 7.x versions, the rule is handled differently if you have included applications that have different default ports. When you select to apply the rule to the default ports only, then for 7.7 systems, the rule is split into separate rules, one per application. For systems running versions 7.3-7.6, the rule is kept as a single rule, but the ports page is updated with each of the default ports. If you are managing devices running down-level software versions, and you want to use default port matching, we recommend that you limit the application's list in each rule to applications that have the same default port.

Step 5 Save or continue editing the rule or configuration.

What to do next

Deploy configuration changes.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Recommendation: use URL conditions for website access control

Use URL conditions to control the websites that users on your network can access.

For complete information, see URL filtering with category and reputation, on page 2086.

Dynamic attributes rule conditions

Dynamic attributes rule conditions allow you to specify access control rules based on real-time properties such as network objects, device types, locations, and security tags. Dynamic attributes can be used as source criteria and destination criteria in access control rules. These criteria help match traffic more flexibly and accurately.

Dynamic attributes configuration and behavior

You can use these types of dynamic attributes to match connections in DNS rules:

- Dynamic objects (Source or destination): The dynamic attributes connector collects data such as networks and IP addresses from cloud providers for use in access control rules. For more information, refer to About the Dynamic Attributes Connector , on page 2621 .
- SGT objects (Source only): These contain tags defined manually or in Cisco ISE. For more information, refer to Source and destination security group tag (SGT) matching, on page 2374 and Security group tags, on page 2972 .
- Location IP objects (Source only): Defined by Cisco ISE.
- Device type objects (Source only): Defined by Cisco ISE, also referred to as endpoint profile objects.

When you configure dynamic attributes for a DNS rule, objects of the same type within a source or destination list use OR logic, while objects of different types use AND logic. For example, if you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originates from (or is destined to) one of those IP addresses.

When you open the **Dynamic Attributes** tab, all **Dynamic Objects** and **Security Group Tags** appear in the list. To remove objects from the list, deselect the options. To find an object, type in the search box.

Time and Day Rule Conditions

You can specify a continuous time range or a recurring time period.

For example, a rule can apply only during weekday working hours, or every weekend, or during a holiday shutdown period.

Time-based rules are applied based on the local time of the device that processes the traffic.

Time-based rules are supported only on Firewall Threat Defense devices. If you assign a policy with a time-based rule to a different type of device, the time restriction associated with the rule is ignored on that device. You will see warnings in this case.

Enable and disable access control rules

Enable or disable access control rules to control whether they are used to evaluate network traffic.

When you create an access control rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing rules in an access control policy, disabled rules are grayed out but can still be modified. You can also change a rule's status in the rule editor.

Procedure

Step 1 In the access control policy editor, right-click the rule you want to change and choose a rule state.

If **View** ( ) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

Step 2 Click **Save**.

What to do next

- Deploy configuration changes.

Copy access control rules from one access control policy to another

You can copy access control rules from one access control policy to another. You can copy the rules either to the **Default** section or the **Mandatory** section of the access control policy.

All the settings of the copied rules, except the comments, are retained in the pasted version

Procedure

Step 1 Do one of the following:

- To copy a single rule, right-click the rule and select **Copy Rule to Different Policy**.
- To copy multiple rules, select their checkboxes, then select **Copy Rules to Different Policy** from the **Select Bulk Action** menu.

Step 2 Select the destination access control policy from the **Access Policy** drop-down list.

Step 3 From the **Place Rules** drop-down list, choose where you want to position the copied rules. You can place them at the top or bottom of either the Mandatory or Default sections.

Step 4 Click **Copy**.

What to do next

- Deploy configuration changes.

Move access control rules to a prefilter policy

You can move access control rules from an access control policy to the associated non-default prefilter policy.

You must first apply a user-defined prefilter policy to the access control policy. The access control rules cannot be moved to the default prefilter policy because the default prefilter policy cannot have rules.

Before you begin

Note these conditions before you proceed:

- When moving an access control rule to a prefilter policy the layer 7 (L7) parameters, such as application or URL filterin, in the access control rule cannot be moved. The L7 parameters are dropped during the operation.
- The comments in the access control rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source access control policy.
- You cannot move access control rules with **Monitor** set as the **Action** parameter.
- The **Action** parameter in the access control rule is changed to a suitable action in the prefilter rule when moved. To know what each action in the access control rule maps to, see this table:

Action in the access control rule	Action in the prefilter rule
Allow	Analyze
Block	Block
Block with reset	Block
Interactive Block	Block
Interactive Block with reset	Block
Trust	Fastpath

- Similarly, based on the action configured in the access control rule, the logging configuration is set to an appropriate setting after the rule is moved, as mentioned in this table.

Action in the access control rule	Enabled logging configurations in the prefilter rule
Allow	None of the check boxes are checked.
Block Block with reset Interactive Block Interactive Block with reset	• Log at Beginning of Connection • Event Viewer • Syslog Server • SNMP Trap
Trust	• Log at Beginning of Connection • Log at End of Connection • Event Viewer • Syslog Server • SNMP Trap

- While moving rules from the source policy, if another user modifies those rules, you will see get a message. You may continue with the process after refreshing the page.

Procedure

Step 1 Do one of the options:

- To move a single rule, right-click the rule and select **Move Rule to Prefilter Policy**.
- To move multiple rules, select their checkboxes, then select **Move Rules to Prefilter Policy** from the **Select Bulk Action** menu.

Step 2 From the **Place Rules** drop-down list, choose where you want to position the moved rules, either **At the bottom** or **At the top**.

Step 3 Click **Move**.

What to do next

- Deploy configuration changes.

Position an access control rule

Position rules correctly within an access control policy to ensure the first match wins behavior produces the intended security outcomes.

You can move an existing rule within an access control policy, or insert new rules in a desired location. When you add or move a rule to a category, the system places it last in the category.

Before you begin

Review rule order guidelines in Best practices for access control rules, on page 2058.

Procedure

Step 1 Do one of these:

- New rule—Insert a new rule by hovering over the line between the existing rules, and clicking **Add Rule**. The location is selected in the **Insert** box in the Add Rule dialog box; you can select a different rule to adjust the location. You can also select **Add Rule Above** or **Add Rule Below** from the right-click menu.
- Existing rules when viewing the rule table—Click and drag the rule to the new position. This action is final, you are not prompted to confirm it.
- Existing rules when viewing the rule table—Right-click a single rule and select **Reposition Rule**. To move multiple rules as a group, select their checkboxes, then select **Reposition Rules** from the **Select Bulk Action** menu. You are prompted for where you want the rule to go.
- Existing rule when editing the rule—Click the **Reposition Rule** icon next to the rule name.

Step 2 When editing or repositioning the rule, choose where you want to move or insert the rule, then click **Move**, **Confirm**, or **Reposition** (depending on what you are doing).

- Choose **into Mandatory** or **into Default**.
- Choose a **into Category**, then choose the category.
- Choose **above rule** or **below rule**, then select the rule.

Step 3 Save the rule if you are editing it.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Add comments to an access control rule

Adding comments to access control rules helps you keep track of the purpose of a rule, and changes made to the rule.

When you create or edit an access control rule, you can add a comment. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change. You can display a list of all comments for a rule along with the user who added each comment and the date the comment was added.

When you save a rule, all comments made since the last save become read-only.

To search access control rule comments, use the **Search Rules** bar on the rule listing page.

Procedure

Step 1 In the access control rule editor, click **Comments**.

Step 2 Enter your comment and click **Add Comment**. You can edit or delete this comment until you save the rule.

Step 3 Save the rule.

Examples for access control rules

These topics provide examples of access control rules.

How to control access using security zones

Configure security zones and access control rules to inspect incoming traffic for intrusions and malware while allowing unrestricted internet access for internal hosts.

Consider a deployment where you want hosts to have unrestricted access to the internet, but you nevertheless want to protect them by inspecting incoming traffic for intrusions and malware.

First, create two security zones: Internal and External. Then, assign interface pairs on one or more devices to those zones, with one interface in each pair in the Internal zone and one in the External zone. Hosts connected to the network on the Internal side represent your protected assets.

Note You are not required to group all internal (or external) interfaces into a single zone. Choose the grouping that makes sense for your deployment and security policies.

Then, configure an access control rule with a destination zone condition set to Internal. This simple rule matches traffic that leaves the device from any interface in the Internal zone. To inspect matching traffic for intrusions and malware, choose a rule action of **Allow** , then associate the rule with an intrusion and a file policy.

Control application usage

Block web-based applications, particularly anonymizers or proxies, by creating access control rules that identify and restrict traffic based on application attributes

Enterprise networks increasingly rely on web-based delivery platforms and rich media applications, often using the same web protocols. Firewall Threat Defense inspects connections to determine the application, enabling access control rules targeting applications rather than just targeting specific TCP/UDP ports.

Although you can select specific applications to allow or block, you can also write rules based on type, category, tag, risk, or business relevance. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

In this use case, we will block any application that belongs to the **anonymizer/proxy** category.

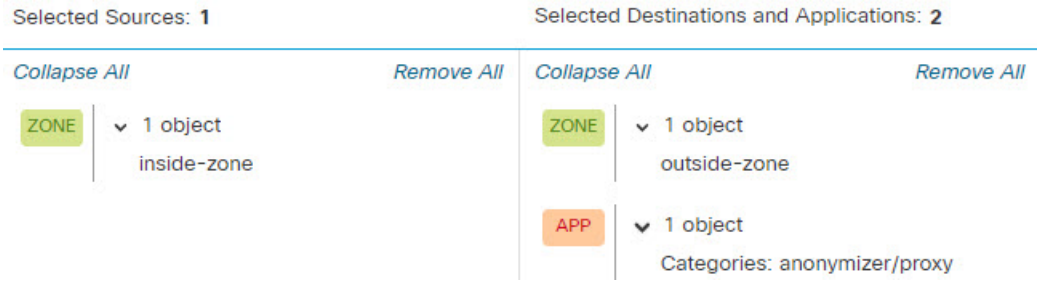
Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** and edit the access control policy.

Step 2 Click **Add Rule** and configure the rule for application control.

a) Name the rule (for example, Block_Anonymizers).

b) For **Action**, select **Block**.



c) If you have configured security zones and want to restrict traffic from inside to outside, click the **Zones** tab, and choose your inside zone as the source zone, and the outside zone as the destination zone.

d) Click the **Applications** tab, select the applications to match, and click **Add Application**.

As you select criteria, such as category and risk level, the list to the right of the criteria updates to show exactly which applications match the criteria. The rule you are writing applies to these applications.

For purposes of this example, choose **anonymizers/proxy** from the **Categories** list and add it to **Destinations and Applications**. The match criteria should now look similar to the following graphic.

Note
For **Port**, leave the default, Application Default. This ensures that the system looks only at the default ports used for a selected application, rather than all ports.

e) Click **Logging** next to the rule action, and enable logging at the start of the connection. You can select a syslog server if you use one.

You must enable logging to get information about any connections blocked by this rule.

Step 3 Move the rule so that it comes after any rules that use protocol and port criteria only, but that would not allow traffic that should be blocked by the application rule.

Matching applications requires Snort inspection. Because Snort inspection is not needed by rules that use protocol and port only, you can improve system performance by grouping these simple rules at the top of the access control policy as much as possible.

Step 4 Deploy the changes.

You can use the application rule hit counts and analysis dashboards to see how this rule is performing and how often users try these applications.

Block threats

You can implement next generation Intrusion Prevention System (IPS) filtering by adding intrusion policies to your access control rules. Intrusion policies analyze network traffic, comparing the traffic contents against known threats. If a connection matches a threat you are monitoring, the system drops the connection, thus preventing the attack.

All other traffic handling occurs before network traffic is examined for intrusions. By associating an intrusion policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy.

You can configure intrusion policies on rules that **allow** traffic only. Inspection is not performed on rules set to **trust** or **block** traffic. In addition, you can configure an intrusion policy as the default action if you do not want to use a simple block.

Security Intelligence policies allow you to preemptively block traffic to or from known bad IP addresses and URLs. This task demonstrates how to add an intrusion policy that allows traffic from the internal 192.168.1.0/24 network to external destinations, assuming block rules exist to eliminate unwanted connections, and adds Security Intelligence to block known threats.

Before you begin

- Apply the IPS license to any managed device that uses this rule.
- Ensure you have created security zones for inside and outside interfaces.
- Create the network object for the inside network.

Procedure

Step 1 Create the access control rule that applies the intrusion policy.

a) Edit the access control policy and add a new rule.

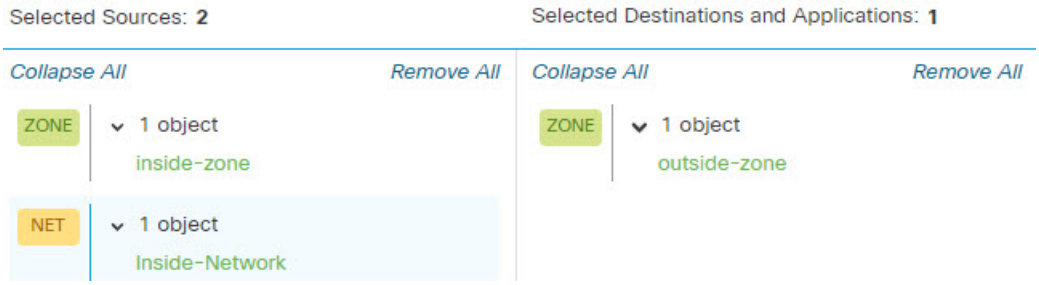
b) Name the rule (for example, Inside_Outside) and set the rule action to **Allow**.

c) Choose **Balanced Security and Connectivity** as the **Intrusion Policy**. You can either accept the default variable set or select your own if you want to customize it.

The **Balanced Security and Connectivity** policy is appropriate for most networks. It provides a good intrusion defense without being overly aggressive, which has the potential of dropping traffic that you might not want to be dropped. If you determine that too much traffic is getting dropped, you can ease up on intrusion inspection by selecting the **Connectivity over Security** policy.

If you need to be aggressive about security, try the **Security over Connectivity** policy. The **Maximum Detection** policy offers even more emphasis on network infrastructure security with the potential for even greater operational impact.

If you create your own custom policy, you can select that one instead.



A discussion of variable sets is beyond the scope of this example. Please read the chapters on intrusion policy for detailed information about variable sets and custom policies.

d) Select the **Zones** tab, and add your inside security zone to the source criteria, and outside zone to the destination criteria.

e) Select the **Networks** tab, and add the network object that defines your inside network to the source criteria.

The match criteria should look similar to the following:

f) Click **Logging** and enable logging at the beginning or end of the connection, or both, as desired.

g) Click **Apply** to save the rule, and then **Save** to save the updated policy.
h) Move the rule to the appropriate location in the access control policy.

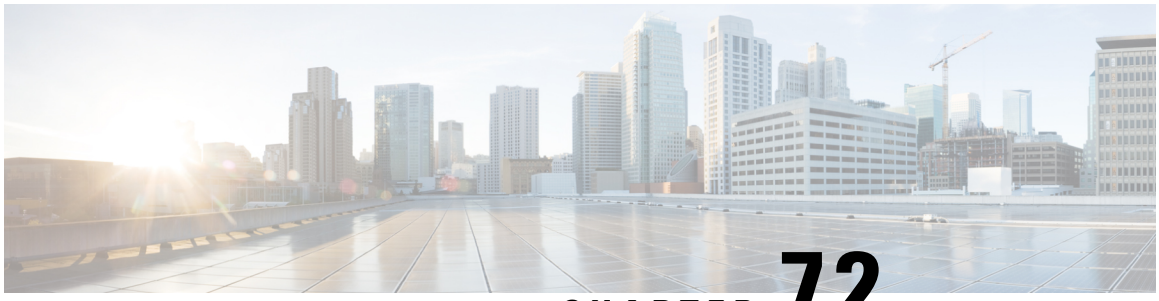
Step 2 Configure the Security Intelligence policy to preemptively drop connections with known bad hosts and sites.

By using Security Intelligence to block connections with hosts or sites that are known to be threats, you save your system the time needed to do deep packet inspection to identify threats in each connection. Security Intelligence provides an early block of undesirable traffic, leaving more system time to handle the traffic you really care about.

a) While editing the access control policy, click the **Security Intelligence** link in the packet path.

The link includes two policies: the DNS policy at the top, and the Security Intelligence (Network and URL) at the bottom. In this example, we are configuring the Network and URL lists. By default, these lists already include the global block and do not block lists, but these lists are empty by default until you add items to them.

b) With **Networks** selected and the **Any** security zone selected, scroll down in the Networks list until you get to the global feeds, and the first Security Intelligence category (probably Attackers). Click Attackers, then scroll to the end of the categories (probably Tor_exit_node), and Shift+Click to select all of the categories. Click **Add To Block List**.
c) Select the **URL** tab, and **Any** security zone, and use Shift+Click to select URL versions of the same categories. Click **Add To Block List**.
d) Click **Save** to save the policy.
e) As necessary, you can add network and URL objects to the block or do not block lists.



The **Do Not Block** lists are not real "allow" lists. They are exception lists. If an address or URL in the exception list also appears in the blocked list, the connection for the address or URL is allowed to pass on to the access control policy.

This way, you can block a feed, but if you later find that a desirable address or site is being blocked, you can use the exception list to override that block without needing to remove the feed entirely.

Keep in mind that these connections are subsequently evaluated by access control, and if configured, an intrusion policy. Thus, if any connections do contain threats, they can be identified and blocked during intrusion inspection.

Use the events and dashboards to determine what traffic is actually being dropped by the policy, and whether you need to add addresses or URLs to the **Do Not Block** lists.

Step 3 Deploy your changes.

CHAPTER 72

URL Filtering Rules

You can implement URL filtering using access control rules.

- URL filtering, on page 2085
- Best practices for URL filtering, on page 2088
- License requirements for URL filtering, on page 2093
- Requirements and prerequisites for URL filtering, on page 2094
- Configure URL filtering with category and reputation, on page 2094
- Manual URL filtering, on page 2101
- HTTP response pages, on page 2103
- Configure URL filtering health monitors, on page 2107
- Dispute URL category and reputation, on page 2107
- Take action if the URL category set changes, on page 2108
- Troubleshoot URL filtering, on page 2110

URL filtering

URL filtering is a security feature that

- controls the websites that users on your network can access,
- provides category and reputation-based filtering with a URL Filtering license, and
- enables manual specification of individual URLs, groups of URLs, and URL lists with any license.

URL filtering types

Use URL filtering to control website access through these methods:

- Category and reputation-based URL filtering—With a URL Filtering license, you can control access to websites based on the URL's general classification (category) and risk level (reputation). This is the recommended option.
- Manual URL filtering—With any license, you can manually specify individual URLs, groups of URLs, and URL lists and feeds to achieve granular, custom control over web traffic. For more information, see Manual URL filtering, on page 2101.

See also Security Intelligence, on page 2027, a similar but different feature for blocking malicious URLs, domains, and IP addresses.

The URL filtering feature is applicable only when you use a web browser to browse websites via the HTTP/HTTPS protocol. For other applications, you must use an FQDN-based access control rule instead of URL filtering. See Access Control Rules for more information.

URL filtering with category and reputation

URL filtering with category and reputation is a web security mechanism that

- controls access to websites based on the category and reputation of requested URLs,
- uses category classifications to group URLs by type (for example, ebay.com belongs to the Auctions category, and monster.com belongs to the Job Search category),
- assesses reputation levels from Unknown risk (level 0) or Untrusted (level 1) to Trusted (level 5) to determine how likely the URL is to be used for purposes that might be against the security policy for your organization, and
- allows URLs to belong to multiple categories simultaneously.

Reputation is determined by the hostname, e.g. all pages on www.cisco.com are considered to have the same reputation.

Benefits of category and reputation-based URL filtering

URL categories and reputations help you quickly configure URL filtering. For example, you can use access control to block untrusted URLs in the Hacking category. You can also use QoS to limit the rate of traffic from sites in the Streaming Video category. There are also categories for types of threats, such as a Spyware and Adware category.

Using category and reputation data simplifies policy creation and administration. It grants you assurance that the system controls web traffic as expected. Because Cisco continually updates its threat intelligence with new URLs, as well as new categories and risk levels for existing URLs, the system uses up-to-date information to filter requested URLs. Sites that (for example) represent security threats, or serve undesirable content may appear and disappear faster than you can update and deploy new policies.

These examples show how the system can adapt:

- If an access control rule blocks all gaming sites, as new domains are registered and classified as Games, the system can block those sites automatically. Similarly, if a QoS rule rate-limits traffic from all streaming video sites, the system can automatically limit traffic to new streaming video sites.
- If an access control rule blocks all malware sites and a shopping page gets infected with malware, the system can recategorize the URL from Shopping to Malware Sites and block that site.
- If an access control rule blocks untrusted social networking sites and somebody posts a link on their profile page that contains links to malicious payloads, the system can change the reputation of that page from Favorable to Untrusted and block it.

Limitations exist for category-based filtering in decryption policy Do Not Decrypt rules.

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from

its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 2054.

For more information, refer to Use categories in URL filtering, on page 2092.

URL category and reputation descriptions

This reference lists URL category and reputation level descriptions for security management.

Category descriptions

You can find a description of each URL category at https://www.talosintelligence.com/categories.

Click **Threat Categories** to view those categories.

Reputation level descriptions

Refer to Web reputation levels for information.

URL filtering data from the Cisco cloud

URL filtering data from the Cisco cloud is a threat intelligence dataset that

- allows traffic handling based on a website's general classification, or *category*, and risk level, or *reputation*,
- is automatically enabled when a URL Filtering license is added, and
- provides real-time threat intelligence evaluation for websites not found in local cache or datasets.

URL filtering data evaluation process

By default, when users browse to a URL whose category and reputation are not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.

Optionally, you can use a local URL dataset of categories and reputations, which can make web browsing faster. When you enable or re-enable URL filtering, the Cloud-Delivered Firewall Management Center automatically queries Cisco for URL data and pushes the dataset to managed devices. Then, when users browse to an URL, the system checks the local dataset and the cache for category and reputation information before submitting it to the cloud for threat intelligence evaluation. To see your options for using the local dataset, including how to disable individual cloud lookups altogether, see URL filtering options, on page 2096.

Automatic updates of URL data is enabled by default. We strongly recommend that you do not disable these updates.

Note The Secure Firewall Threat Defense 200 series device does not store URL category and reputation data locally. It relies entirely on browser cache and cloud-based lookups for URL filtering and reputation evaluation.

The set of URL categories may change periodically. When you receive a change notification, review your URL filtering configurations to make sure traffic is handled as expected. For more information, see Take action if the URL category set changes, on page 2108.

Best practices for URL filtering

Filter by category and reputation

Follow the instructions in Configure URL filtering with category and reputation, on page 2094.

Configure your policy to inspect packets that must pass before a URL can be identified

The system cannot filter URLs before:

- A monitored connection is established between a client and server.
- The system identifies the DNS, HTTP or HTTPS application in the session.
- The system identifies the requested domain or URL (for encrypted sessions, from a non-encrypted domain name, the ClientHello message or the server certificate).

This identification should occur within three to five packets, or after the server certificate exchange in the TLS/SSL handshake if the traffic is encrypted.

Important! To ensure that your system examines these initial packets that would otherwise pass, see Inspection of packets that pass before traffic is identified, on page 2918 and subtopics.

If early traffic matches all other rule conditions but identification is incomplete, the system allows the packet to pass and the connection to be established (or the TLS/SSL handshake to complete). After the system completes its identification, the system applies the appropriate rule action to the remaining session traffic.

Block threat categories

Be sure that your policies specifically address Threat categories, which identify known malicious sites. Do this in addition to blocking sites with poor reputations.

For example, to protect your network from malicious sites, you must block all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives.

For specifics, see **Threat Categories** at the URL in URL category and reputation descriptions, on page 2087.

Position URL rules properly and consider rule order

Position URL rules after all other rules that *must* be hit.

URLs can belong to more than one category. It is possible to want to allow one category of websites and block another—whether explicitly or by relying on the default action. In this case, make sure you create and order URL rules so you get the desired effect, depending on whether the allow or the block should take precedence.

For additional guidelines for rules, see the following topics: Best practices for access control rules, on page 2058.

Handle uncategorized or reputationless URLs appropriately

When you build a URL rule, you first choose the category you want to match. If you explicitly choose **Uncategorized** URLs, you cannot further constrain by reputation.

Uncategorized URLs with Untrusted reputation are handled by the **Malicious Sites** category. If you want to block uncategorized sites with any other reputation level (such as Questionable), you must block all uncategorized sites.

After selecting a category and a reputation level, you can optionally select **Apply to unknown reputation**. For example, you can create a rule that applies to sites with Untrusted, Questionable, and unknown reputations.

You cannot manually assign categories and reputations to URLs, but in access control and QoS policies, you can manually block specific URLs. See Manual URL filtering, on page 2101. See also Dispute URL category and reputation, on page 2107.

URL filtering for encrypted web traffic

When performing URL filtering on encrypted web traffic, the system:

- (If DNS filtering is enabled) Checks to see if the system has previously seen the originating domain or the domain is in the local reputation database, and if so, takes action based on the reputation and category of the domain. Otherwise, the system processes the traffic based on your configurations for encrypted traffic, even if **Retry URL cache miss lookup** is enabled in the access control policy's advanced settings.
- Disregards the encryption protocol; a rule matches both HTTPS and HTTP traffic if the rule has a URL condition but not an application condition that specifies the protocol.
- Does not use URL lists. You must use URL objects and groups instead.
- Matches HTTPS traffic based on the subject common name in the public key certificate used to encrypt the traffic, and also evaluates the reputation of any other URLs presented at any time during the transaction, including the post-decryption HTTP URL.
- Disregards subdomains within the subject common name.
- Does not display an HTTP response page for encrypted connections blocked by access control rules (or any other configuration); see Limitations to HTTP response pages, on page 2103.

URL filtering and TLS server identity discovery considerations

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.

Access control policy advanced settings offer an **Early application detection and URL categorization** option for TLS Server Identity Discovery.

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

Note

- TLS server identity discovery *cannot* be used with any of the following:
  - STARTTLS traffic
  - The HTTP CONNECT method
  - Traffic that is already being decrypted by another device on the network
- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is supported on any Secure Firewall Threat Defense Virtual version deployed in AWS. TLS server identity is incompatible with certain deployment scenarios that involve Gateway Load Balancer (GWLB). Whether the device initiates a server certificate probe depends on its deployment method with GWLB and the traffic direction.
  - Geneve single-arm flow: The probe *is not initiated* for either east–west or north–south traffic. A connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.
  - Geneve dual-arm flow: The probe *is initiated only* for north–south traffic.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

For more information, see TLS server identity discovery, on page 2692.

HTTP/2 URL extraction limitations

The system can extract HTTP/2 URLs from TLS certificates, but not from a payload.

Use manual URL filtering effectively

- Specify URLs using a custom Security Intelligence list or feed object. Do not use a URL object or directly enter a URL into the rule. For details, see Manual URL filtering options, on page 2102.
- If you manually filter specific URLs using URL objects or by entering URLs directly into the rule, carefully consider other traffic that might be affected. To determine whether network traffic matches a URL condition, the system performs a simple substring match. If the requested URL matches any part of the string, the URLs are considered to match.
- If you use manual URL filtering to create exceptions to other rules, position the specific rule with the exceptions above the general rule that would otherwise apply.

Search query parameters in URLs are not used for matching

The system does not use search query parameters in the URL to match URL conditions. For example, consider a scenario where you block all shopping traffic. In that case, using a web search to search for amazon.com is not blocked, but browsing to amazon.com is.

Maintain default access control policy advanced settings

Unless you have good reason to change them, leave these settings on the Advanced tab of your access control policy at their defaults:

- **General Settings**:
  - **Retry URL cache miss lookup**
  - **Enable reputation enforcement on DNS traffic**

For descriptions of these settings, refer to General settings, on page 2691.

Reduce unnecessary usage of connection table space and NAT table slots

Consider a scenario in which URL filtering is enabled and any traffic that does not conform with the URL filtering rules is blocked. In such a scenario, the threat defence device analyses the initial packets in the traffic flow to extract URL information. After analysis, if the flow does not match any URL filtering rules, the flow is blocked. This means that the packets are dropped by the Threat Defense device. However, the associated connection remains in the connection table. This behaviour results in unnecessary use of connection table space and, if NAT is configured, NAT table slots, which can lead to increased consumption of network resources.

There are different ways to prevent this type of scenario. Since most of the traffic will be TCP, you can use the 'block with reset' option for TCP traffic instead of using 'block'. This approach reduces the usage of connection table space and NAT table slots.

URL filtering in high availability deployments

For guidelines for URL filtering with Firepower Management Centers in high availability, see *URL Filtering and Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide*.

Memory limitations for selected device models

Device models with less memory store less URL data locally, and the system may therefore check the cloud more frequently to determine category and reputation for sites that are not in the local database.

Lower-memory devices include

- Firepower 1010
- Firewall Threat Defense Virtual with 8 GB of RAM

HTTPS traffic filtering

HTTPS traffic filtering is a security mechanism that

- determines the requested URL based on information passed during the TLS/SSL handshake using the subject common name in the public key certificate,
- disregards subdomains within the subject common name, requiring manual filtering to use top-level domains only, and
- does not support URL lists, requiring the use of URL objects and groups instead.

HTTPS filtering characteristics

There are several key differences between HTTPS filtering and HTTP filtering:

- Do not include subdomain information when manually filtering HTTPS URLs in access control or QoS policies. For example, use example.com instead of www.example.com.
-

Tip In an decryption policies, you can handle and decrypt traffic to specific URLs by defining a distinguished name decryption policy rule condition. The common name attribute in the subject distinguished name of a certificate contains the site's URL. Decrypting HTTPS traffic allows access control rules to evaluate the decrypted session, which improves URL filtering.

Traffic control by encryption protocol:

The system disregards the encryption protocol (HTTP vs HTTPS) when performing URL filtering in access control or QoS policies. This occurs for both manual and reputation-based URL conditions. In other words, URL filtering treats traffic to these websites identically:

- http://example.com/
- https://example.com/

To configure a rule that matches only HTTP or HTTPS traffic, add an application condition to the rule. For example, you could allow HTTPS access to a site while disallowing HTTP access by constructing two access control rules, each with an application and URL condition.

Application-specific URL filtering rules

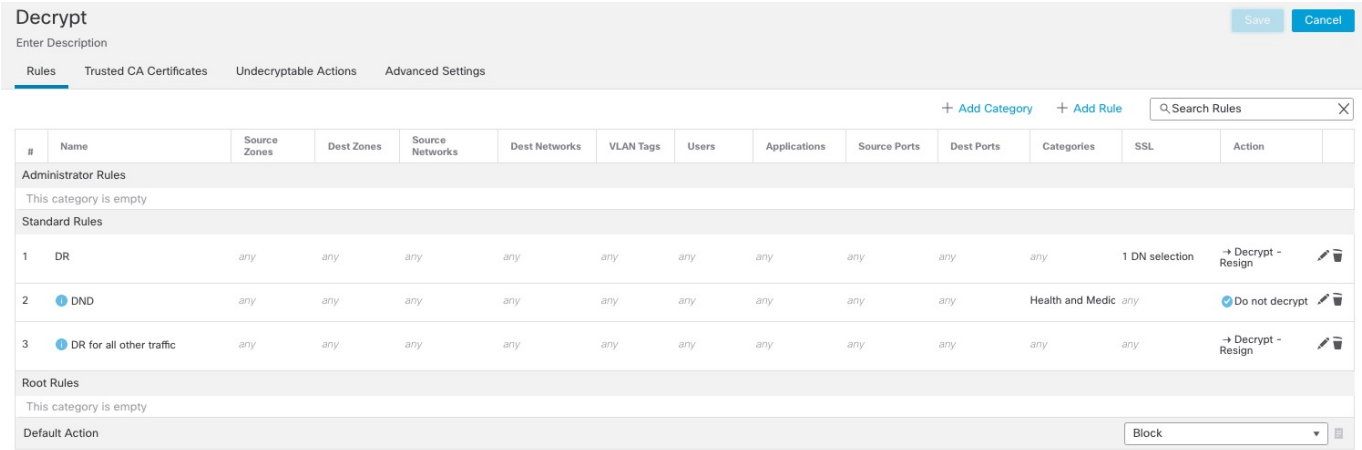
The first rule allows HTTPS traffic to the website:

- Action: Allow
- Application: HTTPS
- URL: example.com

The second rule blocks HTTP access to the same website:

- Action: Block
- Application: HTTP
- URL: example.com

Use categories in URL filtering



Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact

science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 2188.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 2054.

QUIC Fingerprinting

Snort can identify client applications in Quick UDP Internet Connections (QUIC sessions) based on EVE analysis. Refer to QUIC fingerprinting in EVE, on page 2241 for more information.

License requirements for URL filtering

This reference provides the license requirements for URL filtering functionality on Cisco Secure Firewall devices, covering both category and reputation filtering as well as manual filtering options.

Threat Defense License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.

Classic License

- Category and reputation filtering—URL Filtering

- Manual filtering—No additional license.

URL filtering licenses for threat defense devices

Refer to *URL Licenses* in the *Licenses* chapter in the Cisco Secure Firewall Management Center Administration Guide.

Requirements and prerequisites for URL filtering

This reference provides the requirements and prerequisites necessary for implementing URL filtering, including model support, supported domains, and required user roles.

Model support

Any

Secure Firewall 200 does not maintain a local URL database. These options are not relevant for this device type and are automatically changed to Cloud Only lookup when deploying policies: **Enable Automatic Updates**, URL Query Source for the **Local Database Only** and the **Local Database and Cisco Cloud** options.

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Configure URL filtering with category and reputation

This task enables URL filtering with category and reputation to protect your network from malicious websites and to control user access to specific website categories.

URL filtering with category and reputation provides comprehensive web security by evaluating websites based on their content categories and reputation scores. This feature helps prevent access to malicious sites while allowing administrators to control access to specific types of content.

Before you begin

- Assign the URL Filtering license to each managed device that will filter URLs.

Follow these steps to configure URL filtering with category and reputation:

Procedure

Step 1 Review and understand limitations AND guidelines.

Best practices for URL filtering, on page 2088

Step 2 Enable the URL Filtering feature.

Enable URL filtering using category and reputation, on page 2096

Step 3 Configure rules to filter URLs by category and reputation.

Configure URL conditions, on page 2097

For the best protection against malicious sites, you must block sites by reputation and block URLs in all threat categories.

(Optional) Supplement or selectively override category and reputation-based URL filtering, on page 2102

Step 4 (Optional) Allow users to bypass a website block by clicking through a warning page.

This step is optional.

HTTP response pages, on page 2103

Step 5 Order your rules so that traffic hits the key rules first.

URL rule order, on page 2099

Step 6 (Optional) Modify advanced options related to URL filtering.

This step is optional. Generally, use the defaults unless you have a specific reason to change them.

For information about advanced options, refer to Advanced Settings for Access Control, on page 2687.

- **Maximum URL characters to store in connection events**
- **Allow an Interactive Block to bypass blocking for (seconds)**
- **Retry URL cache miss lookup**
- **Enable reputation enforcement on DNS traffic**

Step 7 Deploy your changes.

Deploy configuration changes, on page 202

Step 8 Ensure that your system receives future URL data updates as expected.

Configure URL filtering health monitors, on page 2107

Step 9 Enable other features to protect your network from malicious sites.

See Security Intelligence, on page 2027.

Enable URL filtering using category and reputation

Enable URL filtering to control and monitor web traffic based on website categories and reputation scores, providing enhanced security for your network.

You must be an Admin user to perform this task.

Before you begin

Complete prerequisites described in Configure URL filtering with category and reputation, on page 2094.

Follow these steps to enable URL filtering using category and reputation:

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services**.

Step 2 Configure URL filtering options, on page 2096.

Step 3 Click **Save**.

URL filtering options

Adding a URL Filtering license automatically enables the URL filtering feature. With this feature, the system handles traffic based on a website's general classification (category) and risk level (reputation).

Although by default the system is configured to submit all URLs to the cloud for threat intelligence evaluation, using a local dataset of category and reputation data can make web browsing faster.When you enable or re-enable URL filtering, the Cloud-Delivered Firewall Management Center automatically queries Cisco for URL data and pushes the dataset to managed devices. This process may take some time.

If you use SSL rules to handle encrypted traffic, also see Rule-based decryption rules guidelines and limitations, on page 2188.

Enable automatic updates

If you **Enable Automatic Updates** (the default), the Cloud-Delivered Firewall Management Center checks the cloud every 30 minutes for updates. If you need strict control over when the system contacts external resources, disable automatic updates and instead create a recurring task using the scheduler. See the *Cisco Secure Firewall Management Center Administration Guide*.

Update now

Click **Update Now** to perform a one-time, on demand URL data update. You cannot start an on demand update if an update is already in progress. Although daily updates tend to be small, if it has been more than five days since your last update, new URL data may take as long as 20 minutes to download, depending on your bandwidth. The update itself may take up to 30 minutes to complete.

URL query source

You can choose how the system assigns a category and reputation to the URLs that your users browse to. You can choose:

- **Local Database Only**: Uses the local dataset only. Use this option if you do not want to submit your uncategorized URLs (category and reputation not in the local dataset) to Cisco, for example, for privacy reasons. However, note that connections to uncategorized URLs do *not* match rules with category or reputation-based URL conditions. You cannot assign categories or reputations to URLs manually.
- **Local Database and Cisco Cloud**: Uses the local dataset when possible, which can make web browsing faster. When users browse to an URL whose category and reputation is not in the local dataset or a cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.
- **Cisco Cloud Only** (default): Does not use the local dataset. When users browse to an URL whose category and reputation is not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache. This option guarantees the most up-to-date category and reputation information.

  This option requires Version 7.3 on the device. If you enable this option, devices running earlier versions will use the **Local Database and Cisco Cloud** option.

Cached URLs expire

Caching category and reputation data makes web browsing faster. By default, cached data for URLs never expires, for fastest performance.

To minimize instances of URLs matching on stale data, you can set cached URLs to expire. For more accurate and current threat data, choose a shorter expiration time. A cached URL refreshes after the first time a user on the network visits it after the specified time passes. The first user does not see the refreshed result, but the next user who visits the URL does.

Configure URL conditions

Configure URL conditions to protect your network by controlling access to sites based on URL category and reputation.

URL conditions allow you to control network access based on website categories and reputations, providing protection against malicious sites and enabling security policy enforcement.

Before you begin

Attention As a prerequisite, ensure that you create at least a Monitor rule at the top of your access control policy, containing Category or Reputation parameters. This is essential to see ANY category or reputation data for ANY URLs that hit the particular access control policy.

If there is no rule in the access control policy with the category or reputation parameters configured, the **Connection Events** page in the management center shows no data for Category or Reputation for ANY URL traffic that hits the access control policy.

Follow these steps to configure URL conditions:

Procedure

Step 1 In the rule editor, click the following for URL conditions:

- Access control or QoS—Click **URLs**.
- SSL—Click **Category**.

Step 2 Find and choose the URL categories that you want to control:

In an access control or QoS rule, click **Category**.

For effective protection from malicious sites, you must block URLs in all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives. For a list of Threat categories, see URL category and reputation descriptions, on page 2087.

Be sure to click the arrows at the bottom of the list to see all available categories.

Step 3 (Optional) Constrain URL categories by choosing a **Reputation**.

Note that if you explicitly match **Uncategorized** URLs, you cannot further constrain by reputation. Choosing a reputation level also includes other reputations either more or less severe than the level you choose, depending on the rule action:

- Includes less severe reputations—If the rule allows or trusts web traffic. For example, if you configure an access control rule to allow Favorable (level 4), it also automatically allows Trusted (level 5) sites.
- Includes more severe reputations—If the rule rate limits, decrypts, blocks, or monitors web traffic. For example, if you configure an access control rule to block Questionable sites (level 2), it also blocks Untrusted (level 1) sites.

If you change the rule action, the system automatically changes the reputation levels in URL conditions.

Optionally, select **Apply to unknown reputation**.

Step 4 Click **Add URL** or **Add to Rule**, or drag and drop.

Step 5 (Optional) To choose predefined URL objects, or URL lists and feeds in an access control or QoS rule, click **URL**, select the objects, and add them to the destination.

These objects implement manual URL filtering rather than category-based filtering.

Step 6 Save or continue editing the rule.

URL condition in an access control rule

The following graphic shows the URL condition for an access control rule that blocks all malware sites, all untrusted sites, and all social networking sites with a reputation level of Neutral or worse.

This table summarizes how you build the condition.

Blocked URL	Category	Reputation
Malware sites, regardless of reputation	Malware Sites	ANY
Any untrusted URL (level 1)	ANY	1 - Untrusted
Social networking sites with a reputation level of Neutral or worse (levels 1 through 3)	Social Network	3 - Neutral

Rules with URL conditions

This table lists rules that support URL conditions, and the types of filtering that each rule type supports.

Rule Type	Supports Category and Reputation Filtering?	Supports Manual Filtering?
Access control	Yes	Yes
Decryption policy	Yes	No. Use distinguished name conditions instead.
QoS	Yes	Yes

To use URL filtering in a decryption policy that has **Do Not Decrypt** rule conditions, refer to Use categories in URL filtering, on page 2092.

URL rule order

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.
- If you configure exceptions to a rule, place the exception above the other rule.

DNS filtering

DNS filtering is a URL filtering feature that

- evaluates domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address,
- can often determine category and reputation of encrypted traffic without decryption, and
- is enabled by default through the **Enable reputation enforcement on DNS traffic** option on the **Advanced** tab of each new access control policy.

DNS filtering behavior

DNS filtering slightly modifies URL filtering behavior and is applicable only when URL filtering is enabled and configured.

If DNS filtering cannot determine the URL of encrypted traffic, that traffic is processed using your configurations for encrypted traffic.

Enable DNS filtering to identify URLs during domain lookup

DNS filtering allows you to identify and block URLs based on category and reputation during domain lookup, providing an additional layer of security by preventing access to malicious or unwanted domains before connections are established.

DNS filtering is enabled by default in new access control policies. However, additional configurations may be required in order for this setting to take effect.

Before you begin

- URL filtering using category and reputation must be licensed, enabled, and configured.

  DNS filtering does not use these settings in the URLs tab: URL groups, URL objects, URL lists and feeds, and URLs entered into the "Enter URL" text box.
- Refer to limitations at DNS filtering behavior for block actions, on page 2101.

Procedure

Step 1 In your access control policy's advanced settings, select **Enable reputation enforcement on DNS traffic**.

Step 2 In the same policy, for each access control rule that has URL category and reputation blocking configured:

- Application conditions—If the application condition is anything other than **any** (or empty), add **DNS** to that list. Other DNS-related options are not relevant for this purpose.
- Port condition—If the port/protocol condition is anything other than **any** (or empty), add **DNS_over_TCP** and **DNS_over_UDP**.

Step 3 Save your changes.

What to do next

If you are done making changes, Deploy configuration changes, on page 202.

DNS filtering behavior for block actions

Traffic that matches rules having action **Block with reset**, **Interactive Block**, or **Interactive Block with reset** will be treated as if the rule action were **Block**.

End users trying to access a blocked URL will experience this as an unexplained inability to connect to their page. The connection will spin and then time out.

DNS filtering and events

DNS filtering and events is a logging mechanism that

- generates connection events using specific fields such as DNS Query, URL Category, URL Reputation, and Destination Port,
- populates the DNS Query field with the domain name while leaving the URL field blank for DNS filtering matches, and
- sets the Destination Port to 53.

Event generation behavior

DNS filtering generates events based on the access control rule action:

- When the access control rule action is **Allow** or **Trust**, two connection events will be generated for the same traffic, one for DNS filtering (with the **DNS Query** field populated) and one for URL filtering (with the **URL** field populated).
- The first time the system encounters a particular URL, two events appear for that single session: one event showing uncategorized or reputationless for the DNS Query, and one event showing the actual category and reputation for the URL, which the system retrieves during the DNS Query and applies to the session while processing using standard URL filtering.

Manual URL filtering

Manual URL filtering is a URL filtering capability that

- supplements or selectively overrides category and reputation-based URL filtering by manually filtering individual URLs, groups of URLs, or URL lists and feeds in access control and QoS rules, and
- enables URL filtering without requiring a special license when manually permitting or blocking URLs through Allow or Block rules within an access control policy.

Manual URL filtering implementation examples

Examples:

- You might use access control to block a category of websites that are not appropriate for your organization. However, if the category contains a website that is appropriate, and to which you want to provide access, you can create a manual Allow rule for that site and place it before the Block rule for the category.
- If you prefer not to use category-based URL filtering, you can manually permit or block a URL or a group of URLs by creating an Allow or Block rule within an access control policy. You can perform this type of URL filtering without a special license.

Manual URL filtering is not supported in SSL rules. Use distinguished name conditions instead.

Caution Depending on how you implement manual URL filtering, URL matching may not be what you intend. Refer to Manual URL filtering options, on page 2102.

Manual URL filtering options

There are several ways to specify URLs for manual URL filtering.

Option	Description
(Best practice) Use custom Security Intelligence URL list or feed objects.	This is the recommended method for manual URL filtering. You can create a new list or feed, or choose an existing one in an access control or QoS rule. For more information, see Custom security intelligence lists and feeds, on page 3026 and subtopics.
Use URL objects, individually or as groups. URL objects are described at URLs, on page 3038. Or Enter URLs directly into the access control rule. (The **Enter URL** option on the rule page in the web interface.)	If you do not include a path (that is, there are no slash (/) characters in the URL), the match is based on the server's hostname only. If you include one or more / character, the entire URL string is used for a substring match. Then, a URL is considered a match if any of these are true: • The string is at the beginning of the URL. • The string follows a dot. • The string contains a dot in the beginning. • The string follows the :// characters. For example, ign.com matches ign.com or www.ign.com, but not versign.com. **Note** We recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths. The **Enter URL** option does not support wildcards.

Supplement or selectively override category and reputation-based URL filtering

This task allows you to use Security Intelligence URL lists and feeds to supplement or create exceptions to your category and reputation-based URL filtering rules in access control or QoS policies.

In access control or QoS rules, you can use Security Intelligence URL lists and feeds to supplement, or to specify exceptions to, your category and reputation-based URL filtering rules.

Important! If the list or feed you are configuring in this procedure contains exceptions to category- or reputation-based rules, put this rule above those rules in the rule order.

In SSL rules, use distinguished name conditions to configure parallel behavior.

Before you begin

- Configure URL filtering using category and reputation. Refer to Configure URL conditions, on page 2097.
- Understand important best practices for manual URL filtering. Refer to Best practices for URL filtering, on page 2088 and Manual URL filtering options, on page 2102.
- Configure one or more Security Intelligence objects (lists or feeds) containing the URLs that you want to use for manual filtering. Refer to Custom security intelligence lists and feeds, on page 3026.

Follow these steps to supplement or selectively override category and reputation-based URL filtering:

Procedure

Step 1 Navigate to the access control or QoS policy in which you will define the rule.

Step 2 Create or edit the rule in which you will add the new condition:

- If you are supplementing a category- or reputation-based URL filtering rule, edit the existing rule.
- If you are overriding or creating exceptions to a category- or reputation-based URL filtering rule, create a new rule.

Step 3 Select the list or feed you created as the destination URL criteria.

Step 4 Save the rule.

HTTP response pages

An HTTP response page is a web page that displays when the system blocks web requests using either access control rules or the access control policy default action.

HTTP response page types

The response page displayed depends on how you block the session:

- **Block Response Page**: Overrides the default browser or server page that explains that the connection was denied.
- **Interactive Block Response Page**: Warns users, but also allows them to click a button (or refresh the page) to load the originally requested site. Users may have to refresh after bypassing the response page to load page elements that did not load.

If you do not choose a response page, the system blocks sessions without interaction or explanation.

Limitations to HTTP response pages

The system displays a response page only for unencrypted or decrypted HTTP/HTTPS connections blocked (or interactively blocked) either by access control rules or by the access control policy default action. The system does not display a response page for connections that are blocked by any other policy or mechanism.

The system cannot display a response page if the connection is reset (RST packet sent). If you enable response pages, the system prioritizes that configuration. Even if you choose **Block with reset** or **Interactive Block with reset** as the rule action, the system displays the response page and does not reset matching web connections. To ensure that blocked web connections are reset, you must disable response pages.

- Note that all non-web traffic that matches the rule *is* blocked with reset.

The system does not display a response page for encrypted connections that are blocked by access control rules (or any other configuration). Access control rules evaluate encrypted connections if you did not configure an SSL policy, or your SSL policy passes encrypted traffic.

-
- However, the system does display a response page for connections that are decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream.

The system does not display a response page when web traffic is blocked because of a promoted access control rule (an early-placed blocking rule with only simple network conditions).

If a URL is entered without specifying "http" or "https", and the browser initiates the connection on port 80, and the user clicks through a response page, and the connection is subsequently redirected to port 443, the user will not see a second interactive response page because the response to this URL is already cached.

The system does not display a response page when web traffic is blocked before the system identifies the requested URL. Refer to Best practices for URL filtering, on page 2088.

The system does not display a response page if the block URL access control rule is configured after the allow application rule.

Requirements and prerequisites for HTTP response pages

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Describe the necessary conditions, user roles, and supported domains required for setting up HTTP response pages.

Choose HTTP response pages

HTTP response pages provide feedback to users when their sessions are blocked by access control policies, allowing for better user experience and network transparency.

Reliable display of HTTP response pages depends on your network configuration, traffic loads, and size of the page. Smaller pages are more likely to display successfully.

Procedure

Step 1 In the access control policy editor, select **HTTP Responses** from the **More** drop-down arrow at the end of the packet flow line.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Choose the **Block Response Page** and **Interactive Block Response Page**:

- System-provided—Displays a generic response. Click **View** ( ) to view the code for this page.
- Custom—Create a custom response page. A pop-up window appears, prepopulated with system-provided code that you can replace or modify by clicking **Edit** ( ). A counter shows how many characters you have used.
- None—Disables the response page and blocks sessions without interaction or explanation. To quickly disable interactive blocking for the whole access control policy, choose this option.

Step 3 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Interactive blocking with HTTP response pages

Interactive blocking with HTTP response pages is a security mechanism that

- allows users to load an originally requested site after reading a warning page,
- provides user control over whether to proceed with potentially blocked traffic, and
- enables temporary bypass with configurable duration settings.

Configuration behavior and bypass settings

When you configure interactive blocking, users may have to refresh after bypassing the response page to load page elements that did not load.

Tip To quickly disable interactive blocking for the whole access control policy, display neither the system provided page nor a custom page. The system then blocks all connections without interaction.

If a user does not bypass an interactive block, matching traffic is denied without further inspection. If a user bypasses an interactive block, the access control rule allows the traffic, although the traffic may still be subject to deep inspection and blocking.

By default, a user bypass is in effect for 10 minutes (600 seconds) without displaying the warning page on subsequent visits. You can set the duration to as long as a year, or you can force the user to bypass the block every time. This limit applies to every Interactive Block rule in the policy. You cannot set the limit per rule.

Logging options for interactively blocked traffic are identical to those in allowed traffic. If a user does not bypass the interactive block, the system can log only beginning-of-connection events. When the system initially warns the user, it marks any logged beginning-of-connection event with the `Interactive Block` or `Interactive Block with reset` action. If the user bypasses the block, additional connection events logged for the session have an action of `Allow`.

Configure interactive blocking

Interactive blocking allows users to bypass URL filtering rules while maintaining security controls and logging capabilities.

This procedure describes how to allow users to bypass URL filtering rules.

Procedure

Step 1 As part of access control, configure an access control rule that matches web traffic; see Create and edit access control rules, on page 2066:

- Action—Set the rule action to **Interactive Block** or **Interactive Block with reset**; see Access control rule interactive blocking actions, on page 2047.
- Conditions—Use URL conditions to specify the web traffic to interactively block.
- Logging—Assume users will bypass the block and choose logging options accordingly.
- Inspection—Assume users will bypass the block and choose deep inspection options accordingly; see Access control policies, on page 1997.

Step 2 (Optional) (Optional) In the access control policy **HTTP Responses**, choose a custom interactive-block HTTP response page; see Choose HTTP response pages, on page 2105.

Step 3 (Optional) (Optional) In the access control policy **Advanced** settings, change the user bypass timeout; see Set the user bypass timeout for a blocked website, on page 2107.

After a user bypasses a block, the system allows the user to browse to that page without warning until the timeout period elapses.

Step 4 Save the access control policy.

Step 5 Deploy configuration changes.

Set the user bypass timeout for a blocked website

Set the duration that users can browse after bypassing a URL filtering block before having to bypass the block again.

This procedure explains how to set the time allowed for browsing after the user bypasses a URL filtering block. When the timeout expires, the user must bypass the block again.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control** and edit the policy.

Step 2 Select **Advanced Settings** from the **More** drop-down menu at the end of the packet flow line.

Step 3 Click **Edit** ( ) next to General Settings.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 In the **Allow an Interactive Block to bypass blocking for (seconds)** field, enter the number of seconds that must elapse before the user bypass expires.

Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Configure URL filtering health monitors

The following health policies alert if the system has problems obtaining or updating URL category and reputation data.

- URL Filtering Monitor
- Threat Data Updates on Device

To ensure that these are configured the way you want them, refer to *Health Modules* and *Configuring Health Monitoring* in the *Cisco Secure Firewall Management Center Administration Guide*.

Dispute URL category and reputation

This task allows you to challenge URL categorizations or reputation scores when you disagree with the assignments made by Talos Intelligence.

If you disagree with a category or reputation assigned by Talos, you can submit a request for re-evaluation.

Before you begin

You will need your Cisco account credentials.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center web interface, do one of the following:

Location of dispute option	Path to dispute option
Cloud Services configuration page	a. Navigate to the **Integration** > **Other Integrations** > **Cloud Services** page. b. Select **Dispute URL categories and reputations**.

The Talos web site opens in a separate browser window.

Step 2 Sign in to the Talos site with your Cisco credentials.

Step 3 Review the information and follow the instructions on the Talos page.

Step 4 On the Talos site, review how submitted disputes are handled. Check what response you can expect, if any.

The dispute process is independent of Secure Firewall products.

Take action if the URL category set changes

URL filtering categories may occasionally change to accommodate new web trends and evolving usage patterns. Taking action when these changes occur ensures that your policies continue to function properly and can be deployed successfully.

The set of URL Filtering categories may occasionally change, in order to accommodate new web trends and evolving usage patterns.

These changes affect both policies and events.

Shortly before URL category changes are scheduled to occur, and after they occur, you will see alerts in the list of rules in any access control, SSL, and QoS policy that is affected by the changes, and on URL or Category in rules that you edit.

You should take action when you see these alerts.

Note Updates to the URL category set as described in this topic are distinct from the changes that simply add new URLs to existing categories or re-classify misclassified URLs. This topic does not apply to category changes for individual URLs.

Procedure

Step 1 If you see an alert beside a rule in an access control policy, hover over the alert to see details.

Step 2 If the alert mentions changes to URL categories, edit the rule to see further details.

Step 3 Hover over the URL or Category in the rule dialog to see general information about the type of changes.

Step 4 If you see an alert beside a category, click the alert to view details.

Step 5 If you see a "More information" link in the description of a change, click it to view information about the category on the Talos web site.

Alternatively, see a list and descriptions of all categories at the link in URL category and reputation descriptions, on page 2087.

Step 6 Depending on the type of change, take appropriate action:

Type of Category Change	What The System Will Do	What You Should Do
Existing category will soon be deprecated	Nothing yet. You have a few weeks to change affected rules. If you do not take action in that time, the system eventually will not be able to redeploy the policy.	Remove this category from all rules that include it. If there is a similar new category, consider using that category instead.
New category is added	By default, the system does not use newly added categories.	Consider creating new rules for the new category.
Existing category is deleted	The category will appear in the rule in strikethrough text (that is, with a line through the category name.)	You must delete the obsolete category from the rule before you can deploy the policy.

Step 7 Check your SSL rules (Category) for these changes and take action as needed.

Step 8 Check your QoS rules (URL) for these changes and take action as needed.

What to do next

Deploy configuration changes.

URL category and reputation changes

URL category and reputation changes are system modifications that

- affect how events are categorized and labeled in the system,
- result in different handling of events processed before and after the changes, and
- impact the display of URL reputation information in event viewers.

Effects on event processing

URL category and reputation changes affect events differently based on when they were processed:

- When URL categories change, events that the system processed before the category change will be associated with their original category names and will be labeled with **Legacy**. Events that the system processed after the category change will be associated with the new categories.

  Older, legacy events will age out of the system over time.

- If a URL does not have a reputation at the time it was processed, the URL Reputation column in the event viewer will be empty.

Troubleshoot URL filtering

This reference provides troubleshooting information for common URL filtering issues including missing categories, uninspected packets, registration failures, lookup errors, and performance problems.

Expected URL category is missing from the categories list

The URL filtering feature uses a different set of categories than the Security Intelligence feature. The category that you expect to see may be a Security Intelligence category. To see those categories, look at the **URLs** tab on the **Security Intelligence** tab in an access control policy.

Initial packets are passing uninspected

Refer to Inspection of packets that pass before traffic is identified, on page 2918 and subtopics.

See also DNS filtering, on page 2099.

How can I find the category and reputation of a particular URL?

Do a manual lookup. Refer to *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.

Error when attempting a manual lookup: "cloud lookup failure for <URL>"

Make sure the feature is properly enabled. Refer to the prerequisites in *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.

URL appears to be incorrectly handled based on its URL category and reputation

Problem: The system does not handle the URL correctly based on its URL category and reputation.

Solutions:

- Verify that the URL category and reputation associated with the URL are what you think they are. See *Finding URL Category and Reputation* in the *Cisco Secure Firewall Management Center Administration Guide*.
- These issues may be addressed by settings described in URL filtering options, on page 2096, accessible using Enable URL filtering using category and reputation, on page 2096.
  - The URL cache may hold stale information. See information about the **Cached URLs Expire** setting in URL filtering options, on page 2096.

  - The local data set may not be updated with current information from the cloud. See information about the **Enable Automatic Updates** setting in URL filtering options, on page 2096.
  - The system may be configured to *not* check the cloud for current data. See information about the **Query Cisco cloud for unknown URLs** setting in URL filtering options, on page 2096.

- Your access control policy may be configured to pass traffic to the URL without checking the cloud. See information about the **Retry URL cache miss lookup** setting in General settings, on page 2691.
- See also Best practices for URL filtering, on page 2088.
- If the URL is processed using an SSL rule, see Rule-based decryption rules guidelines and limitations, on page 2188 and Best practice for Decryption policy rule order, on page 2196
- Verify that the URL is being handled using the access control rule that you think it is being handled by, and that the rule does what you think it does. Consider rule order.
- Verify that the local URL category and reputation database on the Cloud-Delivered Firewall Management Center is successfully being updated from the cloud and that managed devices are successfully being updated from the Cloud-Delivered Firewall Management Center.

  Status of these processes are reported in the Health Monitor, in the **URL Filtering Monitor** module and the **Threat Data Updates on Devices** module. For details, see *Health* in the *Cisco Secure Firewall Management Center Administration Guide*.

If you want to immediately update the local URL category and reputation database, go to **Integration** > **Other Integrations** > **Cloud Services**, then click **Update Now** in the **URL Filtering** area. For more information, see URL filtering options, on page 2096.

A URL category or reputation is not correct

For access control or QoS rules: Use manual filtering, paying careful attention to rule order. See Manual URL filtering, on page 2101 and Configure URL conditions, on page 2097.

For SSL rules: Manual filtering is not supported. Instead, use distinguished name conditions.

See also Dispute URL category and reputation, on page 2107.

Web pages are slow to load

There is a tradeoff between security and performance. Some options:

- Consider modifying the **Cached URLs Expire** setting. Choose **Integration** > **Other Integrations** > **Cloud Services**. For information, see URL filtering options, on page 2096.
- Consider deselecting the **Retry URL cache miss lookup** setting in General settings, on page 2691.

Events do not include URL category and reputation

- Make sure you have included applicable URL rules in an access control policy, the rules are active, and the policies have been deployed to the relevant devices.
- URL category and reputation do not appear in an event if the connection is processed before it matches a URL rule.
- The rule that handles the connection must be configured for URL category and reputation.

- Even if you have configured URL categories in the Categories tab in an SSL rule, you must also configure the URLs tab in a rule in your access control policy.

DNS filtering is not working

Make sure you have completed all prerequisites and steps in Enable DNS filtering to identify URLs during domain lookup, on page 2100.

An end user tries to access a blocked URL and the page just spins and times out

When DNS Filtering is enabled and end users access a URL that is blocked, the page will spin but not load. End users are not notified that the page is blocked. This is currently a limitation when DNS filtering is enabled.

Refer to DNS filtering behavior for block actions, on page 2101.

Events include URL category and reputation but URL field is blank

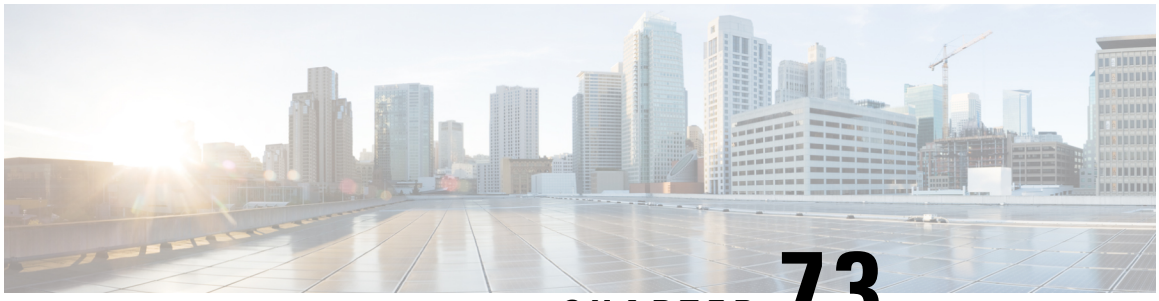
If the DNS Query field is populated and the URL field is empty, this is expected when the DNS filtering feature is enabled.

Refer to DNS filtering and events, on page 2101.

Multiple events are generated for a single transaction

A single web transaction sometimes generates two connection events, one for DNS filtering and one for URL filtering. This is expected when DNS filtering is enabled and:

- the access control rule action for the traffic is Allow or Trust.
- the system encounters a URL for the first time.



Refer to DNS filtering and events, on page 2101.

PART XVIII

Decryption Policies and Encrypted Visibility for Access Control

- Traffic Decryption Overview, on page 2115
- Standard Decryption Policies, on page 2137
- Rule-Based Decryption Policies, on page 2163
- Rule-Based Decryption Rules, on page 2187
- Encrypted Visibility Engine, on page 2239

CHAPTER 73

Traffic Decryption Overview

These topics provide an overview of Transport Layer Security/Secure Sockets Layer (TLS/SSL) inspection, discuss the prerequisites for TLS/SSL inspection configuration, and detail deployment scenarios.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as SSL vs. TLS - What's the Difference?

- Traffic decryption, on page 2115
- How TLS/SSL handshakes work, on page 2116
- Decryption rule and policy basics, on page 2121
- TLS crypto acceleration, on page 2130
- History for decryption policy , on page 2133

Traffic decryption

Traffic decryption enables deep inspection of traffic for analysis.

Traffic handling options

Most traffic on the internet is encrypted and in most cases, you might choose not to decrypt it. You can glean some information from encrypted traffic and you can also block it from your network if desired.

Your choices are:

- Decrypt the traffic and subject it to the full array of deep inspection:
  - Advanced Malware Protection
  - Security intelligence
  - Threat Intelligence Director
  - Application detectors

- URL and category filtering

- Leave the traffic encrypted and set up your access control and decryption policy to look for and potentially block:
  - Old protocol versions (such as Secure Sockets Layer)
  - Unsecure cipher suites
  - Applications with high risk and low business relevance
  - Untrusted issuer Distinguished Names

Access control policy integration

An access control policy is the main configuration that invokes subpolicies and other configurations, including a decryption policy. If you associate a decryption policy with access control, the system uses that decryption policy to handle encrypted sessions before it evaluates the sessions with access control rules. If you do not configure TLS/SSL inspection, or your devices do not support it, access control rules handle all encrypted traffic.

Access control rules also handle encrypted traffic when your TLS/SSL inspection configuration allows the traffic to pass. However, some access control rule conditions require unencrypted traffic, so encrypted traffic might match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improves performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

Note As long as your managed devices have Snort 3 enabled, the system supports decrypting TLS 1.3 traffic. You can enable TLS 1.3 decryption in an decryption policy's advanced options; for more information, see Rule-based decryption policy advanced options, on page 2182.

Notes

Decryption rules require processing overhead that can impact performance. Before you decide to decrypt traffic, see Best practice for deciding when to decrypt traffic, on page 2122.

The system does not support mutual authentication; that is, you cannot upload a client certificate to the Cloud-Delivered Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

If you set the value of TCP maximum segment size (MSS) using FlexConfig, the observed MSS could be less than your setting. For more information, see TCP MSS, on page 1106.

How TLS/SSL handshakes work

In this documentation, the term *TLS/SSL handshake* represents the two-way handshake that initiates encrypted sessions in both the SSL protocol and its successor protocol, TLS.

In an inline deployment, the system processes the TLS/SSL handshake, potentially modifying the ClientHello message and acting as a TCP proxy server for the session.

The figure shows an inline deployment.

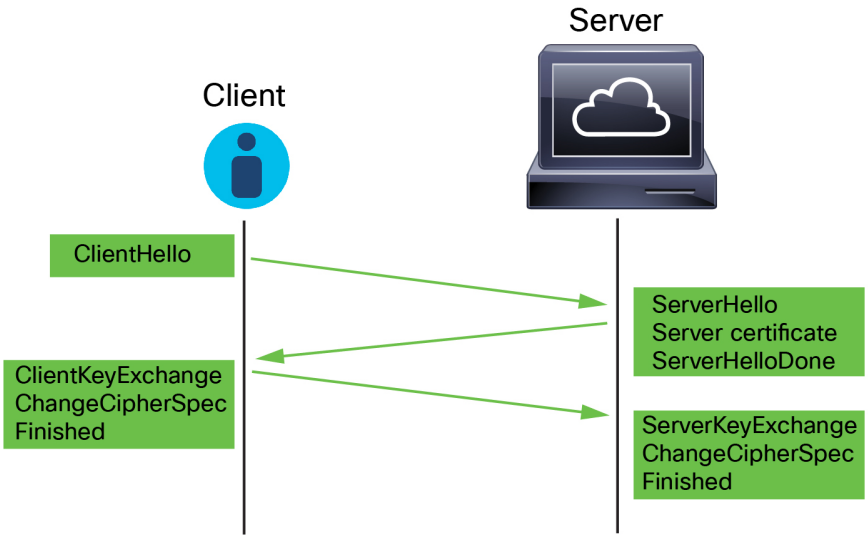
Summary

The key components involved in the TLS/SSL handshake process are:

- Client: Initiates the encrypted session by sending a ClientHello message specifying multiple supported values for each encryption attribute
- Server: Responds with a ServerHello message specifying a single supported value for each encryption attribute, determining the encryption method for the secure session
- Managed device: Monitors TCP sessions for encrypted session initiation attempts and can act as a TCP proxy server
- Handshake messages: Specialized packets that communicate encryption attributes between client and server

Workflow

These stages describe how TLS/SSL handshakes establish encrypted sessions:



1. The client establishes a TCP connection with the server after successfully completing the TCP three-way handshake.
2. The managed device monitors the TCP session for any attempt to initiate an encrypted session.
3. The client and server exchange specialized handshake messages to establish an encrypted session.
   - ClientHello—The client specifies multiple supported values for each encryption attribute.
   - ServerHello—The server specifies a single supported value for each encryption attribute, and the ServerHello response determines which encryption method the system uses during the secure session.
4. After the TLS/SSL handshake completes, the managed device caches encrypted session data and server certificate data.

   This caching allows session resumption without requiring the full handshake and enables faster handshake processing in subsequent sessions that use the same certificate.

ClientHello message handling

The client sends the ClientHello message to the server, which acts as the packet destination, when a secure connection can be established. The client uses this message to initiate the TLS/SSL handshake to respond to a ServerHello message from the destination server.

The following figure shows an example. Also see RFC 8446, sec. 4 . You can also consult a resource such as What Happens in a TLS Handshake? at cloudflare.com.

ClientHello message process

The process consists of these steps:

1. ClientHello initiates the process.

   The ClientHello message contains the Server Name Indication (SNI), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

   The server certificate contains the Subject Alternative Name (SAN), which can have fully qualified domain names and IP addresses. For more information about the SAN, see Distinguished names, on page 2962.

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

Data exchange

If you configure TLS/SSL decryption, when a managed device receives a ClientHello message, the system attempts to match the message to decryption rules that have the **Decrypt - Resign** , or **Decrypt - Known Key** action. The match relies on data from the ClientHello message and from cached server certificate data. The table lists the possible types of data available for matching conditions.

Table 122: Data Availability for Decryption rule Conditions

Decryption rule Condition	Data Present In
Zones	ClientHello
Networks	ClientHello
VLAN Tags	ClientHello
Ports	ClientHello
Users	ClientHello
Applications	ClientHello (Server Name Indicator extension)
Categories	ClientHello (Server Name Indicator extension)
Certificate	Server certificate (potentially cached)
Distinguished Names	Server certificate (potentially cached)
Certificate Status	Server certificate (potentially cached)
Cipher Suites	ServerHello
Versions	ServerHello

Important Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

ClientHello message modifications

If the ClientHello message matches a **Decrypt - Resign** , or **Decrypt - Known Key** rule, the system modifies the ClientHello message.

- (TLS 1.2 only; TLS 1.3 does not support compression.) Compression methods—Strips the `compression_methods` element, which specifies the compression methods the client supports. The system cannot decrypt compressed sessions.
- Cipher suites—Strips cipher suites from the `cipher_suites` element if the system does not support them. If the system does not support any of the specified cipher suites, the system transmits the original, unmodified element. This modification reduces the Unknown Cipher Suite and Unsupported Cipher Suite types of undecryptable traffic.
- Session identifiers—Strips any value from the `Session Identifier` element and the SessionTicket extension (RFC 5077, sec 3.2) that does not match cached session data. If a ClientHello value matches cached data, an interrupted session can resume without the client and server performing the full TLS/SSL handshake. This modification improves the likelihood of session resumption and reduces the Session Not Cached incidents of undecryptable traffic..

- Elliptic curves—Strips elliptic curves from the Supported Elliptic Curves extension if the system does not support them. If the system does not support any of the specified elliptic curves, the managed device removes the extension and strips any related cipher suites from the `cipher_suites` element.
- ALPN extensions—Strips any value from the Application-Layer Protocol Negotiation (ALPN) extension that is unsupported in the system (for example, the HTTP/2 protocol).
- Other Extensions—Strips the Next Protocol Negotiation (NPN) and TLS Channel IDs extensions.

  Decryption rules with a **Decrypt - Resign** , or **Decrypt - Known Key** action now natively support the Extended Master Secret (EMS) extension during ClientHello negotiation, enabling more secure communications. The EMS extension is defined by RFC 7627 .

After the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

If the ClientHello message does *not* match a **Decrypt - Resign** , or **Decrypt - Known Key** rule, the system does not modify the message. It then determines whether the message passes access control evaluation (which can include deep inspection). If the message passes inspection, the system transmits it to the destination server.

ClientHello is *not* modified if traffic matches a **Monitor** rule condition.

Man-in-the-middle

Direct communication between the client and server is not possible during the TLS/SSL handshake. After the message is modified, the Message Authentication Codes (MACs) computed by the client and server no longer match. For all subsequent handshake messages (and for the encrypted session once established), the managed device acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains distinct cryptographic session details.

Note The cipher suites that the system can decrypt are frequently updated and do not correspond directly to the cipher suites you can use in decryption rule conditions. For the current list of decryptable cipher suites, contact Cisco TAC .

How ServerHello and server certificate messages work

Summary

The key components involved in ServerHello and server certificate message handling are:

- Managed device: Processes ServerHello and server certificate messages and performs rule matching
- decryption rules: Define actions to take when messages match specific criteria
- Server certificate data: Certificate information used for matching against internal certificate objects
- TLS/SSL handshake: The secure connection establishment process
- Certificate authority (CA): Used for re-signing certificates in decrypt-resign actions

Workflow

These stages describe how ServerHello and server certificate message handling works:

1. The managed device receives ServerHello and server certificate messages and checks for rule matches.

   If the messages do not match any decryption rules, the managed device performs the Rule-based decryption policy default actions, on page 2179.

2. When messages match a rule that belongs to a decryption policy associated with an access control policy, the managed device performs actions based on the rule configuration.

   - **Monitor**: The TLS/SSL handshake continues to completion. The managed device tracks and logs traffic but does not decrypt it.
   - **Block or Block with Reset**: The managed device blocks the TLS/SSL session and, if configured, resets the TCP connection.
   - **Do Not Decrypt**: The TLS/SSL handshake continues to completion. The managed device does not decrypt the application data exchanged during the TLS/SSL session.

3. For decrypt actions with known key or resign methods, the managed device performs certificate matching and processing.

   - **Decrypt - Known Key**: The managed device attempts to match the server certificate data to an Internal Certificate object previously imported into the Security Cloud Control. Because you cannot generate an Internal Certificate object, and you must possess its private key, we assume you own the server on which you're using known key decryption.
   - **Decrypt - Resign**: The managed device processes the server certificate message and re-signs the server certificate with the previously imported or generated certificate authority (CA). The TLS/SSL handshake continues to completion. The managed device then uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

   If the certificate matches a known certificate, the TLS/SSL handshake continues to completion. The managed device uses the uploaded private key to decrypt and re-encrypt the application data exchanged during the TLS/SSL session.

   If the server changes its certificate between the initial connection with the client and subsequent connections, you must import the new server certificate in the Security Cloud Control for future connections to be decrypted.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Cloud-Delivered Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Decryption rule and policy basics

This section discusses information you should keep in mind when creating your Decryption rules and policies.

Key information for decryption policy creation

Consider this information when creating your decryption policies and rules.

Note Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, refer to a resource such as SSL vs. TLS - What's the Difference?

Guidelines for traffic decryption

Traffic that is encrypted when it passes through the system can be allowed or blocked, but it *cannot* be subjected to deep inspection or the full range of policy enforcement (such as intrusion prevention).

All encrypted connections are sent through the decryption policy to determine if they should be decrypted or blocked.

You can also configure decryption rules to block encrypted traffic of types you know you do not want on your network, such as traffic that uses the nonsecure SSL protocol or traffic with an expired or invalid certificate.

If unblocked, whether or not decrypted, traffic goes through the access control policy for a final allow or block decision.

Only *decrypted* traffic takes advantage of the system's threat defense and policy enforcement features, including:

- Advanced Malware Protection
- Security intelligence
- Threat Intelligence Director
- Application detectors
- URL and category filtering

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which can reduce overall system performance.

Encrypted traffic can be allowed or blocked by policy; encrypted traffic *cannot* be inspected.

Decrypted traffic is subject to threat defense and policy enforcement; decrypted traffic can be allowed or blocked by policy.

Detects encrypted application traffic using StartTLS (SMTPS, POPS, FTPS, TelnetS, IMAPS). Also identifies certain encrypted applications based on Server Name Indication in the TLS ClientHello message or subject distinguished name from the server certificate.

Best practice for deciding when to decrypt traffic

When not to decrypt traffic

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

(Snort 3.) Decryption policy is *not* bypassed for any connections that match access control rules with actions of Trust, Block, or Block with Reset, unless the traffic is prefiltered. The encrypted traffic is first evaluated by decryption policy and then proceeds to the access control policy, where a final allow or block decision is made.

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- URL category and reputation
- Port
- User group

Decryption rules provide a **Do Not Decrypt** action for traffic you do not want to decrypt; for more information, see Decryption rule Do Not Decrypt action, on page 2221.

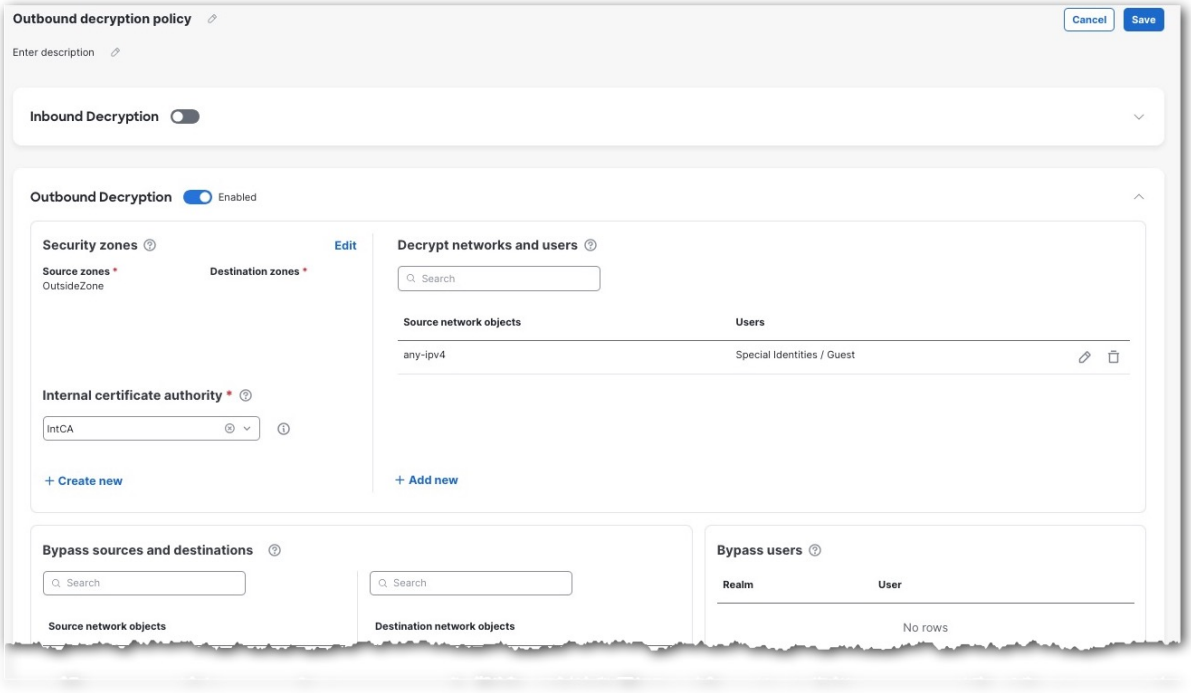
Note The related information links at the end of this topic explain how some aspects of rule evaluation work. Conditions such as URL and application filtering have limitations with respect to encrypted traffic. Make sure you understand those limitations.

For more information about using URL filtering in **Do Not Decrypt** rules, see Decryption rule Do Not Decrypt action, on page 2221.

When to decrypt traffic

All encrypted traffic must be decrypted to take advantage of the system's threat protection and policy enforcement features. If your managed device has sufficient memory and processing power to decrypt traffic, you should decrypt traffic that is not prohibited by law or regulation.

If you must decide what traffic to decrypt, base your decision on the risk of allowing the traffic on your network. The system provides a flexible framework for classifying traffic using rule conditions, which include URL reputation, cipher suite, protocol, and many other factors.



Decryption policy types

Decryption policy types include standard decryption policies and rule-based decryption policies.

Standard decryption policies

We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suitable for users who are not familiar with the complexities of decryption policies.

This section provides an example of setting up a standard decryption policy.

This policy decrypts outbound traffic only. All traffic from the OutsideZone security zone on any IPv4 network is decrypted using an internal CA named `IntCA`.

Key points about decryption policies include:

- The rule is a partial example; more options are available.
- You can configure inbound criteria, outbound criteria, or both.
- In addition to objects, you can also optionally configure outbound decryption exclusions, such as:
  - Undecryptable applications (such as ones that use certificate pinning).
  - URL categories such as medical, trading, and finance.
- You can configure outbound block criteria for certificate status and TLS version.
- A standard policy has advanced policy options that are similar to rule-based policies.

Rule-based decryption policies

Rule-based decryption policies are created using a wizard that guides you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs.

A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time.

Decrypt and re-sign (outgoing traffic)

Decrypt and re-sign of traffic enables the system to act as a man in the middle, intercepting, decrypting, and (if the traffic is allowed to pass) inspecting and re-encrypting traffic. It is used with outgoing traffic where the destination server is outside your protected network and requires the client to trust the firewall's certificate to complete the connection.

How decrypt and re-sign works

The Firewall Threat Defense device negotiates with the client using an internal Certificate Authority (CA) object specified in the rule and builds a TLS/SSL tunnel between the client and the Firewall Threat Defense device. At the same time, the device connects to the destination web site and creates a TLS/SSL tunnel between the server and the Firewall Threat Defense device.

Thus, the client sees the CA certificate configured for the decryption rule instead of the certificate from the destination server. The client must trust the firewall's certificate to complete the connection. The Firewall Threat Defense device then performs decryption/re-encryption in both directions for traffic between the client and the destination server.

Prerequisite

To use the **Decrypt - Resign** rule action, you must create an internal CA object using a CA file and paired private key file. You can generate a CA and private key in the system if you don't already have them.

We simplify the process of configuring the **Decrypt - Resign** rule by automatically adding **Do Not Decrypt** rules to the decryption policy based on your choices for types of traffic to exempt from encryption, such as undecryptable applications. (Typically, these applications use certificate pinning so that decrypting the connection breaks the connection.) For more information, see Create a rule-based decryption policy with outbound connection protection, on page 2165.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Cloud-Delivered Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Incoming traffic decryption

Incoming traffic decryption protects internal servers from external attacks by intercepting and decrypting SSL/TLS encrypted traffic before it reaches the protected network.

Decryption policy requirements

This information applies only to rule-based decryption policies and rules

Note The Firepower System does not support mutual authentication; that is, you cannot upload a client certificate to the Cloud-Delivered Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Inbound decryption types

There are two types of inbound decryption:

- Replace Cert (default): Uses a certificate and key defined in the decryption rule to decrypt traffic. This certificate and key can be the internal server's certificate or a different certificate. You can change the certificate and key at any time. You can replace the certificate in any of the these ways:
  - API as discussed in the *Cisco Secure Firewall Threat Defense REST API Guide*.
  - Automated Certificate Management Environment (ACME).
  - **Objects** > **Object Management** > **PKI** > **Internal Certs** in the Cloud-Delivered Firewall Management Center.

  We recommend you include the certificate authority chain.
- Known Key: Use the internal server's certificate to decrypt incoming traffic. In the event the certificate changes, you must manually update it and consequently interrupt decryption until the new certificate is in place, both in the decryption policy and on the server.

Known key decryption for incoming traffic

The **Decrypt - Known Key** decryption rule action uses a server's private key to decrypt traffic. The **Decrypt - Known Key** rule action is used with incoming traffic, where the destination server is inside your protected network.

The main purpose of decrypting with a known key is to protect your servers from external attacks.

Prerequisites and requirements

To use the **Decrypt - Known Key** rule action, you must create an internal certificate object using the server's certificate file and paired private key file.

Note The system does not support mutual authentication; that is, you cannot upload a client certificate to the Cloud-Delivered Firewall Management Center and use it for **Decrypt - Resign**, **Decrypt - Replace Cert**, or **Decrypt - Known Key** decryption rule actions.

Other decryption rule actions

These topics discuss other decryption rule actions.

Decryption rule components

Each decryption rule has the following components.

State

A rule can have either of two states: enabled or disabled. By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

Position

Rules in a decryption policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number.

Conditions

Conditions specify the specific traffic the rule handles. Conditions can match traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate subject or issuer, certificate status, cipher suite, or encryption protocol version. The use of conditions can depend on target device licenses.

Action

A rule's action determines how the system handles matching traffic. You can monitor, allow, block, or decrypt encrypted matching traffic. Decrypted traffic is subject to further inspection. Note that the system does *not* inspect blocked encrypted traffic.

Logging

A rule's logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. You can log a connection when the system blocks an encrypted session or allows it to pass without decryption, according to the settings in an decryption policy. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. You can log connections to the Cloud-Delivered Firewall Management Center database, as well as to the system log (syslog) or to an SNMP trap server.

Tip Properly creating and ordering decryption rules is a complex task. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the decryption policy interface has a robust warning and error feedback system for rules.

Categories

For information about using decryption rule categories (such as Applications, Category, and Cert Status), see Rule-based decryption rule conditions, on page 2201.

Rule-based decryption rule order evaluation

Rule-based decryption rule order evaluation determines the sequence in which the system evaluates decryption rules in a policy.

Rule evaluation process

This information applies only to rule-based decryption policies and rules.

When you create a rule-based decryption rule in a rule-based decryption policy , you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules.

Note Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

Best practices for access control rules, on page 2058

Multi-rule example

This reference example demonstrates how the firewall handles traffic using a decryption policy that contains multiple rules.

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption rule 5: Decrypt - Resign** is the final rule. If traffic matches, the system re-signs the server certificate with an uploaded CA certificate and decrypts traffic. The decrypted traffic is then evaluated against access control rules, which treat decrypted and unencrypted traffic the same. This additional inspection allows the system to block traffic. All remaining traffic is re-encrypted before being sent to its destination. Traffic that does not match the decryption rule rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

TLS crypto acceleration

TLS crypto acceleration accelerates the following:

- TLS/SSL encryption and decryption
- VPN, including TLS/SSL and IPsec

Supported hardware and acceleration details

The following hardware models support TLS crypto acceleration:

- Secure Firewall 3100
- Secure Firewall 4200
-
- Firepower 4100/9300

  For information about TLS crypto acceleration support on Firepower 4100/9300 Firewall Threat Defense container instances, see the *FXOS Configuration Guide*.

TLS crypto acceleration is *not* supported on any virtual appliances or on any hardware except for the preceding.

Note For more information about TLS crypto acceleration and the 4100/9300, see the *FXOS Configuration Guide*.

Features *not* supported by TLS crypto acceleration include:

- Managed devices where Firewall Threat Defense container instance is enabled.

- If the inspection engine is configured to preserve connections and the inspection engine fails unexpectedly, TLS/SSL traffic is dropped until the engine restarts.

  This behavior is controlled by the **configure snort preserve-connection {enable | disable}** command.

TLS crypto acceleration guidelines and limitations

HTTP-only performance

Using TLS crypto acceleration on a managed device that is not decrypting traffic can affect performance.

Federal information processing standards (FIPS)

If TLS crypto acceleration and Federal Information Processing Standards (FIPS) are both enabled, connections with the following options fail:

- RSA keys less than 2048 bytes in size
- Rivest cipher 4 (RC4)
- Single Data Encryption Standard (single DES)
- Merkle–Damgard 5 (MD5)
- SSL v3

FIPS is enabled when you configure the Cloud-Delivered Firewall Management Center and managed devices to operate in a security certifications compliance mode. To allow connections when operating in those modes, you can configure web browsers to accept more secure options.

For more information:

- Ciphers supported by FIPS: Configure SSL settings, on page 1279.
- Security certifications compliance modes, on page 315.
- Common Criteria.

TLS heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

For more information, see Default handling options for undecryptable traffic, on page 2180.

To determine whether applications are using TLS heartbeat, see Troubleshoot TLS heartbeat, on page 2230.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, refer to *The SSL Preprocessor* section in the "Custom Snort 2 Intrusion Policies for Access Control" document.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

If a significant amount of oversubscription is occurring, you have these options:

- Upgrade your managed devices to increase TLS/SSL processing capacity.
- Change your decryption policies to add **Do Not Decrypt** rules for traffic that is not a high priority to decrypt.

Keep these guidelines in mind if your managed device has TLS crypto acceleration enabled.

View the status of TLS crypto acceleration

This task allows you to determine if TLS crypto acceleration is enabled on your managed devices.

Perform this task in the Cloud-Delivered Firewall Management Center to check the TLS crypto acceleration status for your managed devices.

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center.

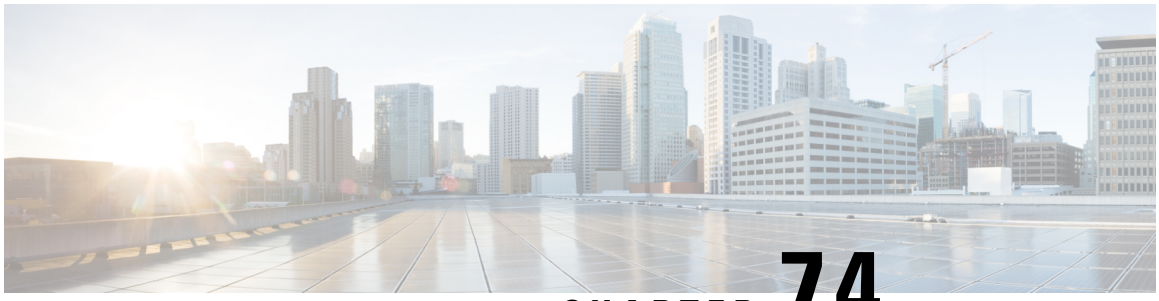
Step 2 Click **Devices** > **Device Management**.

Step 3 Click **Edit** ( ) to edit a managed device.

Step 4 Click **Device** page.

TLS crypto acceleration status is displayed in the General section.

History for decryption policy



Provides a chronological overview of decryption policy features, including version support and configuration changes.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
New decryption policy user interface	December 15, 2025	Any	You have the choice of the following types of decryption policies: • Decryption policy: Also referred to as a standard decryption policy: We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suited for anyone who is not proficient at understanding the ins and outs of decryption policies. • Rule-based decryption policy: Decryption policy you create using a wizard that steps you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs. A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time. New/modified screens: **Policies** > **Decryption** > **Create New** > **Decryption Policy** **Policies** > **Decryption** > **Create New** > **Decryption Policy (Rule-Based)**
QUIC decryption.	20241030	7.6.0 with Snort 3	You can configure the decryption policy to apply to sessions running on the QUIC protocol. QUIC decryption is disabled by default. You can selectively enable QUIC decryption per decryption policy and write decryption rules to apply to QUIC traffic. By decrypting QUIC connections, the system can then inspect the connections for intrusion, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. We modified the decryption policy Advanced Settings to include the option to enable QUIC decryption. See: Decryption Policy Advanced Options

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Easily bypass decryption for sensitive and undecryptable traffic.	20240808	7.6.0	It is now easier to bypass decryption for sensitive and undecryptable traffic, which protects users and improves performance. New decryption policies now include predefined rules that, if enabled, can automatically bypass decryption for sensitive URL categories (such as finance or medical), undecryptable distinguished names, and undecryptable applications. Distinguished names and applications are undecryptable typically because they use TLS/SSL certificate pinning, which is itself not decryptable. For outbound decryption, you enable/disable these rules as part of creating the policy. For inbound decryption, the rules are disabled by default. After the policy is created, you can edit, reorder, or delete the rules entirely. New/modified screens: **Policies** > **Access Control** > **Decryption** > **Create Decryption Policy** See: Decryption Policies
Decryption policy.	20221213	7.3.0	Feature renamed to *decryption policy* to better reflect what it does. We now enable you to configure a decryption policy with one or more **Decrypt - Resign** or **Decrypt - Known Key** rules at the same time. New/modified screens: • **Policies** > **Access Control heading** > **Decryption** (create new decryption policy) • The Create Decryption Policy dialog box now has two tab pages: **Outbound Connections** and **Inbound Connections** . • **Policies** > **Access Control heading** > **Decryption** (edit a decryption rule) **Advanced Settings** has new options discussed in TLS 1.3 decryption best practices, on page 2184 . • **Policies** > **Access Control Heading** > **Access Control** (edit an access control policy), click the word **Decryption** to associate a decryption policy with an access control policy.
TLS 1.3 decryption.	20220609	7.2.0	You can now enable TLS 1.3 decryption in an SSL policy's advanced actions. TLS 1.3 decryption requires the managed device run Snort 3. Other options are available as well; for more information, see TLS 1.3 decryption best practices, on page 2184 . New/modified screens: **SSL Policy** > **Advanced Settings**
SSL policy advanced settings.	20220609	7.2.0	SSL policy advanced settings New/modified screens: **SSL Policy** > **Advanced Settings**

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Ability to specify handling of URLs having unknown reputation.	20220609	7.0.3	For details, see URL filtering with category and reputation, on page 2086 .
ClientHello modification for **Decrypt - Known** key rules.	20220609	7.0.3	For details, see ClientHello message handling, on page 2117 .
Ability to extract the certificate in TLS 1.3 traffic to enable traffic to match URL and application criteria in access control rules.	20220609		New/modified screens: **Policies** > **Access Control** > **(edit an access control policy)** > **Advanced** link. For details, see Rule-based decryption policy advanced options, on page 2182 .
Changes to category and reputation-based URL Filtering.	20220609	7.0.3	For details, see URL filtering with category and reputation, on page 2086 .
TLS crypto acceleration cannot be disabled.	20220609	7.0.3	TLS crypto acceleration is enabled on all supported devices. On a managed device with native interfaces, TLS crypto acceleration cannot be disabled. Removed commands: • **system support ssl-hw-accel enable** • **system support ssl-hw-accel disable** • **system support ssl-hw-status**
Support for TLS crypto acceleration on one container instance on a Firepower 4100/9300 module/security engine.	20220609	7.0.3	You can now enable TLS crypto acceleration for one container instance on a module/security engine. New/modified commands: • **config hwCrypto enable** • **show crypto accelerator status**
TLS/SSL hardware acceleration is now referred to as TLS crypto acceleration .	20220609	7.0.3	The name change reflects that TLS/SSL encryption and decryption acceleration is supported on more devices. New/modified screens: **Devices** > **Device Management** > **Edit** > **Device** > **General** > **TLS Crypto Acceleration**
TLS/SSL hardware acceleration enabled by default.	20220609	7.0.3	TLS/SSL hardware acceleration is enabled by default on all supported devices but can be disabled if desired.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Extended Master Secret extension supported (see RFC 7627).	20220609	7.0.3	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of **Decrypt - Resign** or **Decrypt - Known Key** .
Aggressive TLS 1.3 downgrade.	20220609	7.0.3	Using the **system support ssl-client-hello-enabled aggressive_tls13_downgrade {true|false}** CLI command, you can determine the behavior for downgrading TLS 1.3 traffic to TLS 1.2.
TLS/SSL hardware acceleration introduced.	20220609	7.0.3	Certain managed device models perform TLS/SSL encryption and decryption in hardware, improving performance. By default, the feature is enabled. Affected screen: To view the status of TLS/SSL hardware acceleration , **Devices** > **Device Management** > **Device** , General page.
Category and reputation conditions supported.	20220609	7.0.3	Access control rules or SSL rules with category/reputation conditions.
SafeSearch supported.	20220609	7.0.3	The system displays an HTTP response page for connections decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. SafeSearch filters objectionable content and stops people from searching adult sites.
TLS/SSL policy.	20220609	7.0.3	Feature introduced.

CHAPTER 74

Standard Decryption Policies

The following topics provide details about standard decryption policies.

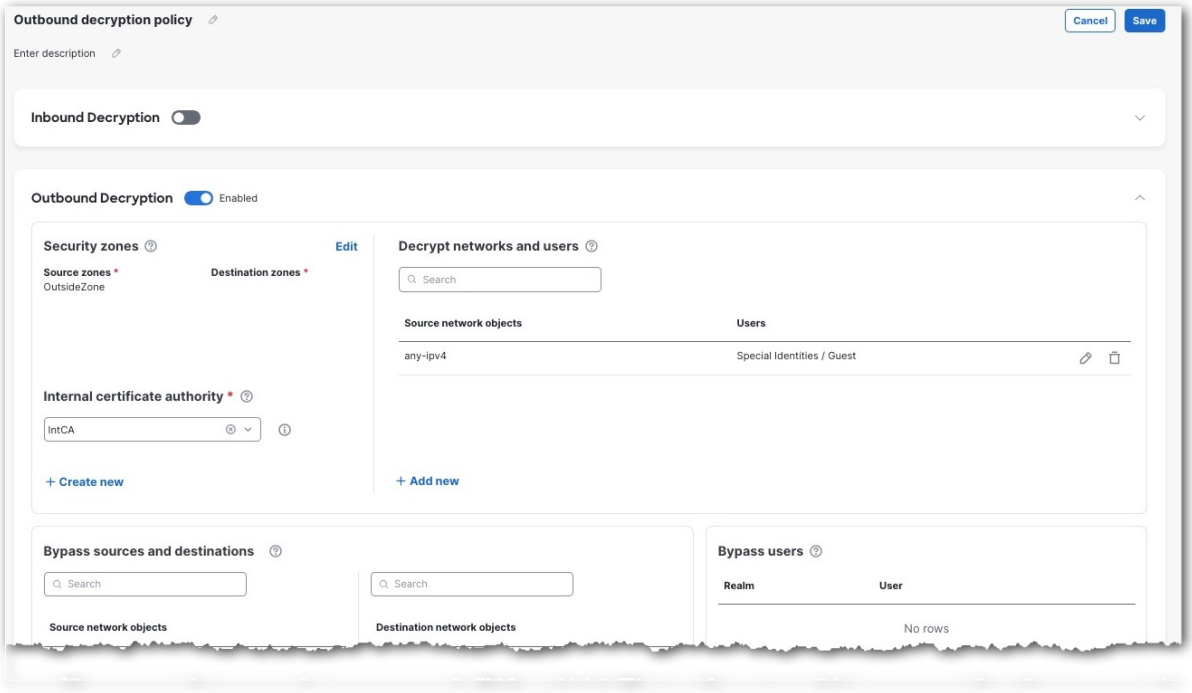
- Standard decryption policies, on page 2137
- Create a new standard decryption policy, on page 2139
- Standard decryption policy advanced options, on page 2157
- Decryption policy actions, on page 2159

Standard decryption policies

A standard decryption policy is a decryption policy type that is simpler to set up than other policy types and optimizes network performance by reducing processing load.

Benefits of standard decryption policies

Traffic decryption requires significant processing and decrypting too much traffic can slow down your system. The standard decryption policy type helps minimize issues commonly experienced by customers by preventing excessive traffic decryption.



Decryption policy types

Decryption policy types include standard decryption policies and rule-based decryption policies.

Standard decryption policies

We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suitable for users who are not familiar with the complexities of decryption policies.

This section provides an example of setting up a standard decryption policy.

This policy decrypts outbound traffic only. All traffic from the OutsideZone security zone on any IPv4 network is decrypted using an internal CA named `IntCA`.

Key points about decryption policies include:

- The rule is a partial example; more options are available.
- You can configure inbound criteria, outbound criteria, or both.
- In addition to objects, you can also optionally configure outbound decryption exclusions, such as:
  - Undecryptable applications (such as ones that use certificate pinning).
  - URL categories such as medical, trading, and finance.
- You can configure outbound block criteria for certificate status and TLS version.
- A standard policy has advanced policy options that are similar to rule-based policies.

Rule-based decryption policies

Rule-based decryption policies are created using a wizard that guides you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs.

A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time.

Standard decryption policy deployment issues to versions earlier than 10.0.0

If you deploy a standard decryption policy to a device that runs a version earlier than 10.0.0, you can encounter compatibility issues.

- If you configured any inbound decryption rules, the rule action is changed to **Decrypt - Known Key** on those devices. For more information about the kinds of incoming decryption actions, see Incoming traffic decryption, on page 2125.
- The advanced policy option **Intelligent Decryption Bypass** requires the device to run version 7.7 or later. By default, this advanced option is disabled. If enabled, policy deployment fails when the device runs a version earlier than 7.7.

Create a new standard decryption policy

A standard decryption policy decrypts and inspects encrypted network traffic.

Decryption policy types

You can create these types of decryption policies:

- Policy to protect *inbound* traffic: Decrypt network traffic coming *into* your network. You typically do this to decrypt and inspect traffic directed to an internal server.
- Policy to protect *outbound* traffic: Decrypt network traffic going *outside* of your network to external servers.

Related Topics

Create a standard decryption policy with inbound protection, on page 2139
Create a standard decryption policy with outbound protection, on page 2144

Create a standard decryption policy with inbound protection

Create a decryption policy to decrypt and inspect traffic directed to an internal server for enhanced network security monitoring.

This task creates a standard decryption policy to decrypt network traffic coming *into* your network. You typically do this to decrypt and inspect traffic directed to an internal server. All options on this page are required.

Before you begin

Review what an inbound protection decryption policy means in Incoming traffic decryption, on page 2125.

To create a decryption policy with outbound protection instead, see Create a standard decryption policy with outbound protection, on page 2144.

Follow these steps to create a standard decryption policy with inbound protection:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **(name of management center)**.

Step 4 In the right pane, click **Management** > **Policies**.

Step 5 Click **Create New** > **Decryption Policy**.

Step 6 In the provided fields, enter a **Name** and optional **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

Step 7 Click **Create Policy**.

Step 8 Slide **Inbound Decryption** to **Enabled** as the following figure shows.

Security zones

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices. Security zones control or decrypt traffic based on its source and destination zone.

Zone configuration requirements

When configuring security zones, consider these requirements:

- If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.
- All zones used in a zone condition must be of the same type (all inline, passive, switched, or routed).
- You cannot use a zone with passive interfaces as a destination zone because devices deployed passively do not transmit traffic.
- Minimize the number of matching criteria whenever possible, especially for security zones, network objects, and port objects. If you specify multiple criteria, the system must match every combination of the criteria contents.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, the rule does not affect that device's performance.

Add security zones (inbound decryption)

Add security zones to an inbound standard decryption policy to specify Firewall Threat Defense device interfaces that send traffic to the internal server.

A security zone specifies a Firewall Threat Defense device interface that sends traffic to the internal server. Typically, for inbound protection, this will be an internal (or *DMZ*) interface.

You must choose both a source and destination security zone.

Before you begin

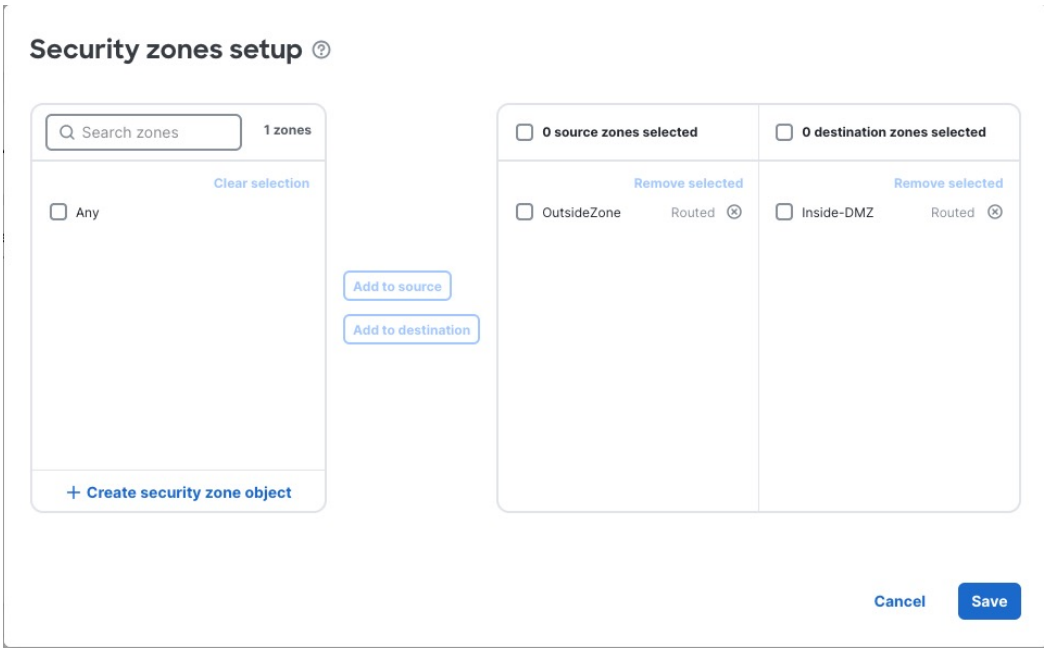
Complete the tasks discussed in Create a standard decryption policy with inbound protection, on page 2139.

Procedure

Step 1 Click **Edit zones** next to Security Zones.

Step 2 In the Security Zones dialog box, do any of the following:

- Select the check box next to a security zone to add to either the source or destination.
- To create a new security zone, click **Create security zone object**.
- Search for a security zone by entering text in the Search Zones field and pressing Enter.



Note

Click **Help** () on any dialog box for more information.

Step 3 Click **Add to Source** to decrypt traffic that matches the source security zone or click **Add to Destination** to decrypt traffic that matches the destination security zone. If you select both source and destination zones, to be decrypted, traffic must match both zones.

Typically, your internal server should be the *destination* of an inbound decryption rule.

The following figure shows an example.

Step 4 Click **Save**.

Step 5 See Internal server details (inbound decryption), on page 2142.

Internal server details (inbound decryption)

Protect your internal servers by decrypting and optionally inspecting traffic directed to them. Add internal servers you wish to protect using network objects, and optionally, ports to specify these servers.

Network conditions and tunnel rules

Networks control or decrypt traffic based on its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

Minimize the number of matching criteria, particularly for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against each combination of the specified criteria.

Behaviour of Decrypt - Replace Cert rules

When using the **Decrypt – Replace Cert** action in an inbound decryption policy, the firewall enforces strict validation of the internal server's certificate against the Trusted CA list defined within the policy. If the certificate fails validation, the firewall does not decrypt the traffic. Decryption fails if the certificate exhibits any of these conditions:

- Expired or Not-Yet-Valid: The current system time is outside the certificate's validity period.
- Untrusted: The signing Certificate Authority (CA) is not present in the Trusted CA list.
- Invalid Signature: The digital signature cannot be verified.

- Revoked or Invalid CRL: The certificate has been revoked, or the Certificate Revocation List (CRL) is invalid or unreachable.

Default handling of invalid certificates:

In a new standard decryption policy, the system generates an inbound SSL rule with the **Server Certificate Status** condition set to **Valid**.

If a server presents a certificate that does not meet these validation criteria, it fails to match the rule and is handled by the default Do Not Decrypt (DND) rule. This DND action is the default behavior for standard mode policies and is not configurable.

You can override the validation using the **Decrypt – Known** key. Refer to Override internal server validation.

Add internal servers

Add internal servers to specify certificates, networks, and ports for traffic decryption, which enables protection of internal servers and optimizes processing time.

This task discusses how to choose certificates to use to decrypt traffic coming to internal servers you want to protect. In addition to choosing a certificate, you can also specify the network and port on which the internal server is located, saving processing time.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with inbound protection, on page 2139.

Follow these steps to add internal servers:

Procedure

Step 1 Click **Add new** under Internal Server Details.

Step 2 In the Internal Servers dialog box, do any of the following:

- Search for an internal certificate by entering text in the search field and pressing Enter.
- From the **Internal certificate object** list, choose an existing certificate or click **Add New** to create a new one.

  Note
  The Secure Firewall Threat Defense device servicing the traffic must trust the certificate you upload to the rule. If you upload a self-signed certificate or a certificate not trusted by a certificate authority, and you want to replace the certificate later, you must update the policy's advanced settings in any of these ways:

  - Add the certificate to the **Trusted CA certificates** list.
  - Select the **Require exact certificate match for inbound decryption** check box.

  For more information about advanced policy options, see Standard decryption policy advanced options, on page 2157.

  For more information about replacing a certificate, see the discussion of Replace Cert in Incoming traffic decryption, on page 2125.

- From the **Destination network object** list, click the network on which the internal server is located or click **Add New** to create a new one.
- (Optional.) From the **Destination port** list, click the port on which to apply the decryption rule or click **Add New** to create a new one.

  For more information, see Upload an internal certificate for inbound protection, on page 2177.

Note

Click **Help** (?) on any dialog box for more information.

Step 3 Click **Save**.

This figure shows an example.

Step 4 Save the decryption policy by clicking **Save** at the top of the page.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Create a standard decryption policy with outbound protection

This task enables you to create a standard decryption policy that protects servers outside your internal network by decrypting outbound connections.

The following task discusses how to create a standard decryption policy to protect servers outside your internal network. To decrypt outbound connections, all options on this page are required except where noted. To bypass or block certain outbound connections, only security zones and bypass or block options are required.

Before you begin

Review what an outbound protection decryption policy means in Decrypt and re-sign (outgoing traffic), on page 2125.

To create a decryption policy with inbound protection instead, see Create a standard decryption policy with inbound protection, on page 2139.

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **(name of management center)**.

Step 4 In the right pane, click **Management** > **Policies**.

Step 5 Click **Create New** > **Decryption Policy**.

Step 6 In the provided fields, enter a **Name** and optional **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

Step 7 Click **Create Policy**.

Step 8 Slide **Outbound Decryption** to **Enabled** as the following figure shows.

Security zones

Security zones segment your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices. Security zones control or decrypt traffic based on its source and destination zone.

Zone configuration requirements

When configuring security zones, consider these requirements:

- If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.
- All zones used in a zone condition must be of the same type (all inline, passive, switched, or routed).
- You cannot use a zone with passive interfaces as a destination zone because devices deployed passively do not transmit traffic.
- Minimize the number of matching criteria whenever possible, especially for security zones, network objects, and port objects. If you specify multiple criteria, the system must match every combination of the criteria contents.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, the rule does not affect that device's performance.

Add security zones (outbound decryption)

Add security zones to an outbound standard decryption policy to specify Firewall Threat Defense device interfaces that send traffic to the external server.

A security zone specifies a Firewall Threat Defense device interface that sends traffic to the external server. You can configure source zones, destination zones, or both to control which traffic gets decrypted.

Before you begin

Complete the tasks discussed in Create a rule-based decryption policy with outbound connection protection, on page 2165.

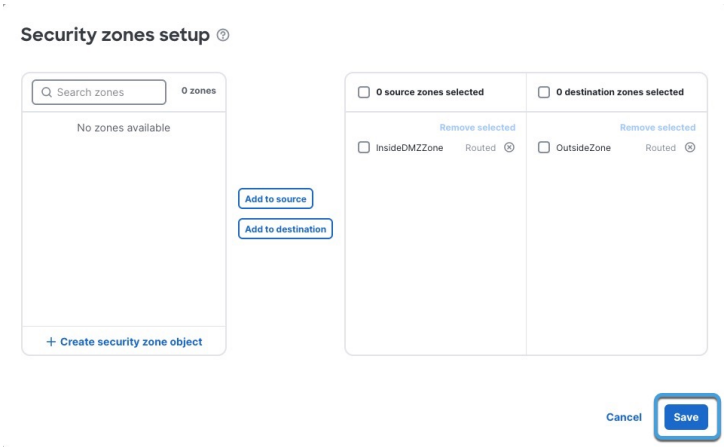
Follow these steps to add security zones to an outbound decryption policy:

Procedure

Step 1 Click **Edit zones** next to Security Zones.

Step 2 In the Security Zones dialog box, do any of the following:

- Select the check box next to a security zone to add to either the source or destination.
- To create a new security zone, click **Create security zone object**.
- Search for a security zone by entering text in the Search Zones field and pressing Enter.



Note

Click **Help** (?) on any dialog box for more information.

Step 3 Click **Add to Source** to decrypt traffic that matches the source network or click **Add to Destination** to decrypt traffic that matches the destination network. If you select both source and destination networks, to be decrypted, traffic must match both security zones.

Typically, the server for which you're decrypting traffic should be in the *destination* zone.

The following figure shows an example.

Step 4 Click **Save**.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Decrypt networks and users

This option enables you to enforce decryption and deep inspection for specific network objects and from specific users and groups in Microsoft AD, LDAP, or Local realms.

Network objects

Networks control or decrypt traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions.

Users and groups

You can choose to decrypt traffic from a subset of users and groups in your identity realms and you can also choose to decrypt traffic from special identities:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For more information, see Add networks and users, on page 2147.

Add networks and users

This task allows you to enforce decryption of outbound traffic from specific networks and from users and groups in Microsoft AD, LDAP, or Local realms.

Only traffic that matches all of the networks and users you select is decrypted.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

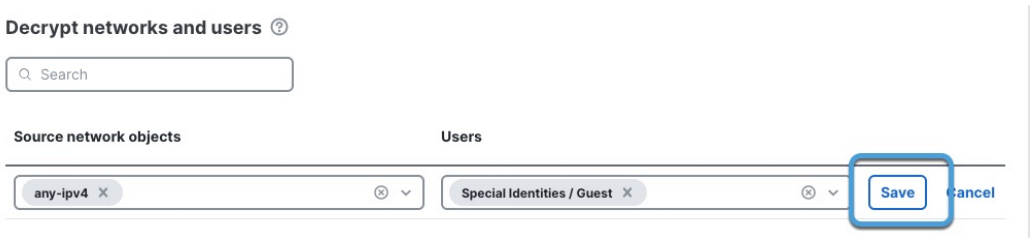
Follow these steps to add networks and users to your decryption policy:

Procedure

Step 1 Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Step 2 Click **Add new** next to Decrypt Networks and Users.

Step 3 From the **Source Network Objects** list, do any of the following:



- In the provided field, enter all or part of an existing network object to filter for that object.
- Select the check box next to a network to decrypt. To decrypt traffic from all networks, click **Add New** and **Save** the row without selecting any networks.
- Click **Add new** to add another network to the list.

  For more information, see Create a network object, on page 2985.

Step 4 From the **Users** list, select the check box next to each user or group name to decrypt.

To decrypt traffic from all users, click **Add New** and **Save** the row without selecting any users.

This figure shows an example of selecting a network and users to decrypt.

Step 5 Click **Save**.

Step 6 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Internal certificate authority

An internal certificate authority resigns the traffic after it has been decrypted.

This topic discusses how to add an internal certificate authority (CA) to an outbound section of a standard decryption policy. The internal CA must be trusted by users on your network to avoid seeing untrusted certificate errors in their web browser.

For more information, see Add an internal CA for outbound protection, on page 2148.

Add an internal CA for outbound protection

This task allows you to add an internal CA to resign outgoing traffic for enhanced security in outbound protection scenarios.

This task discusses how to add an internal CA to resign outgoing traffic.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Follow these steps to add an internal CA for outbound protection:

Procedure

In the **Internal Certificate Authority** list, do any of the following:

- Click the name of an internal CA.
- Click **Create New** to create a new internal CA.

  Click **Help** for more information.

  If you do not already have an internal CA, see:

  - Generate an internal CA for outbound protection, on page 2149
  - Upload an internal CA for outbound protection, on page 2149

Generate an internal CA for outbound protection

This task allows you to generate an internal certificate authority object to protect outbound connections when creating a decryption rule.

This task discusses how you can optionally generate an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Upload a signed certificate issued in response to a CSR, on page 2990.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2987.

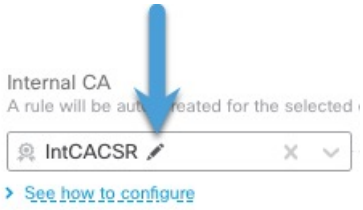
Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Generate CA**.

Step 2 Give the internal CA a **Name** and provide a two-letter **Country Name**.

Step 3 Click **Self-Signed** or **CSR**.

For more information about these options, see Internal certificate authority objects, on page 2987.



Step 4 Enter the requested information in the provided fields.

Step 5 Click **Save**.

Step 6 If you chose **CSR**, after the signing request has been completed, click **Install Certificate** as follows:

a) Repeat the preceding steps in this procedure.

b) Edit the CA from the **Internal CA** list as follows.

c) Click **Install Certificate**.

d) Follow the prompts on your screen to complete the task.

Step 7 Continue creating the policy as discussed in Create a rule-based decryption policy with outbound connection protection, on page 2165.

Upload an internal CA for outbound protection

Upload an internal certificate authority to create a decryption rule that protects outbound connections.

This task discusses how you can optionally upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Upload a signed certificate issued in response to a CSR, on page 2990.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2987.

Follow these steps to upload an internal CA for outbound protection:

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Upload CA**.

Step 2 Give the internal CA a **Name**.

Step 3 Paste or browse to locate the certificate and its private key in the provided fields.

Step 4 If the CA has a password, select the **Encrypted** check box and enter the password in the adjacent field.

Step 5 Continue creating the policy as discussed in Create a rule-based decryption policy with outbound connection protection, on page 2165.

Bypass traffic when decrypting

You can optionally allow certain traffic to pass through the device encrypted without decryption. Bypassing certain traffic has the additional advantage that system resources are not consumed for decrypting it.

Traffic bypass methods

You can review some reasons to leave traffic encrypted here: Best practice for deciding when to decrypt traffic, on page 2122. The system provides these ways to bypass traffic when decrypting:

- Bypass source and destination networks: For example, traffic from internal servers located on an internal/DMZ network that you can trust doesn't need to be decrypted.
- Bypass users: You can bypass decryption for users and groups you trust.
- Bypass undecryptable applications: (Recommended) The typical reason to bypass outgoing traffic to applications is this traffic might use certificate pinning, which is not decryptable.

  For more information, see TLS/SSL pinning, on page 2231.
- Bypass categories: (Recommended) Bypass decrypting URL categories of sites for these reasons:
  - The categories represent applications (like personal finance or health) that might be illegal to decrypt and inspect.
  - Categories of websites Cisco has determined are low-risk.
- Intelligent decryption bypass: Bypass servers based on the threat confidence levels of clients which is determined by the Encrypted Visibility Engine (EVE) and the URL category reputation.

  All devices to which a standard decryption policy with this option enabled are deployed must run version 7.7 or later; otherwise, policy deployment fails.

Bypass sources and destinations

(Optional) Bypass traffic from source or destination network objects. For example, if traffic originates from an internal network that has trusted devices, you can opt not to decrypt that traffic. Networks control or decrypt traffic by its source and destination IP address, using inner headers.

For more information, see Add bypass sources and destinations, on page 2151.

Add bypass sources and destinations

Add bypass sources and destinations to optionally bypass outbound traffic originating from source networks or going to destination networks that you trust.

You should generally bypass traffic only if you trust the traffic from these networks.

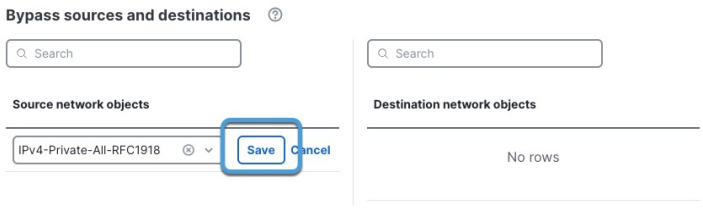
Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Follow these steps to add bypass sources and destinations:

Procedure

Step 1 Click **Add new** under Bypass sources and destinations for either source network objects or destination network objects.



Step 2 In the dialog box that is displayed, do any of the following:

- Search for a network object by entering text in the search field and pressing Enter.
- From the **Source network object** or **Destination network object** list, choose an existing network object or click **Add New** to create a new one.

Note

Click **Help** (?) on any dialog box for more information.

The following figure shows an example.

Step 3 Click **Save**.

Step 4 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Bypass users

(Optional) You can choose to bypass decryption for users and groups in Microsoft Active Directory, LDAP, and Local realms. These users are typically ones you trust.

Bypass user configuration

You can choose to bypass a subset of users and groups in your identity realms and you can also choose to bypass from special identities:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For more information, see Add bypass users, on page 2152.

Add bypass users

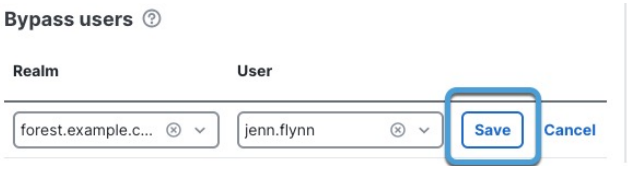
Bypass decryption for users and groups in selected Microsoft AD, LDAP, and Local realms.

This task allows you to exclude specific users and groups from decryption processing by adding them to a bypass list.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Follow these steps to add bypass users:



Procedure

Step 1 Click **Add new** under Bypass users.

Step 2 In the dialog box that is displayed:

- From the **Realm** list, click the name of a realm.
- From the **User** list, select the check box next to one or more users or groups for which to bypass decryption.

The following figure shows an example.

Step 3 Click **Save**.

Step 4 Repeat the preceding steps as many times as necessary to bypass more users and groups.

Bypass applications

(Optional) You can bypass decryption for applications that cannot be decrypted.

Bypass application configuration

Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail.

Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL certificate pinning guidelines, on page 2194.

Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the Secure Firewall Application Detectors page; the **undecryptable** tag identifies applications Cisco determines are undecryptable.

The list of undecryptable applications is maintained by Cisco.

For more information, see Add bypass applications, on page 2153.

Add bypass applications

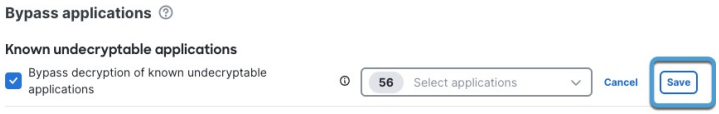
Bypass decryption for applications that are typically undecryptable due to their use of certificate pinning or other security mechanisms that prevent standard SSL/TLS decryption.

This task discusses how to bypass decryption for applications (typically because those applications are undecryptable due to their using certificate pinning as discussed in TLS/SSL pinning, on page 2231).

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Procedure



Step 1 Select the **Bypass decryption of known undecryptable applications** check box.

Step 2 Click **Edit applications**.

Step 3 From the list, do any of the following:

- Click **Select All** to select all applications that Cisco has determined are undecryptable.
- Select the check box next to the name of an application for which to bypass decryption.
- Clear the check box next to the name of an application to decrypt connections to anyway.

The following figure shows an example.

Step 4 Under Selected applications and filters, click **Add New** to add applications or application filters to bypass. Click **Help** for more information.

Step 5 Click **Save**.

Step 6 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Bypass URL categories and reputations

(Optional) Select categories and reputations, such as personal finance or health, that you do not want to decrypt.

URL categories and reputations information

URL categories and reputations are maintained by Cisco Talos.

For more information about categories, see Intelligence Categories.

For more information about reputations, see Web reputation levels.

To add URL categories and reputations to your decryption policy, see Add bypass URL categories and reputations, on page 2154.

Note Depending on the laws in your area, decryption of such traffic might be prohibited. Consult an authority in your area for more information.

Add bypass URL categories and reputations

This task allows you to bypass decryption for specific URL categories and reputations to improve performance and reduce processing overhead for trusted or sensitive content.

This task is optional and discusses how to bypass decryption of categories and reputations, based on ratings provided by Cisco Talos.

The following figure shows the list of categories and reputations we recommend.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Follow these steps to add bypass URL categories and reputations:

Procedure

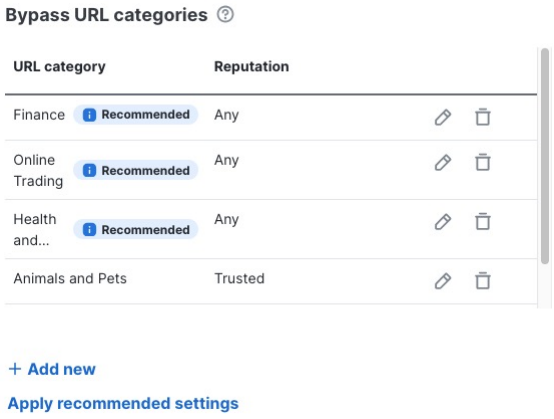
Step 1 In the Bypass URL categories section, do any of the following:

- To edit an existing category/reputation, click **Edit** ( ).
- To delete an existing category/reputation, click **Delete** ( ).
- To add a new category/reputation, click **Add new**.

- To return the list of categories and reputations to the ones Cisco recommends, click **Apply recommended settings**.

Step 2 To add or edit a category/reputation, from the first list, click the name of a category.

For more information about categories, see Intelligence Categories.



Step 3 From the second list, click the name of a reputation.

For more information about reputations, see Web reputation levels.

The following figure shows an example of using Cisco's defaults and adding the Animals and Pets category with the Trusted reputation.

Step 4 Click **Save**.

This figure shows an example.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Intelligent decryption bypass

Classification and setup details

To set up Intelligent Decryption Bypass for an outbound decryption rule, locate **Intelligent Decryption Bypass** and set it to **Slider enabled** ( ) to *not* decrypt traffic for very low-risk clients connecting to trusted servers, based on the threat confidence levels of clients which are determined by the Encrypted Visibility Engine (EVE) and the URL category reputation.

To view the current list of clients classified by trust level, visit Secure Firewall Application Detectors. For example, CNN.com is classified as Very Low. Make sure you understand what traffic you are choosing to *not* decrypt.

Block connections

You can choose to block any of these connection types:

- SSL and TLS versions because some are considered unsecure.

- Connections based on certificate status. For example, block outbound traffic to a server with an expired certificate because that server might not be trustworthy.

For more information, see Add block connections, on page 2156.

Add block connections

This task enables you to block outbound connections based on either old SSL or TLS versions or based on the server certificate status, enhancing security by preventing connections using insecure protocols or untrusted certificates.

This task discusses how to block connections based on either old SSL or TLS versions; or based on the server certificate status.

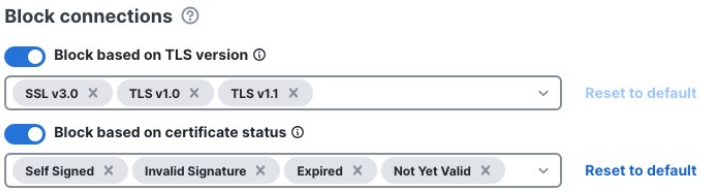
Note Blocking affects *all outbound connections* and takes precedence over all other bypass and decryption conditions you choose.

Before you begin

Complete the tasks discussed in Create a standard decryption policy with outbound protection, on page 2144.

Procedure

Step 1 Locate the Block connections section.



Step 2 To block outbound traffic based on its SSL or TLS protcol version, slide **Block based on TLS versions** to **Slider enabled** ( ).

Step 3 To block outbound traffic based on server certificate status, slide **Block based on certificate status** to **Slider enabled** ( ).

Step 4 You have the following options:

- From the list, select the check box next to an option to add that protocol or status to the policy.
- Click **x** next to an item to remove it from the list.
- Click **Reset to default** to return the list entries to their original values.

The following figure shows an example of blocking traffic with both TLS versions and server certificate status. Self-signed was added to the list of server certificates to block.

Step 5 If you're finished configuring your policy, see Decryption policy actions, on page 2159.

Standard decryption policy advanced options

Advanced decryption policy options allow you to fine-tune SSL/TLS decryption behavior. These optional settings control certificate matching, legacy site bypassing, protocol handling, and logging configuration. We recommend setting all advanced options to their default values unless specific requirements dictate otherwise.

Bypass legacy Cisco undecryptable sites

Enable this option to bypass decryption for websites with Distinguished Names (DNs) that Cisco has determined are undecryptable. To view the list of DNs, go to **Objects** > **Object Management** > **Distinguished Name** > **Object Groups**.

Require exact certificate match for inbound decryption

Enable this option to require the use of the internal server's certificate in the decryption policy (this option is referred to as *known key decryption*). The default is to use a different certificate, which is more convenient for replacing the policy's certificate when needed. For more information, see Incoming traffic decryption actions, on page 2223.

Override internal server validation with Decrypt – Known key

To accommodate internal servers that do not meet standard validation requirements, you can modify the policy behavior by enabling **Require exact certificate match** under **Advanced Options**.

When this option is enabled, the decryption method shifts from **Decrypt – Replace Cert** to **Decrypt – Known Key**. In this mode, the system does not perform standard CA validation. Instead, it requires the certificate presented by the internal server to be an exact match for the certificate configured in the Cloud-Delivered Firewall Management Center.

Enable adaptive TLS server identity probe

Automatically enabled when TLS 1.3 decryption is enabled. A *probe* is a partial TLS connection with the server, the purpose of which is to obtain the server certificate and cache it. (If the certificate is already cached, the probe is never established.)

If TLS 1.3 Server Identity Discovery is disabled on the access control policy with which the decryption policy is associated, we attempt to use the Server Name Indication (SNI), which is not as reliable.

The adaptive TLS server identity probe occurs on any of the following conditions as opposed to on every connection as in earlier releases:

- Certificate Issuer—Matched when the value of **Issuer DNs** in a decryption rule's DN rule condition is matched.

  For more information, refer to Conditions for distinguished name rules in decryption policies, on page 2208.

- Certificate Status—Matched when any of the **Cert Status** conditions are matched in a decryption rule.

  For more information, refer to Certificate Status Decryption rule conditions, on page 2214.

- Internal/External Certificate—Internal certificates can be matched by the certificate used in **Decrypt - Known Key** rule actions; external certificates can be matched in **Certificates** rule conditions.

For more information, refer to Known key decryption for incoming traffic, on page 2126 and Certificate rule conditions, on page 2207.

- Application ID—Can be matched by **Applications** rule conditions in either an access control policy or a decryption policy.

  For more information, refer to Application rule conditions, on page 1701.

- URL Category—Can be matched by **URLs** rule conditions in an access control policy.

  For more information, refer to Recommendation: use URL conditions for website access control , on page 1704.

Note **Enable adaptive TLS server discovery mode** is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Security Cloud Control, the connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.

Decryption event logging options

To expedite troubleshooting and to inform yourself about how your decryption policies are working, we recommend you enable all logging options: bypassed traffic, decrypted traffic, and blocked traffic.

Enable QUIC Decryption

Whether to apply decryption rules to connections that use the HTTP/3 over the QUIC protocol. When you decrypt QUIC connections, the system can inspect the contents of the sessions for intrusions, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. QUIC support is in line with RFC 9000, 9001, 9002, 9114, 9204.

Consider the following when implementing QUIC decryption:

- On high availability or clustered devices, QUIC decryption works only if the connection remains on the same node. If the connection fails over, or is forwarded to another node, the connection drops and must be re-established. Multi-instance is supported without restrictions.
- Rules that apply to QUIC traffic would include the UDP protocol with destination port 443.
- Access control rules that apply to QUIC traffic would include the HTTP/3 or QUIC protocols, either explicitly or by implication.

The following limitations apply to QUIC decryption:

- QUIC decryption applies to Firewall Threat Defense 7.6+ only. Devices running a lower release cannot decrypt QUIC connections.
- Connections from browsers using the Chromium stack (Google Chrome, Opera, Edge) cannot be decrypted for outbound traffic. But inbound traffic from the same browsers can be decrypted.
- Connection Migration as described in RFC 9000 is not supported. The concept of Connection ID in QUIC allows endpoints to retain the same connection in the event of address change.
- Key update, session resumption, and QUIC version 2 are not supported.

- Interactive Block and Interactive Block with Reset (in access control rules) is not supported. These actions will work as Block and Block with Reset.
- The active connection-ID per connection is limited to 5. If necessary, you can modify these limits using the **system support quic-tuning** and **system support quic-tuning-reset** commands in the device CLI.

Enable TLS 1.3 decryption

Whether to apply decryption rules to TLS 1.3 connections. If you do not enable this option, the decryption rules apply to TLS 1.2 or lower traffic only. See TLS 1.3 decryption best practices, on page 2184.

Save the policy

After you have configured advanced policy options, see Decryption policy actions, on page 2159.

Add trusted CA certificates

Add trusted CA certificates to your decryption policy to ensure proper handling of your organization's certificates during traffic decryption.

This task is optional but strongly recommended. Adding issuer CAs for your organization's certificates helps avoid issues with decrypting traffic in your decryption policy.

Before you begin

Complete the tasks discussed in:

- Create a standard decryption policy with inbound protection, on page 2139
- Create a rule-based decryption policy with outbound connection protection, on page 2165

Follow these steps to add trusted CA certificates:

Procedure

Step 1 In your policy, expand **Advanced Options**.

Step 2 In the **Trusted CA certificates** list, do any of the following:

- Click the name of a trusted CA certificate from the list.
- To remove *all* certificates from the list, click .
- To return the list to its original values, click **Add recommended**.

Decryption policy actions

You can perform these actions on a decryption policy.

- Copy a decryption policy
- Convert a standard decryption policy to a rule-based decryption policy, and
- Generate a report about the decryption policy.

Related Topics

Convert a standard decryption policy to a rule-based decryption policy, on page 2160
Copy a decryption policy, on page 2160
Generate a decryption policy report, on page 2161

Convert a standard decryption policy to a rule-based decryption policy

This task allows you to use the additional customization available in a rule-based decryption policy.

After converting to a rule-based decryption policy, you cannot convert it back to a standard decryption policy. Also, you cannot convert any rule-based decryption policy to a standard decryption policy.

Before you begin

Create a decryption policy as discussed in this guide.

Follow these steps to convert a standard decryption policy to a rule-based decryption policy:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **(name of management center)**.

Step 4 In the right pane, click **Management** > **Policies**.

Step 5 Next to the decryption policy you wish to convert, in the Actions column, click More icon (···) then click **Convert policy mode**.

Step 6 You are required to confirm the action.

The system creates a backup policy with **-backup** appended to the name of the original policy. The original policy retains its name.

Copy a decryption policy

Copy an existing decryption policy to create a new policy with the same rules and settings.

Copying a decryption policy duplicates any rules in the policy and all of the policy's settings.

Before you begin

Create a decryption policy as discussed in this guide.

Follow these steps to copy a decryption policy:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **(name of management center)**.

Step 4 In the right pane, click **Management** > **Policies**.

Step 5 Next to the decryption policy you wish to copy, in the Actions column, click More icon (⋯) then click **Copy policy**.

Step 6 When prompted, provide a name for the policy.

Step 7 Click **Save**.

Generate a decryption policy report

This task enables you to create a comprehensive decryption policy report for analysis and documentation purposes.

This topic discusses how to create a decryption policy report that includes these items (among other things):

- List of rules
- List of cipher suites
- Policy's default action
- Trusted CA certificates

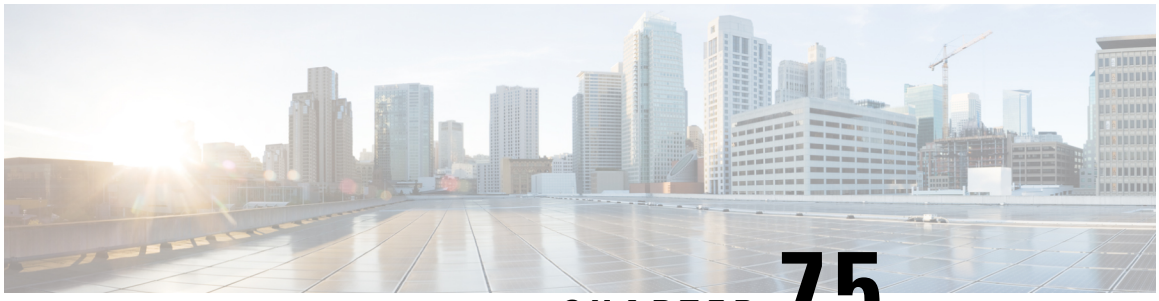
Before you begin

Create a decryption policy as discussed in this guide.

Follow these steps to generate a decryption policy report:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.



Step 2 Click **Firewall**.

Step 3 Click **Administration** > **(name of management center)**.

Step 4 In the right pane, click **Management** > **Policies**.

Step 5 Next to the decryption policy you wish to create a report, in the Actions column, click More icon (⋯) then click **Generate report**.

The system creates a PDF report and opens it for you using your default PDF application.

CHAPTER 75

Rule-Based Decryption Policies

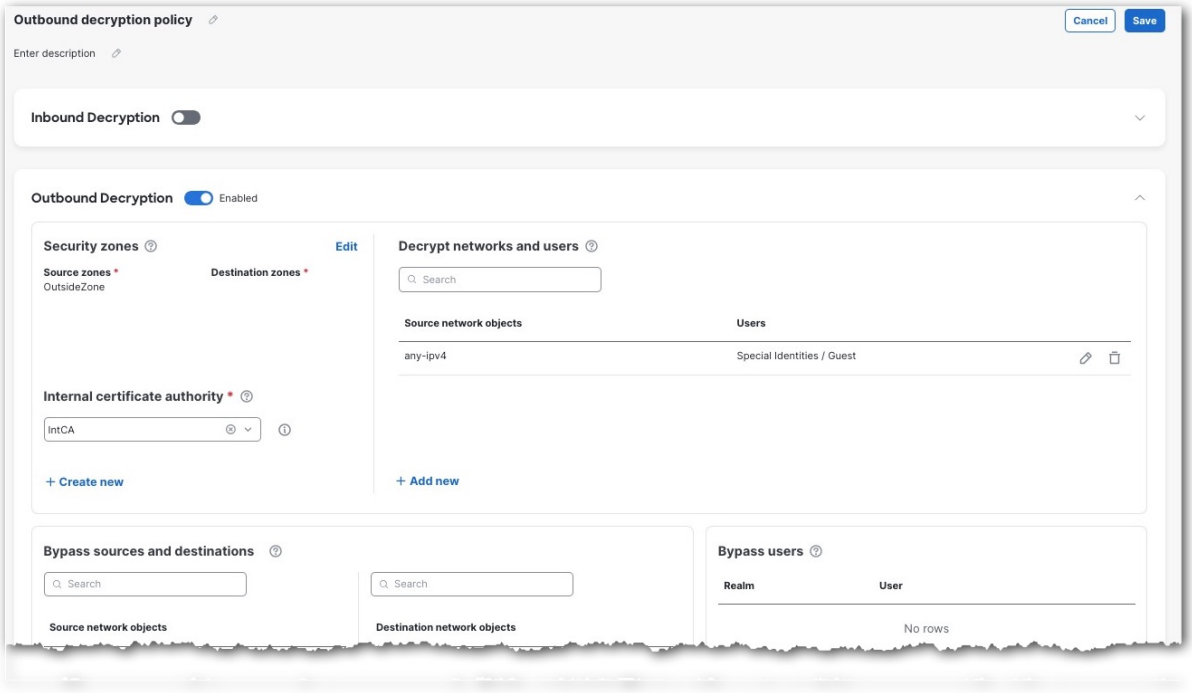
The following topics provide details about rule-based decryption policies.

- Rule-based decryption policies, on page 2163
- Create a rule-based decryption policy , on page 2165
- Rule-based decryption policy default actions, on page 2179
- Default handling options for undecryptable traffic, on page 2180
- Rule-based decryption policy advanced options, on page 2182

Rule-based decryption policies

You can create a decryption policy using a wizard that guides you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules, reorder rules, or make other changes to suit your needs.

A rule-based decryption policy is the most flexible but also the most complex. You can convert a standard decryption policy to a rule-based policy at any time.



Decryption policy types

Decryption policy types include standard decryption policies and rule-based decryption policies.

Standard decryption policies

We recommend the standard decryption policy type because it's easy to set up with a wizard-like appearance, enabling you to easily pick security zones, users and networks, and other objects to use in your policy. A standard decryption policy is particularly suitable for users who are not familiar with the complexities of decryption policies.

This section provides an example of setting up a standard decryption policy.

This policy decrypts outbound traffic only. All traffic from the OutsideZone security zone on any IPv4 network is decrypted using an internal CA named `IntCA`.

Key points about decryption policies include:

- The rule is a partial example; more options are available.
- You can configure inbound criteria, outbound criteria, or both.
- In addition to objects, you can also optionally configure outbound decryption exclusions, such as:
  - Undecryptable applications (such as ones that use certificate pinning).
  - URL categories such as medical, trading, and finance.
- You can configure outbound block criteria for certificate status and TLS version.
- A standard policy has advanced policy options that are similar to rule-based policies.

Rule-based decryption policies

Rule-based decryption policies are created using a wizard that guides you through the available options for inbound decryption, outbound decryption, or both. After you create the rule-based decryption policy, you can add more rules to it, reorder rules, or make other changes to suit your needs.

A rule-based decryption policy is the most flexible but also the most potentially complicated. You can convert a standard decryption policy to a rule-based policy at any time.

Create a rule-based decryption policy

A decryption policy is a rule-based security policy that controls how encrypted network traffic is handled.

Create decryption policy to protect outbound and inbound network connections through various rule actions.

You can create any of these types of decryption policies:

- *Outbound protection* policy with rules that protect outbound connections. The destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action. We also create additional rules with a **Do Not Decrypt** action that excludes traffic you specify (such as traffic that uses certificate pinning).

  Refer to Create a rule-based decryption policy with outbound connection protection, on page 2165 for guidance on creating a decryption rule with outbound connection.

- *Inbound protection* policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action. We also create additional rules with a **Do Not Decrypt** action that excludes traffic you specify (such as traffic that uses certificate pinning.) These rules are disabled initially but you can modify and enable them later if you wish.

  Refer to Create a rule-based decryption policy with inbound connection protection, on page 2169 or guidance on creating a decryption rule with inbound connection.

- Other actions (including **Do Not Decrypt**, **Block**, and **Block with Reset**).

  See Create a rule-based decryption policy with other rule actions, on page 2178

Create a rule-based decryption policy with outbound connection protection

This task creates a decryption policy that protects outbound connections by intercepting and decrypting SSL/TLS traffic between internal clients and external servers, then re-encrypting the traffic with an internal CA certificate.

This task discusses how to create a decryption policy with a rule that protects outbound connections; that is, the destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Create change management tickets, on page 175 and Policies and objects that support change management, on page 169.

Before you begin

You can optionally must upload or generate an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

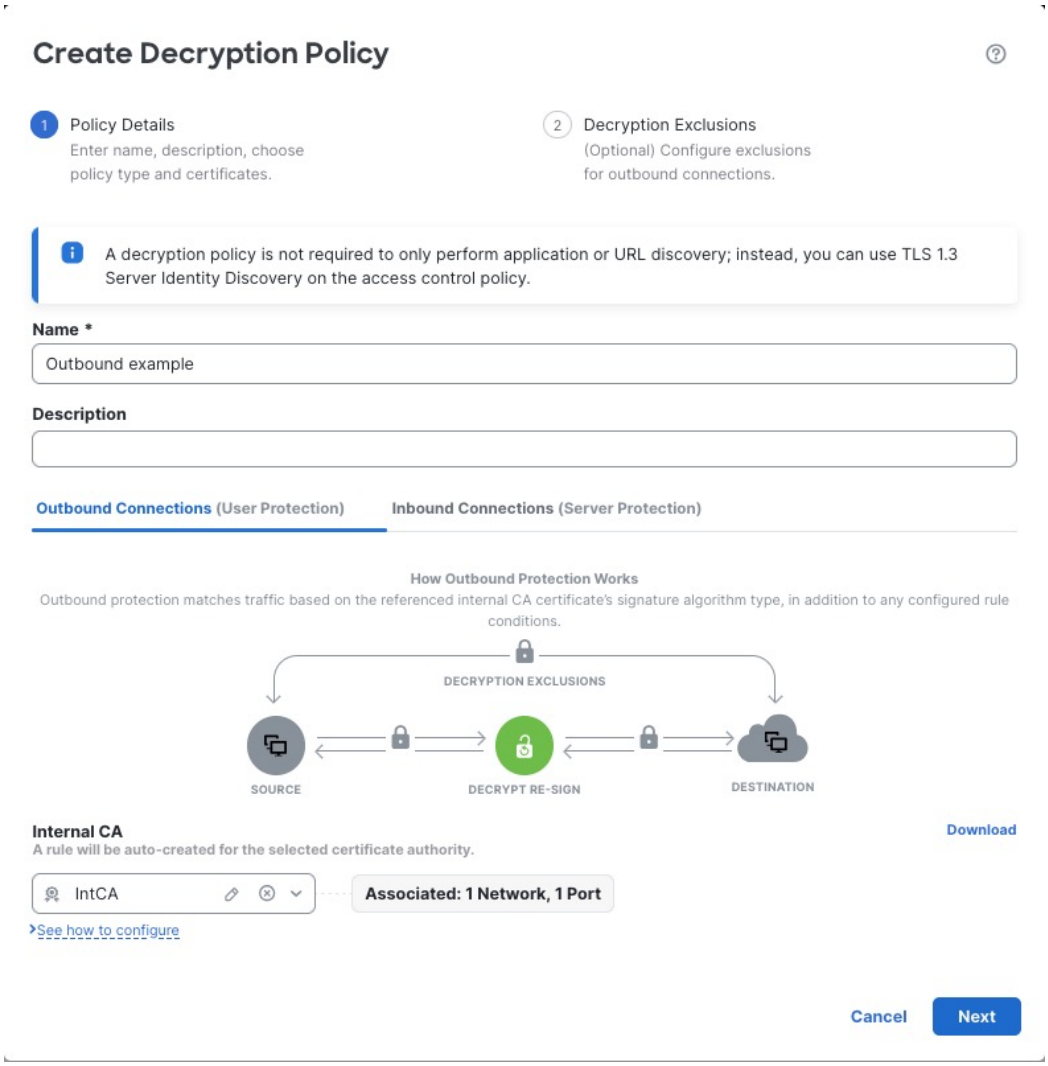
- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI objects, on page 2986.
- At the time you create this decryption policy.

Follow these steps to create a rule-based decryption policy with outbound connection protection:

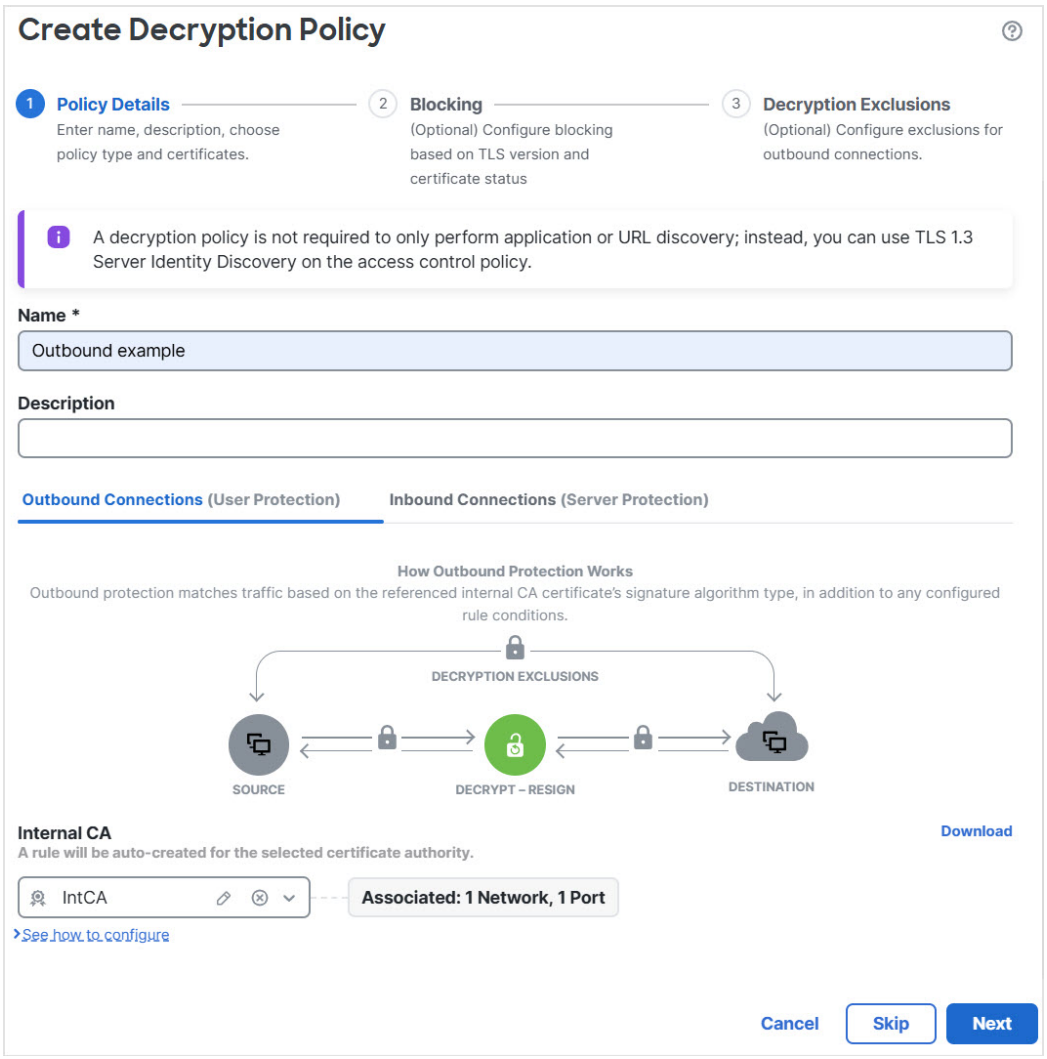
Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Administration** > **Integrations** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.



Step 3 Click **Create Decryption Policy**.



Step 4 Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

Step 5 Click the **Outbound Connections** tab.

Create Decryption Policy
1 Policy Details
Enter name, description, choose policy type and certificates.
2 Decryption Exclusions
(Optional) Configure exclusions for outbound connections.
A decryption policy is not required to only perform application or URL discovery; instead, you can use TLS 1.3 Server Identity Discovery on the access control policy.
Name *
Outbound example
Description
Outbound Connections (User Protection)
Inbound Connections (Server Protection)
How Outbound Protection Works
Outbound protection matches traffic based on the referenced internal CA certificate's signature algorithm type, in addition to any configured rule conditions.

Next

Step 6 From the **Internal CA** list, upload or choose certificates for the rules.

For more information about internal certificates, see Generate an internal CA for outbound protection, on page 2149 and Upload an internal CA for outbound protection, on page 2149.

a) (Optional.) Choose networks and ports.

For more information:

- Network rule conditions, on page 1701
- Best practice: use application-based rules over port-based rules, on page 1703

b) Click **Next**.

c) Continue with Configure Rule-based decryption policy exclusions, on page 2171.

What to do next

- Add rule conditions: Rule-based decryption rule conditions, on page 2201
- Add a default policy action: Rule-based decryption policy default actions, on page 2179
- Configure logging options for the default action .
- Set advanced policy properties: Rule-based decryption policy advanced options, on page 2182.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy configuration changes.

Create a rule-based decryption policy with inbound connection protection

This task creates a decryption policy that protects inbound connections using either a **Decrypt - Known Key** rule action.

This task discusses how to create a decryption policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

Before you begin

You must upload an internal certificate for your internal server before you can create a decryption policy that protects inbound connections. You can do this in any of the following ways:

- Create an internal certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal Certs** and referring to PKI objects, on page 2986.
- At the time you create this decryption policy.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Create change management tickets, on page 175 and Policies and objects that support change management, on page 169.

Follow these steps to create a decryption policy with inbound connection protection:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Tools & Services** > **Firewall Management Center** > **Policies** > **Access Control** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

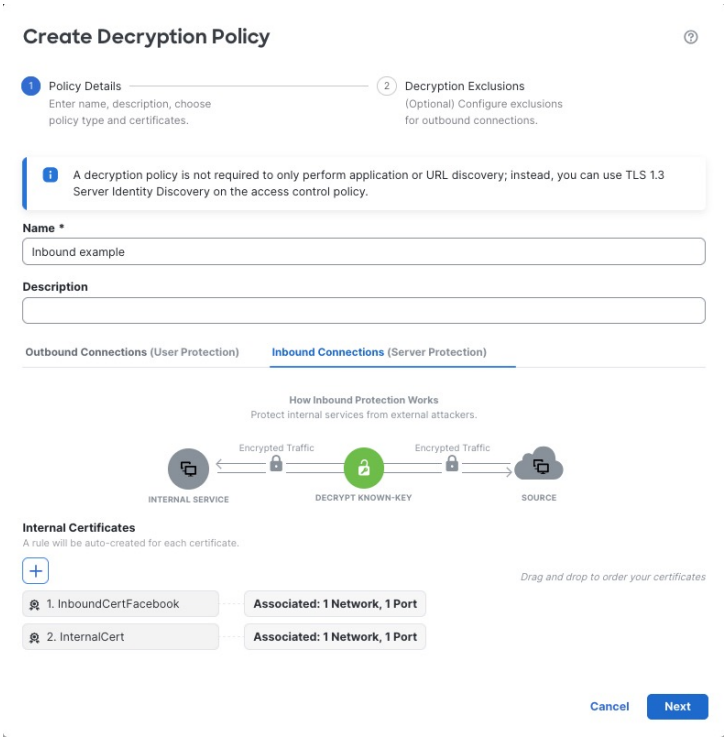
Step 4 Perform these steps:

a) Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- #,;,{,},=,$,<,>

b) From the **Internal Certificates** list, upload or choose certificates for the rules.



For more information about internal CA certificates, see Internal certificate authority objects, on page 2987.

c) (Optional.) Choose networks and ports.

For more information:

- Network rule conditions, on page 1701
- Best practice: use application-based rules over port-based rules, on page 1703

d) Click the **Inbound Connections** tab.

e) Click **Next**.

Step 5 Continue with Configure Rule-based decryption policy exclusions, on page 2171.

Step 6 Click **Save**.

What to do next

- Add rule conditions: Rule-based decryption rule conditions, on page 2201
- Add a default policy action: Rule-based decryption policy default actions, on page 2179

- Configure logging options for the default action.
- Set advanced policy properties: Rule-based decryption policy advanced options, on page 2182.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy configuration changes.

Rule-based decryption policy block connections

Block connections to servers with unsecure TLS versions and server certificate statuses while creating a rule-based decryption policy to enhance network security.

This topic provides details about how to block connections to servers with unsecure TLS versions and server certificate statuses while creating a rule-based decryption policy . The **Block with Reset** rules are created in your decryption policy that are disabled by default.

Procedure

Step 1 Complete the tasks mentioned in:

- Create a rule-based decryption policy with outbound connection protection, on page 2165
- Create a rule-based decryption policy with inbound connection protection, on page 2169

Step 2 Configure the blocking options on the **Blocking** page.

The **Blocking** page provides blocking options. By default, all the options are *disabled* for decryption policy actions.

- **Block connections based on TLS version**—Check this check box to block connections to servers using unsecure TLS versions. By default, **SSL v3.0**, **TLS v1.0**, and **TLS v1.1** which are known to be vulnerable, are selected. You can choose other versions from the drop-down list.
- **Block connections based on server certificate status**—Check this check box to block connections to servers with unsecure server certificate statuses. By default, **Invalid Signature**, **Expired**, **Not Yet Valid**, and **Invalid Certificate** are selected. You can choose other statuses from the drop-down list.

Click **Delete** (✕) to remove the selections or click **Reset to default** to revert back to the default selections.

Step 3 Click **Next**.

What to do next

Continue with Configure Rule-based decryption policy exclusions, on page 2171.

Configure Rule-based decryption policy exclusions

This task helps you create exclusions in your decryption policy to prevent decryption of traffic that should remain encrypted for compliance, security, or functional reasons.

This task discusses how to exclude certain types of traffic from decryption. We create **Do Not Decrypt** rules in your decryption policy for this purpose. The rules are initially enabled only for an outbound decryption policy (a policy that uses the **Decrypt - Resign** policy action).

Before you begin

You must upload an internal CA certificate for your managed device before you can create a rule-based decryption policy that protects outbound connections. You can do this in any of the following ways:

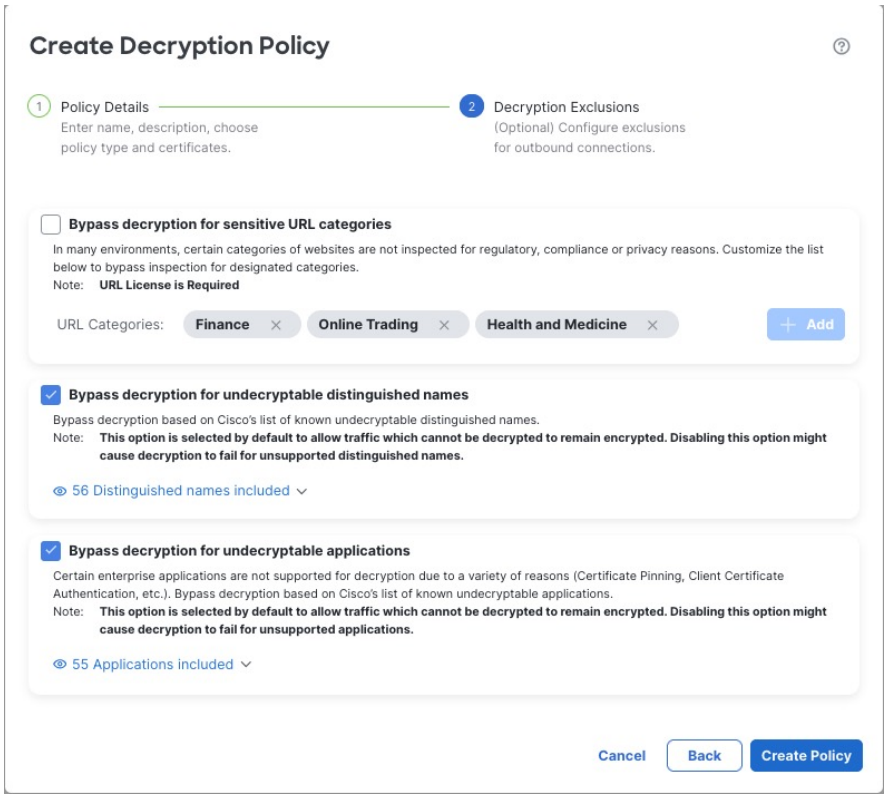
- Create an internal CA certificate object by going to **Objects** > **Object Management** > **PKI** > **Internal CAs** and referring to PKI objects, on page 2986.
- At the time you create this decryption policy.

Follow these steps to configure decryption policy exclusions:

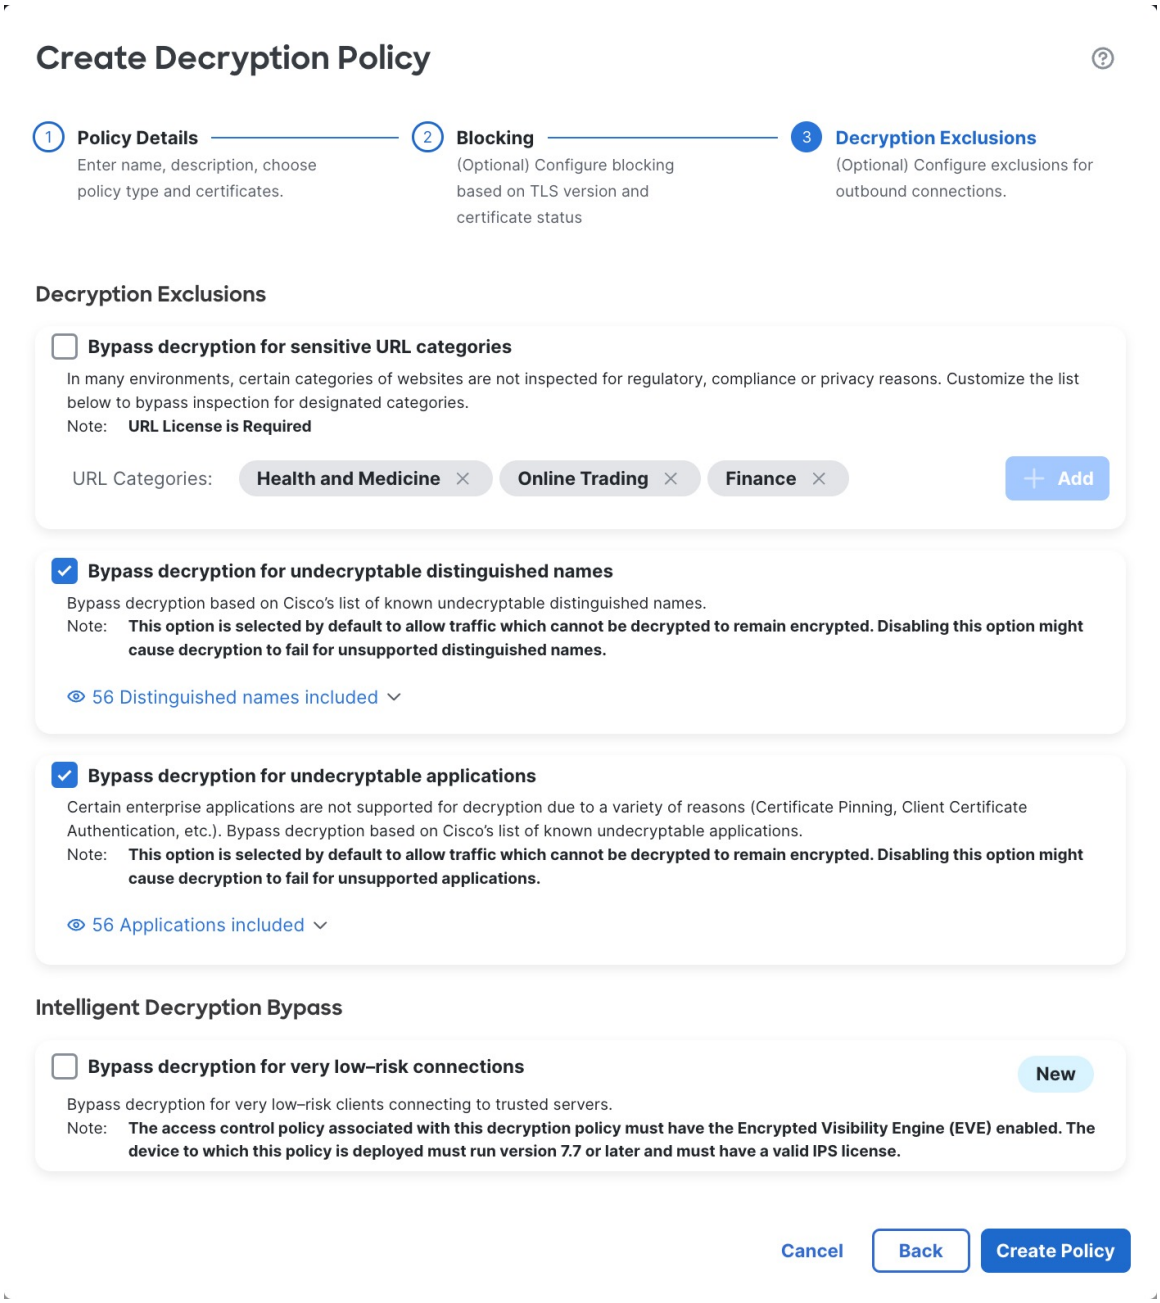
Procedure

Step 1 Complete the tasks discussed in:

- Create a rule-based decryption policy with outbound connection protection, on page 2165
- For more information, see Create a rule-based decryption policy with inbound connection protection, on page 2169



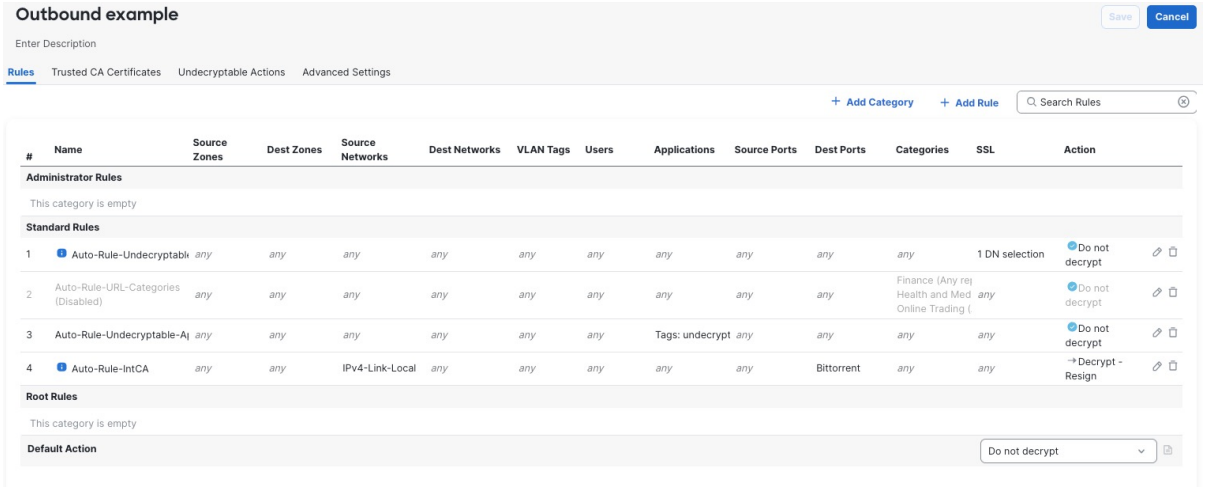
Step 2 Select the appropriate exclusion options based on your security requirements.



The exclusions page provides the following options. All options are *enabled* for an outbound protection policy (**Decrypt - Resign** rule action) and *disabled* for all other decryption policy actions.

Item	Description
Bypass decryption for sensitive URL categories	Check the box to not decrypt traffic from the indicated categories. Depending on the laws in your area, decryption certain traffic, such as finance or health-related, might be prohibited. Consult an authority in your area for more information. Click **Add** to add more categories. Click **Delete** (✕) to remove categories.
Bypass decryption for undecryptable distinguished names	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL certificate pinning guidelines, on page 2194. The list of undecryptable distinguished names is maintained by Cisco.

Item	Description
Bypass decryption for undecryptable applications	Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with *certificate pinning*, which is discussed in TLS/SSL certificate pinning guidelines, on page 2194. Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the Secure Firewall Application Detectors page; the **undecryptable** tag identifies applications Cisco determines are undecryptable. The list of undecryptable applications is maintained by Cisco.



This figure shows default options.

Step 3 Click **Create Policy**.

This figure shows a sample outbound protection policy.

In the preceding example, the **Do Not Decrypt** rules corresponding to your choices for rule exclusions are automatically added before the **Decrypt - Resign** rule. The rule for sensitive URL categories is disabled because, by default, that exclusion is disabled. Had you selected the **Bypass decryption for sensitive URL categories** check box, the rule would have been enabled.

What to do next

- Add rule conditions: Rule-based decryption rule conditions, on page 2201
- Add a default policy action: Rule-based decryption policy default actions, on page 2179
- Configure logging options for the default action .
- Set advanced policy properties: Rule-based decryption policy advanced options, on page 2182.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy configuration changes.

Generate an internal CA for outbound protection

This task allows you to generate an internal certificate authority object to protect outbound connections when creating a decryption rule.

This task discusses how you can optionally generate an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Upload a signed certificate issued in response to a CSR, on page 2990.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2987.

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Generate CA**.

Step 2 Give the internal CA a **Name** and provide a two-letter **Country Name**.

Step 3 Click **Self-Signed** or **CSR**.

For more information about these options, see Internal certificate authority objects, on page 2987.

Step 4 Enter the requested information in the provided fields.

Step 5 Click **Save**.

Step 6 If you chose **CSR**, after the signing request has been completed, click **Install Certificate** as follows:

a) Repeat the preceding steps in this procedure.

b) Edit the CA from the **Internal CA** list as follows.

c) Click **Install Certificate**.

d) Follow the prompts on your screen to complete the task.

Step 7 Continue creating the policy as discussed in Create a rule-based decryption policy with outbound connection protection, on page 2165.

Upload an internal CA for outbound protection

Upload an internal certificate authority to create a decryption rule that protects outbound connections.

This task discusses how you can optionally upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects** > **Object Management** as discussed in Upload a signed certificate issued in response to a CSR, on page 2990.

Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in Internal certificate authority objects, on page 2987.

Follow these steps to upload an internal CA for outbound protection:

Procedure

Step 1 From the **Internal CA** list, click **Create New** > **Upload CA**.

Step 2 Give the internal CA a **Name**.

Step 3 Paste or browse to locate the certificate and its private key in the provided fields.

Step 4 If the CA has a password, select the **Encrypted** check box and enter the password in the adjacent field.

Step 5 Continue creating the policy as discussed in Create a rule-based decryption policy with outbound connection protection, on page 2165.

Upload an internal certificate for inbound protection

This task helps you manage certificate objects and configure decryption for secure access control by uploading an internal certificate for inbound protection.

This task discusses how to upload an internal certificate when you create a decryption rule that protects inbound connections. You can also upload the internal certificate using **Objects** > **Object Management** as discussed in Import a CA certificate and private key, on page 2988.

Before you begin

Make sure you have an internal certificate in one of the formats discussed in Internal certificate authority objects, on page 2987.

Follow these steps to upload an internal certificate for inbound protection:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Administration** > **Integrations** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.

Step 3 Click **Create Decryption Policy**.

Step 4 Enter a name for the policy in the **Name** field and an optional description in the **Description** field.

Step 5 Click the **Inbound Connections** tab.

Step 6 From the **Internal Certificates** list, click **Add** (+).

Step 7 If an internal certificate object exists, click its name. Otherwise, click **Upload**.

a) Enter the required information.

See Add internal certificate objects, on page 2997.

Continue creating the decryption policy as discussed in Create a rule-based decryption policy with inbound connection protection, on page 2169.

Install an internal CA on client machines

To decrypt outbound traffic, the Firewall Threat Defense acts as a man-in-the-middle, first decrypting traffic (and subjecting it to deep inspection if you choose), then re-encrypting the traffic with a different internal CA. When the encrypted traffic is returned to the client, the client must trust the CA, or users see errors in their browser.

For example, the error might be:

```
www.example.com uses an invalid security certificate. The certificate is not trusted because

the issuer certificate is unknown
```

To avoid this, import the internal CA on your client machines (typically using network policies). For more information, consult a resource such as:

- Windows: Distribute Certificates to Client Computers by Using Group Policy
- macOS: Use a third party tools that is equivalent to Windows Group Policy Object (GPO). Consult the documentation provided with your system for more information.

Create a rule-based decryption policy with other rule actions

Create and manage decryption policies in the Secure Firewall Management Center to control encrypted traffic actions, such as **Do Not Decrypt**, **Block**, **Block With Reset**, or **Monitor**.

To create a decryption rule with a **Do Not Decrypt**, **Block**, **Block With Reset**, or **Monitor** rule action, create a decryption policy and edit the policy to add the rule.

When you create a rule-based decryption policy , you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules, and multiple **Decrypt - Resign** rules.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see Create change management tickets, on page 175 and Policies and objects that support change management, on page 169.

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Administration** > **Integrations** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.

Step 3 Perform these actions:

a) Give the policy a unique **Name** and, optionally, a **Description**.

The following characters are not supported in decryption policy names:

- Leading period
- `#,;,{,},=,$,<,>`

b) Click **Next**.

c) The bypass page is provided for your information only; you cannot bypass traffic for other types of decryption (such as **Block**).

d) Click **Create Policy**.

e) Wait for the policy to be created.

Step 4 Click **Edit** (✎) next to the decryption policy name.

Step 5 Click **Add Rule**.

a) Give the rule a **Name**.
b) From the **Action** list, click a rule action and see one of the sections for more information:
   - Decryption rule Do Not Decrypt action, on page 2221
   - Decryption rule blocking actions, on page 2222
   - Decryption rule monitor action, on page 2220

Step 6 Click **Save**.

What to do next

- Add rule conditions: Rule-based decryption rule conditions, on page 2201
- Add a default policy action: Rule-based decryption policy default actions, on page 2179
- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide* .
- Set advanced policy properties: Rule-based decryption policy advanced options, on page 2182.
- Associate the decryption policy with an access control policy as described in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy configuration changes.

Rule-based decryption policy default actions

The default action for a rule-based decryption policy determines how the system handles decryptable encrypted traffic that does not match any non-monitor rule in the policy. When you deploy a rule-based decryption policy without a decryption rules, the default action determines how all decryptable traffic on your network is handled. Note that the system does not perform any kind of inspection on encrypted traffic that the default action blocks.

To set the policy default action:

1. Log in to the Security Cloud Control if you haven't already done so.
2. Click **Administration** > **Integrations** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.
3. Click **Edit** ( ) next to the name of the decryption policy.
4. In the Default Action row, click one of the actions from the list.

Table 123: Decryption policy Default Actions

Default Action	Effect on Encrypted Traffic
Block	Block the TLS/SSL session without further inspection.

Default Action	Effect on Encrypted Traffic
Block with reset	Block the TLS/SSL session without further inspection and reset the TCP connection. Choose this option if traffic uses a connectionless protocol like UDP. In that case, the connectionless protocol tries to reestablish the connection until it is reset. This action also displays a connection reset error in the browser so the users are informed that the connection is blocked.
Do not decrypt	Inspect the encrypted traffic with access control.

Default handling options for undecryptable traffic

This reference provides information about identifying and managing undecryptable TLS/SSL traffic types in decryption policies. It covers handling handshake errors, unsupported cipher suites, compressed sessions, and session caching issues, along with user-facing actions for blocking or allowing such encrypted connections.

Table 124: Undecryptable traffic types

Type	Description	Default Action	Available Action
Compressed Session	The TLS/SSL session applies a data compression method.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
SSLv2 Session	The session is encrypted with SSL version 2. Note that traffic is decryptable if the ClientHello message is SSL 2.0, and the remainder of the transmitted traffic is SSL 3.0.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unknown Cipher Suite	The system does not recognize the cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unsupported Cipher Suite	The system does not support decryption based on the detected cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action

Type	Description	Default Action	Available Action
Session not cached	The TLS/SSL session has session reuse enabled, the client and server reestablished the session with the session identifier, and the system did not cache that session identifier.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Handshake Errors	An error occurred during TLS/SSL handshake negotiation.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Decryption Errors	An error occurred during traffic decryption.	Block	Block Block with Reset

When you first create a decryption policy, logging connections that are handled by the default action is disabled by default. Because the logging settings for the default action also apply to undecryptable traffic handling, logging connections handled by the undecryptable traffic actions is disabled by default.

Note that if your browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. For more information, see Rule-based decryption rules guidelines and limitations, on page 2188.

Set default handling for undecryptable traffic

Set undecryptable traffic actions to handle certain types of encrypted traffic the system cannot decrypt or inspect, ensuring proper network security enforcement for encrypted connections.

You can set undecryptable traffic actions at the rule-based decryption policy level to handle certain types of encrypted traffic the system cannot decrypt or inspect. When you deploy arule-based decryption policy that contains no decryption rules, the undecryptable traffic actions determine how all undecryptable encrypted traffic on your network is handled.

Depending on the type of undecryptable traffic, you can choose to:

- Block the connection.
- Block the connection, then reset it. This option is preferrable for connectionless protocols like UDP, which keep trying to connect until the connection is blocked.
- Inspect the encrypted traffic with access control.
- Inherit the default action from the rule-based decryption policy.

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Administration** > **Integrations** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.

Step 3 Click **Edit** ( ) next to the name of the decryption policy.

Step 4 In the decryption policy editor, click **Undecryptable Actions**.

Step 5 For each field, choose either the decryption policy's default action or another action you want to take on the type of undecryptable traffic. See Default handling options for undecryptable traffic, on page 2180 and Rule-based decryption policy default actions, on page 2179 for more information.

Step 6 Click **Save** to save the policy.

What to do next

- Configure default logging for connections handled by the undecryptable traffic actions; see *Logging Connections with a Policy Default Action* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Deploy configuration changes.

Rule-based decryption policy advanced options

A rule-based decryption policy 's **Advanced Settings** page contains global settings. These settings apply to all managed devices that are configured for Snort 3.

A rule-based decryption policy advanced settings are all ignored on any managed device that runs:

- A version earlier than 7.1
- Snort 2

Block flows requesting ESNI

Encrypted Server Name Indication (ESNI (link to draft proposal)) is a way for a client to tell a TLS 1.3 server what the client is requesting. Because the SNI is encrypted, the system cannot identify the server. You can choose to block these connections.

Disable HTTP/3 advertisement

This option strips HTTP/3 (RFC 9114) from the ClientHello in TCP connections. HTTP/3 is part of the QUIC transport protocol, not the TCP transport protocol. Blocking clients from advertising HTTP/3 provides protection against attacks and evasion attempts potentially burried within QUIC connections.

Propagate untrusted server certificates to clients

This setting applies only to traffic matching a **Decrypt - Resign** rule action.

Enable this option when the server certificate is untrusted. The managed device substitutes its certificate authority (CA) for the server certificate. An *untrusted* server certificate is one that is not listed as a trusted CA in the Security Cloud Control(**Objects**, **Objects** > **Object Management** > **PKI** > **Trusted CAs**).

Enable TLS 1.3 decryption

Whether to apply decryption rules to TLS 1.3 connections. If you do not enable this option, the decryption rules apply to TLS 1.2 or lower traffic only. See TLS 1.3 decryption best practices, on page 2184.

Enable adaptive TLS server identity probe

Automatically enabled when TLS 1.3 decryption is enabled. A *probe* is a partial TLS connection with the server, the purpose of which is to obtain the server certificate and cache it. (If the certificate is already cached, the probe is never established.)

If TLS 1.3 Server Identity Discovery is disabled on the access control policy with which the decryption policy is associated, we attempt to use the Server Name Indication (SNI), which is not as reliable.

The adaptive TLS server identity PROBE occurs on any of these conditions as opposed to on every connection as in earlier releases:

- Certificate Issuer—Matched when the value of **Issuer DNs** in a decryption rule's DN rule condition is matched.

  For more information, see Conditions for distinguished name rules in decryption policies, on page 2208.

- Certificate Status—Matched when any of the **Cert Status** conditions are matched in a decryption rule.

  For more information, see Certificate Status Decryption rule conditions, on page 2214.

- Internal/External Certificate—Internal certificates can be matched by the certificate used in **Decrypt - Known Key** rule actions; external certificates can be matched in **Certificates** rule conditions.

  For more information, see Known key decryption for incoming traffic, on page 2126 and Certificate rule conditions, on page 2207.

- Application ID—Can be matched by **Applications** rule conditions in either an access control policy or a decryption policy.

  For more information, see Application rule conditions, on page 1701.

- URL Category—Can be matched by **URLs** rule conditions in an access control policy.

  For more information, see Recommendation: use URL conditions for website access control , on page 1704.

Note **Enable adaptive TLS server discovery mode** is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Security Cloud Control, the connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.

Enable QUIC Decryption

Whether to apply decryption rules to connections that use the HTTP/3 over the QUIC protocol. When you decrypt QUIC connections, the system can inspect the contents of the sessions for intrusions, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. QUIC support is in line with RFC 9000, 9001, 9002, 9114, 9204.

Consider the following when implementing QUIC decryption:

- On high availability or clustered devices, QUIC decryption works only if the connection remains on the same node. If the connection fails over, or is forwarded to another node, the connection drops and must be re-established. Multi-instance is supported without restrictions.
- Rules that apply to QUIC traffic would include the UDP protocol with destination port 443.
- Access control rules that apply to QUIC traffic would include the HTTP/3 or QUIC protocols, either explicitly or by implication.

The following limitations apply to QUIC decryption:

- QUIC decryption applies to Firewall Threat Defense 7.6+ only. Devices running a lower release cannot decrypt QUIC connections.
- Connections from browsers using the Chromium stack (Google Chrome, Opera, Edge) cannot be decrypted for outbound traffic. But inbound traffic from the same browsers can be decrypted.
- Connection Migration as described in RFC 9000 is not supported. The concept of Connection ID in QUIC allows endpoints to retain the same connection in the event of address change.
- Key update, session resumption, and QUIC version 2 are not supported.
- Interactive Block and Interactive Block with Reset (in access control rules) is not supported. These actions will work as Block and Block with Reset.
- The active connection-ID per connection is limited to 5. If necessary, you can modify these limits using the **system support quic-tuning** and **system support quic-tuning-reset** commands in the device CLI.

TLS 1.3 decryption best practices

Both the rule-based decryption policy and the access control policy have advanced options that affect how traffic is handled, whether the traffic is being decrypted or not.

The advanced options are:

- Decryption policy:
  - TLS 1.3 decryption
  - TLS adaptive server identity probe
- Access control policy: TLS 1.3 Server Identity Discovery

  The access control policy setting takes precedence over the decryption policy setting.

Use the following table to decide which option to enable:

TLS adaptive server identity probe setting (decryption policy)	TLS 1.3 Server Identity Discovery setting (access control policy)	Result	Recommended when
Enabled	Disabled	Adaptive probe sent if decryption policy contains *any* rule conditions specified in Rule-based decryption policy advanced options, on page 2182 *and* if the server certificate is not cached.	• You're not using application or URL conditions in access control rules • You're decrypting traffic
Enabled	Enabled	Probe is always sent if the server certificate is not cached.	Use only if your access control rules have URL or application conditions
Disabled	Enabled	Probe is always sent if the server certificate is not cached.	Not recommended.
Disabled	Disabled	Probe is never sent.	Very limited usefulness; use only if not decrypting traffic and not using application or URL conditions in the access control rule

Note A cached TLS server's certificate is available to all Snort instances on a particular Firewall Threat Defense. The cache can be cleared with a CLI command and is automatically cleared when the device is rebooted.

For more information, see the discussion of TLS server identity discovery on secure.cisco.com.

CHAPTER 76

Rule-Based Decryption Rules

The following topics discuss how to manage rule-based decryption rules.

- Rule-based decryption, on page 2187
- Requirements and prerequisites for Rule-based decryption rules, on page 2187
- Rule-based decryption rules guidelines and limitations, on page 2188
- Best practice for Decryption policy rule order, on page 2196
- Rule-based decryption rule traffic handling, on page 2197
- Rule-based decryption rule conditions, on page 2201
- Rule-based decryption rule actions, on page 2220
- Monitor TLS/SSL hardware acceleration, on page 2226
- Troubleshoot Rule-based decryption rules, on page 2228
- Troubleshoot using crypto archives, on page 2236

Rule-based decryption

Decryption rules are a granular method that

- handle encrypted traffic across multiple managed devices
- provide options to block traffic without inspection, inspect without decrypting, or decrypt for access control analysis, and
- support access control rule evaluation.

Requirements and prerequisites for Rule-based decryption rules

This reference provides the domain support and user role requirements necessary for Rule-based decryption rules.

Supported domains

Any

User roles

- Network Admin

Rule-based decryption rules guidelines and limitations

Keep these points in mind when setting up your rule-based decryption rule. Properly configuring rule-based decryption rule is a complex task, but one that is essential to building an effective deployment that handles encrypted traffic. Many factors influence how you configure rules, including certain application behavior that you cannot control.

In addition, rules can preempt each other, require additional licenses, or contain invalid configurations. Thoughtfully configured rules can also reduce the resources required to process network traffic. Creating overly complex rules and ordering rules the wrong way can adversely affect performance.

For detailed information, see Best practices for access control rules, on page 2058.

Guidelines for using TLS/SSL decryption

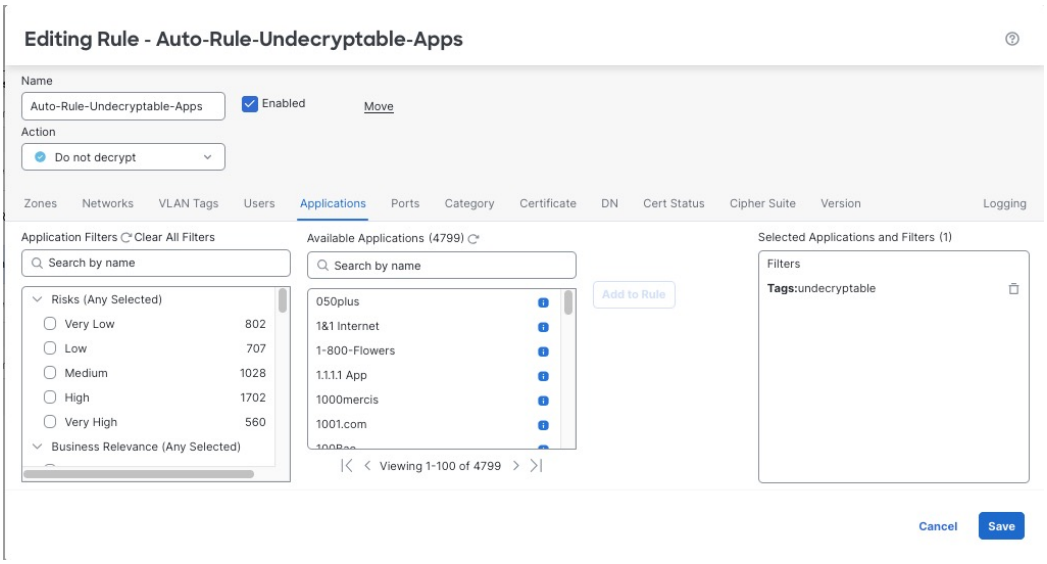
General guideline

Rule-based decryption rules require processing overhead that can impact performance. Determine which traffic must be decrypted and subjected to deep inspection before you set up any policies or rules.

- You cannot decrypt traffic on a device that uses passive interface.
- You cannot decrypt traffic on a device that uses inline tap interface.
- You cannot decrypt traffic on a device that uses TCP state bypass (only if the interfaces are in routed mode).

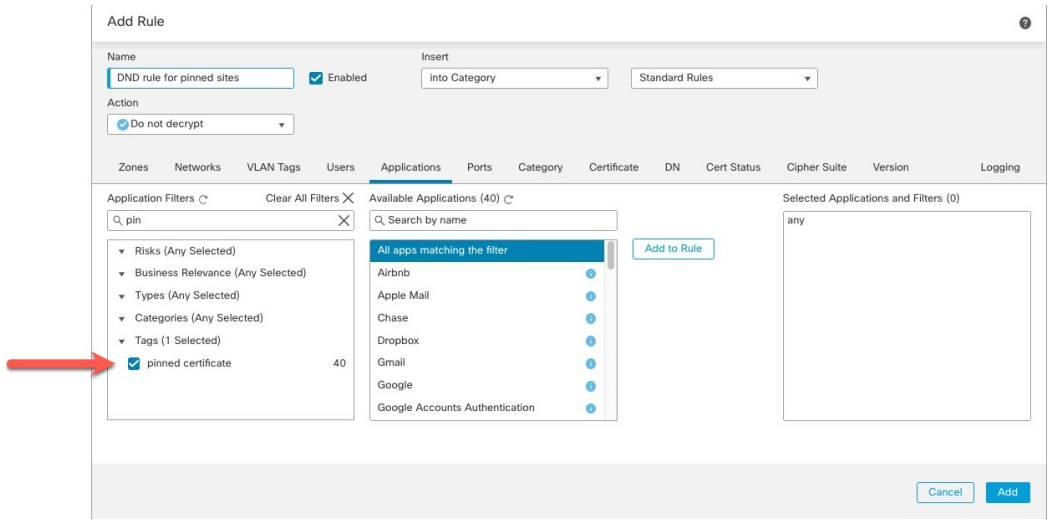
Guidelines for undecryptable traffic

We can determine that certain traffic is not decryptable either because the website itself is not decryptable or because the website uses TLS/SSL pinning, which effectively prevents users from accessing a decrypted site without errors in their browser.



For more information about certificate pinning, see TLS/SSL pinning, on page 2231.

We maintain the list of these sites as follows:



- A Distinguished Name (DN) group named **Cisco-Undecryptable-Sites**
- The **pinned certificate** or **undecryptable** application filter

If you are decrypting traffic and you do not want users to see errors in their browsers when going to these sites, we recommend you set up a **Do Not Decrypt** rule toward the bottom of your decryption rules.

If you use the decryption policy wizard to create a policy for outbound traffic protection, a **Do Not Decrypt** rule for pinned certificates is created for you as the following example shows.

An example of setting up a **pinned certificate** application filter follows.

Rule-based decryption rules unsupported features

This reference provides guidance for handling RC4, DES, and TLS 1.3 limitations in the Cisco Firepower System, including configuration requirements for decryption policies when dealing with unsupported cipher suites and interface types.

RC4 cipher not unsupported

The Rivest Cipher 4 (also referred to as *RC4* or *ARC4* cipher is known to have vulnerabilities and is considered unsecure.
decryption policies identify the RC4 cipher suite as unsupported; you should configure the **Unsupported Cipher Suite** action in the decryption policies policy's **Undecryptable Actions** page to match your organization's requirements. For more information, see Default handling options for undecryptable traffic, on page 2180.

Passive, inline tap mode, and SPAN interfaces not supported

TLS/SSL traffic cannot be decrypted on passive, inline tap mode, or SPAN interfaces.

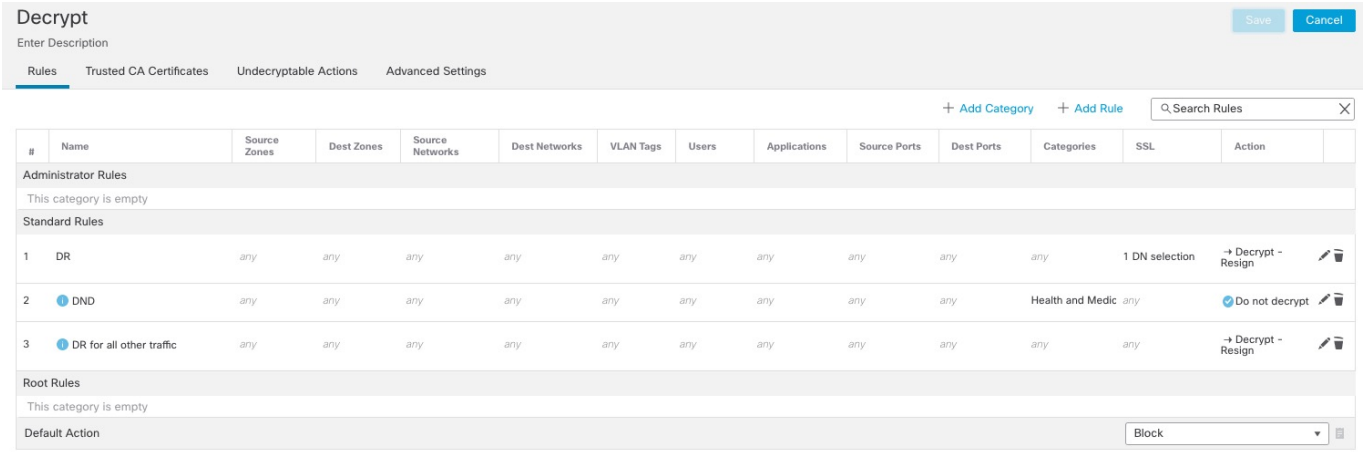
Guidelines for TLS/SSL Do Not Decrypt configuration

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)



- URL category and reputation
- Port
- User group

Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is not based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 2188.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 2054.

Best practices for TLS/SSL incoming traffic decryption

Certificate and key association
Known key rule action

You can associate one or more server certificates and paired private keys with a **Decrypt - Known Key** rule action.

If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys. Because you must have access to the private key, this action is best suited to decrypt traffic incoming to servers your organization controls.

Restrictions and considerations

Note these restrictions when configuring decryption rules:

- Anonymous cipher suite unsupported:

  By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

  You cannot use the **Decrypt - Resign**, **Decrypt - Replace Cert** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

- Cannot match on Distinguished Name or Certificate:

  You cannot match on **Distinguished Name** or **Certificate** rule conditions when creating a decryption rule with a **Decrypt - Known Key** action. The assumption is that if this rule matches traffic, the certificate, subject DN, and issuer DN already match the certificate associated with the rule.

- Do not use Version or Cipher Suite rule conditions.

Important *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

- Elliptic Curve Digital Signature Algorithm (ECDSA) certificate results in blocked traffic:

  (TLS 1.3 decryption enabled only.) If you use an ECDSA certificate with a **Decrypt - Known Key** rule action, matching traffic will be blocked. To avoid this, use a certificate with another type of certificate.

TLS/SSL Decrypt - Resign guidelines

You can associate one internal Certificate Authority (CA) certificate and private key with the **Decrypt - Resign** action. If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains different cryptographic session details, and allows the system to decrypt and reencrypt traffic.

- Use the **Decrypt - Resign** rule action for decrypting *outgoing* traffic, as opposed to incoming traffic for which we recommend the **Decrypt - Known Key** rule action.

  For more information about **Decrypt - Known Key**, see .

- Always check the **Replace Key Only** check box when you set up a **Decrypt - Resign** rule action.

  When a user browses to a web site that uses a *self-signed* certificate, the user sees a security warning in the web browser and is aware that they are communicating with an unsecure site.

  When a user browses to a web site that uses a trusted certificate, the user does not see a security warning.

Certificate algorithm compatibility

If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's signature algorithm type, in addition to any configured rule conditions. Because you associate one CA certificate with a **Decrypt - Resign** action, you cannot create a decryption rule that decrypts multiple types of outgoing traffic encrypted with different signature algorithms. In addition, any external certificate objects and cipher suites you add to the rule must match the associated CA certificate encryption algorithm type.

- For example, outgoing traffic encrypted with an elliptic curve (EC) algorithm matches a **Decrypt - Resign** rule only if the action references an EC-based CA certificate; you must add EC-based external certificates and cipher suites to the rule to create certificate and cipher suite rule conditions.
- Similarly, a **Decrypt - Resign** rule that references an RSA-based CA certificate matches only outgoing traffic encrypted with an RSA algorithm; outgoing traffic encrypted with an EC algorithm does not match the rule, even if all other configured rule conditions match.

Guidelines and limitations

Anonymous cipher suite unsupported:

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

- **Do not use Version or Cipher Suite rule conditions**:

Important *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

- Decrypt - Resign rule action and a Certificate Signing Request: To use a **Decrypt - Resign** rule action, you should create a Certificate Signing Request (CSR) and have it signed by a trusted certificate authority. (You can use the FMC to create a CSR: **Objects** > **Object Management** > **PKI** > **Internal Certs**.)

  To be used in a **Decrypt - Resign** rule, your certificate authority (CA) must have at least one of these extensions

  - **CA: TRUE**

    For more information, see the discussion of Basic Constraints in RFC3280, section 4.2.1.10.

  - **KeyUsage=CertSign**

    For more information see RFC 5280, section 4.2.1.3.

  To verify your CSR or CA has at least one of the preceding extensions, you can use the **openssl** command as discussed in a reference such as the openssl documentation.

This is necessary because for **Decrypt - Resign** inspection to work, the certificate that used in the decryption policy generates certificates on-the-fly and signs them so as to act as man-in-the middle and proxy all TLS/SSL connections.

- **Certificate pinning**: If the customer's browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. To allow this traffic, configure a decryption rule with the **Do Not Decrypt** action to match the server certificate common name or distinguished name.
- **Non-matching cipher suite**: This error is displayed if you attempt to save a decryption rule with a cipher suite that does not match the certificate.

  ```
  Traffic cannot match this rule; none of your selected cipher suites contain a
  signature algorithm that the resigning CA's signature algorithm
  ```

- **Untrusted Certificate Authority**: If the client does not trust the Certificate Authority (CA) used to re-sign the server certificate, it warns the user that the certificate should not be trusted. To prevent this, import the CA certificate into the client trusted CA store. Alternatively, if your organization has a private PKI, you can issue an intermediate CA certificate signed by the root CA which is automatically trusted by all clients in the organization, then upload that CA certificate to the device.
- **HTTP proxy limitation**: The system cannot decrypt traffic if an HTTP proxy is positioned between a client and your managed device, and the client and server establish a tunneled TLS/SSL connection using the CONNECT HTTP method. The **Handshake Errors** undecryptable action determines how the system handles this traffic.
- **Upload signed CA**: If you create an internal CA object and choose to generate a certificate signing request (CSR), you cannot use this CA for a **Decrypt - Resign** action until you upload the signed certificate to the object.
- **Mismatched signature algorithm**: If you configure a rule with the **Decrypt - Resign** action, and mismatch signature algorithm type for one or more external certificate objects or cipher suites, the policy editor displays an **Information** ( ) next to the rule. If you mismatch signature algorithm type for all external certificate objects, or all cipher suites, the policy displays a warning icon **Warning** ( ) next to the rule, and you cannot deploy the access control policy associated with the decryption policy.

TLS/SSL block guidelines

If your decryption rule is associated with an access control policy that has a rule with an action of either **Interactive Block** or **Interactive Block with reset**, the system displays a customizable response page.

If you enabled logging in your rule, two connection events are displayed (in **Analysis** > **Unified Events**): One event for the interactive block and another event to indicate whether or not the user chose to continue to the site or not.

Related Topics

HTTP response pages, on page 2103

TLS/SSL certificate pinning guidelines

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

Because TLS/SSL pinning is used to avoid man-in-the-middle attacks, there is no way to prevent or work around it. We recommend adding a **Do Not Decrypt** rule before the **Decrypt - Resign** rule so pinning traffic is excluded from being decrypted.

- Create a **Do Not Decrypt** for those applications rule ordered before **Decrypt - Resign** rules.
- Instruct users to access the applications using a web browser.

For more information about rule ordering, see Best practice for Decryption policy rule order, on page 2196.

To determine whether applications are using TLS/SSL pinning, see Troubleshoot TLS/SSL pinning, on page 2231.

TLS/SSL heartbeat guidelines

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, refer to *The SSL Preprocessor* section in the "Custom Snort 2 Intrusion Policies for Access Control" document.

For more information, refer to TLS heartbeat, on page 2229.

TLS/SSL anonymous cipher suite limitation

Anonymous cipher suites impact decryption rules.

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see RFC 5246, appendix F.1.1.1. (Replaced for TLS 1.3 by RFC 8446 appendix C.5.)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

You can add an anonymous cipher suite to the **Cipher Suite** condition in a decryption rule, but the system automatically strips anonymous cipher suites during ClientHello processing. For the system to use the rule, you must also configure your decryption rules in an order that prevents ClientHello processing. For more information, refer to Best practice for Decryption policy rule order, on page 2196

TLS/SSL normalizer guidelines

If you enable the **Normalize Excess Payload** option in the inline normalization preprocessor, when the preprocessor normalizes decrypted traffic, it might drop a packet and replace it with a trimmed packet. This does not end the TLS/SSL session. If the traffic is allowed, the trimmed packet is encrypted as part of the TLS/SSL session.

Other Rule-based decryption rule guidelines

Consider users and groups configuration when creating decryption rules. If you add a group or user to a rule, then change your realm settings to exclude that group or user, the rule has no effect. (The same applies to

disabling the realm.) For more information about realms, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Consider all relevant categories when configuring decryption rules. If your decryption policy has a **Decrypt - Resign** action but web sites are not being decrypted, check **Category** page on rules associated with that policy.

In some cases, a web site redirects to another site for authentication or other purposes and the redirected site might have a different URL categorization than the site you're trying to decrypt. For example, `gmail.com` (**Web based email** category) redirects to `accounts.gmail.com` (**Internet Portals** category) for authentication. Be sure to include all relevant categories in the SSL rule.

Note In order to fully process traffic based on URL category, you must also configure URL filtering. See the URL Filtering Rules, on page 2085 chapter.

Consider configuring cloud query settings for URLs not in the local database. If you create a **Decrypt - Resign** rule and users browse to a web site whose category and reputation are not in the local database, data might not be decrypted. Some web sites are not categorized in the local database and, if not, data from those web sites is not decrypted by default.

You can control this behavior with the **Query Cisco cloud for unknown URLs** setting in **Integration** > **Other Integrations** > **Cloud Services**

Best practice for Decryption policy rule order

General rule ordering

Order your rules with specific conditions (such as IP addresses and networks) *before* rules with general conditions (such as applications).

Allow traffic from certificate pinned sites

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

- To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you *cannot* log in to a Facebook mobile application but *can* log in to Facebook using Safari or Chrome.) You can use Firepower Management Center connection events as further proof of TLS/SSL pinning
- Configure an SSL rule with the **Do Not Decrypt** action to match the server certificate common name or distinguished name. In the SSL policy, order this rule before all **Decrypt - Resign** rules that also match the traffic.

You can retrieve the pinned certificate from the client's browser after a successful connection to the website. You can also view the certificate from the logged connection event, regardless of whether the connection succeeded or failed.

Note TLS/SSL pinning is not limited to mobile applications.

Prioritize ClientHello modifications

Place rules that match on conditions that are available in the ClientHello message before rules that match on ServerHello or server Certificate conditions.

When a managed device processes an SSL handshake, it can modify the ClientHello message to increase the likelihood of decryption. For example, it may remove compression methods because the system cannot decrypt compressed sessions.

The system modifies ClientHello messages only if it can conclusively match them to an SSL rule with either a **Decrypt - Resign**or **Decrypt - Known Key**action. The first time the system detects an encrypted session to a new server, server Certificate data is not available for ClientHello processing, which can result in an undecrypted first session. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with server Certificate conditions and process the message to maximize decryption potential.

If you place rules that match on ServerHello or server Certificate conditions (certificate, distinguished names, certificate status, cipher suites, version) before rules that match on ClientHello conditions (zones, networks, VLAN tags, ports, users, applications, URL categories), you can preempt ClientHello modification and increase the number of undecrypted sessions.

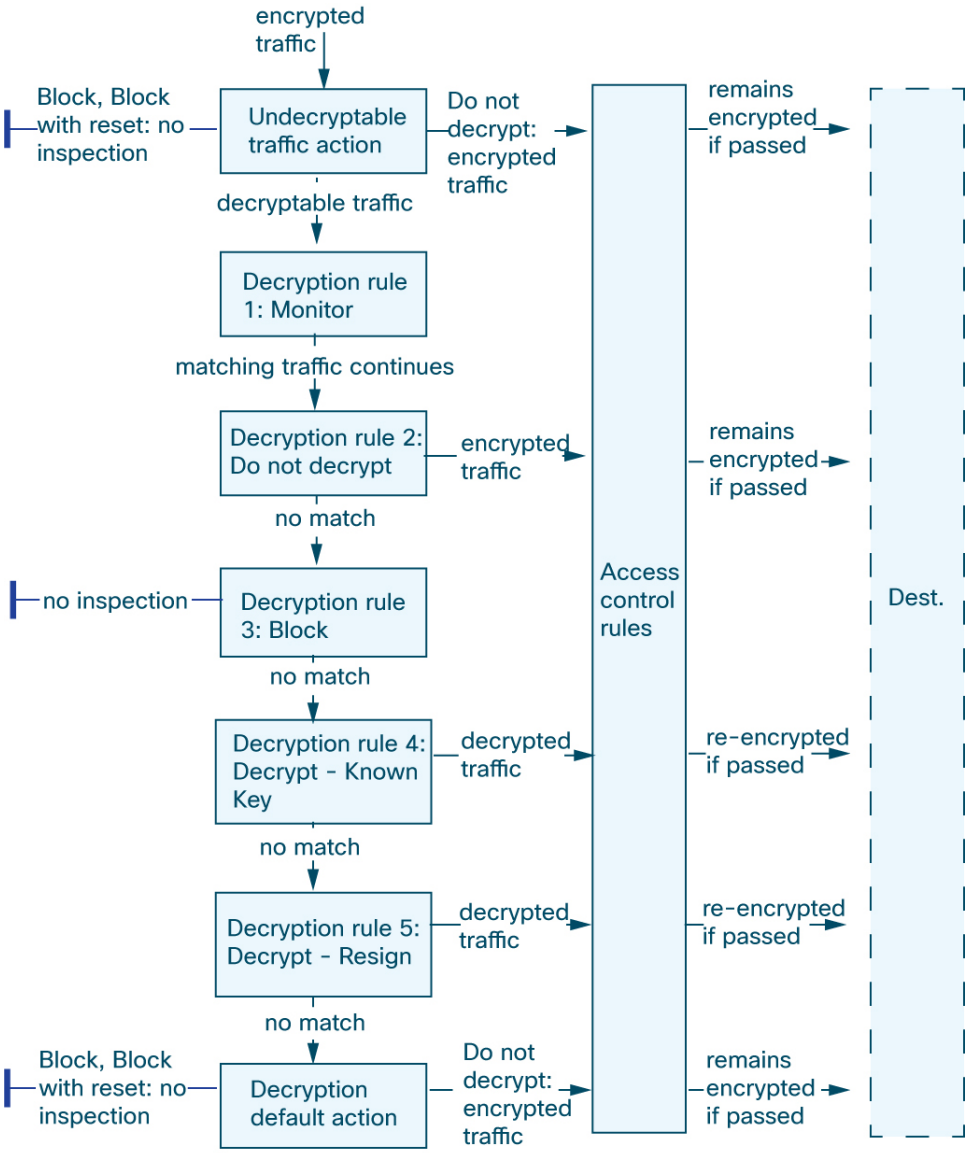
SSL policy bypass situations

The SSL policy is bypassed for any connections that match access control rules with actions of **Trust**, **Block**, or **Block with reset** if those rules:

- Use security zone, network, geolocation, and port only as the traffic matching criteria.
- Precede other rules that require inspection, such as rules that match connections based on application or URL, or allow rules that apply intrusion or file inspection.

Rule-based decryption rule traffic handling

Rule-based decryption rule traffic handling is a security mechanism that matches traffic to rule-based decryption rules in a specified order to determine appropriate actions.



Traffic matching and processing behavior

The system matches traffic to rule-based decryption rules in the order you specify. In most cases, the system handles encrypted traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does inspect encrypted and undecryptable traffic with access control. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads.

Traffic handling process

This scenario summarizes the ways that Rule-based decryption rule handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- Undecryptable Traffic Action evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- Rule 1: Monitor evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.

- Rule 2: Do Not Decrypt evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.
- Rule 3: Block evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- Rule 4: Decrypt - Known Key evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- Rule 5: Decrypt - Resign is the final rule. If traffic matches, the system re-signs the server certificate with an uploaded CA certificate and decrypts traffic. The decrypted traffic is then evaluated against access control rules, which treat decrypted and unencrypted traffic the same. This additional inspection allows the system to block traffic. All remaining traffic is re-encrypted before being sent to its destination. Traffic that does not match the decryption rule rule continues to the next rule.
- Default Action handles all traffic that does not match any of the decryption rule. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

Encrypted traffic inspection configuration

You must create reusable public key infrastructure (PKI) objects to control encrypted traffic based on encrypted session characteristics and decrypt encrypted traffic. You can add this information on the fly when uploading trusted certificate authority (CA) certificates to the a decryption policy and creating decryption rule, creating the associated object in the process. However, configuring these objects ahead of time reduces the chance of improper object creation.

Decrypting encrypted traffic with certificates and paired keys

The system can decrypt incoming encrypted traffic if you configure an internal certificate object by uploading the server certificate and private key used to encrypt the session. If you reference that object in a decryption policy rule with an action of **Decrypt - Known Key** and traffic matches that rule, the system uses the uploaded private key to decrypt the session.

The system can also decrypt outgoing traffic if you configure an internal CA object by uploading a CA certificate and private key. If you reference that object in a decryption rule with an action of **Decrypt - Resign** and traffic matches that rule, the system re-signs the server certificate passed to the client browser, then acts as a man-in-the-middle to decrypt the session. You can optionally replace the self-signed certificate key only and not the entire certificate, in which case users see a self-signed certificate key notice in the browser.

Controlling traffic based on encrypted session characteristics

The system can control encrypted traffic based on the cipher suite or server certificate used to negotiate the session. You can configure one of several different reusable objects and reference the object in a decryption rule condition to match traffic. This table describes the different types of reusable objects you can configure:

If you configure...	You can control encrypted traffic based on whether...
A cipher suite list containing one or more cipher suites	The cipher suite used to negotiate the encrypted session matches a cipher suite in the cipher suite list
A trusted CA object by uploading a CA certificate your organization trusts	The trusted CA trusts the server certificate used to encrypt the session, whether: • The CA issued the certificate directly • The CA issued a certificate to an intermediate CA that issued the server certificate
An external certificate object by uploading a server certificate	The server certificate used to encrypt the session matches the uploaded server certificate
A distinguished name object containing a certificate subject or issuer distinguished name	The subject or issuer common name, country, organization, or organizational unit on the certificate used to encrypt the session matches the configured distinguished name

Rule-based decryption rule order evaluation

Rule-based decryption rule order evaluation determines the sequence in which the system evaluates decryption rules in a policy.

Rule evaluation process

This information applies only to rule-based decryption policies and rules.

When you create a rule-based decryption rule in a rule-based decryption policy , you specify its position using the **Insert** list in the rule editor. Decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL category and reputation, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network)

should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules.

Note Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

Best practices for access control rules, on page 2058

Rule-based decryption rule conditions

A rule-based decryption rule condition identifies the type of encrypted traffic the rule handles. Conditions can be simple or complex, and you can specify more than one condition type per rule. Only if traffic meets all the conditions in a rule does the rule apply to the traffic.

Condition evaluation and rule actions

If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a certificate condition but no version condition evaluates traffic based on the server certificate used to negotiate the session, regardless of the session SSL or TLS version.

Every rule-based decryption policy has an associated action that determines handling and logging for matching encrypted traffic:

- Handling: Most importantly, the rule action governs whether the system will monitor, trust, block, or decrypt encrypted traffic that matches the rule's conditions.
- Logging: The rule action determines when and how you can log details about matching encrypted traffic.

Your TLS/SSL inspection configuration handles, inspects, and logs decrypted traffic:

- The decryption policy's undecryptable actions handle traffic that the system cannot decrypt.
- The policy's default action handles traffic that does not meet the condition of any non-Monitor decryption rule.

You can log a connection event when the system blocks or trusts an encrypted session. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. Connection logs for encrypted sessions contain details, such as the certificate used to encrypt that session. You can log only end-of-connection events.

- For blocked connections (Block, Block with reset), the system immediately ends the sessions and generates an event.
- For Do Not Decrypt connections, the system generates an event when the session ends.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).

- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

User rule conditions

A user rule condition is a traffic matching mechanism that

- matches traffic based on whether the user initiating the connection or the group to which they belong
- can be configured for users in Microsoft Active Directory realms only, and
- enables policy enforcement based on user identity and group membership.

Special identities users

In addition to configuring users and groups for configured realms, you can set policies for the special identities users:

- Failed Authentication: User who failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified such as users who are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

User rule condition example

Configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

Application rule conditions

Application rule conditions are application awareness and control mechanisms that

- identify and classify applications through IP traffic analysis
- enable control with organized filters
- require one enabled detector for each condition.

Application filters and control benefits

System-provided *application filters* help perform control by organizing applications according to basic characteristics, such as type, risk, business relevance, category, and tags. You can also create reuseable, user-defined filters using combinations of system-provided filters, or custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled, the system automatically enables all available system-provided detectors, or the most recently modified user-defined detector. For more information about application detectors, see Application detectors.

You can utilize both application filters and individually specified applications to ensure complete coverage. Understand the application's requirements to effectively order access control rules.

Application filters help you to quickly configure application control effectively. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

The system characterizes detected applications using several criteria which form effective filters.

Table 125: Application characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email applications are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Category rule conditions

Category rule conditions are policy elements that

- enable control of web access based on Cisco Talos intelligence
- support policy creation through URL filtering without relying on company vertical, intent, or declared security, and
- can be included in decryption policies to manage encrypted traffic.

Additional information

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

For more information, see URL filtering, on page 2085.

If you are using category rule conditions in decryption policies in a rule with the **Do Not Decrypt** rule action, see Decryption rule Do Not Decrypt action, on page 2221.

Server certificate-based rule conditions

Server certificate-based rule conditions are decryption rules configurations that

- handle and decrypt encrypted traffic based on server certificate characteristics
- inspect traffic using certificate attributes, status, cipher suites, and session versions, and
- enhance secure traffic management and visibility through certificate validation criteria.

Server certificate attribute conditions

You can configure decryption rules based on these server certificate attributes:

- **Distinguished name conditions**: Allow you to handle and inspect encrypted traffic based on the CA that issued a server certificate, or the certificate holder. Based on the issuer distinguished name, you can handle traffic based on the CA that issued a site's server certificate.
- **Certificate conditions**: In decryption rules allow you to handle and inspect encrypted traffic based on the server certificate used to encrypt that traffic. You can configure a condition with one or more certificates; traffic matches the rule if the certificate matches any of the condition's certificates.
- **Certificate status conditions**: In decryption rules allow you to handle and inspect encrypted traffic based on the status of the server certificate used to encrypt the traffic, including whether a certificate is valid, revoked, expired, not yet valid, self-signed, signed by a trusted CA, whether the Certificate Revocation List (CRL) is valid; whether the Server Name Indication (SNI) in the certificate matches the server in the request.
- **Cipher suite conditions**: In decryption rules allow you to handle and inspect encrypted traffic based on the cipher suite used to negotiate the encrypted session.
- **Session conditions**: In decryption rules allow you to inspect encrypted traffic based on the SSL or TLS version used to encrypt the traffic.

To detect multiple cipher suites in a rule, the certificate issuer, or the certificate holder, you can create reusable cipher suite list and distinguished name objects and add them to your rule. To detect the server certificate and certain certificate statuses, you must create external certificate and external CA objects for the rule.

Certificate rule conditions

When you build a certificate-based decryption rule condition, you can upload a server certificate and save it as an external certificate *object* The certificate object is reusable and associates a name with a server certificate. Alternately, you can configure certificate conditions with existing external certificate objects and object groups.

You can search the **Available Certificates** field in the rule condition based for external certificate objects and object groups based on these certificate distinguished name characteristics:

- Subject or issuer common name (CN), or if the URL is contained in the certificate's Subject Alternative Name (SAN)

  The URL the user enters in the browser matches the Common Name (CN)

- Subject or issuer organization (O)
- Subject or issuer organizational unit (OU)

You can choose to match against multiple certificates in a single certificate rule condition. If the certificate used to encrypt the traffic matches any of the uploaded certificates, the encrypted traffic matches the rule.

You can add a maximum of 50 external certificate objects and external certificate object groups to the **Selected Certificates** in a single certificate condition.

Note these items:

- You cannot configure a certificate condition if you also select the **Decrypt - Known Key** action. That action requires you to select a server certificate to decrypt traffic. Therefore, the certificate already matches the traffic.
- If you configure a certificate condition with an external certificate object, any cipher suites you add to a cipher suite condition or internal CA objects you associate with the **Decrypt - Resign** action, must match the external certificate's signature algorithm type. For example, if your rule's certificate condition references an EC-based server certificate, any cipher suites you add or CA certificates you associate with the **Decrypt - Resign** action, must also be EC-based. If you mismatch signature algorithm types in this case, the policy editor displays a warning next to the rule.
- When the system first detects an encrypted session to a new server, it does not have certificate data for ClientHello processing. As a result, the first session may not be decrypted. After the initial session, the managed device caches data from the server Certificate message. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with certificate conditions and process the message to maximize decryption potential.

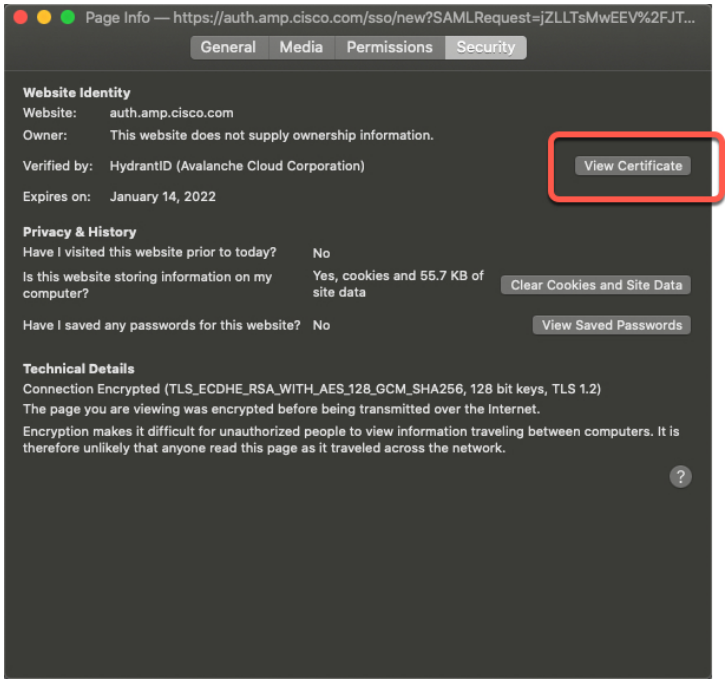
Conditions for distinguished name rules in decryption policies

Learn to use distinguished name conditions in a decryption rule. If you're not sure, you can find a certificate's Subject Alternative Name (SAN) and Common Name using a web browser. You can then you can add those values to a decryption rule as distinguished name conditions.

For detailed information about SANs, see RFC 5280, section 4.2.1.6.

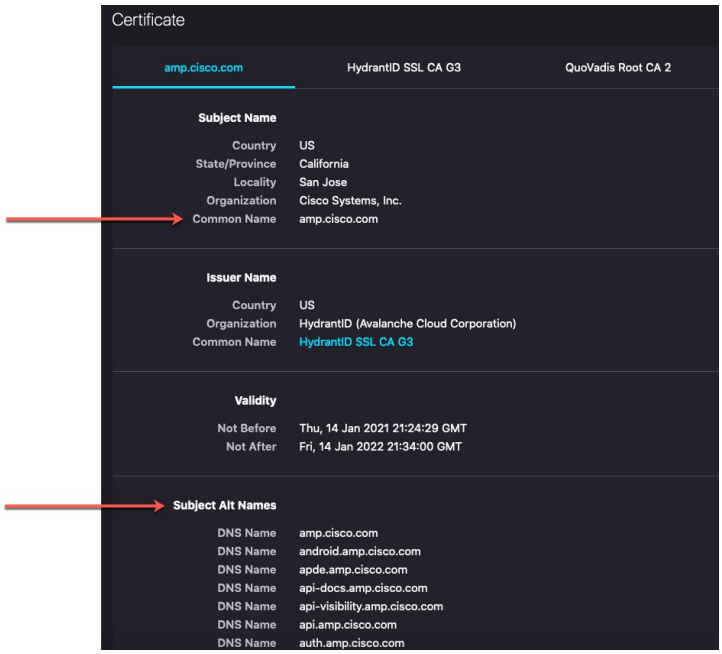
Overview

Distinguished name (DN) conditions allow you to specify certificate field values in decryption rules. This helps control which encrypted traffic is decrypted or excluded from decryption based on the certificate’s Common Name (CN) and Subject Alternative Name (SAN)



Identifying Certificate Values

Use these steps to find a certificate's Common Name. These steps also work to find the Common Name and SANs for a self-signed certificate.



These instructions use Firefox as an example, but other browsers work similarly. The following procedure uses `amp.cisco.com` as an example.

1. Browse to `amp.cisco.com` in Firefox.
2. In the browser's location bar, to the left of the URL, click .
3. Click **Connection secure** > **More Information**.

   (For a non-secure or self-signed certificate, click **Connection not secure** > **More Information**.)
4. On the Page Info dialog box, click **View Certificate**.

5. The next page shows certificate details.

Note the following:

- `CN=auth.amp.cisco.com`, if used as a DN rule condition, would match ONLY that host name (that is, SNI). The SNI `amp.cisco.com` would NOT match.
- Wildcards can be used in DNs to match multiple domains.

  For example, to match `auth.amp.cisco.com`, use `CN=*.amp.cisco.com`. To match `auth.us.amp.cisco.com`, use `CN=*.*.amp.cisco.com`.

  A DN like `CN=*.example.com` matches `www.example.com` but NOT `example.com`. To match both SNIs, use two DNs in the rule condition.
- Avoid overly broad wildcards like `CN=*.google.com` matches a very large number of SANs. Instead of `CN=*.google.com`, use a DN object like `CN=*.youtube.com` as the DN object so it matches names like `www.youtube.com`.

  You can also use variations of the SNI that match SANs like `CN=*.youtube.com`, `CN=youtu.be`, `CN=*.yt.be`, and so on.
- A self-signed certificate should work the same way. You can confirm it's a self-signed certificate by the fact the issuer DN is the same as the subject DN.

Example: DN rule matching

Suppose you want to prevent decryption for traffic going to `amp.cisco.com` or YouTube. Configure DN rule conditions such as:

These DN conditions would match URLs like:

- www.amp.cisco.com
- auth.amp.cisco.com
- auth.us.amp.cisco.com
- www.youtube.com
- kids.youtube.com
- www.yt.be

These DN conditions would not match any of the URLs listed, so the traffic would not match the Do Not Decrypt rule. However, it might match another decryption rules in the same decryption policy .

- amp.cisco.com
- youtube.com

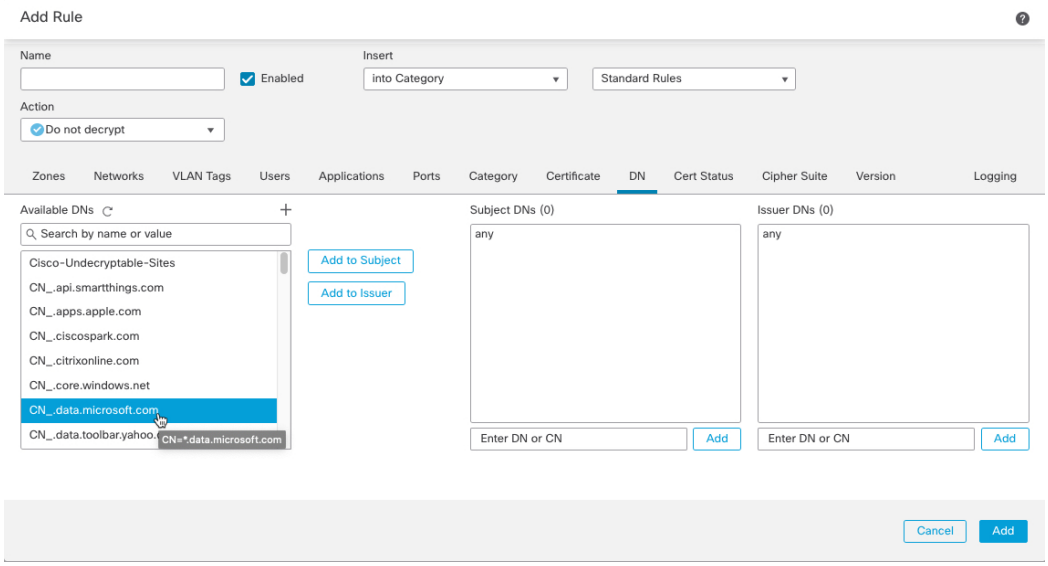
- yt.be

To match any of the preceding host names, add more CNs to the rule (for example, adding `CN=yt.be` would match that URL.)

System behavior: SNI and SANs usage

The host name in the client request is called the Server Name Indication (SNI). During the TLS handshake, the client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

If the SNI matches the CN or a SAN in the certificate, the SNI is used for DN rule matching.



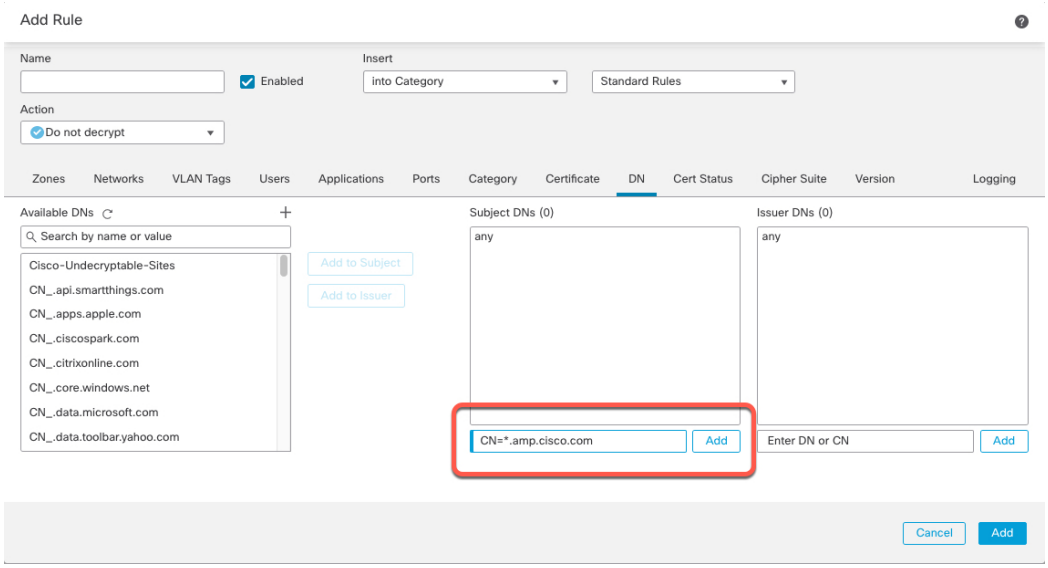
If there is no SNI, or the SNI does not match the certificate, the CN is used for DN rule matching.

Add a DN rule condition

After you identify the CN you want to match,, edit the decryption rule by using an existing DN, creating a new DN object, or adding the DN directly.

- Use an existing DN.

  Click the name of a DN and then click either **Add to Subject** or **Add to Issuer**. (**Add to Subject** is much more common.) To view the value of a DN object, hover the mouse pointer over it.)



- Create a new DN object.

  Click **Add** (+) to the right of Available DNs. The DN object must consist of a name and a value.

- Add the DN directly.

  Enter the DN in the field at the bottom of the **Subject DNs** field or the **Issuer DNs** field. (**Subject DNs** is more common.) After you enter the DN, click **Add**.

Related Topics

Distinguished names, on page 2962

Trust external certificate authorities

Trust CAs by adding root and intermediate CA certificates to your decryption policy, then use these trusted CAs to verify server certificates used to encrypt traffic.

If a trusted CA certificate contains an uploaded certificate revocation list (CRL), you can also verify whether a trusted CA revoked the encryption certificate.

Tip Upload all certificates in a root CA's chain of trust to the list of trusted CA certificates, including the root CA certificate and all intermediate CA certificates. Otherwise, it is more difficult to detect trusted certificates issued by intermediate CAs. Also, if you configure certificate status conditions to trust traffic based on the root issuer CA, all traffic within a trusted CA's chain of trust can be allowed without decryption, rather than unnecessarily decrypting it.

For more information, see Trusted CA objects, on page 2993.

Note When you create a decryption policy, the policy's **Trusted CA Certificate** tab page is populated with several trusted CA certificates, including the **Cisco-Trusted-Authorities** group, which is added to the **Select Trusted CAs** list.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Decryption**.

Step 2 Click **Edit** ( ) next to the decryption policy to edit.

Step 3 Click **Add Rule** to add a new decryption rule or click **Edit** ( ) to edit an existing rule.

Step 4 Click the **Certificates** tab.

Step 5 Find the trusted CAs you want to add from the **Available Certificates**, as follows:

- To add a trusted CA object on the fly, which you can then add to the condition, click **Add** ( ) above the **Available Certificates** list.
- To search for trusted CA objects and groups to add, click the **Search by name or value** prompt above the **Available Certificates** list, then enter either the name of the object, or a value in the object. The list updates as you type to display matching objects.

Step 6 To select an object, click it. To select all objects, right-click and then **Select All**.

Step 7 Click **Add to Rule**.

Tip
You can also drag and drop selected objects.

Step 8 Add or continue editing the rule.

The trusted CA certificates are configured in your decryption policy and can be used to verify server certificates for secure traffic inspection.

What to do next

- Add a certificate status decryption rule condition to your SSL rule.
- Deploy configuration changes.

Certificate Status Decryption rule conditions

For each certificate status decryption rule you configure, you can match traffic against the presence or absence of a given status. You can select several statuses in one rule condition. If the certificate matches any of the selected statuses, the rule matches the traffic.

You can choose to match against the presence or absence of multiple certificate statuses in a single certificate status rule condition. The certificate needs to match only one of the criteria to match the rule.

You should consider, when setting this parameter, whether you're configuring a decrypt rule or a block rule. Typically, you should click **Yes** for a block rule and **No** for a decrypt rule. Examples:

- If you're configuring a **Decrypt - Resign** rule, the default behavior is to decrypt traffic with an expired certificate. To change that behavior, click **No** for **Expired** so traffic with an expired certificate is not decrypted and resigned.
- If you're configuring a **Block** rule, the default behavior is to allow traffic with an expired certificate. To change that behavior click **Yes** for **Expired** so traffic with an expired certificate is blocked.

This table describes how the system evaluates encrypted traffic based on the status of the encrypting server's certificate.

Table 126: Certificate status rule condition criteria

Status Check	Status Set to Yes	Status Set to No
Revoked	The policy trusts the CA that issued the server certificate, and the CA certificate uploaded to the policy contains a CRL that revokes the server certificate.	The policy trusts the CA that issued the certificate, and the CA certificate uploa policy does not contain a CRL that rev certificate.
Self-signed	The detected server certificate contains the same subject and issuer distinguished name.	The detected server certificate contains subject and issuer distinguished names
Valid	All of these are true: • The policy trusts the CA that issued the certificate. • The signature is valid. • The issuer is valid. • None of the policy's trusted CAs revoked the certificate. • The current date is between the certificate Valid From and Valid To date.	At least one of these is true: • The policy does not trust the CA t certificate. • The signature is invalid. • The issuer is invalid. • A trusted CA in the policy revoke certificate. • The current date is before the cert From date. • The current date is after the certifi date.
Invalid signature	The certificate's signature cannot be properly validated against the certificate's content.	The certificate's signature is properly val the certificate's content.
Invalid issuer	The issuer CA certificate is not stored in the policy's list of trusted CA certificates.	The issuer CA certificate is stored in th of trusted CA certificates.
Expired	The current date is after the certificate Valid To date.	The current date is before or on the cer To date.
Not yet valid	The current date is before the certificate Valid From date.	The current date is after or on the certi From date.

Status Check	Status Set to Yes	Status Set to No
Invalid certificate	The certificate is not valid. At least one of these is true: • Invalid or inconsistent certificate extension; that is, a certificate extension had an invalid value (for example, an incorrect encoding) or some value inconsistent with other extensions. • The certificate cannot be used for the specified purpose. • The Basic Constraints path length parameter has been exceeded. For more information, see RFC 5280, section 4.2.1.9. • The certificate's value for Not Before or Not After is invalid. These dates can be encoded as UTCTime or GeneralizedTime For more information, see RFC 5280 section 4.1.2.5. • The format of the name constraint is not recognized; for example, an email address format of a form not mentioned in RFC 5280, section 4.2.1.10. This could be caused by an improper extension or some new feature not currently supported. An unsupported name constraint type was encountered. OpenSSL currently supports only directory name, DNS name, email, and URI types. • The root certificate authority is not trusted for the specified purpose. • The root certificate authority rejects the specified purpose.	The certificate is valid. All of these are tru • Valid certificate extension. • The certificate can be used for the spe purpose. • Valid Basic Constraints path length. • Valid values for Not Before and Not A • Valid name constraint. • The root certificate is trusted for the s purpose. • The root certificate accepts the specifie

Status Check	Status Set to Yes	Status Set to No
Invalid CRL	The Certificate Revocation List (CRL) digital signature is not valid. At least one of these is true: • The value of the CRL's Next Update or Last Update field is invalid. • The CRL is not yet valid. • The CRL has expired. • An error occurred when attempting to verify the CRL path. This error occurs only if extended CRL checking is enabled. • CRL could not be found. • The only CRLs that could be found did not match the scope of the certificate.	The CRL is valid. All of these are true: • Next Update and Last Update fiel • The CRL's date is valid. • The path is valid. • The CRL was found. • The CRL matches the certificate's
Server mismatch	The server name does not match the server's Server Name Indication (SNI) name, which could indicate an attempt to spoof the server name.	The server name matches the SNI name to which the client is requesting access

Note that even though a certificate might match more than one status, the rule causes an action to be taken on the traffic only once.

Checking whether a CA issued or revoked a certificate requires uploading root and intermediate CA certificates and associated CRLs as objects. You then add these trusted CA objects to an decryption policy's list of trusted CA certificates.

Cipher suite rule conditions

The system provides predefined cipher suites you can add to a cipher suite rule condition for Block or Block WITH Reset rule actions. You can also add cipher suite list objects containing multiple cipher suites.

Important Cipher suite rule conditions should be used only to *block* traffic, they should not be used to *decrypt* traffic.

Note You cannot add new cipher suites. You can neither modify nor delete predefined cipher suites.

You can add a maximum of 50 cipher suites and cipher suite lists to the **Selected Cipher Suites** in a single cipher suite condition. The system supports adding these cipher suites to a cipher suite condition:

- SSL_RSA_FIPS_WITH_3DES_EDE_CBC_SHA
- SSL_RSA_FIPS_WITH_DES_CBC_SHA
- TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA

- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_128_CBC_SHA256
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA
- TLS_DHE_RSA_WITH_CAMELLIA_256_CBC_SHA256
- TLS_DHE_RSA_WITH_DES_CBC_SHA
- TLS_DH_Anon_WITH_AES_128_GCM_SHA256
- TLS_DH_Anon_WITH_AES_256_GCM_SHA384
- TLS_DH_Anon_WITH_CAMELLIA_128_CBC_SHA
- TLS_DH_anon_WITH_CAMELLIA_128_CBC_SHA256

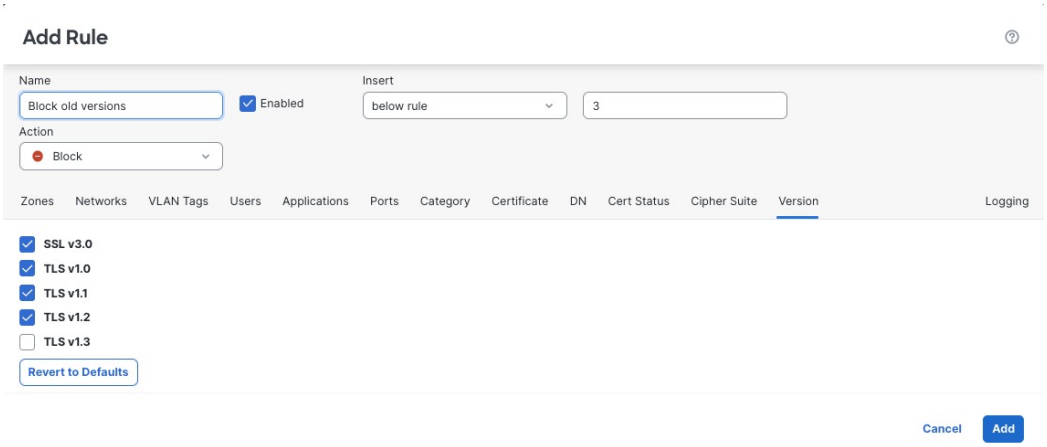
Note these considerations:

- If you add cipher suites not supported for your deployment, you cannot deploy your configuration. For example, passive deployments do not support decrypting traffic with the any of the ephemeral Diffie-Hellman (DHE) or ephemeral elliptic curve Diffie-Hellman (ECDHE) cipher suites. Creating a rule with these cipher suites prevents you from deploying your access control policy.
- You can add an anonymous cipher suite to the **Cipher Suite** condition in decryption policy. To use the rule, you must also configure your settings in an order that prevents ClientHello processing. For more information, refer to Best practice for Decryption policy rule order, on page 2196.
- When you specify a cipher suite as a rule condition, the rule matches the negotiated cipher suite in the ServerHello message, not the entire list from the ClientHello message. During ClientHello processing, the managed device removes unsupported cipher suites from the ClientHello message. If all specified cipher suites are removed, the system retains the original list. If the system keeps unsupported cipher suites, it cannot decrypt the session during subsequent evaluation.

Encryption protocol version rule conditions

You can choose to match against traffic encrypted with SSL version 3.0, or TLS version 1.0, 1.1, or 1.2. By default, all protocol versions are selected when you create a rule; if you select multiple versions, encrypted traffic that matches any of the selected versions matches the rule. You must select at least one protocol version when saving the rule condition.



You can use SSL 3.0 in a Do Not Decrypt, Block, or Block with Reset rule action.

You *cannot* select SSL v2.0 in a version rule condition; the system does not support decrypting traffic encrypted with SSL version 2.0. You can configure an undecryptable action to allow or block this traffic without further inspection. For more information, see Set default handling for undecryptable traffic, on page 2181.

Important Protocol version rule conditions should be used *only* to *block* traffic, they should not be used to *decrypt* traffic.

For example, to block all SSL v3.0, TLS v1.0, TLS v1.1, and TLS v1.2 traffic, set the options as follows:

Figure 386: Block all SSL v3.0, TLS v1.0, TLS v1.1, and TLS 1.2 traffic

Rule-based decryption rule actions

Rule-based decryption rule actions are operational functions that define how the system processes SSL/TLS traffic based on configured decryption rules.

Available actions

The system provides various actions for rule-based decryption rule.

Decryption rule monitor action

The **Monitor** action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled. The ClientHello message is not modified if traffic matches a **Monitor** rule condition.

Monitor action traffic handling

Traffic that matches a **Monitor** rule is processed in this sequence:

1. Traffic matches the Monitor rule condition and connection logging is forced.
2. Traffic is then matched against additional rules, if present, to determine whether to trust, block, or decrypt it.
3. The first non-Monitor rule matched determines traffic flow and any further inspection.
4. If there are no additional matching rules, the system uses the default action.

The system automatically logs end-of connection events for monitored traffic to the Security Cloud Control database, regardless of the logging configuration of the rule or default action that later handles the connection.

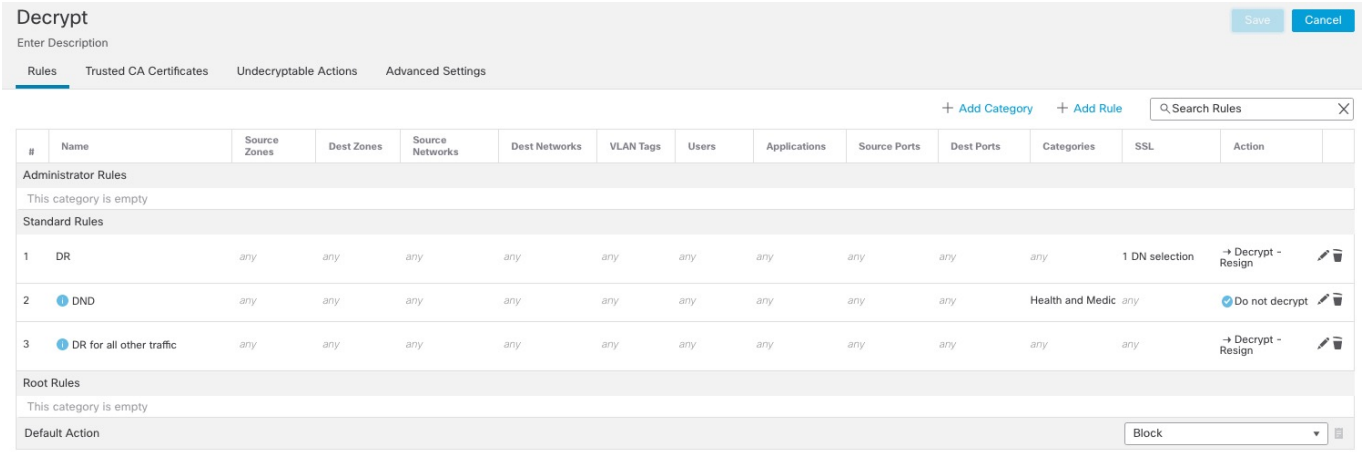
Decryption rule Do Not Decrypt action

The Do Not Decrypt action passes encrypted traffic for evaluation by the access control policy's rules and default action. Because some access control rule conditions require unencrypted traffic, this traffic might match fewer rules. The system cannot perform deep inspection on encrypted traffic, such as intrusion or file inspection.

Typical use cases for do not decrypt rules

Typical reasons for a **Do Not Decrypt** rule action include:

- When decrypting TLS/SSL traffic is prohibited by law.
- Sites you know you can trust.
- Sites you can disrupt by inspecting traffic (such as Windows Update).
- To view the values of TLS/SSL fields using connection events. (You do not need to decrypt traffic to view connection event fields.) .



For more information, see Default handling options for undecryptable traffic, on page 2180

Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the WebMD website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for WebMD and everything else. General information about decryption rules can be found in Guidelines for using TLS/SSL decryption, on page 2188.

Note Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see Recommendations for application control, on page 2054.

Decryption rule blocking actions

decryption rule blocking actions provide different termination methods to control connection handling.

Available blocking actions

The system provides these decryption rule actions for traffic you do not want to pass through the system:

- **Block**: Terminates the connection, resulting in an error in the client browser. The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It is not obvious from this message that you blocked the connection on purpose.
- **Block with reset**: Terminates and resets the connection, resulting in an error in the client browser. The error indicates the connection was reset but does not indicate why.

Tip You cannot use the **Block** or **Block with reset** action in a passive or inline (tap mode) deployment because the device does not directly inspect the traffic. If you create a rule with the **Block** or **Block with reset** action that contains passive or inline (tap mode) interfaces within a security zone condition, the policy editor displays a warning (⚠) next to the rule.

Decryption rule decrypt actions

Decrypt - Known Key, and **Decrypt - Resign** are rule actions that decrypt encrypted traffic. The system inspects decrypted traffic with access control. Access control rules handle decrypted and unencrypted traffic

identically — you can inspect it for discovery data as well as detect and block intrusions, prohibited files, and malware. The system reencrypts allowed traffic before passing it to its destination.

Certificate authority recommendations

We recommend you use a certificate from a trusted Certificate Authority (CA) to decrypt traffic. This prevents **Invalid Issuer** from being displayed in the SSL Certificate Status column in connection events.

For more information about adding trusted objects, see Trusted certificate authority objects, on page 2992.

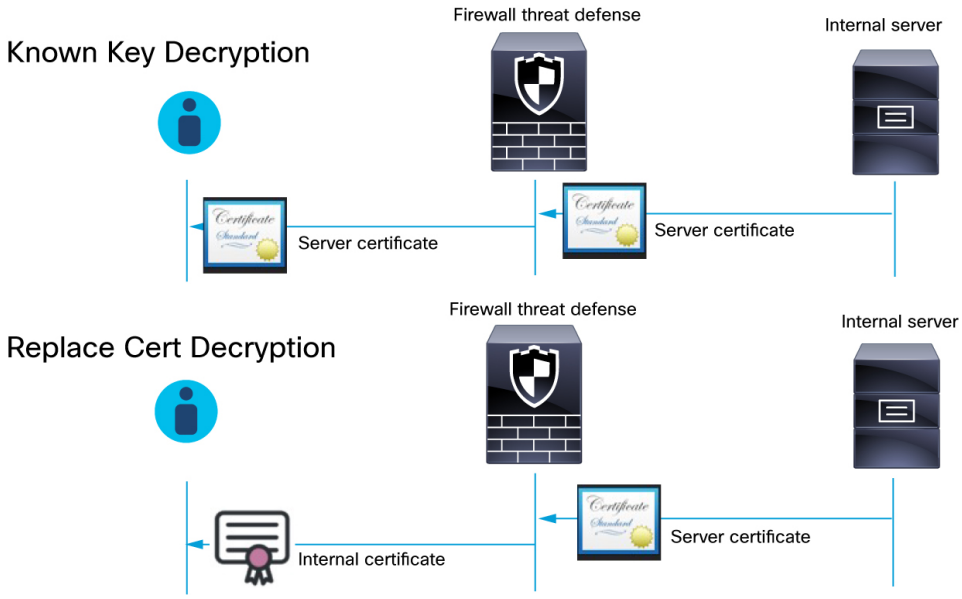
TLS 1.3 decryption best practices, on page 2184

Incoming traffic decryption actions

Both the **Decrypt - Replace Cert** and **Decrypt - Known Key** decryption actions enable you to decrypt incoming traffic to a server that you want to protect from malicious attacks.

Decryption action comparison

The **Decrypt - Replace Cert** decryption action is provided as an alternative to **Decrypt - Known Key** for these reasons:



- Certificates can expire or need to be replaced anytime.

  If you choose the **Decrypt - Known Key** action, decryption can stop and the rule can stop functioning when a certificate is replaced for any reason.

- With **Decrypt - Replace Cert**, the connection matches and traffic is decrypted. Deploying the certificate on the device hours or days later is not an issue.

- **Decrypt - Replace Cert** gives you the flexibility to have separate internal and external facing certificates. For example, you could use `payroll.example.local` as an internal server hostname, but use `payroll.example.com` as an externally-facing hostname. You can also use an Enterprise PKI certificate for an internal server but use DigiCert or some other public provider for my external certificate.

The figure shows the difference between **Decrypt - Replace Cert** and **Decrypt - Known Key** decryption actions.

This table provides more information.

	Known Key	Replace Cert
Must match certificate installed on internal server or resource	Yes	No
The device must trust the internal certificate (that is, it must be chained to Trusted CAs list in the decryption policy)	No	No
Certificate hostnames can be different between device-installed certificate and that on the internal server	No, certificates must be identical. (Although multiple SANs can be on the certificates to accommodate different internal and external host names.)	Yes, certificates and certificate host names can be completely different, as long as the internal certificate is trusted by the user's device.
Works if the internal server certificate is expired	Yes – As long as it matches the certificate installed on the device.	No – an expired certificate causes broken trust, and therefore a mismatch.

Replace an internal certificate (decrypt - replace cert only)

Replace expiring internal certificates in decryption policies to maintain secure encrypted traffic inspection capabilities.

This task discusses how to replace the internal certificate used in an incoming decryption rule using the Cloud-Delivered Firewall Management Center.

You can also replace the certificate using the API as discussed in *Cloud-Delivered Firewall Management Center REST API Quick Start Guide*.

The system indicates that an internal certificate is *expiring* when today's date is within 30 days of its expiration date. The following figure shows an example.

Before you begin

You must choose the **Decrypt - Replace Cert** decryption rule action in one of these ways:

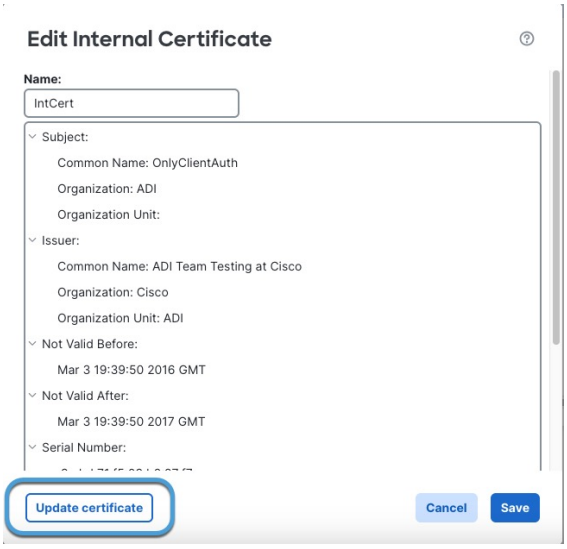
- In a rule-based decryption policy by clicking the action from the rule's **Action** list.
- Create a standard decryption policy, which always uses the **Decrypt - Replace Cert** rule action.

Follow these steps to replace an internal certificate using the Decrypt - Replace Cert rule action:

Procedure

Step 1 Log in to Security Cloud Control if you haven't already done so.

Step 2 Click **Firewall**.



Step 3 Click **Administration** > **(name of** Cloud-Delivered Firewall Management Center**)** > **Objects** > **PKI** > **Internal Certs**.

Step 4 Locate the internal certificate that is expired or expiring (for example, an expired certificate is indicated by 

).

Step 5 Click **Edit** (✎).

Step 6 Click **Update Certificate** as this figure shows.

Step 7 Enter the requested information; see Upload an internal certificate for inbound protection, on page 2177 for more information.

Step 8 Follow the prompts on your screen to complete the action.

Decrypt - Resign rule action

The **Decrypt - Resign** rule action is a decryption rule action that enables you to decrypt *outgoing* traffic so the traffic can be subjected to deep inspection.

Select internal certificate objects

This task enables you to create a decryption rule with a **Decrypt - Known Key** action by selecting and assigning internal certificates to decrypt server traffic. You can add, manage, and save certificate selections for decryption rules in your configuration.

Use this procedure when configuring decryption rules that require internal certificates to decrypt traffic from specific servers.

Before you begin

To create a decryption rule with a **Decrypt - Known Key** action, you must add internal certificates for the servers to decrypt traffic. For more information, see Internal certificate objects, on page 2996.

Procedure

Step 1 Click **Edit** ( ) in the field next to the decryption rule **Action**.

Step 2 In the Select Internal Certificate Objects dialog box, do the following:
Available Certificates list: Click the name of a certificate and click **Add to Rule** to use it in this rule. You can add one or more certificates to the rule.

Selected Certificates list: Displays internal certificates used in the rule. To remove a certificate, click **Delete** ( ).

Step 3 To save these changes, click **OK**.

Monitor TLS/SSL hardware acceleration

TLS/SSL hardware acceleration monitoring is a set of topics that discuss how to monitor the status of TLS/SSL hardware acceleration.

Informational counters

Monitor TLS/SSL hardware acceleration performance and interpret KEY counter values, such as PRIV_KEY_RECV and SECU_PARAM_RECV, to assess system load and connection activity using the **show counters** command.

If a system under load is working well, you should see large counts for the following counters. Because there are two sides to the tracker process per connection, you can see these counters increase by two per connection. The PRIV_KEY_RECV and SECU_PARAM_RECV counters are the most important, and are highlighted. The CONTEXT_CREATED and CONTEXT_DESTROYED counters relate to the allocation of cryptographic chip memory.

```
> show counters
Protocol      Counter                          Value   Context
SSLENC        CONTEXT_CREATED                 258225   Summary
SSLENC        CONTEXT_DESTROYED               258225   Summary
TLS_TRK       OPEN_SERVER_SESSION             258225   Summary
TLS_TRK       OPEN_CLIENT_SESSION             258225   Summary
TLS_TRK       UPSTREAM_CLOSE                  516450   Summary
TLS_TRK       DOWNSTREAM_CLOSE                516450   Summary
TLS_TRK       FREE_SESSION                    516450   Summary
TLS_TRK       CACHE_FREE                      516450   Summary
TLS_TRK       PRIV_KEY_RECV                   258225   Summary
TLS_TRK       NO_KEY_ENABLE                   258225   Summary
TLS_TRK       SECU_PARAM_RECV                 516446   Summary
TLS_TRK       DECRYPTED_ALERT                 258222   Summary
TLS_TRK       DECRYPTED_APPLICATION         33568976   Summary
TLS_TRK       ALERT_RX_CNT                    258222   Summary
TLS_TRK       ALERT_RX_WARNING_ALERT          258222   Summary
TLS_TRK       ALERT_RX_CLOSE_NOTIFY           258222   Summary
TCP_PRX       OPEN_SESSION                    516450   Summary
TCP_PRX       FREE_SESSION                    516450   Summary
TCP_PRX       UPSTREAM_CLOSE                  516450   Summary
TCP_PRX       DOWNSTREAM_CLOSE                516450   Summary
TCP_PRX       FREE_CONN                       258222   Summary
TCP_PRX       SERVER_CLEAN_UP                 258222   Summary
TCP_PRX       CLIENT_CLEAN_UP                 258222   Summary
```

Alert counters

Alert counters identify potential issues based on standardized alert types.

These counters are based on the TLS 1.2 specification. FATAL or BAD alerts could indicate issues. However, ALERT_RX_CLOSE_NOTIFY is normal.

For details, see RFC 5246 section 7.2.

```
TLS_TRK       ALERT_RX_CNT                      311   Summary
TLS_TRK       ALERT_TX_CNT                        2   Summary
TLS_TRK       ALERT_TX_IN_HANDSHAKE_CNT           2   Summary
TLS_TRK       ALERT_RX_IN_HANDSHAKE_CNT           2   Summary
TLS_TRK       ALERT_RX_WARNING_ALERT            308   Summary
TLS_TRK       ALERT_RX_FATAL_ALERT                3   Summary
TLS_TRK       ALERT_TX_FATAL_ALERT                2   Summary
TLS_TRK       ALERT_RX_CLOSE_NOTIFY             308   Summary
TLS_TRK       ALERT_RX_BAD_RECORD_MAC             2   Summary
TLS_TRK       ALERT_TX_BAD_RECORD_MAC             2   Summary
TLS_TRK       ALERT_RX_BAD_CERTIFICATE            1   Summary
```

Error counters

Error counters help you interpret system performance data to identify potential issues and optimize performance using the show counters command.

Fatal counters

Monitor and interpret TLS/SSL hardware acceleration fatal counters to identify serious errors, assess system health, and troubleshoot persistent crypto acceleration issues on Cisco devices. Reset or review counters for proactive system maintenance and support.

Fatal counters indicate serious errors. These counters should be at or near 0 on a healthy system. This is an example list of the fatal counters.

```
> show counters
Protocol     Counter                          Value   Context
CRYPTO       RING_FULL                            1   Summary
CRYPTO       ACCELERATOR_CORE_TIMEOUT             1   Summary
CRYPTO       ACCELERATOR_RESET                    1   Summary
CRYPTO       RSA_PRIVATE_DECRYPT_FAILED           1   Summary
```

The RING_FULL counter is not a fatal counter, but indicates how often the system overloaded the cryptographic chip. The ACCELERATOR_RESET counter is the number of times the TLS crypto acceleration process failed unexpectedly, which also causes the failure of pending operations, which are the numbers you see in ACCELERATOR_CORE_TIMEOUT and RSA_PRIVATE_DECRYPT_FAILED.

If you have persistent problems, disable TLS crypto acceleration (or **config hwCrypto disable**) and work with Cisco TAC to resolve the issues.

Note You can do additional troubleshooting using the **show snort tls-offload** and **debug snort tls-offload** commands. Use the **clear snort tls-offload** command to reset the counters displayed in the **show snort tls-offload** command to zero.

Troubleshoot Rule-based decryption rules

This topic discusses how to troubleshoot rule-based decryption rules.

TLS/SSL oversubscription

TLS/SSL oversubscription is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

TLS/SSL oversubscription details

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions**:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

Troubleshoot TLS/SSL oversubscription

Monitor and troubleshoot TLS/SSL oversubscription by configuring decryption policies, enabling logging, and adding SSL Flow Flags to connection event views in Cloud-Delivered Firewall Management Center.

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are experiencing SSL oversubscription. You must add at least the **SSL Flow Flags** event to the table view of connection events.

Before you begin

- Configure a decryption policy with a setting for **Handshake Errors** on **Undecryptable Actions** page.

  For more information, see Set default handling for undecryptable traffic, on page 2181.

- Enable logging for your SSL rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Follow these steps to troubleshoot TLS/SSL oversubscription:

Procedure

Step 1 Click **Analysis** > **Unified Events**

Step 2 Click the colum picker ( ) icon and add additional columns **TLS Flow Flags** and **TLS Flow Messages**.

Step 3 Click **Apply**.
TLS/SSL oversubscription is indicated by the values of `ERROR_EVENT_TRIGGERED` and `OVER_SUBSCRIBED` in the **SSL Flow Flags** column.

Step 4 If TLS/SSL oversubscription is occurring, log in to the managed device and enter any of the following commands:

Command	Result
show counters	If the value of **TCP_PRX BYPASS_NOT_ENOUGH_MEM** is large, consider upgrading your device to one with a larger capacity for SSL traffic or use **Do NOT Decrypt** rules for lower priority encrypted traffic.
show snort TLS-offload	If the value of **BYPASS_NOT_ENOUGH_MEM** is large, consider upgrading your device to one with a larger capacity for SSL traffic or use **Do NOT Decrypt** rules for lower priority encrypted traffic.

TLS heartbeat

A TLS heartbeat extension enables applications to confirm active TLS or DTLS connections.

TLS heartbeat handling

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by RFC6520. TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

Related Topics

Troubleshoot TLS heartbeat, on page 2230

Troubleshoot TLS heartbeat

This task helps you identify TLS heartbeat activity in your network to determine if applications are using the TLS heartbeat extension.

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are seeing traffic with the TLS heartbeat extension. You must add at least the **SSL Flow Messages** event to the table view of connection events.

TLS heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column in the table view of connection events.

Before you begin

To determine if applications in your network use TLS heartbeat, first perform these tasks:

- Configure an decryption policy with a setting for **Decryption Errors** on **Undecryptable Actions** page.

  For more information, refer to Set default handling for undecryptable traffic, on page 2181.

- Enable logging for your SSL rules as discussed in Secure Firewall Management Center and Threat Defense Management Network Administration.

Follow these steps to troubleshoot TLS heartbeat:

Procedure

Step 1 Click **Analysis** > **Unified Events**

Step 2 Click the colum picker ( ) icon and add additional columns **TLS Flow Flags** and **TLS Flow Messages**.

Step 3 Click **Apply**.
TLS heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column.

Step 4 If applications in your network use TLS heartbeat, refer to Rule-based decryption rules guidelines and limitations, on page 2188.

TLS/SSL pinning

TLS/SSL pinning is a security mechanism that

- validates server certificates against a predetermined set of trusted certificates or keys
- prevents man-in-the-middle attacks by rejecting connections to servers with unexpected certificates, and
- requires applications to maintain a local store of trusted certificate information for validation.

TLS/SSL pinning implementation details

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you *cannot* log in to a Facebook mobile application but *can* log in to Facebook using Safari or Chrome.) You can use Firepower Management Center connection events as further proof of TLS/SSL pinning

Note TLS/SSL pinning is not limited to mobile applications.

If applications in your network use SSL pinning, see TLS/SSL certificate pinning guidelines, on page 2194.

Related Topics

Troubleshoot TLS/SSL pinning, on page 2231

Troubleshoot TLS/SSL pinning

This task helps you identify and confirm whether applications in your network are using TLS/SSL pinning by analyzing SSL connection events and flow DATA.

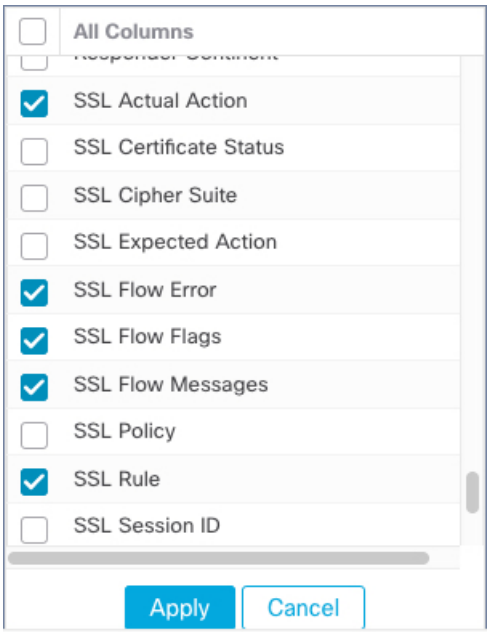
You can view connection events to determine whether or not the devices are experiencing TLS/SSL pinning. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

Before you begin

- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.
- Log in to a mobile application like Facebook. If a network connection error displays, log in to Facebook using Chrome or Safari. If you *can* log in using a web browser but not the native application, TLS/SSL pinning is likely occurring.

Follow these steps to troubleshoot TLS/SSL pinning:

Procedure



Step 1 Click **Analysis** > **Connections** > **Events**.

Step 2 Click **Table View of Connection Events**.

Step 3 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

The columns are added in the order discussed in the section on connection and security intelligence event fields in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Step 4 Click **Apply**.

Step 5 Analyze the SSL flow DATA to identify SSL pinning behavior.

Step 6 If you determine that applications in your network use SSL pinning, see Rule-based decryption rules guidelines and limitations, on page 2188.

What to do next

You can use TLS/SSL connection events to confirm TLS/SSL pinning is occurring by looking for any of the following:

- Applications that send an SSL ALERT Message as soon as the CLIENT receives the SERVER_HELLO, SERVER_CERTIFICATE, SERVER_HELLO_DONE message from the SERVER, followed by a TCP Reset, exhibit the following symptoms. (The ALERT, `Unknown CA (48)`, can be viewed using a packet capture.)
  - The SSL Flow Flags column displays `ALERT_SEEN` but *not* `APP_DATA_C2S` or `APP_DATA_S2C`.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: `CLIENT_ALERT`, `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`.
  - `Success` is displayed in the SSL Flow Error column.
- Applications that send no alerts but instead send TCP Reset after the SSL handshake is FINISHED exhibit the following symptoms:
  - The SSL Flow Flags column does *not* display `ALERT_SEEN`, `APP_DATA_C2S`, or `APP_DATA_S2C`.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`, `CLIENT_KEY_EXCHANGE`, `CLIENT_CHANGE_CIPHER_SPEC`, `CLIENT_FINISHED`, `SERVER_CHANGE_CIPHER_SPEC`, `SERVER_FINISHED`.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: `CLIENT_HELLO`, `SERVER_HELLO`, `SERVER_CERTIFICATE`, `SERVER_KEY_EXCHANGE`, `SERVER_HELLO_DONE`, `CLIENT_KEY_EXCHANGE`, `CLIENT_CHANGE_CIPHER_SPEC`, `CLIENT_FINISHED`,`SERVER_CHANGE_CIPHER_SPEC`, `SERVER_FINISHED`.
  - `Success` is displayed in the SSL Flow Error column.

Troubleshoot unknown or bad certificates or certificate authorities, on page 2233

Troubleshoot unknown or bad certificates or certificate authorities

Enable logging for TLS/SSL decryption rules to monitor connection events and identify certificate-related issues. This helps you diagnose problems with certificate authorities, bad certificates, or unknown certificates in your TLS/SSL connections.

You can view connection events to determine whether or not the devices are experiencing unknown certificate authorities, bad certificates, or unknown certificates. This procedure can also be used if a TLS/SSL certificate has been pinned. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

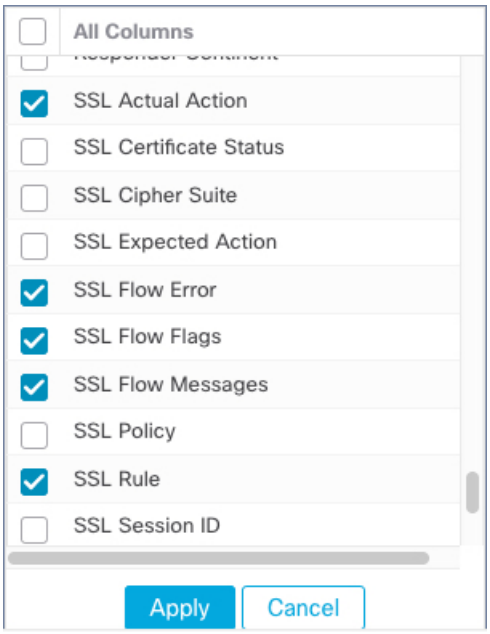
Before you begin

- Set up a decryption rule.

- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Follow these steps to troubleshoot unknown or bad certificates or certificate authorities:

Procedure



Step 1 Click **Analysis** > **Connections** > **Events**.

Step 2 Click **Table View of Connection Events**.

Step 3 Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

The columns are added in the order discussed in the section on connection and security intelligence event fields in the Secure Firewall Management Center and Threat Defense Management Network Administration guide.

Step 4 Click **Apply**.

Step 5 Review the SSL flow flags to determine if a certificate or certificate authority is bad or missing.

SSL flow flag	Meaning
CLIENT_ALERT_SEEN_UNKNOWN_CA	Indicates a valid certificate chain or partial chain was received by an SSL client application, but the certificate was not accepted because the CA certificate could not be located or could not be matched with a known, trusted CA. This message always indicates an unrecoverable error.
CLIENT_ALERT_SEEN_BAD_CERTIFICATE	A certificate was corrupt, contained signatures that did not verify correctly, or had other problems.
CLIENT_ALERT_SEEN_CERTIFICATE_UNKNOWN	Some other (unspecified) issue arose in processing the certificate, rendering it unacceptable.

Verify TLS/SSL cipher suites

This task helps you resolve cipher suite incompatibility errors that occur when saving a decryption rule that has cipher suite conditions. The error indicates that one or more of the cipher suites you chose for the decryption rule condition are incompatible with the certificate used in the decryption rule.

This topic discusses actions you must take if you see the following error when saving a decryption rule that has cipher suite conditions:

```
Traffic cannot match this rule; none of your selected cipher suites contain a signature
algorithm that matches the resigning CA's signature algorithm
```

Before you begin

To resolve the issue, you must have access to the certificate you're using.

Note The tasks in this topic assume knowledge of how TLS/SSL encryption works.

Follow these steps to verify TLS/SSL cipher suites:

Procedure

Step 1 When you attempt to save a decryption rule rule with either **Decrypt - Resign** or **Decrypt - Known Key** with specified cipher suites, the following error is displayed:

Example:

```
Traffic cannot match this rule; none of your selected cipher suites contain a
signature algorithm that the resigning CA's signature algorithm
```

Step 2 Locate the certificate you're using to decrypt traffic and, if necessary, copy the certificate to a system that can run openssl commands.

Step 3 Run the following command to display the signature algorithm used by the certificate:

Example:

openssl x509 -in *CertificateName* **-text -noout**

The first few lines of output are displayed similar to the following:

```
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 4105 (0x1009)
    Signature Algorithm: ecdsa-with-SHA256
```

Step 4 The **Signature algorithm** tells you the following:

- The cryptographic function used (in the preceding example, **ECDSA** means Elliptic Curve Digital Signature Algorithm).
- The hash function used to create a digest of the encrypted message (in the preceding example, **SHA256**).

Step 5 Search a resource such as *OpenSSL at University of Utah* for cipher suites that match those values. The cipher suite must be in RFC format.
You can also search a variety of other sites, such as Server Side TLS at the Mozilla wiki or Appendix C of RFC 5246. Cipher Suites in TLS/SSL (Schannel SSP) in Microsoft documentation has a detailed explanation of cipher suites.

Step 6 If necessary, translate the OpenSSL name to an RFC name that the Firepower Management System uses. See the RFC mapping list on the on the `https://testssl.sh` site.

Step 7 The previous example, **ECDSA-with-SHA256**, can be found in the Modern Compatibility List on the Mozilla wiki.

Choose only cipher suites that have **ECDSA** and **SHA-256** in the name. These cipher suites follow:

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES128-SHA256
```

Find the corresponding RFC cipher suite on RFC mapping list. These cipher suites follow:

```
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
```

Step 8 Add the preceding cipher suites to your decryption rule.

Troubleshoot using crypto archives

Crypto issues are difficult to triage. Crypto archives help you to troubleshoot these issues. A crypto archive contains crypto session information about the crypto request, peer information, the component that sent the crypto request, and the timed-out crypto session information.

About crypto archives

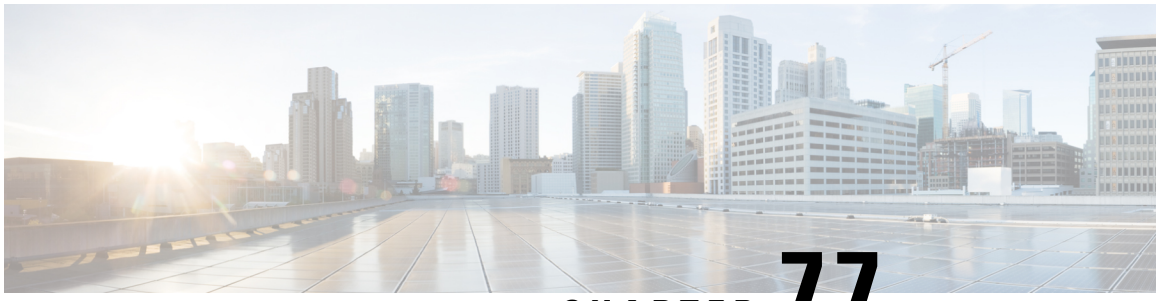
Threat defense does not save keys and initialization vectors (IVs) for the session. For SSL and IPsec, you can also view these information:

- For SSL: Session SSL version, source, destination IP addresses, and ports.
- For IPsec: IPsec security association information.

A ring can hold 2000 crypto command entries. Threat defense pushes the crypto command in one of the rings and pulls out the result after completing the crypto request. Crypto archive files now have the timed-out crypto request's ring and entry index. The ring and its entry index help in troubleshooting problematic crypto commands.

The crypto archive has two formats: a text file and a binary file. You can use the **debug menu ctm 103** command to decode the binary file. The crypto archive files are available at disk0:/crypto_archive.

For example:



```
FTD# debug menu ctm 103 crypto_eng0_arch_4.bin
[Nitrox V Archive Header v1.0 Info]

In this example, the highlighted information shows the timeout ring, the crash time (timeout entry), and SSL session information.

Supported devices for crypto archives

These devices with Nitrox V crypto accelerator support crypto archives:

- Cisco Firepower 3105, 3110, 3120, 3130, 3140
- Cisco Firepower 4112, 4115, 4125, 4145
- Cisco Firepower 9300 SM-40, SM-48 and SM-56
- Cisco Secure Firewall 4200

CHAPTER 77

Encrypted Visibility Engine

Encrypted Visibility Engine (EVE) is used to identify client applications and processes utilizing Transport Layer Security (TLS) encryption. It enables visibility and allows administrators to take actions and enforce policy within their environments. The EVE technology can also be used to identify and stop malware.

- Encrypted Visibility Engine, on page 2239
- How EVE works, on page 2240
- Indications of compromise events, on page 2241
- QUIC fingerprinting in EVE, on page 2241
- Configure EVE, on page 2242
- Configure EVE exception rules, on page 2243
- Use case - Block Traffic Based on the EVE Threat Confidence Score, on page 2247

Encrypted Visibility Engine

The encrypted visibility engine (EVE) is used to provide more visibility into the encrypted sessions without the need to decrypt them. These insights into encrypted sessions are obtained by Cisco's open-source library that is packaged in Cisco's vulnerability database (VDB). The library fingerprints and analyzes incoming encrypted sessions and matches it against a set of known fingerprints. This database of known fingerprints is also available in the Cisco VDB.

Key capabilities

Important features of Encrypted Visibility Engine (EVE) include the following:

- Access control policy actions on traffic using information derived from EVE
- Vulnerability Database (VDB) integration with Cisco Secure Firewall for assigning applications to EVE-detected processes with high confidence values
- Custom application detector creation for mapping EVE-detected processes to user-defined applications and overriding built-in process confidence values
- Detection of the operating system type and version of clients that create Client Hello packets in encrypted traffic
- Quick UDP Internet Connections (QUIC) traffic fingerprinting and analysis with server name display in the URL field of the **Connection Events** page

For custom application detector configuration, see the **Configuring Custom Application Detectors** and **Specifying EVE Process Assignments** sections in the **Application Detection** chapter of the Cisco Secure Firewall Management Center Device Configuration Guide.

Note The encrypted visibility engine feature is supported only on Cloud-Delivered Firewall Management Center-managed devices running Snort 3. This feature is not supported on Snort 2 devices and Firewall Device Manager-managed devices.

Attention To use EVE on Cloud-Delivered Firewall Management Center, you must have a valid IPS license on your device. In the absence of a IPS license, the policy displays a warning and deployment is not allowed.

Note

- EVE can detect the operating system type and version of SSL sessions. Normal usage of the operating system, such as running applications and package management software, can trigger OS detection. To view client OS detection, in addition to enabling the EVE toggle button, you must enable **Hosts** under **Policies** > **Network Discovery**. To view a list of possible operating systems on the host IP address, click **Analysis** > **Hosts heading** > **Network Map**, and then choose the required host.
- After enabling EVE for your access control policy, ensure that you have turned on logging for the access control rules within that policy to display the expected results on the EVE dashboard whenever any specific rule conditions are met. For more information on how to turn on logging, see Create and Edit Access Control Rules.

How EVE works

Encrypted Visibility Engine (EVE) provides the ability to identify and control applications without enabling TLS decryption. By using fingerprints of known malicious processes, EVE technology can also be used to identify and block encrypted malicious traffic without outbound decryption.

Summary

The key components involved in how EVE works are:

- Client Hello inspection: EVE examines the initial TLS handshake packet to create client fingerprints
- Fingerprint database: Contains over 5,000 identified client processes mapped to applications
- Machine learning technology: Processes over one billion TLS fingerprints and over 10,000 malware samples daily
- Cisco Vulnerability Database (VDB): Delivers updated fingerprints to customers

Workflow

These stages describe how EVE identifies and processes client applications:

1. EVE inspects the Client Hello portion of the TLS handshake to identify client processes. The Client Hello is the initial data packet that is sent to the server. This gives a good indication of the client process on the host.
2. The system combines the fingerprint with other data such as destination IP address to provide the basis for EVE's application identification. By identifying specific application fingerprints during the TLS session establishment, the system can identify the client process and take appropriate action, such as allowing or blocking it.
3. If EVE does not recognize a fingerprint, it identifies the client application and estimates the threat score of the first flow using the destination details, such as IP address, port, and server name. At this point, the status of the fingerprints are randomized and the status can be viewed in the debug logs. For subsequent flows with the same fingerprint, EVE skips reanalysis and marks the fingerprint status as unlabeled. If you intend to block traffic based on EVE's Low or Very Low score thresholds, the initial flow is blocked. Future flows are allowed once the application's fingerprint is cached.
4. Through machine learning (ML) technology, Cisco processes over one billion TLS fingerprints and over 10000 malware samples daily to create and update EVE fingerprints. These updates are then delivered to customers using Cisco Vulnerability Database (VDB) package.

Indications of compromise events

An Indication of Compromise (IoC) event is a security detection mechanism that

- identifies connection events with a very high malware confidence level, as reported by EVE,
- triggers for encrypted sessions generated from a host using a malicious client, and
- provides information such as the IP address, MAC address, operating system information of the malicious host, and timestamp of the suspicious activity.

A session with an Encrypted Visibility Threat Confidence score of 'Very High' as seen in connection events generates an IoC event. You must enable **Hosts** from **Policies** > **Network Discovery**. In the Cloud-Delivered Firewall Management Center, view the IoC event existence from here:

- Click **Analysis** > **Unified Events** and choose the Encrypted Visibility fields and IoC field from the column picker option.

QUIC fingerprinting in EVE

QUIC fingerprinting in EVE is a Snort identification mechanism that

- detects applications over QUIC without enabling decryption,
- identifies malware without enabling decryption, and
- detects service applications for access control rule assignment based on the service detected over the QUIC protocol.

Configure EVE

Configure the Encrypted Visibility Engine (EVE) to detect client applications and monitor or block encrypted traffic based on threat confidence levels.

The Encrypted Visibility Engine (EVE) provides visibility into encrypted traffic by analyzing client application behavior and threat indicators. You can operate EVE in Monitor mode for detection only or Protect mode to actively block threats.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

Step 3 Choose **Encrypted Visibility Engine** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 On the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.

Step 5 Choose the **Monitor** mode or the **Protect** mode.

- Choose the **Monitor** mode to detect client applications and monitor encrypted traffic.
- Choose the **Protect** mode to monitor and block encrypted traffic based on the threat confidence level of the client processes. You can use this mode to monitor and block malicious connections at two threat confidence levels:
  - **High**: Use this level to block connections with threat confidence levels ranging from High to Very High.
  - **Very High**: Use this level to block connections with threat confidence levels that are categorized as Very High.

Step 6 Click **Save** and then deploy the access control policy.

Note
To manage exceptions, refer to Configure EVE exception rules, on page 2243.

What to do next

Deploy configuration changes.

View Encrypted Visibility Engine events

This task allows you to access and view connection events generated by the Encrypted Visibility Engine (EVE) in the Cloud-Delivered Firewall Management Center.

After enabling the **Encrypted Visibility Engine** and deploying your access control policy, you can start sending live traffic through your system. You can view the logged connection events in the **Unified Events** page.

Perform this procedure to access the connection events in the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Click **Analysis** > **Unified Events**.

You can also view the connection events in the **Connection Events** page. Click **Analysis** > **Connections** > **Events** to access the **Connection Events** page.

The Encrypted Visibility Engine can identify the client process that initiated a connection and the operating system in the client, and indicate if the process contains malware or not.

Step 2 In the **Unified Events** page, explicitly enable these columns that are added for the Encrypted Visibility Engine:

- **Encrypted Visibility Process Name**
- **Encrypted Visibility Process Confidence Score**
- **Encrypted Visibility Threat Confidence**
- **Encrypted Visibility Threat Confidence Score**
- **Detection Type**
- **EVE Fingerprint**
- **EVE Process Name**
- **EVE Process Confidence Score**
- **EVE Threat Confidence**
- **EVE Threat Confidence Score**
- **Detection Type**

For information about these fields, see Connection and Security-Related Connection Event Fields in the *Cisco Secure Firewall Management Center Administration Guide*.

Note
On the **Connection Events** page, if processes are assigned applications, the **Detection Type** column displays **Encrypted Visibility Engine**, indicating that the client application was identified by the Encrypted Visibility Engine. Without application assignments to process names, the **Detection Type** column displays **AppID**, indicating that the engine that identified the client application was AppID.

Configure EVE exception rules

Configure Encrypted Visibility Engine (EVE) exception rules to ensure the continuity of trusted connections and services by bypassing EVE's block action. This allows trusted networks and processes to be exempted from EVE's block verdict based on the threat confidence level.

You can create an Encrypted Visibility Engine (EVE) exception rule to ensure the continuity of trusted connections and services by bypassing the EVE's block action. You can add attributes such as process names and destination IP address to the exception rule. For example, you may want to bypass EVE's block verdict for trusted networks. All the connections in the bypassed networks are exempted from EVE's block verdict based on the threat confidence level.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** ( ) next to the access control policy you want to edit.

Step 3 Choose **Encrypted Visibility Engine** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 On the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.

Step 5 Choose the **Protect** mode to monitor and block encrypted traffic based on the threat confidence level of the client processes.

You can use this mode to monitor and block malicious connections at two threat confidence levels:

- **High**: Use this level to block connections with threat confidence levels ranging from High to Very High.
- **Very High**: Use this level to block connections with threat confidence levels that are categorized as Very High.

Step 6 Click **Manage exceptions** to view and add exception rules.

Step 7 On the **Encrypted Visibility Engine (EVE) Exception List** window, click **+Add Exception Rules** and add the required attributes.

a) Under the **Process Name** tab, enter an EVE-identified process name, and click **+Add** on the right side of the window.

You can add multiple process names to the same exception rule. The EVE exception list based on process names works only with EVE-identified process names, which are case and space sensitive.

b) Under the **Network Objects** tab, perform one of the following:

- Choose one or more network objects from the **Available Networks** list and add the same to the **Selected Source Network** or **Selected Destination Network** list.
- To create a new network object, click **+Create Network Object**.
  1. Enter a **Name** and an optional **Description**.
  2. Choose the required network type—**Host, Range, Network, or FQDN**. Enter the relevant IP address if you choose **Host, Range, or Network**. If you choose **FQDN**, enter the fully Qualified Domain Name(**FQDN**) and choose the required option from the **Lookup** drop-down list.
  3. If you want to allow configuration overrides, check the **Allow overrides** checkbox.
  4. Click **Add**.

c) To create a new dynamic attribute, click **+Create Dynamic Attribute.**

1. Enter a **Name** and an optional **Description**.

2. Click **Add**. You can configure this object using Cisco Secure Dynamic Attribute Connector (CSDAC) or Management Center APIs.

d) (Optional) In the **Comment** field available on all the tabs, you can enter a reason for adding the required network objects and dynamic attributes to the EVE exception rule.

Step 8 Click **Save** and then deploy the access control policy.

Note When a connection matches an exception rule, it bypasses the EVE's block verdict. You can view EVE's action in the **Connection Events** or **Unified Events** page. The **Reason** column header displays **EVE Exempted** for identification of such EVE-bypassed traffic.

Add exception rule from unified events

Add exception rules for connections that are blocked by EVE using the information in the Unified Events page.

Use the **Unified Events** page to add exception rules for connections that are blocked by EVE. The Cloud-Delivered Firewall Management Center adds an exception rule to the **Encrypted Visibility Engine (EVE) exception list** object. Note that the exception rules added to this list are applicable for all the access control policies that have EVE enabled.

Before you begin

Exception list is supported only from threat defense version 7.6.0 or later.

Follow these steps to add exception rules for connections that are blocked by EVE:

Procedure

Step 1 Click **Analysis** > **Unified Events**.

Step 2 In the **Reason** column with **Encrypted Visibility Block** as the reason, click the **Ellipsis**(⋮) icon inside the cell.

Step 3 Choose **Add EVE Exception Rule** from the drop-down list.

Step 4 In the **Encrypted Visibility Engine** window that is displayed, the rule is automatically added to the bottom of the exception list. You can review and make changes to the added rule before saving and deploying the configuration.

Upgrade EVE exception rules

On Secure Firewall version 7.7 and earlier, Encrypted Visibility Engine (EVE) exception rules are configured for each policy separately. From Secure Firewall version 10.0.0, the EVE exception list is part of the global domain. As a result, the EVE exception rules are configured in the global domain and applied to all the policies on which EVE is enabled, to block traffic.

EVE exception rule upgrade behavior

When you are upgrading the Management Center from version 7.7 to 10.0.0, all the EVE exception rules from the leaf domains that contain leaf domain network objects, are identified and stored. After the upgrade is complete:

- All EVE exception rules from global domain policies, as well as rules from leaf domain policies that reference global domain objects or inline IP addresses, are consolidated into a single global EVE exception list. Some policies may now include EVE exception rules that were not present before the upgrade as a result.
- All policies that contain EVE exception rules are marked as out-of-date.

If the exception rules from leaf domains contain leaf domain network or dynamic objects, these rules are removed during the upgrade process. The upgrade script log file records all the merged and deleted exception rules and includes the corresponding access control policy and domain for each rule. The log file is located at */var/log/sf/Cisco_Secure_FW_Mgmt_Center_Upgrade10.0.0/800_post/1114_eve_rules.pl.log*.

When you deploy the configuration for the first time after the upgrade, a warning message on the Management Center lists all the deleted EVE exception rules. The warning message also states that there could be possible traffic impact if the rules are not reconfigured in the global EVE exception list. The warning message appears only when you deploy the configuration for the first time after the upgrade is complete.

For Secure Firewall devices running version 7.7 and earlier that are mapped to Management Center running version 10.0.0, only **Very High** threat confidence connection events are sent to the **Security-Related Connection Events** table. For Secure Firewall devices running version 10.0.0, EVE **Blocked** and **Medium+** EVE threat confidence connection events are sent to the **Security-Related Connection Events** table.

Change management support during EVE upgrade:

- When you upgrade the Management Center to version 10.0.0, all active change management tickets that contain access control policies on which EVE is enabled will have their EVE exception rules automatically merged with the global EVE exception list.
- The merging of EVE exception rules with the global EVE exception list occurs regardless of the ticket's approval state. This ensures that no exception rules are lost during the upgrade.

EVE ticket preview generation behavior:

- If a change management ticket contains a policy that is locked and it contains only EVE-related modifications, such as EVE settings or exception rules, the EVE ticket preview will not be automatically regenerated after the upgrade.
- If the ticket contains other policy modifications in addition to EVE-related modifications, the EVE ticket preview will be generated normally.

Use case - Block Traffic Based on the EVE Threat Confidence Score

About Encrypted Visibility Engine

You can use the Encrypted Visibility Engine (EVE) to identify client applications and processes using Transport Layer Security (TLS) encryption. EVE provides more visibility into the encrypted sessions without decryption. Based on EVE's findings, administrators can enforce policy actions on the traffic within their environments. You can also use the EVE to identify and stop malware.

Benefits

Administrators can leverage and adjust EVE's threat score to block malicious encrypted traffic. If the probability that the incoming traffic is malicious, then based on the threat score, you can configure EVE to block the connection.

Sample Business Scenario

A large corporate network uses Snort 3 as its primary intrusion detection and prevention system. In a rapidly evolving threat landscape, adoption of robust network security measures is necessary and important. The security team uses EVE to enhance encrypted traffic inspection without the need to implement full man-in-the-middle (MITM) decryption. The EVE technology uses fingerprints of known malicious processes to identify and stop malware. Network administrators must have the flexibility to configure EVE's block traffic thresholds to block potentially malicious connections, which are based on their configured block thresholds.

Prerequisites

- You must be running management center 7.4.0 or later, and the managed threat defense must also be 7.4.0 or later.
- Ensure that you have a valid Intrusion Prevention System (IPS) license and Snort 3 is the detection engine.

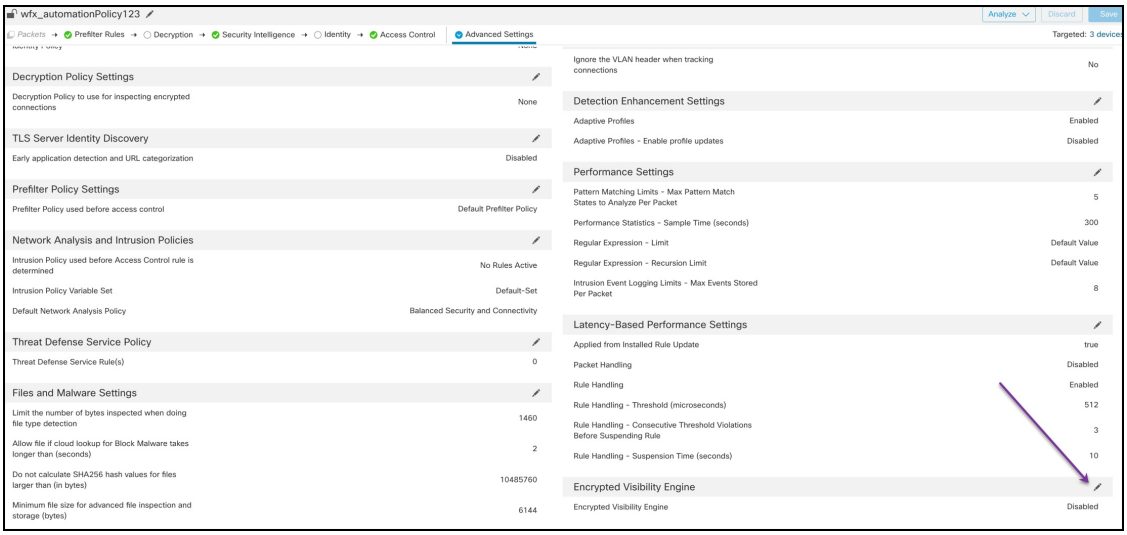
High-Level Workflow

1. EVE analyzes the incoming traffic and gives a verdict on the probability of incoming traffic being malware or not.
2. If EVE detects incoming traffic to be malware with a certain level of confidence, you can configure EVE to block that traffic.
3. The packets are first checked for malware probability or threat score, and the threat score is compared with the block threshold that you have set.
4. If the threat score is higher than the configured threshold, EVE blocks the traffic.

5. If the threat score is lesser than the configured threshold, EVE takes no action.

Configure Block Thresholds in EVE

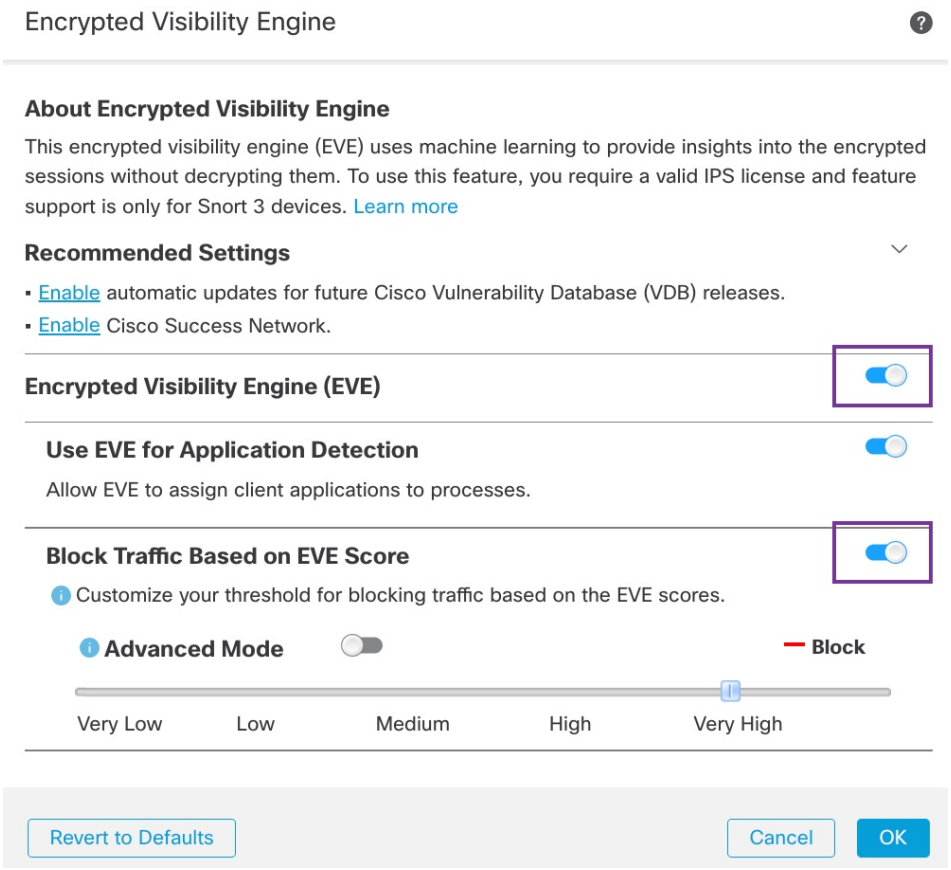
This procedure shows how to block potentially malicious traffic, based on the EVE threat confidence score of 90 percent or higher.



Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

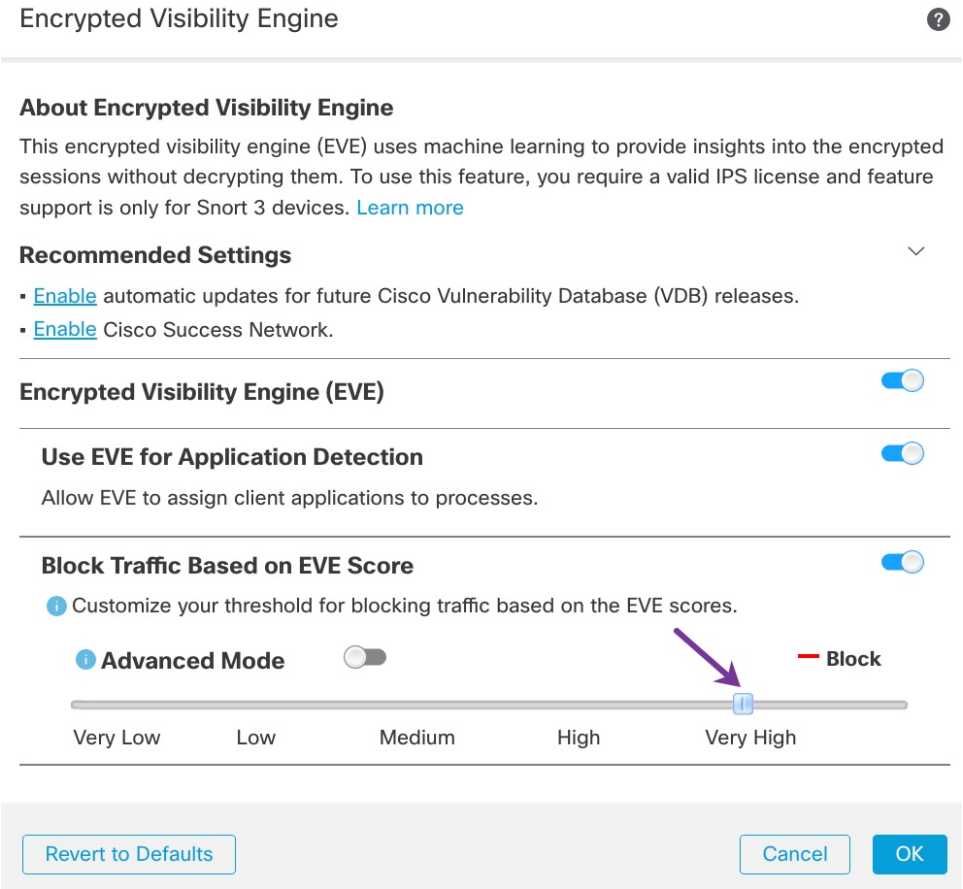
Step 2 Click **Edit** (✎) next to the access control policy you want to edit.



Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Encrypted Visibility Engine**.

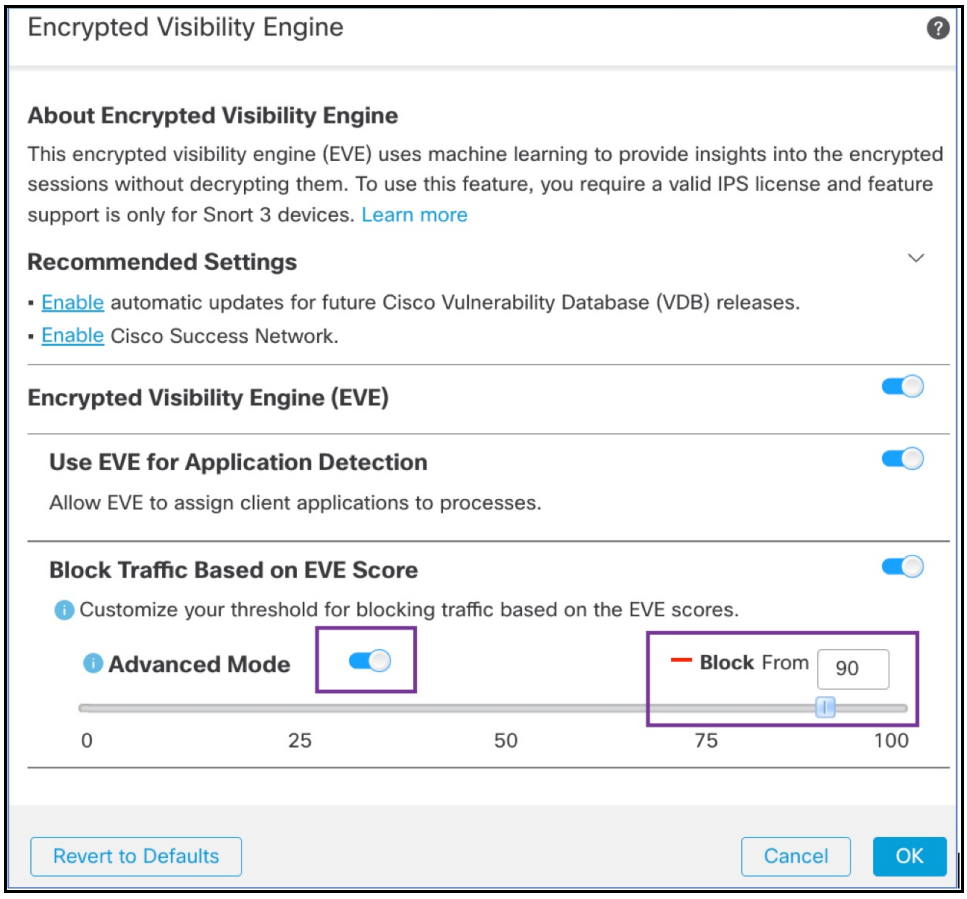
Step 5 In the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.



Step 6 Enable the **Block Traffic Based on EVE Score** toggle button. Any incoming traffic that is a potential threat is blocked by default.

Note
By default, the threshold at which malware is blocked is 99 percent, which means:

- If EVE detects the traffic to be malware with 99 percent confidence or higher, EVE blocks the traffic.
- If EVE detects the traffic to be malware with less than 99 percent confidence, EVE takes no action.



Step 7 Use the slider to adjust the threshold for blocking based on EVE threat confidence. This ranges from **Very Low** to **Very High**. In this example, the slider is set to **Very High**.

Step 8 For further granular control, enable the **Advanced Mode** toggle button. Now, you can assign a specific EVE Threat Confidence Score for blocking traffic. The default threshold is 99 percent.

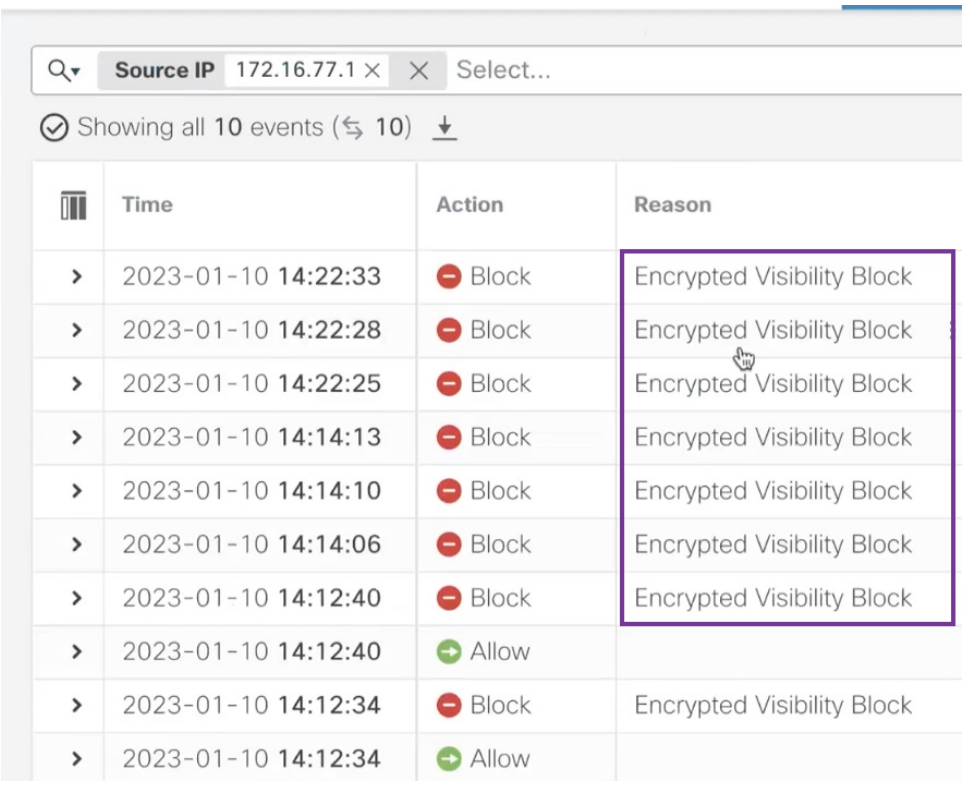
Step 9 In this example, change the block threshold to **90** percent.

Attention
As a best practice, we recommend that you do not set the block threshold to below 50 percent to ensure optimum performance.

Step 10 Click **OK**.

Step 11 Click **Save**.

What to do next



Deploy configuration changes.

View EVE Events

Procedure

Step 1 To verify the block action, choose **Analysis** > **Connections** > **Events**. You can also view the events from the **Unified Events** viewer.

Step 2 If you have configured EVE to block traffic, the **Reason** field shows **Encrypted Visibility Block**.

Step 3 The following is an example of the **Encrypted Visibility Process Name** as **test_malware**, **Encrypted Visibility Threat Confidence** as **Very High**, and **Encrypted Visibility Threat Confidence Score** as **90** percent.

CHAPTER 78

Identity Overview

The following topics discuss user identity:

- User identity, on page 2255
- Recommendation: identity realm limit, on page 2269
- Cloud-Delivered Firewall Management Center host and user limits, on page 2269
- User limits for microsoft azure active directory realms, on page 2271

User identity

User identity information can help you to identify the source of policy breaches, attacks, or network vulnerabilities, and trace them to specific users.

User identity information can help you determine:

- Who owns the host targeted by an intrusion event that has a Vulnerable (level 1: red) impact level.
- Who initiated an internal attack or portscan.
- Who is attempting unauthorized access to a specified host.
- Who is consuming an unreasonable amount of bandwidth.
- Who has not applied critical operating system updates.
- Who is using instant messaging software or peer-to-peer file-sharing applications in violation of company policy.
- Who is associated with each indication of compromise on your network.

Armed with this information, you can use other features of the system to mitigate risk, perform access control, and take action to protect others from disruption. These capabilities also significantly improve audit controls and enhance regulatory compliance.

After you configure user identity sources to gather user data, you can perform user awareness and user control.

For more information about identity sources, see About user identity sources, on page 2256.

Identity terminology

Identity terminology is a set of concepts that

- identifies users on networks using identity sources
- enables user awareness from authoritative and non-authoritative sources, and
- manages user access using identity policies.

Key identity terminology

This topic discusses common terminology for user identity and user control.

- **User awareness**: Identifying users on your network using *identity sources* (such as, TS Agent, or Cisco ISE). User awareness enables you to identify users from both *authoritative* (such as Active Directory) and *non-authoritative* (application-based) sources. To use Active Directory as an identity source, you must configure a realm and directory. For more information, see About user identity sources, on page 2256.
- **User control**: Configuring an *identity policy* that you associate with an *access control policy*. (The identity policy is then referred to as an access control *subpolicy*.) The identity policy specifies the identity source and, optionally, users and groups belonging to that source. By associating the identity policy with an access control policy, you determine whether to monitor, trust, block, or allow users or user activity in traffic on your network. For more information, see Access Control Policies, on page 1997.
- **Authoritative identity source**: a trusted server that validates user logins (for example, Active Directory). You can use the data obtained from authoritative logins to perform user awareness and user control. Authoritative user logins are obtained from passive and active authentications:
  - *Passive authentications* occur when a user authenticates through an external repository. ISE/ISE-PIC, the TS Agent, Microsoft Active Directory, and Microsoft Azure Active Directory, and the Passive Identity Agent are passive authentication user repositories supported by the system.

    Passive authentications occur when a user authenticates with Cisco ISE.
  - *Active authentications* occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, and TS Agent, and the Passive Identity Agent, which are passive only).
- **Non-authoritative identity source**: an unknown or untrusted server that validates the user login. Traffic-based detection is the only non-authoritative identity source supported by the system. You can use the data obtained from non-authoritative logins to perform user awareness.

About user identity sources

Learn how to select and configure user identity sources for the firewall to enable user awareness and access control policies. This overview covers supported identity sources, authentication types, and key considerations for optimizing user identity management.

The table provides a brief overview of the user identity sources supported by the system. Each identity source provides a store of users for user awareness. These users can then be controlled with identity and access control policies.

User Identity Source	Server Requirements	Login Type	Authentication Type	User Control	For more, see...
Captive portal	OpenLDAP Microsoft Active Directory Microsoft Azure Active Directory	Authoritative	Active	Yes	Captive portal identity source, on page 2351 Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal), on page 2310
Passive authentication	OpenLDAP Microsoft Active Directory	Non-authoritative	Active	Yes	Create an LDAP realm or an Active Directory realm and realm directory, on page 2325
Passive authentication	Microsoft Azure Active Directory	Passive	Passive	Yes	Configure Microsoft Entra ID for passive authentication, on page 2293
Passive authentication with the TS Agent	Microsoft Windows Terminal Server	Authoritative	Passive	Yes	Terminal services agent identity source, on page 2501
Passive authentication with pxGrid Cloud identity source	Cisco ISE	Non-authoritative	Passive	Yes	pxGrid Cloud identity source, on page 2433
Remote Access VPN	OpenLDAP or Microsoft Active Directory	Authoritative	Active	Yes	Remote access VPN identity sources, on page 2495
	RADIUS	Authoritative	Active	No, awareness only	
ISE/ISE-PIC	Microsoft Active Directory	Authoritative	Passive	Yes	The ISE/ISE-PIC identity source, on page 2373
Traffic-based detection (Configured in the network discovery policy.)	—	Non-authoritative	—	No, awareness only	Traffic-based detection identity sources

Consider the information when selecting identity sources to deploy:

- You must use traffic-based detection for non-LDAP user logins.

- You must use traffic-based detection or captive portal to record failed login or authentication activity. A failed login or authentication attempt does not add a new user to the list of users in the database.
- The captive portal identity source requires a managed device with a routed interface. You *cannot* use an inline (also referred to as tap mode) interface with captive portal.

Data from those identity sources is stored in the Security Cloud Control's users database and the user activity database. You can configure Security Cloud Control-server user downloads to automatically and regularly download new user data to your databases.

After you configure identity rules using the desired identity source, you must associate each rule with an access control policy and deploy the policy to managed devices for the policy to have any effect. For more information about access control policies and deployment, see Associate prefilter, decryption, and identity policies with an access control, on page 2016.

For general information about user identity, see User identity, on page 2255.

Best practices for user identity

General recommendations for identity policy setup

Review the following recommendations before you set up identity policies.

- Know user limits
- Health monitor
- Use latest version of ISE/ISE-PIC, two types of remediation
- Captive portal requires routed interface, several individual tasks

Microsoft active directory and LDAP

Create one realm per LDAP server or Active Directory domain. The system supports Active Directory, LDAP, and other user repositories for user awareness and control. The association between an Active Directory or LDAP repository and the Security Cloud Control is referred to as a *realm*. For details about which versions are supported, see Supported servers for realms, on page 2278.

- The only user identity source supported by LDAP is captive portal. To use other identity sources (with the exception of ISE/ISE-PIC), you must use Active Directory.
- For Active Directory only: Create one *directory* per domain controller. For details, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325
- Users and groups in trust relationships between two domains are supported provided you add all Active Directory domains and domain controllers as realms and directories, respectively. For more information, see Realms and trusted domains, on page 2275.

Passive Identity Agent identity source

The passive identity agent software can monitor multiple Microsoft Active Directory servers and domain controllers and send user name and IP address information to the Security Cloud Control. For more information, see The passive identity agent identity source, on page 2403.

pxGrid Cloud Identity Source

The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud identity source enables you to use subscription and user data from Cisco ISE in Cloud-Delivered Firewall Management Center access control rules. Also, the identity source uses constantly changing dynamic objects from Cisco ISE in access control policies in the Cloud-Delivered Firewall Management Center.

For more information, see pxGrid Cloud identity source, on page 2433.

Proxy sequence

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

Health monitor

The Security Cloud Control health monitor provides valuable information about the status of various Security Cloud Control functions, including user/realm mismatches, Snort memory usage, and ISE connection status.

- For more information about health modules, see *Health Modules* in the *Cisco Secure Firewall Management Center Administration Guide*.
- To set up policies to monitor health modules, see *Creating Health Policies* in the *Cisco Secure Firewall Management Center Administration Guide*.

Device-specific user limits

- User limits are discussed in User limits for microsoft active directory.
- If you use the ISE/ISE-PIC identity source, you can optionally limit the subnets the Cloud-Delivered Firewall Management Center monitors to reduce memory usage using identity mapping filters as discussed in Create an identity policy, on page 2507.

Use the latest version of ISE/ISE-PIC

If you expect to use the ISE/ISE-PIC identity source, we strongly recommend you always use the latest version to make sure you get the latest features and bug fixes.

- pxGrid 2.0 (which is used by version 2.6 patch 6 or later; or 2.7 patch 2 or later) also changes the remediation used by ISE/ISE-PIC from Endpoint Protection Service (EPS) to Adaptive Network Control (ANC). If you upgrade ISE/ISE-PIC, you must migrate your mediation policies from EPS to ANC.
- More information about using ISE/ISE-PIC can be found in Best practices for ISE/ISE-PIC integration, on page 2376.
- To set up the ISE/ISE-PIC identity source, see ISE/ISE-PIC configurations for user control , on page 2379.

Captive portal information

You can use captive portal active authentication with any of the following: LDAP, Microsoft AD, or Microsoft Azure AD (SAML).

- For LDAP, see Captive portal identity source, on page 2351.
- For Microsoft AD, see Captive portal identity source, on page 2351.
- For Microsoft Azure AD (SAML), see Create a Microsoft Azure AD (SAML) realm, on page 2289.

TS agent information

The TS Agent user identity source is required to identify user sessions on a Windows Terminal Server. The TS Agent software must be installed on the Terminal Server machine as discussed in the *Cisco Terminal Services (TS) Agent Guide*. In addition, you must synchronize the time on your TS Agent server with the time on the Security Cloud Control.

- TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.
- For more information, see Best practices for TS agent configuration, on page 2502.

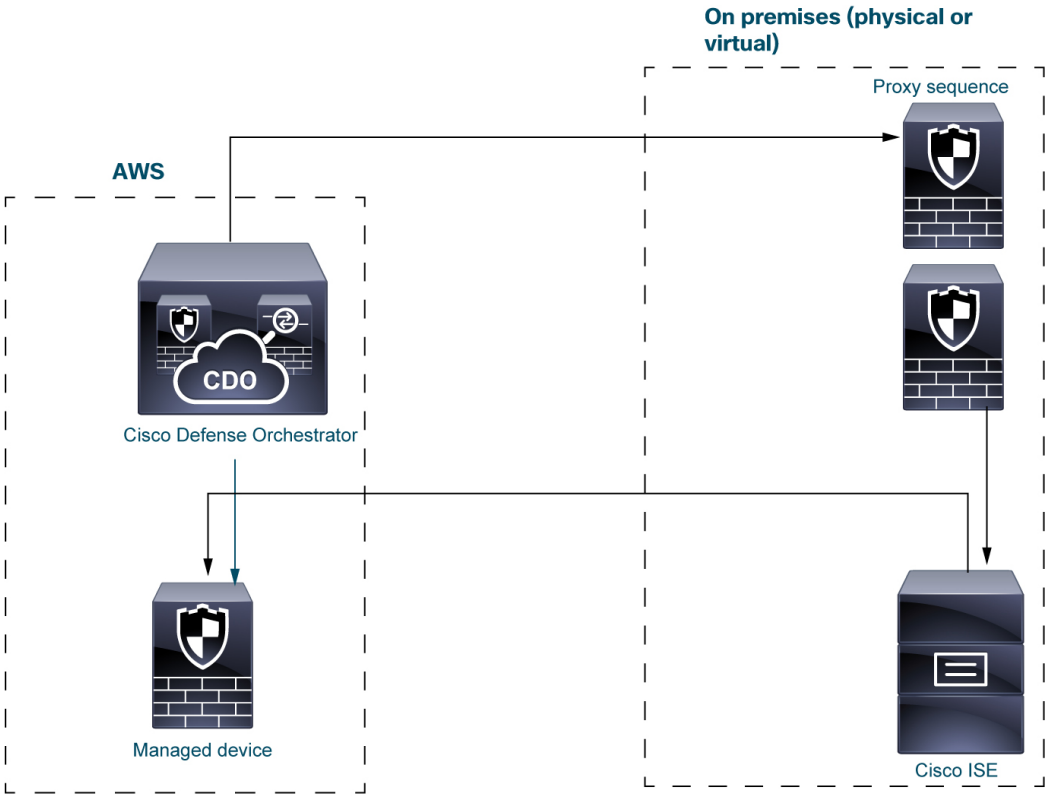
Associate the identity policy with an access control policy

After you configure your realm, directory, and user identity source, you must set up identity rules in an identity policy. To make the policy effective, you must associate the identity policy with an access control policy.

- For more information about creating an identity policy, see Create an identity policy, on page 2507.
- For more information about creating identity rules, see Create an identity rule, on page 2515.
- To associate an identity policy with an access control policy, see Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Identity deployments

The Secure Firewall Management Center uses various identity sources, such as TS Agent, ISE/ISE-PIC, pxGrid Cloud, passive identity agent, and captive portal, to collect and manage user and group data for access control and user awareness.



User data collection and storage

When the system detects user data from a user login, from any identity source, the user from the login is checked against the list of users in the Security Cloud Control user database. If the login user matches an existing user, the data from the login is assigned to the user. Logins that do not match existing users cause a new user to be created, unless the login is in SMTP traffic. Non-matching logins in SMTP traffic are discarded.

The group to which the user belongs is associated with the user as soon as the user is seen by the Security Cloud Control.

Here are examples of identity deployments.

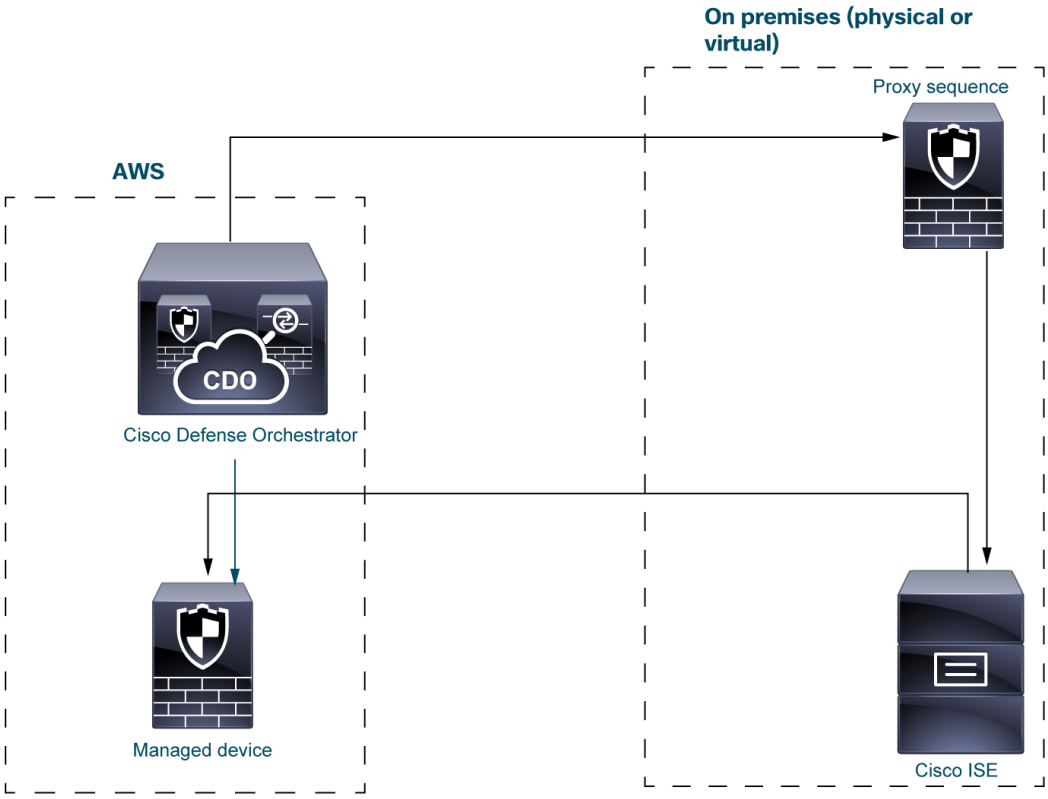
The sample deployments discussed in this section are based on the system shown in this figure.

In the preceding figure, Security Cloud Control and one managed device are deployed to AWS and the other devices are located on premises. These devices can be either physical or virtual; they just need to be able to communicate with each other.

The two on-premises managed devices are intended to be used as a proxy sequence. You must add those devices to Security Cloud Control as well.

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

LDAP or Active Directory are required only for TS Agent and captive portal, as the following paragraphs explain.



For more information about setting up a system like this, see Set up an identity policy, on page 2263.

ISE/ISE-PIC identity source

When you deploy the ISE/ISE-PIC identity source, Security Cloud Control contacts the proxy sequence if Security Cloud Control cannot contact the ISE/ISE-PIC server directly. Users, groups, and subscriptions are sent from the ISE/ISE-PIC server to the managed device in AWS.

You can optionally have an LDAP server in an ISE/ISE-PIC deployment but because it's optional, it isn't shown in this figure.

For more information about ISE/ISE-PIC, see The ISE/ISE-PIC identity source, on page 2373.

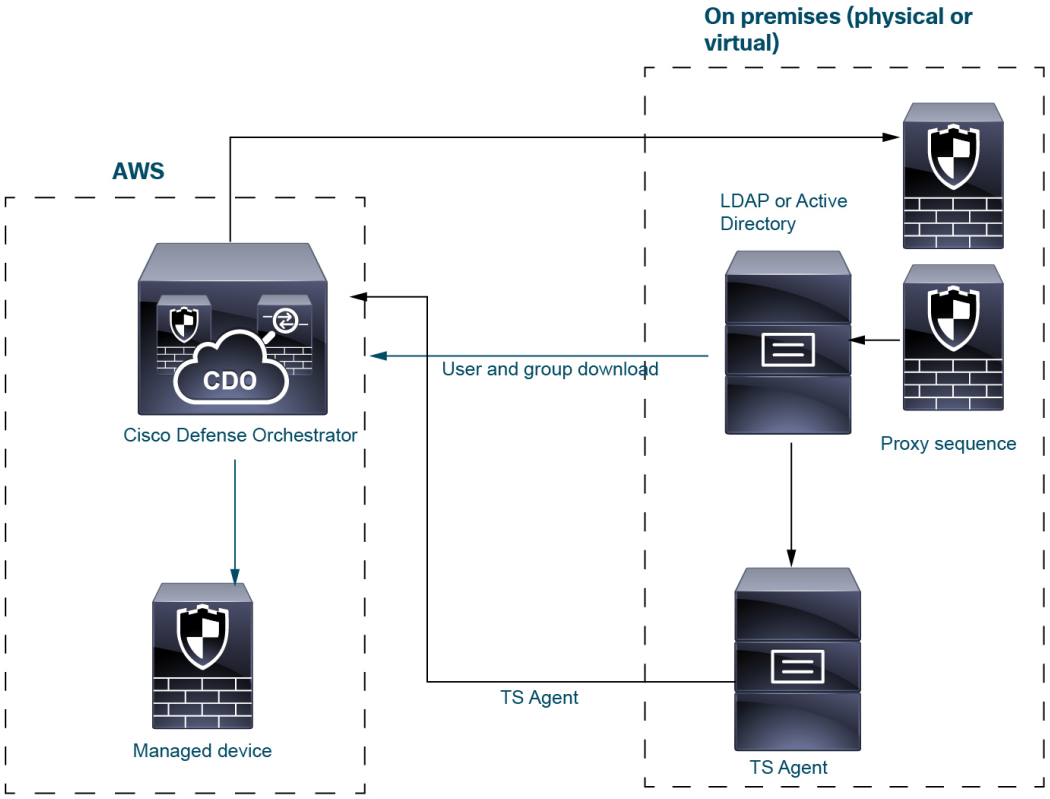
Passive identity agent source

Software that monitors one or several Microsoft AD domain controllers, sending user name and IP address information to the Security Cloud Control.

For more information, see The passive identity agent identity source, on page 2403.

pxGrid cloud identity source

pxGrid Cloud Identity Source



The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud identity source enables you to use subscription and user data from Cisco ISE in Cloud-Delivered Firewall Management Center access control rules. Also, the identity source uses constantly changing dynamic objects from Cisco ISE in access control policies in the Cloud-Delivered Firewall Management Center.

For more information, see pxGrid Cloud identity source, on page 2433.

TS Agent identity source

The Terminal Services (TS) Agent software runs on a Microsoft Server and sends Security Cloud Control user information based on the port range the users log in to the server with. TS Agent gets user identity information from LDAP or Active Directory and sends it to Security Cloud Control.

For more information about the TS Agent identity source, see Terminal services agent identity source, on page 2501.

Captive portal

You can use captive portal active authentication with any of these

- LDAP

  For more information, see Captive portal identity source, on page 2351.

- Microsoft AD

  For more information, see Captive portal identity source, on page 2351.

- Microsoft Azure AD (SAML)

  For more information, see Create a Microsoft Azure AD (SAML) realm, on page 2289.

Set up an identity policy

Set up an identity policy to control user access and filter network traffic using various user identity sources such as TS Agent, ISE/ISE-PIC, Microsoft Azure AD (SAML), captive portal.

An identity policy is not required if all these conditions are true:

- You use the ISE or ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies.

This topic provides a high-level overview of setting up an identity policy using any available user identity source: TS Agent, ISE/ISE-PIC, Microsoft Azure AD (SAML), captive portal.

Procedure

	Command or Action	Purpose
Step 1	Choose your identity source.	• To use Microsoft Active Directory or LDAP, continue with the next step. • To use a Microsoft Azure AD (SAML) realm, see Create a Microsoft Azure AD (SAML) realm, on page 2289. • To use the Cisco ISE identity source, see Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390. • To use the passive identity agent identity source, see The passive identity agent identity source, on page 2403. • To use the pxGrid Cloud identity source, see pxGrid Cloud identity source, on page 2433.
Step 2	(Optional.) Create a proxy sequence.	A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.) Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over. See Create a proxy sequence, on page 2288.
Step 3	(Optional.) Create a realm and directory, one realm for every domain in the forest that contain users you want to use in user control. Also create one directory for every domain controller. Only users and groups that have corresponding Cloud-Delivered Firewall Management Center realms and directories can be used in identity policies.	Creating a realm, realm directory, and proxy sequence is optional if any of these are true: • You use SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.

	Command or Action	Purpose
		• You are using an identity policy only to filter network traffic. • A proxy sequence is required only if you use Security Cloud Control (Security Cloud Control) and it cannot directly communicate with Active Directory or ISE/ISE-PIC. The *realm* is a trusted user and group store, typically a Microsoft Active Directory repository. The Cloud-Delivered Firewall Management Center downloads users and groups at intervals you specify. You can include or exclude users and groups from being downloaded. See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325. For details about the options to create a realm, see Realm fields, on page 2281. A *directory* is an Active Directory domain controller that organizes information about a computer network's users and network shares. An Active Directory controller provides Directory Services for the realm. Active Directory distributes user and group objects across multiple domain controllers, which are peers that propagate local changes between each other by the use of Directory Services. For more information, see the Active Directory technical specification glossary on MSDN. You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm's **Directory** tab page to match user and group credentials for user control. **Note** Configuring a realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.
Step 4	Synchronize users and groups from the realm.	To be able to control users and groups, you must synchronize them with the Cloud-Delivered Firewall Management Center. You can synchronize them with users and groups whenever you want or you can configure the

	Command or Action	Purpose
		system to synchronize them at a specified interval. When you synchronize users and groups, you can specify exceptions; for example, you can exclude the Engineering group from all user control for that realm, or you can exclude the user **`joe.smith`** from user controls that apply to the Engineering group. See Synchronize users and groups, on page 2330
Step 5	(Optional.) Create a realm sequence.	A realm sequence is an ordered list of realms that, when used in an identity policy, causes the system to search the realms in the specified order to find users to match the rule. See Create a realm sequence, on page 2332.
Step 6	Create a method to retrieve user and group data (the *identity source*).	Set up an identity source with its unique configuration to be able to control users and groups using data stored in the realm. Identity sources include TS Agent, captive portal, or Remote VPN. See one of these: • Configure the captive portal for user control, on page 2355 • Configure Remote Access VPN for AD-authenticated users, on page 2496
Step 7	Create an identity policy.	An identity policy contains one or more identity rules, optionally organized in categories. See Create an identity policy, on page 2507. **Note** Configuring a realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.
Step 8	Create one or more identity rules.	Identity rules enable you to specify a number of matching criteria, including the type of authentication, network zones, networks or geolocation, realms, realm sequences, and so on. See Create an identity rule, on page 2515.
Step 9	Associate your identity policy with an access control policy.	An access control policy filters and optionally inspects traffic. An identity policy must be associated with an access control policy to have any effect. See Associate prefilter, decryption,

	Command or Action	Purpose
		and identity policies with an access control, on page 2016.

What to do next

1. Deploy the access control policy to at least one managed device.

   To use your policy to control user activity, the policy must be deployed to the managed devices to which clients connect. See Deploy configuration changes, on page 202.

2. Monitor user activity.

   View a list of active sessions collected by user identity sources or a list of user information collected by user identity sources. .

User activity database

The user activity database on the Cloud-Delivered Firewall Management Center is a logging system that contains records of user activity on your network detected or reported by all of your configured identity sources.

User activity logging events

The system logs events in these circumstances:

- When it detects individual logins or logoffs.
- When it detects a new user.
- When a system administrator manually delete a user.
- When the system detects a user that is not in the database, but cannot add the user because you have reached your user limit.
- When you resolve an indication of compromise associated with a user, or enable or disable indication of compromise rules for a user.

Note If the TS Agent monitors the same users as another passive authentication identity source (such as the ISE/ISE-PIC), the Cloud-Delivered Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Cloud-Delivered Firewall Management Center.

You can view user activity detected by the system using the Cloud-Delivered Firewall Management Center. (**Analysis** > **Users heading** > **User Activity**.)

Users database

A users database on the Cloud-Delivered Firewall Management Center is a system component that

- contains a record for each user detected or reported by all configured identity sources
- stores data obtained from authoritative sources for user control, and
- prioritizes user data based on identity source type when user limits are reached.

User database management and limitations

For more information about the supported non-authoritative and authoritative identity sources, refer to About user identity sources, on page 2256.

The total number of users the Cloud-Delivered Firewall Management Center can store depends on the Cloud-Delivered Firewall Management Center model. After the user limit is reached, the system prioritizes previously-undetected user data based on its identity source, as described in this list:

- Non-authoritative identity source: If the new user is from a non-authoritative identity source, the system does not add the user to the database. To allow new users to be added, you must delete users manually or with a database purge.
- Authoritative identity source: If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period and adds the new user to the database.

If an identity source is configured to exclude specific user names, user activity data for those user names are not reported to the Cloud-Delivered Firewall Management Center. These excluded user names remain in the database, but are not associated with IP addresses.

If you have Cloud-Delivered Firewall Management Center high availability configured and the primary fails, no logins reported by a captive portal, ISE/ISE-PIC, TS Agent, or Remote Access VPN device can be identified during failover downtime, even if the users were previously seen and downloaded to the Cloud-Delivered Firewall Management Center. The unidentified users are logged as Unknown users on the Cloud-Delivered Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

Note If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Cloud-Delivered Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the Cloud-Delivered Firewall Management Center.

When the system detects a new user session, the user session data remains in the users database until one of these conditions occurs:

- A user on the Cloud-Delivered Firewall Management Center manually deletes the user session.
- An identity source reports the logoff of that user session.
- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

Recommendation: identity realm limit

We limit you to a maximum of 25 realms regardless of Firewall Threat Defense model; the same limit applies to the Cloud-Delivered Firewall Management Center.

The number of *users* you can download to a system is limited according to the information provided in:

Cloud-Delivered Firewall Management Center user limit, on page 2270

Cloud-Delivered Firewall Management Center host and user limits

Cloud-Delivered Firewall Management Center host and user limits are restrictions that define the maximum number of hosts and users that can be managed or supported by the system.

User and host limit details

These topics describe the user and host limits for the Cloud-Delivered Firewall Management Center.

Cloud-Delivered Firewall Management Center host limit

Cloud-Delivered Firewall Management Center host limit describes the storage capacity that

- allows the system to store a maximum of 600,000 hosts in its host database
- automatically adds a host to the network map when activity is detected for an IP address in your monitored network, and
- controls host visibility and contextual data access based on network map inclusion.

Host limit recommendations

The system can store up to 600,000 hosts but we recommend limits based on the number of devices managed.

Number of devices managed by Security Cloud Control	Recommended number of hosts
1-50	100,000
51-300	300,000
301-1000	600,000

You cannot view contextual data for hosts not in the network map. However, you can perform access control. For example, you can perform application control on traffic to and from a host not in the network map, even though you cannot use a compliance allow list to monitor the host's network compliance.

Note The system counts MAC-only hosts separately from hosts identified by both IP addresses and MAC addresses. All IP addresses associated with a host are counted together as one host.

Reaching the Host Limit and Deleting Hosts

When you reach the host limit, the network discovery policy controls what happens when you detect a new host. You can drop the new host, or replace the host that has been inactive for the longest time. You can also set the period after which the system removes a host from the network map due to inactivity. Although you can manually delete a host, an entire subnet, or all of your hosts from the network map, if the system detects activity associated with a deleted host, it re-adds the host.

Cloud-Delivered Firewall Management Center user limit

A user is added to the Cloud-Delivered Firewall Management Center user database when:

- The user is downloaded from a realm.
- A captive portal or RA-VPN user logs in.
- A user is detected from any identity source (for example, TS Agent).

A Cloud-Delivered Firewall Management Center can store a maximum of 600,0000 users in its host database but we recommend these limits.

Number of devices managed by Cisco Security Cloud	Recommended number of users
1-50	100,000
51-300	300,000
301-1000	600,000

Note The Secure Firewall 200 series can download a *cumulative total* of 10,000 user IPs, SXP/SGT mappings, endpoint profiles, and dynamic objects. After a total of 10,000 have been downloaded, the Secure Firewall 200 stops downloading any objects until some previously downloaded objects have been removed. (For example, if users log out, the memory is free for other objects.) This limit applies regardless of how many devices Cisco Security Cloud manages.

Because of its limited capacity, we recommend you *do not* use a Secure Firewall 220 as a proxy sequence.

Only authoritative users are available for user control with access control policies.

The Cloud-Delivered Firewall Management Center can store 600,000 sessions in its user database.

When the system detects a new, previously-undetected user after the limit has been reached, it prioritizes user data based on their identity source:

- If the new user is from a non-authoritative source, the system does not add the non-authoritative user to the database. To allow new users to be added, you must delete users manually or purge the database.

- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period of and adds the new authoritative user to the database.

  If there are only authoritative users, the system deletes the authoritative user who has remained inactive for the longest period of time and adds the new user to the database.

Troubleshooting information can be found in Troubleshoot user control, on page 2526.

Tip Note that if you are using traffic-based detection, you can restrict user logging by protocol to help minimize username clutter and preserve space in the database. For example, you could prevent the system from adding users discovered in AIM, POP3, and IMAP traffic because you know it is traffic from specific contractors or visitors you do not want to monitor.

User limits for microsoft azure active directory realms

This reference provides user limit information for Microsoft Azure Active Directory realms, showing how different device models handle user monitoring and login capacity.

Microsoft azure active directory user limits

About user limits

Your Cloud-Delivered Firewall Management Center model determines how many individual users you can monitor.

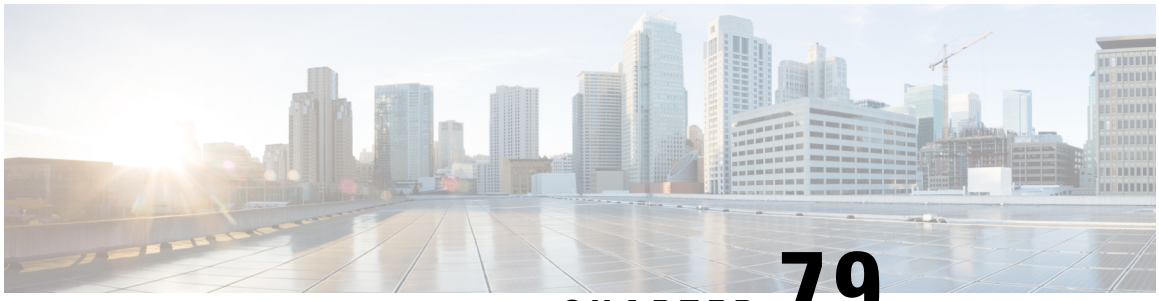
Note the following:

- The maximum number of *downloaded* users depends on your Cloud-Delivered Firewall Management Center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

Note The system downloads all user sessions to all Firewall Threat Defense devices. If you have devices with different user concurrent user session limits, the Firewall Threat Defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your Cloud-Delivered Firewall Management Center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

Refer to these tables.

Table 127: Maximum Downloaded Users by Cloud-Delivered Firewall Management Center Model[1]



Cloud-Delivered Firewall Management Center Model	Number of Dynamic Attributes Connector Connectors	Maximum Downloaded Users
Firewall Management Center Virtual (any supported hypervisor)	10	50,000
Firewall Management Center Virtual 300 (any supported hypervisor)	20	150,000

[1]—Cloud-Delivered Firewall Management Center models are subject to end of life and end of sale. For more information, see End-Of-Life and End-Of-Sale Notices.

Table 128: Maximum Concurrent User Login Limits by Firewall Threat Defense

Firewall Threat Defense Model	Maximum Concurrent User Logins
Firewall Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	50,000
Secure Firewall 220	10,000 (see note)
Firepower 1010, 1120, 1140, 1150 Firepower 2110, 2120, 2130 Secure Firewall 3110, 3120, 3130, 3140	50,000
Firepower 2140 Secure Firewall 3130, 3140	150,000
Firepower 4140, 4145, 4150 Firepower 9300 Secure Firewall 4215	225,000
Secure Firewall 4225, 4245	300,000

Note The Secure Firewall 200 series can download a *cumulative total* of 10,000 user IPs, SXP/SGT mappings, endpoint profiles, and dynamic objects. After a total of 10,000 have been downloaded, the Secure Firewall 200 stops downloading any objects until some previously downloaded objects have been removed. (For example, if users log out, the memory is free for other objects.)

CHAPTER 79

Realms

The following topics describe realms and identity policies:

- Realms and realm sequences, on page 2273
- License requirements for realms, on page 2280
- Requirements and prerequisites for realms, on page 2281
- Prerequisites for kerberos authentication, on page 2281
- Realm fields, on page 2281
- Realm directory and synchronize fields, on page 2285
- Create a proxy sequence, on page 2288
- Create a Microsoft Azure AD (SAML) realm, on page 2289
- Create a Microsoft Azure AD Realm, on page 2316
- Create an LDAP realm or an Active Directory realm and realm directory, on page 2325
- Create a realm sequence, on page 2332
- Cross-domain trust setups with Cloud-Delivered Firewall Management Center, on page 2333
- Manage a realm, on page 2341
- Compare realms, on page 2342
- Troubleshoot realms and user downloads, on page 2342
- History for realms, on page 2348

Realms and realm sequences

Realms are connections between the Cloud-Delivered Firewall Management Center and the user accounts on the servers you monitor that

- specify the connection settings and authentication filter settings for the server,
- specify the users and user groups whose activity you want to monitor, and
- query the user repository for user metadata on authoritative users, as well as some non-authoritative users: POP3 and IMAP users detected by traffic-based detection and users detected by traffic-based detection, a TS Agent, or ISE/ISE-PIC.

Realm configuration requirements

You can add multiple domain controllers as directories in a realm, but they must share the same basic realm information. The directories in a realm must be exclusively LDAP or exclusively Active Directory (AD)

servers. After you enable a realm, your saved changes take effect next time the Cloud-Delivered Firewall Management Center queries the server.

To perform user awareness, you must configure a realm for any of the supported server types. The system uses these connections to query the servers for data associated with POP3 and IMAP users, and to collect data about LDAP users discovered through traffic-based detection.

The system uses the email addresses in POP3 and IMAP logins to correlate with LDAP users on an Active Directory or OpenLDAP. For example, if a managed device detects a POP3 login for a user with the same email address as an LDAP user, the system associates the LDAP user's metadata with that user.

To perform user control, you can configure any of these:

- A realm or realm sequence for an Active Directory server, or for ISE/ISE-PIC

Note Configuring a Microsoft AD realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.

- A realm or realm sequence for a Microsoft AD server for the TS Agent.
- For captive portal, an LDAP realm.

  A realm sequence is not supported for LDAP.

You can nest Microsoft AD groups and the Cloud-Delivered Firewall Management Center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

User synchronization

You can configure a realm or realm sequence to establish a connection between the Cloud-Delivered Firewall Management Center and an LDAP or Microsoft AD server to retrieve user and user group metadata for certain detected users:

- LDAP and Microsoft AD users authenticated by captive portal or reported by ISE/ISE-PIC. This metadata can be used for user awareness and user control.
- POP3 and IMAP user logins detected by traffic-based detection, if those users have the same email address as an LDAP or AD user. This metadata can be used for user awareness.

The Cloud-Delivered Firewall Management Center obtains this information and metadata about each user:

- LDAP user name
- First and last names
- Email address
- Department
- Telephone number

Important To reduce latency between the Cloud-Delivered Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Cloud-Delivered Firewall Management Center.

For example, if your Cloud-Delivered Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

User activity data

User activity data is stored in the user activity database and user identity data is stored in the users database. If your access control parameters are too broad, the Cloud-Delivered Firewall Management Center obtains information on as many users as it can and reports the number of users it failed to retrieve in the Tasks tab page of the Message Center.

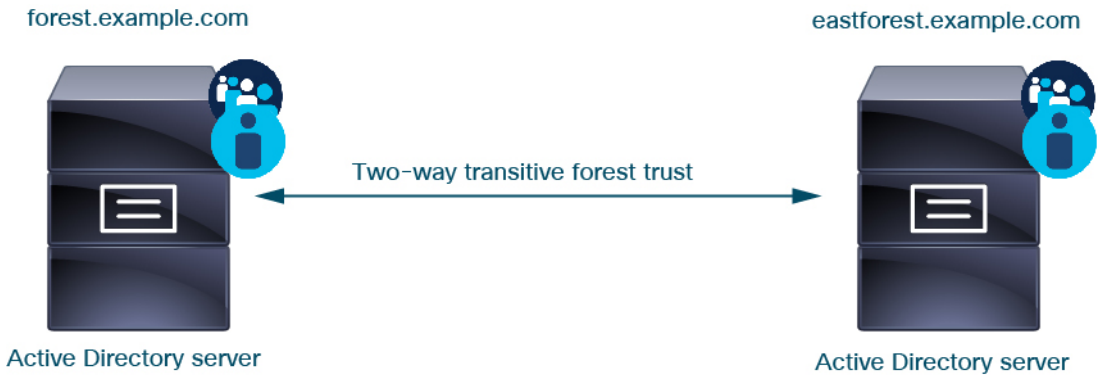
To optionally limit the subnets on which a managed device watches for user awareness data, you can use the **configure identity-subnet-filter** command as discussed in the *Cisco Secure Firewall Threat Defense Command Reference*.

Note If you remove a user that has been detected by the system from your user repository, the Cloud-Delivered Firewall Management Center does *not* remove that user from its users database; you must manually delete it. However, your LDAP changes *are* reflected in access control rules when the Cloud-Delivered Firewall Management Center next updates its list of authoritative users.

Realms and trusted domains

When you configure a Microsoft Active Directory (AD) *realm* in the Cloud-Delivered Firewall Management Center, it is associated with a Microsoft Active Directory or LDAP *domain*.

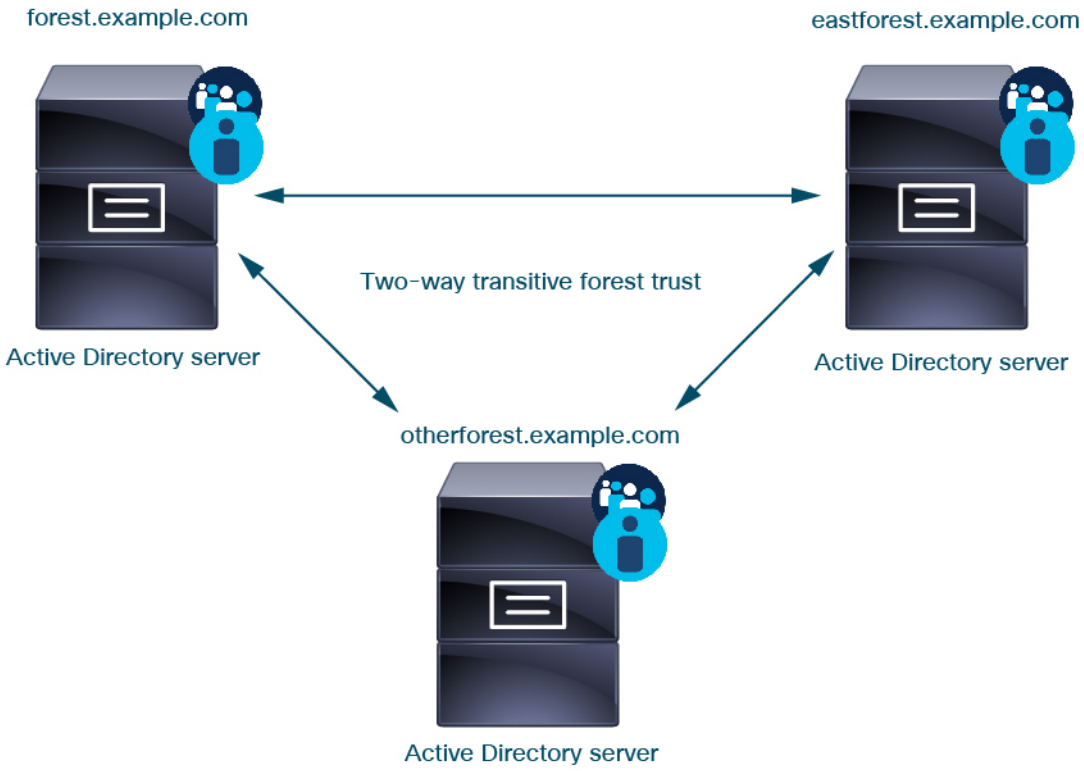
Microsoft active directory forests and trust relationships



A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B.

The system supports AD forests that are configured in a trust relationship. There are several types of trust relationships; this guide discusses two-way, transitive forest trust relationships. This simple example shows two forests: **forest.example.com** and **eastforest.example.com**. Users and groups in each forest can be authenticated by AD in the other forest, provided you configure the forests that way.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 foreign security principals (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

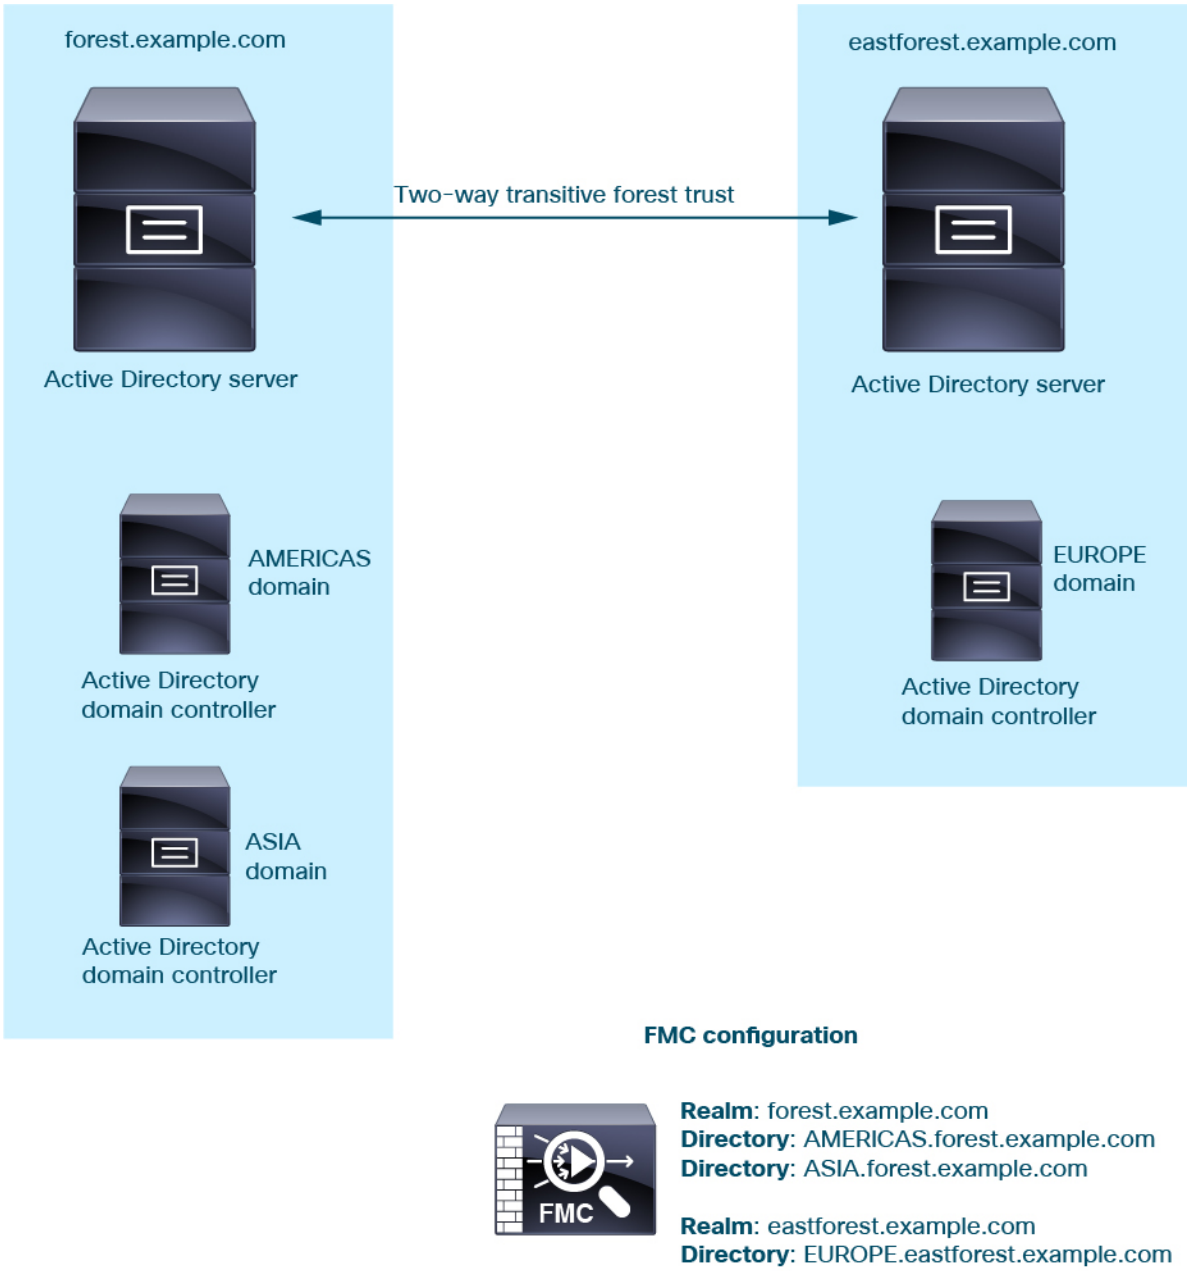


You need not configure a realm for any domain that has no users you wish to use in access control policies.

Figure 387: Two-forest configuration with two-way transitive trust

To continue the example, suppose you have three AD forests (one of which could be a subdomain or an independent forest), all set up as two-way transitive forest relationships, all users and groups are available in all three forests as well as in the system. (As in the preceding example, all three AD domains must be set up as realms and all domain controllers must be configured as directories in those realms.)

Figure 388: Three-forest configuration with two-way transitive trust



Finally, you can set up the Cloud-Delivered Firewall Management Center to be able to enforce identity policies on users and groups in a two-forest system with two-way transitive forest trust. Suppose each forest has at least one domain controller, each of which authenticates different users and groups. For the Cloud-Delivered Firewall Management Center to be able to enforce identity policies on those users and groups, you must set

up each domain containing relevant users as Cloud-Delivered Firewall Management Center realm and each domain controller as Cloud-Delivered Firewall Management Center directory in the respective realm.

Failure to properly configure the Cloud-Delivered Firewall Management Center prevents some of the users and groups from being able to be used in policies. You will see warnings when you try to synchronize users and groups in that case.

Figure 389: Multi-domain forest configuration

Using the preceding example, set up the Cloud-Delivered Firewall Management Center as follows:

- Realm for any domain in **forest.example.com** that contains users you want to control with access control policies
  - Directory in the realm for **AMERICAS.forest.example.com**
  - Directory in the realm for **ASIA.forest.example.com**
- Realm for any domain in **eastforest.example.com** that contains users you want to control with access control policies
  - Directory in the realm for **EUROPE.eastforest.example.com**

Note The Cloud-Delivered Firewall Management Center uses the AD field **msDS-PrincipalName** to resolve references to find user and group names in each domain controller. **msDS-PrincipalName** returns a NetBIOS name.

Supported servers for realms

You can configure realms to connect to the following types of servers, providing they have TCP/IP access from the Cloud-Delivered Firewall Management Center:

Server Type	Supported for ISE/ISE-PIC data retrieval?	Supported for TS Agent data retrieval?	Supported for captive portal data retrieval?
Microsoft Active Directory on Windows Server 2012, 2016, and 2019	Yes	Yes	Yes
OpenLDAP on Linux	No	No	Yes

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, refer to Global Catalog on learn.microsoft.com.

Note If the TS Agent is installed on a Microsoft Active Directory Windows Server shared with another passive authentication identity source (ISE/ISE-PIC), the Cloud-Delivered Firewall Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Cloud-Delivered Firewall Management Center.

Note the following about your server group configurations:

- To perform user control on user groups or on users in groups, you must configure user groups on the LDAP or Active Directory server.
- Group names cannot start with `s-` because it is used internally by LDAP.

Neither group names nor organizational unit names can contain special characters like asterisk (*), equals (=), or backslash (\); otherwise, users in those groups or organizational units are not downloaded and are not available for identity policies.

- To configure an Active Directory realm that includes or excludes users who are members of a sub-group on your server, note that Microsoft recommends that Active Directory has no more than 5000 users per group in Windows Server 2012. For more information, see Active Directory Maximum Limits—Scalability on MSDN.

  If necessary, you can modify your Active Directory server configuration to increase this default limit and accommodate more users.

- To uniquely identify the users reported by a server in your Remote Desktop Services environment, you must configure the Cisco Terminal Services (TS) Agent. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users. (Microsoft changed the name *Terminal Services* to *Remote Desktop Services*.)

  For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Supported server object class and attribute names

Map user metadata attributes from your LDAP servers to the correct firewall fields to ensure user information is accurately retrieved and populated in the firewall.

The servers in your realms *must* use the attribute names listed in the following table for the Cloud-Delivered Firewall Management Center to retrieve user metadata from the servers. If the attribute names are incorrect on your server, the Cloud-Delivered Firewall Management Center cannot populate its database with the information in that attribute.

Table 129: Map of attribute names to Cloud-Delivered Firewall Management Center fields

Metadata	Cloud-Delivered Firewall Management Center Attribute	LDAP ObjectClass	Active Directory Attribute	OpenLDAP Attribute
LDAP user name	Username	• user • inetOrgPerson	samaccountname	cn uid
first name	First Name		givenname	givenname
last name	Last Name		sn	sn
email address	Email		mail userprincipalname (if mail has no value)	mail
department	Department		department distinguishedname (if department has no value)	ou
telephone number	Phone		telephonenumber	telephonenumber

Note The LDAP ObjectClass for groups is `group`, `groupOfNames`, (`group-of-names` for Active Directory) or `groupOfUniqueNames`.

For more information about ObjectClasses and attributes, see these references:

- Microsoft Active Directory:
  - ObjectClasses: All Classes on MSDN
  - Attributes: All Attributes on MSDN
- OpenLDAP: RFC 4512

License requirements for realms

This topic outlines the specific license requirements necessary to enable and manage realms.

Threat Defense License

Any

Classic License

Control

Requirements and prerequisites for realms

Model support

Any.

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin

Prerequisites for kerberos authentication

If you're using Kerberos to authentication captive portal users, keep the following in mind.

Hostname character limit

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS response character limit

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Realm fields

Configure a realm to manage user authentication, directory access, and session timeouts for Active Directory, LDAP, or LOCAL user repositories in the Secure Firewall Management Center. Learn how to set realm type, credentials, supported characters, and session duration for identity policies and RA-VPN configurations.

Realm configuration fields

These settings apply to all Active Directory servers or domain controllers (also referred to as *directories*) in a realm.

Name

A unique name for the realm.

- To use the realm in identity policies, the system supports alphanumeric and special characters.
- To use the realm in RA VPN configurations, the system supports alphanumeric, hyphen (-), underscore (_), and plus (+) characters.

Description

(Optional.) Enter a description of the realm.

Type

The type of realm, **AD** for Microsoft Active Directory, **LDAP** for other supported LDAP repositories, or **LOCAL**. For a list of supported LDAP repositories, see Supported servers for realms, on page 2278. You can authenticate captive portal users with an LDAP repository; all others require Active Directory.

Note Only captive portal supports an LDAP realm.

The realm type **LOCAL** is used for configuring LOCAL user settings. The LOCAL realm is used in remote access user authentication.

Add the following LOCAL User Information for the LOCAL realm:

- **Username**—Name of the LOCAL user.
- **Password**—LOCAL user password.
- **Confirm Password**—Confirm the LOCAL user password.

Note **Click Add another LOCAL user** to add more users to the LOCAL realm.

You can add more users after creating the realm and update password for the LOCAL users. You can also create multiple LOCAL realms but cannot disable them.

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

AD Join Username and AD Join Password

(Available on the **Realm Configuration** tab page when you edit a realm.)

For Microsoft Active Directory realms intended for Kerberos captive portal active authentication, the distinguished username and password of any Active Directory user with appropriate rights to create a Domain Computer account in the Active Directory domain.

Keep the following in mind:

- DNS must be able to resolve the domain name to an Active Directory domain controller's IP address.
- The user you specify must be able to join computers to the Active Directory domain.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

If you choose **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Protocol** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

Group Attribute

(Available on the **Realm Configuration** tab page.)

These group attributes are available for Microsoft Active Directory or LDAP realms.

- Member: A user attribute that indicates the groups to which a user belongs. Each user entry contains a Member attribute that lists the groups the user is part of, rather than each group listing its members.
- Unique Member: A group attribute that lists the distinguished names (DNs) of the members of the group.

Directory Username and Directory Password

The distinguished username and password for a user with appropriate access to the user information you want to retrieve.

Note the following:

- For OpenLDAP, the user's access privileges are determined by the `<level>` parameter discussed in section 8 of the OpenLDAP specification. The user's `<level>` should be `auth` or better.
- The user name must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

Note The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet or Password Storage Cheat Sheet on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

Base DN

(Optional.)The directory tree on the server where the Security Cloud Control should begin searching for user data. If you don't specify a **Base DN**, the system retrieves the top-level DN provided you can connect to the server.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`.

Group DN

(Optional.)The directory tree on the server where the Security Cloud Control should search for users with the group attribute. A list of supported group attributes is shown in Supported server object class and attribute names, on page 2279. If you don't specify a **Group DN**, the system retrieves the top-level DN provided you can connect to the server.

Note The following is the list of characters the system *supports* in users, groups, DNS in your directory server. Using any characters other than these could result in the system failing to download users and groups.

Entity	Supported characters
User name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Group name	**a-z A-Z 0-9 ! # $ % ^ & ( ) _ - { } ' . ~ `**
Base DN and Group DN	**a-z A-Z 0-9 ! @ $ % ^ & * ( ) _ - . ~ `**

A space is not supported anywhere in a user name, including at the end.

Proxy

From the list, click one or more managed devices or a proxy sequence. These devices must be able to communicate with Active Directory or ISE/ISE-PIC to retrieve user data for identity policies.

These fields are available when you edit an existing realm.

User Session Timeout

(Available on the **Realm Configuration** tab page when you edit a realm.)

Enter the number of minutes before user sessions time out. The default is 1440 (24 hours) after the user's login event. After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Security Cloud Control as Unknown (except for **Failed Captive Portal Users**).

In addition, if you set up ISE/ISE-PIC without a realm and the timeout is exceeded, a workaround is required. For more information, contact Cisco TAC.

You can set timeout values for the following:

- **User Agent and ISE/ISE-PIC Users**: Timeout for users tracked by the user agent or by ISE/ISE-PIC, which are types of passive authentication.

  The timeout value you specify does *not* apply to pxGrid SXP session topic subscriptions (for example, destination SGT mappings). Instead, session topic mappings are preserved as long as there is no delete or update message for a given mapping from ISE.

  For more information about ISE/ISE-PIC, see The ISE/ISE-PIC identity source, on page 2373.

- **Terminal Services Agent Users**: Timeout for users tracked by the TS Agent, which is a type of passive authentication. For more information, see Terminal services agent identity source, on page 2501.

- **Captive Portal Users**: Timeout for users who successfully log in using the captive portal, which is a type of active authentication. For more information, see Captive portal identity source, on page 2351.

- **Failed Captive Portal Users**: Timeout for users who do not successfully log in using the captive portal. You can configure the **Maximum login attempts** before the user is seen by the Security Cloud Control as Failed Auth User. A Failed Auth User can optionally be granted access to the network using access control policy and, if so, this timeout value applies to those users.

  For more information about failed captive portal logins, see Captive portal fields, on page 2367.

- **Guest Captive Portal Users**: Timeout for users who log in to the captive portal as a guest user. For more information, see Captive portal identity source, on page 2351.

Realm directory and synchronize fields

Configure Active Directory realm directory and user synchronization fields to enable secure authentication, user data lookup, and group management in the Secure Firewall Management Center. Learn how to specify server, encryption, domain, and group settings for optimized user awareness and access control.

Realm directory fields

These settings apply to individual servers (such as Active Directory domain controllers) in a realm.

Hostname / IP Address

Fully qualified host name of the Active Directory domain controller machine. To find the fully qualified name, see Find the active directory server's name, on page 2328.

If you're using Kerberos for authenticating captive portal, also make sure you understand these considerations:

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Port

The server's port.

Encryption

(Strongly recommended.) The encryption method to use:

- **`STARTTLS`**—encrypted LDAP connection
- **`LDAPS`**—encrypted LDAP connection
- **`None`**—unencrypted LDAP connection (unsecured traffic)

To communicate securely with an Active Directory server, see Connect securely to Active Directory or LDAP, on page 2328.

CA Certificate

The TLS/SSL certificate to use for authentication to the server. You must configure **`STARTTLS`** or **`LDAPS`** as the **Encryption** type to use a TLS/SSL certificate.

If you are using a certificate to authenticate, the name of the server in the certificate must match the server **Hostname / IP Address**. For example, if you use 10.10.10.250 as the IP address but **`computer1.example.com`** in the certificate, the connection fails.

Interface used to connect to Directory server

Required only for RA VPN authentication so the Secure Firewall Threat Defense can connect securely to your Active Directory server. This interface is not used for downloading users and groups, however.

You can choose only a routed interface group. For more information, see Interfaces, on page 2980.

Click one of these options:

- **Resolve via route lookup**: Use routing to connect to the Active Directory server.
- **Choose an interface**: Choose a specific managed device interface group to connect to the Active Directory server.

User synchronize fields

AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Enter query to look for users and groups

Base DN:

(Optional.) The directory tree on the server where the Cloud-Delivered Firewall Management Center should begin searching for user data.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`.

Group DN:

(Optional.) The directory tree on the server where the Cloud-Delivered Firewall Management Center should search for users with the group attribute. A list of supported group attributes is shown in Supported server object class and attribute names, on page 2279.

Note Neither the group name nor the organizational unit name can contain special characters like asterisk (*), equals (=), backslash (\) because users in those groups are not downloaded and cannot be used in identity policies.

Load Groups

Enables you to download users and groups for user awareness and user control.

Available Groups, Add to Include, Add to Exclude

Limits the groups that can be used in policy.

- Groups that are displayed in the **Available Groups** field are available for policy unless you move groups to the **Included Groups and Users** or **Excluded Groups and Users** field.
- If you move groups to the **Included Groups and Users** field, only those groups and users they contain are downloaded and user data is available for user awareness and user control.
- If you move groups to the **Excluded Groups and Users** field, all groups and users they contain *except* these are downloaded and available for user awareness and user control.
- To include users from groups that are not included, enter the user name in the field below **User Inclusion** and click **Add**.
- To exclude users from groups that are not excluded, enter the user name in the field below **User Exclusion** and click **Add**.

Note The users that are downloaded to the Cloud-Delivered Firewall Management Center is calculated using the formula **R = I - (E+e) + i**, where

- R is list of downloaded users
- I is included groups
- E is excluded groups
- e is excluded users
- i is included users

Synchronize Now
Click to synchronize groups and users with AD.

Begin automatic synchronization at
Enter the time and time interval at which to download users and groups from AD.

Create a proxy sequence

Create a proxy sequence to enable reliable user repository connectivity and failover support for managed devices.

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

Note To use a proxy sequence with a SAML - Azure AD realm, the managed device must run version 7.4.2 or later.

Because of its limited capacity, we recommend you *do not* use a Secure Firewall 220 as a proxy sequence.

Before you begin

You must add at least two managed devices to Security Cloud Control, all of which must be able to communicate with Active Directory or ISE/ISE-PIC.

Follow these steps to create a proxy sequence:

Procedure

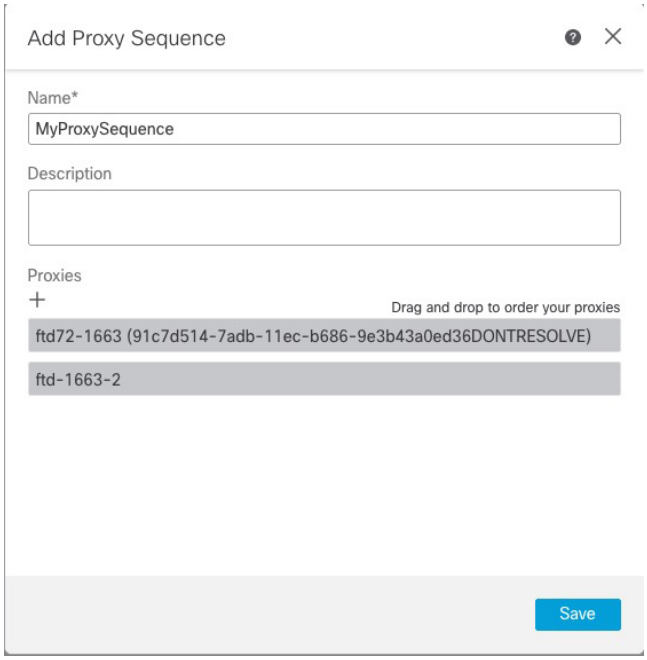
Step 1 Log in to the Security Cloud Control if you have not already done so.

Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 3 Click **Add Proxy Sequence**.

Step 4 In the **Name** field, enter a name to identify the proxy sequence.

Step 5 (Optional.) In the **Description** field, enter a description for the proxy sequence.



Step 6 Under Proxies, click **Add** (+).

Step 7 Click the name of each managed device to add to the sequence.

To narrow your search, enter all or part of a realm name in **Filter** field.

Click **OK**.

Step 8 In the Add Proxy Sequence dialog box, drag and drop the proxies in the order in which you want Security Cloud Control to search for them.
The following figure shows an example of a proxy sequence consisting of two proxies. The top proxy will be searched for users before the bottom proxy. Both proxies must be able to communicate with either Active Directory or ISE/ISE-PIC.

Step 9 Click **Save**.

What to do next

See Create an identity policy, on page 2507.

Create a Microsoft Azure AD (SAML) realm

You can use a Microsoft Azure Active Directory (AD) (now called *Entra ID*) realm for either passive authentication or active authentication.

Authentication options

Passive authentication

Passive authentications occur when a user authenticates with Cisco ISE.

You have these options, depending on your choice of user and group repository:

- To use Cisco ISE as a repository for users and to perform passive authentication using Entra ID. For more information, see:
  - How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291
  - How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS, on page 2292
- To download groups from Entra ID.

  For more information about setting up Entra ID, see Configure Microsoft Entra ID for passive authentication, on page 2293.

Active authentication

Active authentications occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, and TS Agent, and the Passive Identity Agent, which are passive only).

To use Microsoft Entra ID as a captive portal requires users to authenticate with Entra ID. We refer to the realm as a Security Assertion Markup Language (SAML) realm because SAML is used to establish a trust relationship between:

- A *service provider* (the Secure Firewall Threat Defense device or devices to which authentication requests are sent).
- An *identity provider* (Microsoft Entra ID).

SAML is an open standard developed by the OASIS standards body; for more information, see the SAML Overview.

For more information, see Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal), on page 2302.

Create a Microsoft Azure AD realm for passive authentication

Create and configure a Microsoft Azure AD (SAML) (now called *Entra ID*) realm for passive authentication use with the Security Cloud Control.

This configuration enables passive authentication between Microsoft Entra ID and your firewall system through proper realm setup and access control policy integration.

Procedure

Step 1 Configure Microsoft Entra ID.

Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log.

See Configure Microsoft Entra ID for passive authentication, on page 2293.

Step 2 Configure Cisco ISE.

The way you configure ISE depends on how users authenticate with your system. For more information, see Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD, on page 2293.

Step 3 Create a Cisco ISE identity source.

The identity source enables ISE to communicate with the Cloud-Delivered Firewall Management Center.

Step 4 Get the information required to configure your Microsoft Azure AD realm.

This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID.

Step 5 Configure and verify your realm.

Test the realm's configuration before you start to use it in access control policies.

Create a Microsoft Azure AD (SAML) realm as discussed in Create a Microsoft Azure AD (SAML) realm, on page 2289

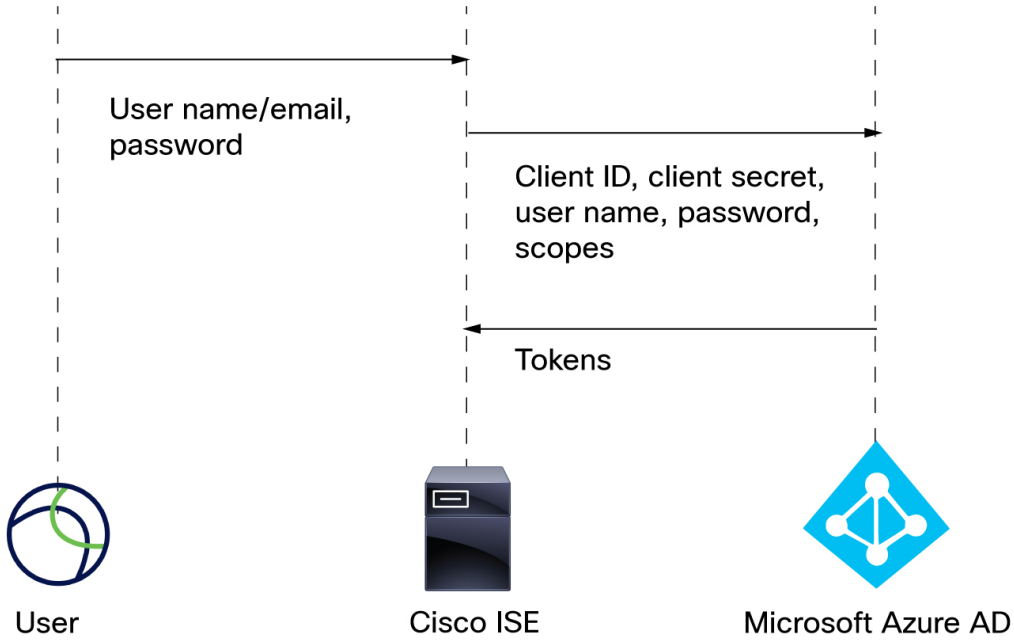
Step 6 Create access control policies and rules using your Microsoft Azure AD (SAML) realm.

Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy.

See Creating a basic access control policy, on page 2004 and Create and edit access control rules, on page 2066.

What to do next

See How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291.



How Entra ID and Cisco ISE authentication with resource owned password credentials works

Summary

The key components involved in the Entra ID authentication with resource owned password credentials process are:

- User: Logs in with credentials using a VPN client
- Cisco Secure Client: VPN client that sends user credentials
- Entra ID (formerly Azure AD): Validates credentials and issues tokens
- Cisco ISE: Receives tokens and manages user sessions
- Cloud-Delivered Firewall Management Center: Receives user sessions from ISE

Workflow

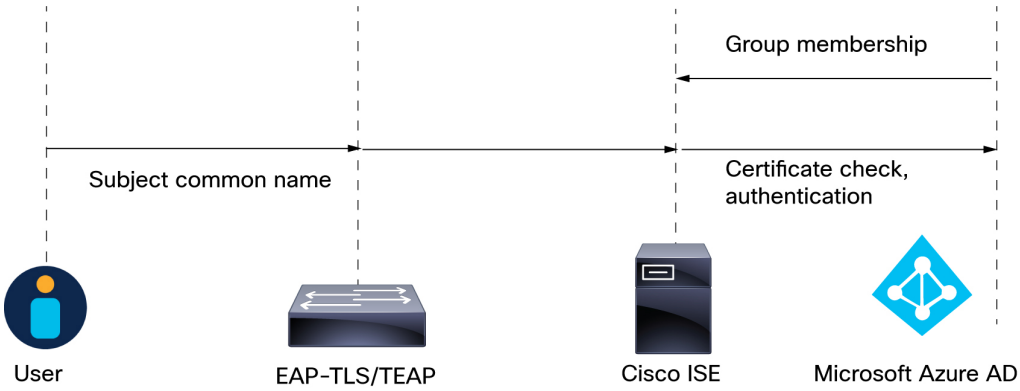
These stages describe how Entra ID and Cisco ISE authentication with resource owned password credentials works:

1. The user logs in with a user name (or email address) and password using a VPN client like Cisco Secure Client.
2. The client ID, client secret, user name, password, and scopes are sent to Entra ID.
3. Tokens are sent from Entra ID to Cisco ISE, which sends user sessions to the Cloud-Delivered Firewall Management Center.

   For details about configuring Cisco ISE, see Configure ISE 3.0 REST ID with Azure Active Directory.

   Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS



Tunnel Extensible Authentication Protocol (TEAP), defined by RFC7170, can be used with ISE and the Security Cloud Control for secure authentication.

Summary

The key components involved in this authentication process are:

- User device: Provides certificate through EAP-TLS or TEAP protocol
- ISE: Validates certificate and performs user lookup through Azure Graph API
- Entra ID: Provides user attributes and group information for authorization

Workflow

These stages describe how the authentication process works and are based on Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory:

1. The user's certificate is sent to ISE through EAP-TLS or TEAP with EAP-TLS as the inner method.
2. ISE evaluates the user's certificate (validity period, trusted certificate authority, certificate revocation list, and so on).
3. ISE takes the certificate subject name (CN) and performs a look-up to the Azure Graph API to fetch the user's groups and other attributes. This is referred to by Azure as User Principal name (UPN).
4. ISE authorization policies are evaluated against the user's attributes returned from Azure.

Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD

In a Microsoft Azure AD (SAML)Microsoft Azure AD (now called *Entra ID*) realm, it's the responsibility of ISE to send user sessions (login, logout) to the Cloud-Delivered Firewall Management Center. This topic discusses how to set up ISE for use with an Azure AD realm.

Resource owned password credentials authentication

To use ISE with Microsoft Azure AD (SAML)Microsoft Azure ADMicrosoft Azure AD implemented through Representational State Transfer (REST) Identity (ID) service with the help of Resource Owner Password Credentials (ROPC), see Configure ISE 3.0 REST ID with Azure Active Directory.

TEAP/EAP-TLS

To use ISE with authorization policies based on Azure AD group membership and other user attributes with EAP-TLS or TEAP as the authentication protocols, see Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory.

What to do next

Get required information For Your Microsoft Azure AD realm, on page 2296

Configure Microsoft Entra ID for passive authentication

Configure Microsoft Entra ID to enable passive authentication and user group synchronization with the Security Cloud Control.

This task provides basic information about how to set up a Microsoft Entra ID (formerly called *Microsoft Azure Active Directory (AD)*) as a realm you can use with the Security Cloud Control. We expect you to already be familiar with Entra ID; if not, consult documentation or a support resource before you get started.

Procedure

Step 1 Grant your Entra ID application the Microsoft Graph permissions.

Grant your Entra ID application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Security Cloud Control to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Security Cloud Control:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Step 2 Set up an event hub.

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Security Cloud Control uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important
You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Security Cloud Control:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Step 3 Enable the audit log.

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Step 4 Configure Cisco ISE for Entra ID.

To send user session information to the Security Cloud Control, configure Cisco ISE for Entra ID as discussed in Configure ISE 3.0 REST ID with Azure Active Directory.

What to do next

See Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD, on page 2293.

Configure Entra ID basic settings

Set up Entra ID realm authentication to enable the Cloud-Delivered Firewall Management Center to download and periodically update users and groups from Entra ID.

This configuration enables SAML realm authentication for Entra ID (formerly Azure AD) in Secure Firewall Management Center, allowing integration with Microsoft Graph services and audit logging capabilities.

Before you begin

Follow these steps to configure Entra ID basic settings:

Procedure

Step 1 Give your application the Microsoft Graph permission.

Grant your Entra ID application (formerly called *Azure AD*) the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Cloud-Delivered Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Cloud-Delivered Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Step 2 Set up an event hub.

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Cloud-Delivered Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important

You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Security Cloud Control:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Step 3 Enable the audit log.

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Get required information For Your Microsoft Azure AD realm

This task enables you to collect the necessary credentials and configuration information from Microsoft Entra ID (formerly Azure AD) and Event Hubs to establish a SAML authentication realm in your Secure Firewall Management Center.

This task explains how to get the information required to set up a Microsoft Azure AD (now called *Entra ID*) realm in the Security Cloud Control. You might have already obtained this information when you set up Microsoft Entra ID as discussed in Configure Microsoft Entra ID for passive authentication, on page 2293.

Procedure

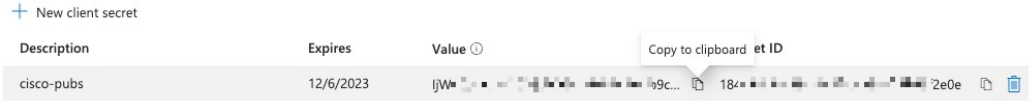
Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

Step 2 At the top of the page, click **Microsoft Entra ID**.

Step 3 In the left column, click **App Registrations**.

a) If necessary, filter the list of displayed apps to show the one you want to use.

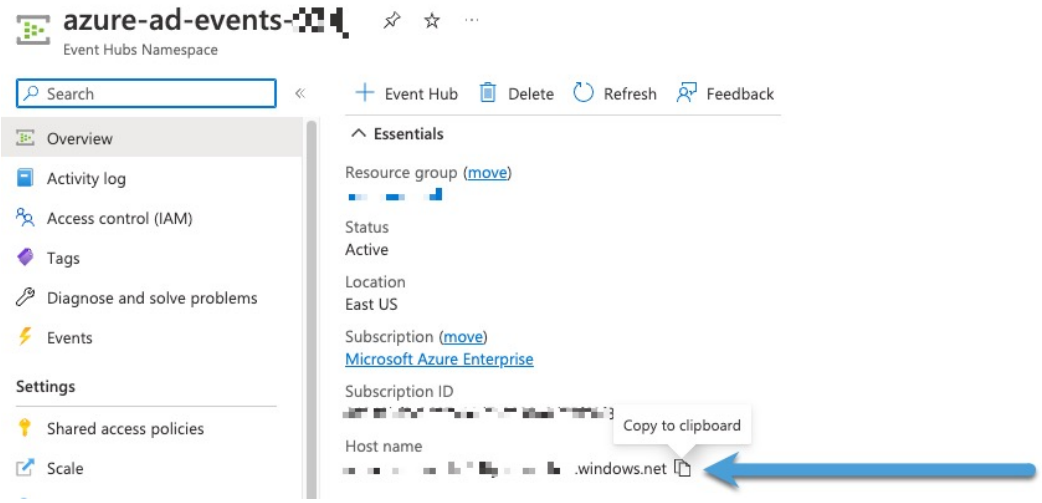
b) Click the name of your app.



c) Click **Copy** ( ) next to the following values on this page and paste those values to a text file.

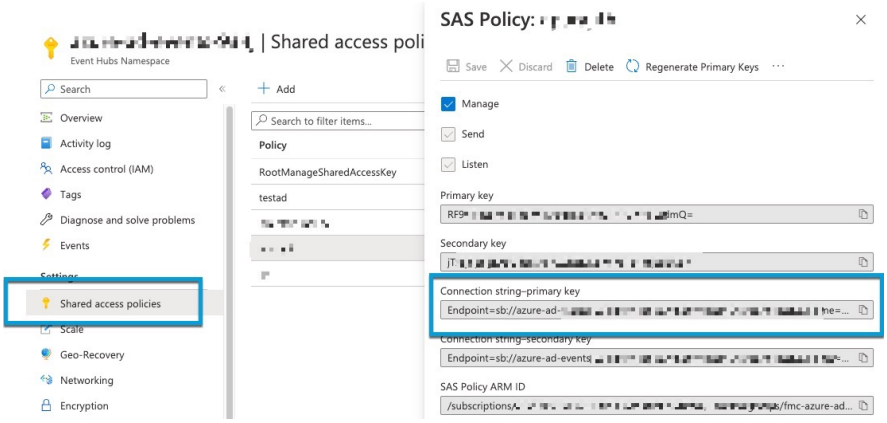
- **Application (Client) ID**
- **Directory (tenant) ID**

d) Click **Client Credentials**.



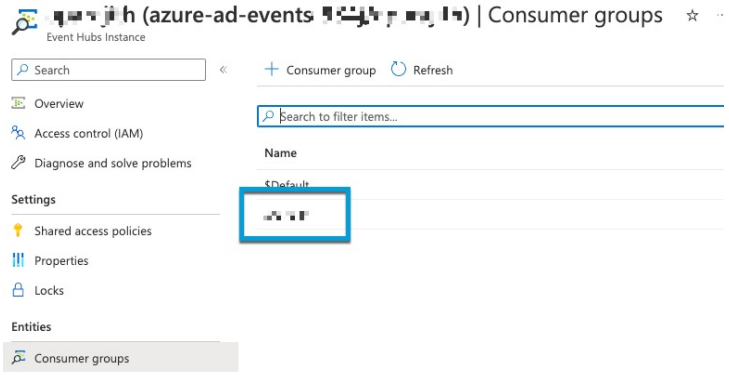
e) Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

1. Click **New Client Secret**.
2. Enter the required information in the provided fields.
3. Click **Add**.
4. Click **Copy** ( ) next to Value as the following figure shows.



Step 4 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

a) In the right pane, click **Copy** ( ) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.



b) Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).
c) In the left pane, under Settings, click **Shared access policies**.
d) Click the name of a policy.
e) Click **Copy** ( ) next to **Connection string-primary key**.

Step 5 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down this value or copy it to the clipboard. This is your consumer group name.

Step 6 In the left pane, click **Overview**.

Step 7 Click **Copy** ( ) next to **Namespace**.

This is your event hubs topic name.

Create a Microsoft Azure AD (SAML) realm for passive authentication

A Microsoft Azure AD (SAML) realm for passive authentication retrieves groups from Microsoft Azure Active Directory (now called *Entra ID*) and logged-in user session data from Cisco ISE to authenticate users.

Authentication options

You have the following authentication options:

- Resource owned password credentials (ROPC): Enables users to log in with a client like Cisco Secure Client using a user name and password. ISE sends user sessions to the Cloud-Delivered Firewall Management Center. For more information, see How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291.

  Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

- Extensible Authentication Protocol (EAP) Chaining with Tunnel-based Extensible Authentication Protocol (TEAP) and Transport Layer Security (TLS), abbreviated EAP/TEAP-TLS: TEAP is a tunnel-based EAP method that establishes a secure tunnel and executes other EAP methods under the protection of that secured tunnel. ISE is used to validate user credentials and to send user sessions to the Cloud-Delivered Firewall Management Center. For more information, see How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS, on page 2292.

To configure the realm, complete all tasks in this order:

1. Configure Entra ID basic settings, on page 2295.
2. Get required information for your realm as discussed in Get required information For Your Microsoft Azure AD realm, on page 2296.
3. Microsoft Azure AD (SAML) realm: SAML details, on page 2299.

Microsoft Azure AD (SAML) realm: SAML details

Set up a Microsoft Entra ID (SAML) realm to enable user authentication through passive or active methods with integration between the Secure Firewall Management Center and Azure AD and identity providers.

This task discusses the first step in a multi-step wizard that creates a Microsoft Azure AD (SAML) realm. You must complete all steps in the wizard to set up your realm. The steps are different depending on whether you create the realm for active or passive authentication.

Before you begin

Complete all tasks before you create your realm:

- (Passive authentication with Cisco ISE only.) If you're using Cisco ISE as the repository for users and groups, set up ISE:
  - How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291
  - How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS, on page 2292
- To use Entra ID as the repository for users and groups, see Configure Microsoft Entra ID for passive authentication, on page 2293.
- Get required information for your realm as discussed in Get required information For Your Microsoft Azure AD realm, on page 2296.

Follow these steps to configure a Microsoft Entra ID (SAML) realm:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 3 Click **Add Realm** > **SAML - Azure AD**.

Step 4 Enter the required information.

Item	Description
Name	Unique name to identify the realm.
Description	(Optional.) Description of the realm.
Identity Provider	Always displays **Azure AD**.
Configuration Type	Click one of these options: • **Passive Authentication with ISE** for passive authentication. • **Passive authentication or captive portal with Azure AD** for to use Entra ID as a user store for either passive authentication or active authentication (that is, captive portal).

Step 5 Click **Next**.

The realm creation wizard advances to the next step based on your selected configuration type.

What to do next

Continue with one of these tasks:

- Passive authentication: Microsoft Azure AD (SAML) realm: Azure AD details, on page 2300.
- Active authentication: Microsoft Azure AD (SAML) realm: SAML service provider (SP) metadata, on page 2312.

Microsoft Azure AD (SAML) realm: Azure AD details

Configure the Entra ID (SAML) realm to enable authentication and user data management through Azure AD integration.

This task discusses one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
Name	Enter a unique name to identify this realm.
Client Secret **Tenant ID** **Event Hubs Host Name** **Event Hub Name** **Event Hub Connection String**	Enter the information you found as discussed in:. • Passive authentication: Create a Microsoft Azure AD realm for passive authentication, on page 2290 • Active authentication: Get required information for your Microsoft Azure AD realm (active authentication only), on page 2307
(Optional.) **User Groups**	Slide to **Slider enabled** ( ) to specify groups to include or exclude from policy.
(Optional.) **Excluded User Groups**	If you enter one or more group names in this field, all groups and users they contain *except* these are downloaded and available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive.
(Optional.) **Included User Groups**	If you enter one or more group names in this field, only those groups and users they contain are downloaded and user data is available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive. We recommend that you use the Included User Groups field to download only those groups that you intend to monitor with Secure Firewall.

Step 3 Click **Test**.
Make sure the test connection succeeds before you continue to the next step.

Step 4 Click **Next**.

The Entra ID (SAML) realm configuration is completed with Azure AD details, and the connection test confirms successful integration.

Configure Microsoft Azure AD (SAML) realm user session timeout

Set the session timeout to define how long inactive ISE or captive portal user sessions remain active before automatic termination in a Microsoft Entra ID (SAML) realm configuration.

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

This option sets the number of seconds before an inactive session is terminated by the system.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
ISE users	Default is 1440 minutes (24 hours).
Captive portal users	Default is 1440 minutes (24 hours).

After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Cloud-Delivered Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Step 3 Click **Save**.

Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal)

Create and configure a Microsoft Azure Active Directory (Entra ID) realm to enable secure user authentication, certificate management, and access control for protected network resources.

This topic discusses the high-level tasks of creating a Microsoft Azure Active Directory (AD) realm (now called *Entra ID*) for use with the Security Cloud Control.

Before you begin

If you enabled change management, you must open or edit, assign, and approve a ticket for each of the following objects before you can create the realm:

- Base URL
- Service provider certificate enrollment (PKCS12 format)
- Identity provider certificate enrollment (manual format)
- The realm itself (create and assign the ticket until realm creation is complete, then approve it)

For more information, see Opening a ticket for configuration changes, on page 176 and Policies and objects that support change management, on page 169.

Follow these steps to create a Microsoft Azure Active Directory (Entra ID) realm:

Procedure

Step 1 Create a fully-qualified host name (FQDN) using your DNS server and upload the Firewall Threat Defense's internal certificate to the Security Cloud Control.

You can consult a resource such as this one if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your Security Cloud Control.

Consult a DNS server reference.

Step 2 Create a network object with an associated internal certificate.

See Create a network object, on page 2985.

Step 3 Get a signed certificate and upload it to the Secure Firewall Threat Defense to which Entra ID authentication requests will be sent.

The certificate should be signed by a trusted Certificate Authority (CA) and delivered to you in **.p12** format (also referred to as PKCS#12; see also this article on ssl.com).

For background, see the section on public key infrastructure in Cisco Secure Firewall Management Center Device Configuration Guide or stackoverflow.com.

To upload the signed certificate, see Install a certificate using a PKCS12 file, on page 3087.

Step 4 Configure Microsoft Entra ID basic settings.

Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log.

See Configure Entra ID basic settings, on page 2295.

Step 5 Create a single sign-on (SSO) app in Entra ID.

The SSO app enables users that request access to a protected network resource to authenticate with Entra ID. The SSO app has both the federation XML that you can use to simplify realm creation as well as the identity provider certificate the Secure Firewall Threat Defense requires to security authenticate with Entra ID.

See Configure a single sign-on (SSO) app in Entra ID, on page 2305.

Step 6 Get the information required to configure your Microsoft Azure AD (SAML) realm.

This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID.

See Get required information For Your Microsoft Azure AD realm, on page 2296.

Step 7 Configure a decryption policy with a **Decrypt - Resign** rule for the Azure Authentication Service so users can access web pages using the HTTPS protocol.

The Microsoft Azure AD (SAML) realm can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the realm. The Microsoft Azure AD (SAML) realm itself is seen by the system as the **Azure Authentication Service** application.

Create a decryption rule with decrypt - resign action, on page 2307.

Step 8 Do the following:

a) Create identity policy with an active authentication rule.

The identity policy enables selected users in your realm access resources after authenticating with the Microsoft Azure AD (SAML) realm.

For more information, see Create an identity policy, on page 2507.

b) Create access control policies and rules using your Microsoft Azure AD realm.

Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy.

See Creating a basic access control policy, on page 2004 and Create and edit access control rules, on page 2066.

c) Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the Microsoft Azure AD (SAML) realm.

For more information, see Associate prefilter, decryption, and identity policies with an access control, on page 2016.

What to do next

See Configure Entra ID basic settings, on page 2295.

Configure Entra ID basic settings

Set up Entra ID realm authentication to enable the Cloud-Delivered Firewall Management Center to download and periodically update users and groups from Entra ID.

This configuration enables SAML realm authentication for Entra ID (formerly Azure AD) in Secure Firewall Management Center, allowing integration with Microsoft Graph services and audit logging capabilities.

Before you begin

Follow these steps to configure Entra ID basic settings:

Procedure

Step 1 Give your application the Microsoft Graph permission.

Grant your Entra ID application (formerly called *Azure AD*) the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Cloud-Delivered Firewall Management Center to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Cloud-Delivered Firewall Management Center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

Step 2 Set up an event hub.

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Cloud-Delivered Firewall Management Center uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important
You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

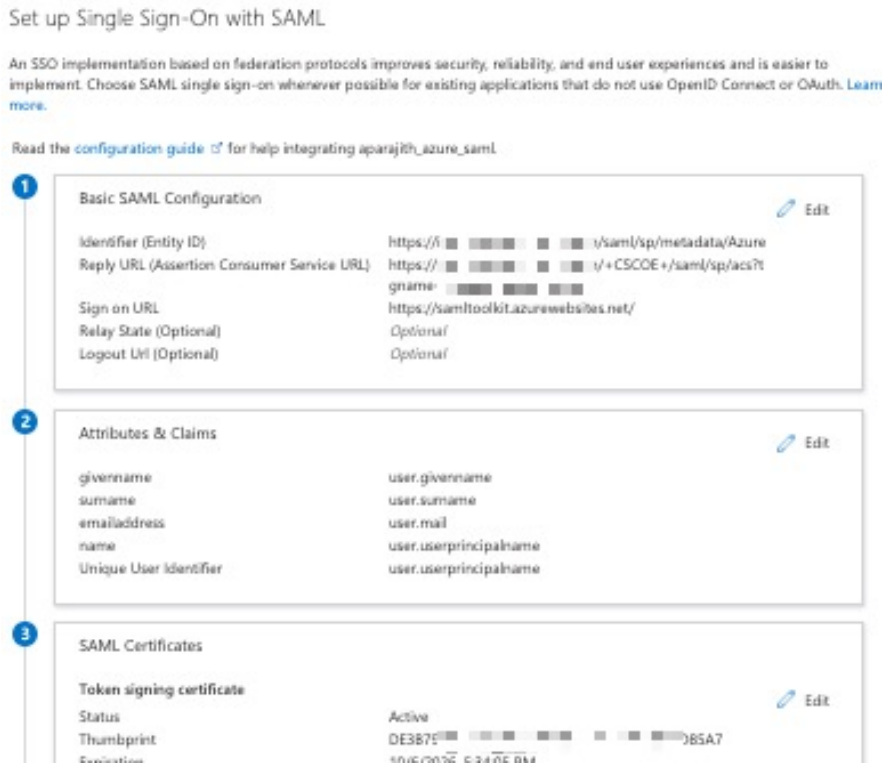
Required information from this step for setting up the Entra ID realm in the Security Cloud Control:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Step 3 Enable the audit log.

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

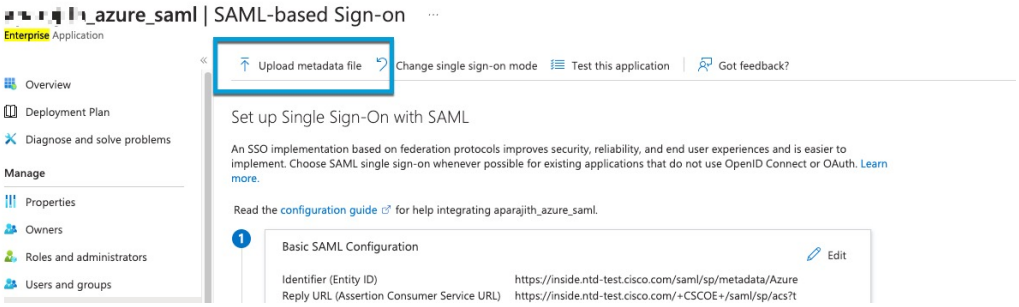
Configure a single sign-on (SSO) app in Entra ID



Create a Microsoft Entra ID app to enable single sign-on (SSO) for users accessing a protected network.

This task discusses how to create an app in Microsoft Entra ID to handle single sign-on (SSO) from Entra ID when a network user attempts to access a protected network.

Procedure



Step 1 In the Microsoft Entra ID portal, click **Enterprise Applications** on the home page and follow the instructions in Configure Microsoft Entra SSO on learn.microsoft.com.

The following figure shows part of the SSO app configuration. You must provide some of the information displayed on this page when you configure the Microsoft Azure AD (SAML) realm. For more information, see Get required information for your Microsoft Azure AD realm (active authentication only), on page 2307.

Step 2 (Optional.) If you have already configured the Microsoft Azure AD (SAML) realm, click **Upload metadata file** at the top of the page to quickly provide configuration values for the SSO app.

The following figure shows an example.

Step 3 Add users and groups to your app as discussed in Add a user account to an enterprise application on learn.microsoft.com

What to do next

See Get required information for your Microsoft Azure AD realm (active authentication only), on page 2307.

Create a decryption rule with decrypt - resign action

This task creates a decryption policy that enables secure inspection and authentication of encrypted traffic using the firewall and the Azure Authentication Service.

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the SAML realm. The realm can authenticate traffic only after it has been decrypted.

Procedure

Step 1 If you haven't done so already, log in to the Security Cloud Control.

Step 2 If you haven't done so already, create an internal certificate authority object to decrypt TLS/SSL traffic as discussed in PKI objects, on page 2986.

Step 3 Click **Policies** > **FTD Policies**.

Step 4 Click **Policies** > **Access Control heading** > **Decryption**.

Step 5 Click **New Policy**.

Step 6 Enter a **Name** and choose a **Default Action** for the policy. Default actions are discussed in Rule-based decryption policy default actions, on page 2179.

Step 7 Click **Save**.

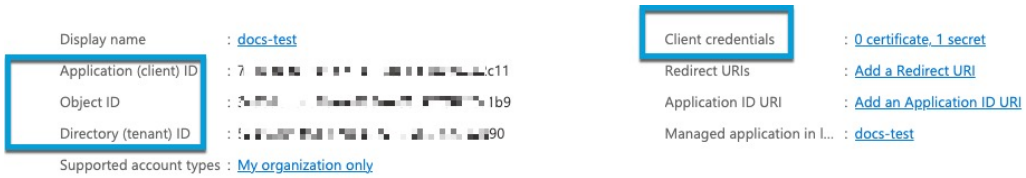
Step 8 At the top of the page, click **Save**.

Get required information for your Microsoft Azure AD realm (active authentication only)

This task explains how to get the information required to set up a Microsoft Azure AD realm (now called *Entra ID*) in the Cloud-Delivered Firewall Management Center.

Follow these steps to get required information for your Microsoft Azure AD realm:

Procedure



Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

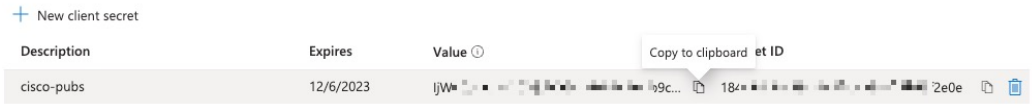
a) At the top of the page, click **Microsoft Entra ID**.

b) In the left column, click **App Registrations**.

c) If necessary, filter the list of displayed apps to show the one you want to use.

d) Click the name of your app.

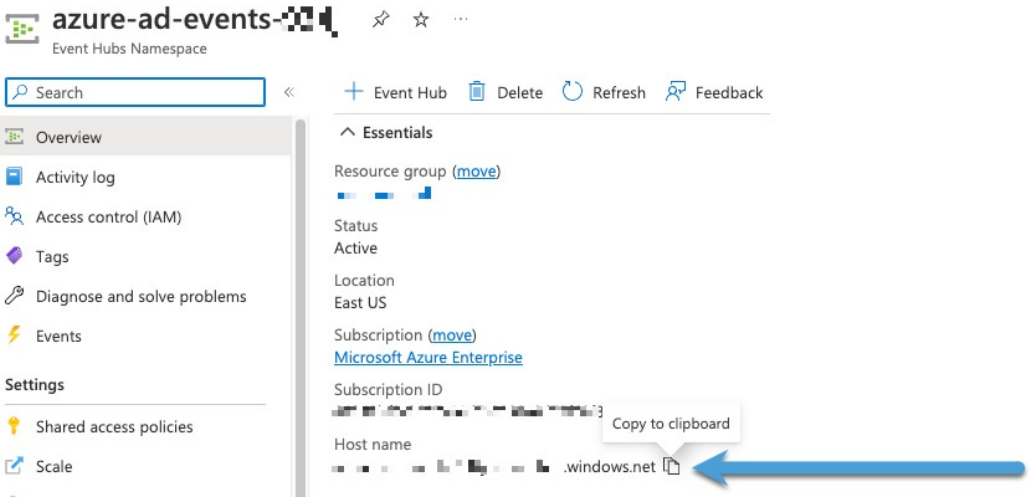
e) Click **Copy** ( ) next to the following values on this page and paste those values to a text file.



- **Application (Client) ID**

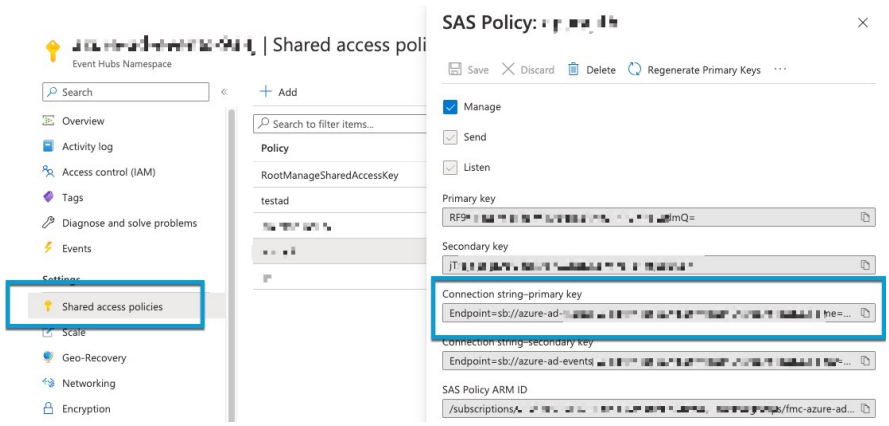
- **Directory (tenant) ID**

f) Click **Client Credentials**.



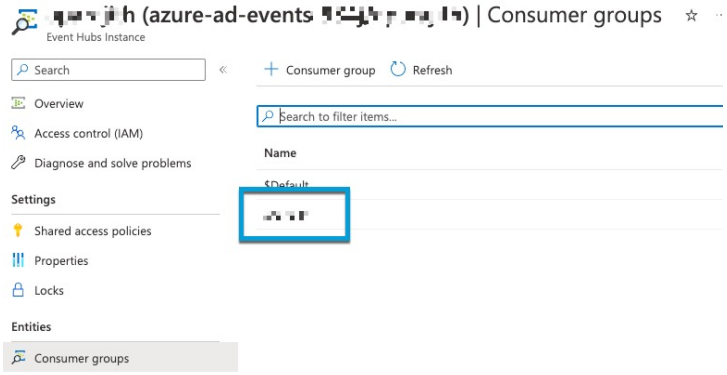
Step 2 Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

a) Click **New Client Secret**.
b) Enter the required information in the provided fields.
c) Click **Add**.
d) Click **Copy** ( ) next to Value as the following figure shows.



Step 3 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

a) In the right pane, click **Copy** ( ) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.

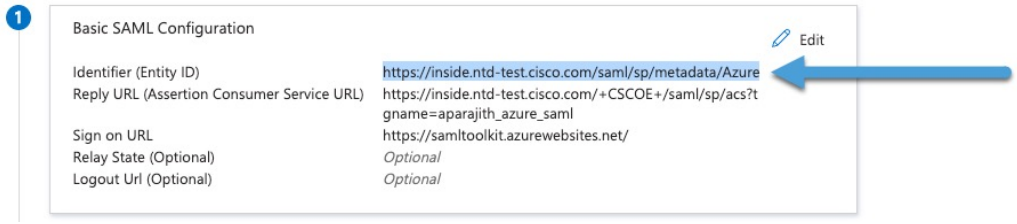


b) Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).
c) In the left pane, under Settings, click **Shared access policies**.
d) Click the name of a policy.
e) Click **Copy** ( ) next to **Connection string-primary key**.

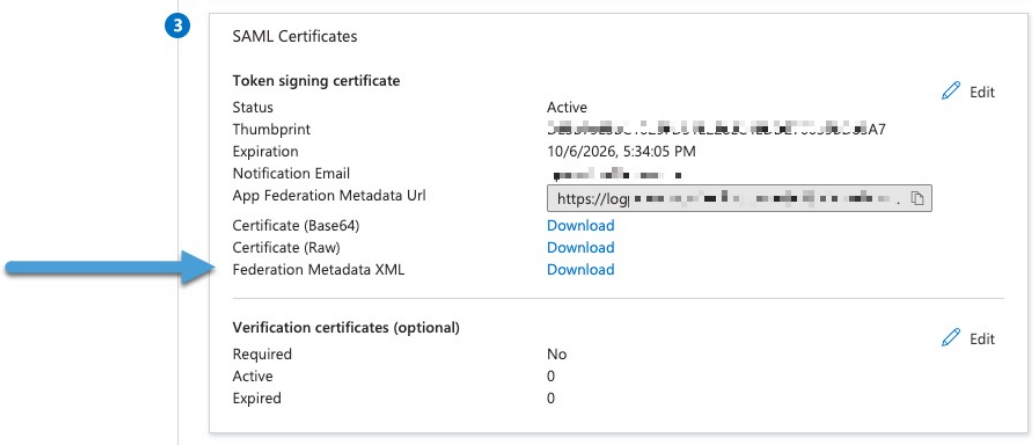
Step 4 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down the following value or copy it to the clipboard. This is your consumer group name.

Step 5 In the left pane, click **Overview**.



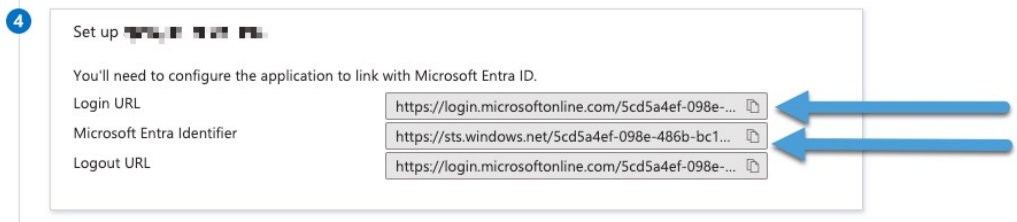
Step 6 Click **Copy** ( ) next to **Namespace**.



This is your event hubs topic name.

Step 7 Return to the home page and log in if necessary: https://portal.azure.com/#home.

a) Click **Microsoft Entra ID**.
b) In the left pane, click **Enterprise Applications.**
c) If necessary, filter the list of applications to locate yours.
d) Click the name of your enterprise application.
e) Click **Get Started** under Set up single sign on.
f) On your SSO app page, copy the value of Identifier (Entity ID) to the clipboard.
The following figure shows an example.



g) On your SSO app page, click the **Download** link next to Federation Metadata XML, as this figure shows. The following figure shows an example.

h) If you've already set up your SSO app, *you can stop here*. The Federation Metadata XML contains all the information required to configure the identity provider in the Cloud-Delivered Firewall Management Center.

i) (Optional if you already downloaded the federation XML.) Click **Copy** ( ) next to both of these values and save them to a text file.
This figure shows an example.

What to do next

See Create a decryption rule with decrypt - resign action, on page 2307.

Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal)

Create a Microsoft Entra ID SAML realm for active authentication where users must authenticate with Microsoft Entra ID before accessing protected resources.

In active authentication (also referred to as *captive portal*), Microsoft Entra ID is the user store. When a user tries to access a protected resource as defined in access control rules, the user must authenticate with Microsoft Entra ID first.

To configure the realm, complete all tasks in the following order.

Procedure

Step 1 Configure Entra ID basic settings, on page 2295.

Step 2 Configure a single sign-on (SSO) app in Entra ID, on page 2305.

Step 3 Get required information for your Microsoft Azure AD realm (active authentication only), on page 2307

Microsoft Azure AD (SAML) realm: SAML details

Set up a Microsoft Entra ID (SAML) realm to enable user authentication through passive or active methods with integration between the Secure Firewall Management Center and Azure AD and identity providers.

This task discusses the first step in a multi-step wizard that creates a Microsoft Azure AD (SAML) realm. You must complete all steps in the wizard to set up your realm. The steps are different depending on whether you create the realm for active or passive authentication.

Before you begin

Complete all tasks before you create your realm:

- (Passive authentication with Cisco ISE only.) If you're using Cisco ISE as the repository for users and groups, set up ISE:
  - How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291
  - How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS, on page 2292
- To use Entra ID as the repository for users and groups, see Configure Microsoft Entra ID for passive authentication, on page 2293.
- Get required information for your realm as discussed in Get required information For Your Microsoft Azure AD realm, on page 2296.

Follow these steps to configure a Microsoft Entra ID (SAML) realm:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 3 Click **Add Realm** > **SAML - Azure AD**.

Step 4 Enter the required information.

Item	Description
Name	Unique name to identify the realm.
Description	(Optional.) Description of the realm.
Identity Provider	Always displays **Azure AD**.
Configuration Type	Click one of these options: • **Passive Authentication with ISE** for passive authentication. • **Passive authentication or captive portal with Azure AD** for to use Entra ID as a user store for either passive authentication or active authentication (that is, captive portal).

Step 5 Click **Next**.

The realm creation wizard advances to the next step based on your selected configuration type.

What to do next

Continue with one of these tasks:

- Passive authentication: Microsoft Azure AD (SAML) realm: Azure AD details, on page 2300.
- Active authentication: Microsoft Azure AD (SAML) realm: SAML service provider (SP) metadata, on page 2312.

Microsoft Azure AD (SAML) realm: SAML service provider (SP) metadata

Configure the SAML service provider metadata to enable secure authentication between your Secure Firewall Threat Defense and Microsoft Entra ID.

This task discusses one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Before you begin

Complete the tasks discussed in Microsoft Azure AD (SAML) realm: SAML details, on page 2299

Follow these steps to configure the SAML service provider metadata:

Procedure

Step 1 Continue from Microsoft Azure AD (SAML) realm: SAML details, on page 2299.

Step 2 Enter the following information.

Item	Description
Base URL	From the list, click the network object you previously created. Network users are directed to this URL when they try to access protected network resources. You can also click **Add** (+) to create an object now.
Entity ID	Your SSO app's entity ID.
Assertion Consumer Services (ACS) URL	Automatically generated from the preceding values.
Service Provider Certificate	From the list, click the certificate to use to decrypt requests to the Secure Firewall Threat Defense. You can also click **Add** (+) to create an object now.
Download Service Provider Metadata	(Optional.) Download the metadata associated with the service provider (that is, managed device) to simplify configuring your Microsoft Entra ID SSO app.

Step 3 Click **Next**.

What to do next

Microsoft Azure AD (SAML) Realm: SAML identity provider (IdP) metadata, on page 2313.

Microsoft Azure AD (SAML) Realm: SAML identity provider (IdP) metadata

Configure SAML identity provider metadata to enable authentication with Microsoft Entra ID in a secure firewall environment.

This task discusses one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Before you begin

Complete the tasks discussed in Microsoft Azure AD (SAML) realm: SAML service provider (SP) metadata, on page 2312.

Follow these steps to configure SAML identity provider metadata:

Procedure

Step 1 Continue from Microsoft Azure AD (SAML) realm: SAML service provider (SP) metadata, on page 2312.

Step 2 If you previously downloaded the Entra ID SSO app's federation XML, click **Upload XML** and upload it now. You can then skip the next step.

Step 3 Enter the following information.

Item	Description
Entity ID	Enter your identity provider's entity ID.
Single Sign on (SSO) URL	Enter the app's SSO URL.
IdP Certificate	From the list, click the certificate to use to authenticate with Microsoft Entra ID. You can also click **Add** (+) to create an object now.

Step 4 Click **Next**.

What to do next

Microsoft Azure AD (SAML) realm: SAML details, on page 2299.

Microsoft Azure AD (SAML) realm: Azure AD details

Configure the Entra ID (SAML) realm to enable authentication and user data management through Azure AD integration.

This task discusses one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
Name	Enter a unique name to identify this realm.
Client Secret	Enter the information you found as discussed in:. • Passive authentication: Create a Microsoft Azure AD realm for passive authentication, on page 2290 • Active authentication: Get required information for your Microsoft Azure AD realm (active authentication only), on page 2307
Tenant ID	
Event Hubs Host Name	
Event Hub Name	
Event Hub Connection String	
(Optional.) **User Groups**	Slide to **Slider enabled** (toggle) to specify groups to include or exclude from policy.

Item	Description
(Optional.) **Excluded User Groups**	If you enter one or more group names in this field, all groups and users they contain *except* these are downloaded and available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive.
(Optional.) **Included User Groups**	If you enter one or more group names in this field, only those groups and users they contain are downloaded and user data is available for user awareness and user control. Enter one group name per line followed by a line break. Group names are case-sensitive. We recommend that you use the Included User Groups field to download only those groups that you intend to monitor with Secure Firewall.

Step 3 Click **Test**.
Make sure the test connection succeeds before you continue to the next step.

Step 4 Click **Next**.

The Entra ID (SAML) realm configuration is completed with Azure AD details, and the connection test confirms successful integration.

Configure Microsoft Azure AD (SAML) realm user session timeout

Set the session timeout to define how long inactive ISE or captive portal user sessions remain active before automatic termination in a Microsoft Entra ID (SAML) realm configuration.

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

This option sets the number of seconds before an inactive session is terminated by the system.

Procedure

Step 1 Continue from the preceding step in the wizard.

Step 2 Enter the following information.

Item	Description
ISE users	Default is 1440 minutes (24 hours).
Captive portal users	Default is 1440 minutes (24 hours).

After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Cloud-Delivered Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Step 3 Click **Save**.

Create a Microsoft Azure AD Realm

You can use a Microsoft Azure Active Directory (AD) realm with Cisco ISE to authenticate users and get user sessions for user control. We get groups from Azure AD and logged-in user session data from Cisco ISE.

Authentication options

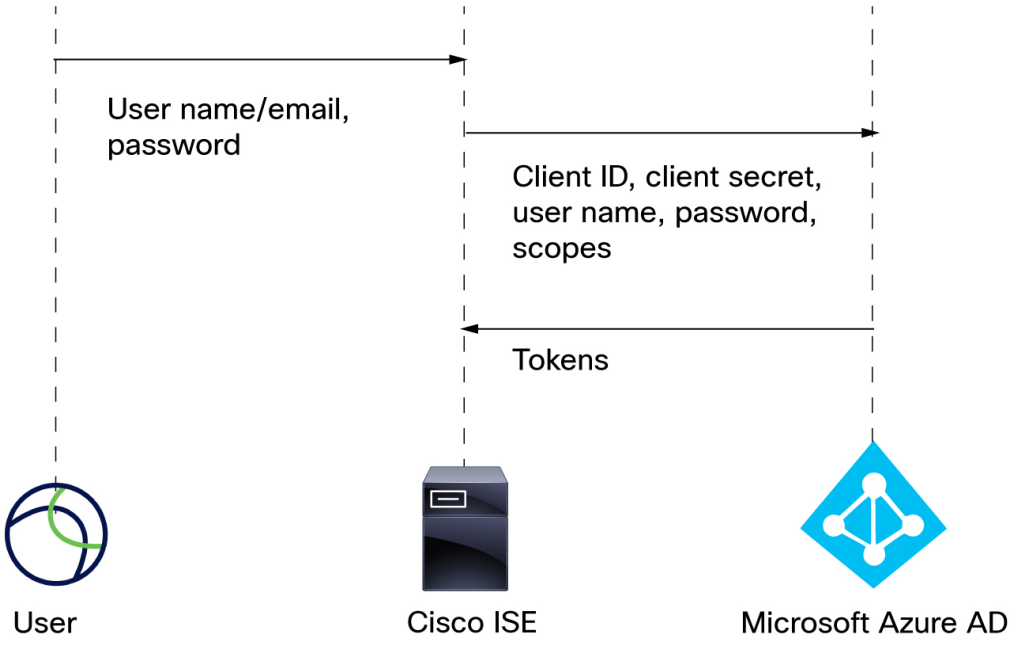
You have two authentication options:

- Resource owned password credentials (ROPC): Enables users to log in with a client like AnyConnect using a user name and password. ISE sends user sessions to the Cloud-Delivered Firewall Management Center. For more information, see How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291.

  Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

- Extensible Authentication Protocol (EAP) Chaining with Tunnel-based Extensible Authentication Protocol (TEAP) and Transport Layer Security (TLS), abbreviated EAP/TEAP-TLS: TEAP is a tunnel-based EAP method that establishes a secure tunnel and executes other EAP methods under the protection of that secured tunnel. ISE is used to validate user credentials and to send user sessions to the Cloud-Delivered Firewall Management Center. For more information, see How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS, on page 2292.

Note Before deploying policies related to a Microsoft Azure AD realm, see User limits for microsoft azure active directory realms, on page 2271.



How Entra ID and Cisco ISE authentication with resource owned password credentials works

Summary

The key components involved in the Entra ID authentication with resource owned password credentials process are:

- User: Logs in with credentials using a VPN client
- Cisco Secure Client: VPN client that sends user credentials
- Entra ID (formerly Azure AD): Validates credentials and issues tokens
- Cisco ISE: Receives tokens and manages user sessions
- Cloud-Delivered Firewall Management Center: Receives user sessions from ISE

Workflow

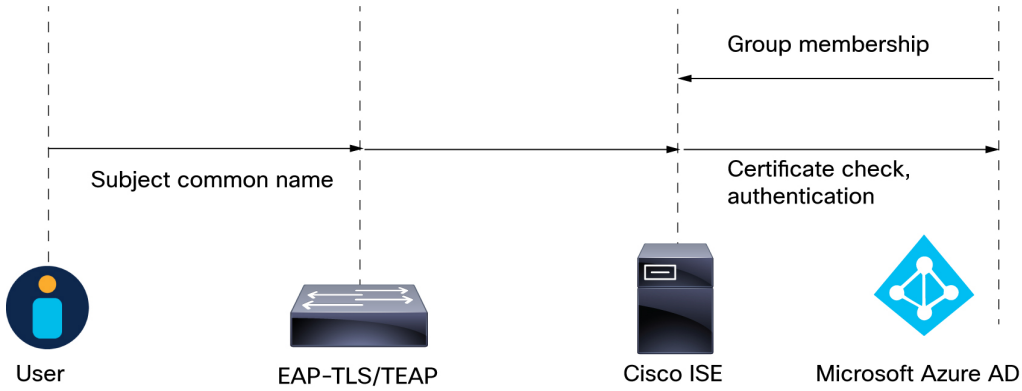
These stages describe how Entra ID and Cisco ISE authentication with resource owned password credentials works:

1. The user logs in with a user name (or email address) and password using a VPN client like Cisco Secure Client.
2. The client ID, client secret, user name, password, and scopes are sent to Entra ID.
3. Tokens are sent from Entra ID to Cisco ISE, which sends user sessions to the Cloud-Delivered Firewall Management Center.

   For details about configuring Cisco ISE, see Configure ISE 3.0 REST ID with Azure Active Directory.

   Additional resource: Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com.

How Entra ID and Cisco ISE authentication works with TEAP/EAP-TLS



Tunnel Extensible Authentication Protocol (TEAP), defined by RFC7170, can be used with ISE and the Security Cloud Control for secure authentication.

Summary

The key components involved in this authentication process are:

- User device: Provides certificate through EAP-TLS or TEAP protocol
- ISE: Validates certificate and performs user lookup through Azure Graph API
- Entra ID: Provides user attributes and group information for authorization

Workflow

These stages describe how the authentication process works and are based on Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory:

1. The user's certificate is sent to ISE through EAP-TLS or TEAP with EAP-TLS as the inner method.
2. ISE evaluates the user's certificate (validity period, trusted certificate authority, certificate revocation list, and so on).
3. ISE takes the certificate subject name (CN) and performs a look-up to the Azure Graph API to fetch the user's groups and other attributes. This is referred to by Azure as User Principal name (UPN).
4. ISE authorization policies are evaluated against the user's attributes returned from Azure.

Create a Microsoft Azure AD realm for passive authentication

Create and configure a Microsoft Azure AD (SAML) (now called *Entra ID*) realm for passive authentication use with the Security Cloud Control.

This configuration enables passive authentication between Microsoft Entra ID and your firewall system through proper realm setup and access control policy integration.

Procedure

Step 1 Configure Microsoft Entra ID.

Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log.

See Configure Microsoft Entra ID for passive authentication, on page 2293.

Step 2 Configure Cisco ISE.

The way you configure ISE depends on how users authenticate with your system. For more information, see Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD, on page 2293.

Step 3 Create a Cisco ISE identity source.

The identity source enables ISE to communicate with the Cloud-Delivered Firewall Management Center.

Step 4 Get the information required to configure your Microsoft Azure AD realm.

This information includes client and tenant IDs, client secret, and other information store in Microsoft Entra ID.

Step 5 Configure and verify your realm.

Test the realm's configuration before you start to use it in access control policies.

Create a Microsoft Azure AD (SAML) realm as discussed in Create a Microsoft Azure AD (SAML) realm, on page 2289

Step 6 Create access control policies and rules using your Microsoft Azure AD (SAML) realm.

Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy.

See Creating a basic access control policy, on page 2004 and Create and edit access control rules, on page 2066.

What to do next

See How Entra ID and Cisco ISE authentication with resource owned password credentials works, on page 2291.

Configure Microsoft Entra ID for passive authentication

Configure Microsoft Entra ID to enable passive authentication and user group synchronization with the Security Cloud Control.

This task provides basic information about how to set up a Microsoft Entra ID (formerly called *Microsoft Azure Active Directory (AD)*) as a realm you can use with the Security Cloud Control. We expect you to already be familiar with Entra ID; if not, consult documentation or a support resource before you get started.

Procedure

Step 1 Grant your Entra ID application the Microsoft Graph permissions.

Grant your Entra ID application the following permissions to Microsoft Graph as discussed in Authorization and the Microsoft Graph Security API on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Security Cloud Control to download users and groups from Entra ID the first time.

Required information from this step for setting up the Entra ID realm in the Security Cloud Control:

- Name of the app you registered
- **Application (client) ID**

- **Client secret**
- **Directory (tenant) ID**

Step 2 Set up an event hub.

Set up the event hub as discussed in Quickstart: Create an event hub using Azure portal on the Microsoft site. The Security Cloud Control uses the event hub audit log to download periodic updates to users and groups.

More information: Features and terminology in Azure Event Hubs.

Important
You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

Required information from this step for setting up the Entra ID realm in the Security Cloud Control:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

Step 3 Enable the audit log.

Enable the audit log as discussed in Tutorial: Stream Azure Active Directory logs to an Azure event hub on the Microsoft site.

Step 4 Configure Cisco ISE for Entra ID.

To send user session information to the Security Cloud Control, configure Cisco ISE for Entra ID as discussed in Configure ISE 3.0 REST ID with Azure Active Directory.

What to do next

See Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD, on page 2293.

Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD

In a Microsoft Azure AD (SAML)Microsoft Azure AD (now called *Entra ID*) realm, it's the responsibility of ISE to send user sessions (login, logout) to the Cloud-Delivered Firewall Management Center. This topic discusses how to set up ISE for use with an Azure AD realm.

Resource owned password credentials authentication

To use ISE with Microsoft Azure AD (SAML)Microsoft Azure ADMicrosoft Azure AD implemented through Representational State Transfer (REST) Identity (ID) service with the help of Resource Owner Password Credentials (ROPC), see Configure ISE 3.0 REST ID with Azure Active Directory.

TEAP/EAP-TLS

To use ISE with authorization policies based on Azure AD group membership and other user attributes with EAP-TLS or TEAP as the authentication protocols, see Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory.

What to do next

Get required information For Your Microsoft Azure AD realm, on page 2296

Get required information For Your Microsoft Azure AD realm

This task enables you to collect the necessary credentials and configuration information from Microsoft Entra ID (formerly Azure AD) and Event Hubs to establish a SAML authentication realm in your Secure Firewall Management Center.

This task explains how to get the information required to set up a Microsoft Azure AD (now called *Entra ID*) realm in the Security Cloud Control. You might have already obtained this information when you set up Microsoft Entra ID as discussed in Configure Microsoft Entra ID for passive authentication, on page 2293.

Procedure

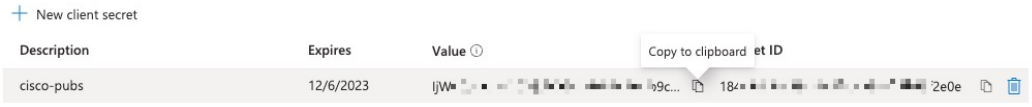
Step 1 Log in to https://portal.azure.com/ as a user with at least the Product Designer role.

Step 2 At the top of the page, click **Microsoft Entra ID**.

Step 3 In the left column, click **App Registrations**.

a) If necessary, filter the list of displayed apps to show the one you want to use.

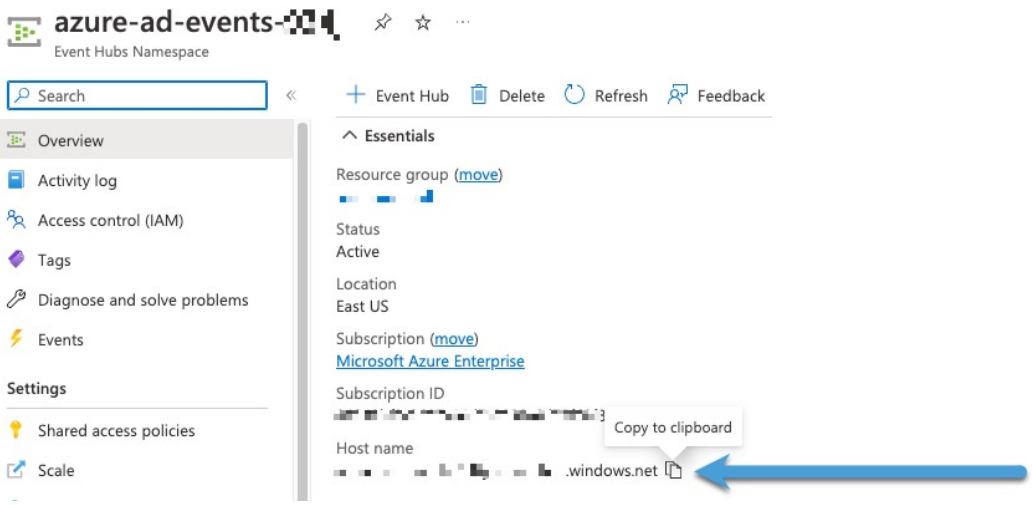
b) Click the name of your app.



c) Click **Copy** ( ) next to the following values on this page and paste those values to a text file.

- **Application (Client) ID**
- **Directory (tenant) ID**

d) Click **Client Credentials**.

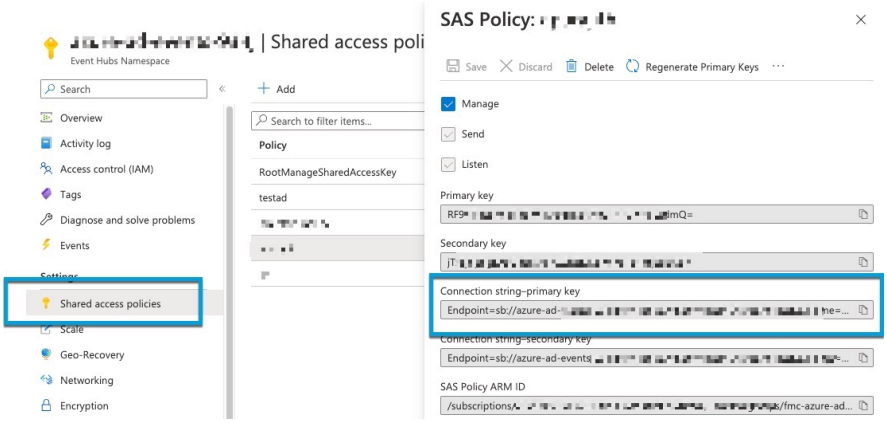


e) Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

1. Click **New Client Secret**.
2. Enter the required information in the provided fields.
3. Click **Add**.
4. Click **Copy** ( ) next to Value as the following figure shows.

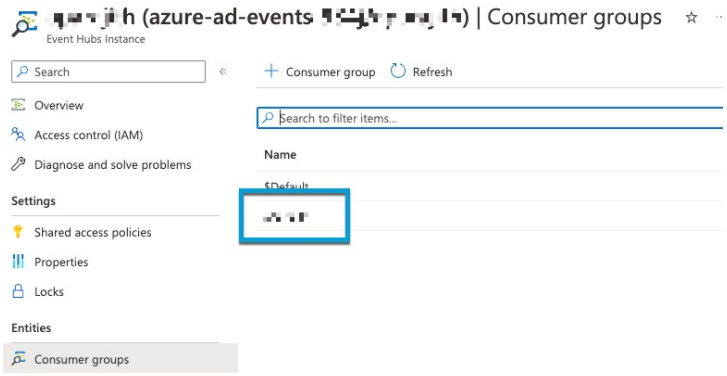
Step 4 From https://portal.azure.com/, click **Event Hubs** > **(name of an event hub)**.

a) In the right pane, click **Copy** ( ) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.



b) Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

c) In the left pane, under Settings, click **Shared access policies**.



d) Click the name of a policy.

e) Click **Copy** ( ) next to **Connection string-primary key**.

Step 5 Click **Overview** > **Entities** > **Event Hubs** > **(name of an event hub)** > **Entities** > **Consumer Groups**.

Write down this value or copy it to the clipboard. This is your consumer group name.

Step 6 In the left pane, click **Overview**.

Step 7 Click **Copy** ( ) next to **Namespace**.

This is your event hubs topic name.

Create an Azure AD realm

This task creates a *realm* (a connection between the Cloud-Delivered Firewall Management Center and a Microsoft Azure AD realm) to enable user and identity control through access control policies.

Note To perform user and identity control with an Azure AD realm, you need only an access control policy with an associated Azure AD realm. You do not need to create an identity policy.

Before you begin

Complete all of the following tasks:

- Configure ISE as discussed in Configure Cisco ISE for Microsoft Azure AD (SAML)Microsoft Azure AD, on page 2293
- Create an ISE identity source as discussed in ISE/ISE-PIC configuration, on page 2382
- Get values required for the Azure AD realm as discussed in Get required information For Your Microsoft Azure AD realm, on page 2296.
- Configure Azure AD as discussed in Configure Microsoft Entra ID for passive authentication, on page 2293

If you enabled Change Management, you must approve all certificates used in this procedure. Open a new ticket or edit an existing one. For more information, see Create change management tickets, on page 175 and .Policies and objects that support change management, on page 169

Follow these steps to create an Azure AD realm:

Procedure

Step 1 Click **Administration** > **Integrations** > **Firewall Management Center** and choose **(select a management center)** > **Devices**

Step 2 Click **Integration** > **Other Integrations** > **Realms** > **Realms**.

Step 3 To create a new realm, click **Add Realm** > **Azure AD**.

Step 4 Enter the required information.

Item	Description
Name	
(Optional.) **Description**	
Client ID	Enter the information you found as discussed in Get required information For Your Microsoft Azure AD realm, on page 2296.
Client Secret	
Tenant ID	
Event Hubs Host Name	
Event Hub Name	
Event Hub Connection String	
(Optional.) **Excluded User Groups**	Enter one or more groups from which to *not* download users for identity control. Users in these groups will not be available for use in access control policies. Enter one group name per line followed by a line break. Group names are case-sensitive.

Step 5 Enter the values you found as discussed in Get required information For Your Microsoft Azure AD realm, on page 2296.

Step 6 Click **Test**.

Step 7 Fix any errors that are displayed in the test.

Step 8 Click **Save**.

What to do next

Create an access control policy and rule as discussed in Creating a basic access control policy, on page 2004.

Azure AD user session timeout

Set the Entra ID user session timeout for ISE or ISE-PIC to define how long users stay authenticated, ensuring network access control after timeout via the User Session Timeout page when editing an Entra ID realm.

The Azure AD user session timeout for ISE/ISE-PIC is available on the **User Session Timeout** page when you edit an Azure AD realm.

The default value 1440 minutes (24 hours). After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the Cloud-Delivered Firewall Management Center as Unknown (except for **Failed Captive Portal Users**).

Create an LDAP realm or an Active Directory realm and realm directory

Before you begin

If you're using Kerberos authentication for captive portal, see the following section before you begin: Prerequisites for kerberos authentication, on page 2281 .

If you have enabled Change Management, you must open or edit, assign, and approve a ticket for each of the following objects before you can create the realm:

- If you're connecting securely to Microsoft AD or LDAP, the server's trusted certificate authority.
- The realm itself.

For more information, see Opening a ticket for configuration changes, on page 176 and Policies and objects that support change management, on page 169.

If you are managing devices with Security Cloud Control (Security Cloud Control), create a proxy sequence first as discussed in Create a proxy sequence, on page 2288 .

Important To reduce latency between the Cloud-Delivered Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Cloud-Delivered Firewall Management Center.

For example, if your Cloud-Delivered Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Cloud-Delivered Firewall Management Center.

The following procedure enables you to create a *realm* (a connection between the Cloud-Delivered Firewall Management Center and an Active Directory realm) and a *directory* (a connection between the Cloud-Delivered Firewall Management Center and an LDAP server or an Active Directory domain controller).

(Recommended.) To connect securely from the Cloud-Delivered Firewall Management Center to your Active Directory server, first perform the following tasks:

- Export the active directory server's root certificate, on page 2329

- Find the active directory server's name, on page 2328

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, refer to 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

For more information about realm and directory configuration fields, see Realm fields, on page 2281 and Realm directory and synchronize fields, on page 2285 .

A step-by-step example of setting up a realm with cross-domain trust is shown in Cross-domain trust setups with Cloud-Delivered Firewall Management Center, on page 2333 .

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, refer to Global Catalog on learn.microsoft.com.

Note You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

Procedure

Step 1 Log in to the Security Cloud Control. Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**

Step 2 To create a new realm, choose from **Add Realm** drop-down list.

Step 3 To perform other tasks (such as enable, disable, or delete a realm), see Manage a realm, on page 2341 .

Step 4 Enter realm information as discussed in Realm fields, on page 2281 .

Step 5 (Optional.) From the **Proxy** list, click a managed device or proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so.

Step 6 In the Directory Server Configuration section, enter directory information as discussed in Realm directory and synchronize fields, on page 2285 .

Step 7 (Optional.) To configure another domain for this realm, click **Add another directory** .

Step 8 Click **Configure Groups and Users** .

Information	Description
AD Primary Domain	Domain for the Active Directory server where users should be authenticated. For additional information, see Realm fields, on page 2281 . You must create the realm with the original domain name of the domain and not any alternative user principal name (UPN) suffixes of the domain. Otherwise, users and groups fail to download and identity policies will not be enforced. For example, if the original domain is `domain.example.com` and the alternative UPN name is`domain2.mydomain.com`, you must configure the realm to use `domain.example.com`. For more information about configuring an alternative UPN suffix, see a resource like Configuring Alternate Login ID on learn.microsoft.com.
Base DN	The directory tree on the server where the Cloud-Delivered Firewall Management Center should begin searching for user data.
Group DN	The directory tree on the server where the Cloud-Delivered Firewall Management Center should begin searching for group data.
Proxy	From the list, click one or more managed devices or a proxy sequence. These devices must be able to communicate with Active Directory or ISE/ISE-PIC to retrieve user data for identity policies.
Load Groups	Click to load groups from the Active Directory server. If no groups are displayed, enter or edit information in the **AD Primary Domain** , **Base DN** , and **Group DN** fields and click **Load Groups** . For more information about those fields, see Realm fields, on page 2281 .
Available Groups section	Limit the groups to use in policy by moving them to either the **Included Groups and Users** or **Excluded Groups and Users** list. Moving one group to the **Included Groups and Users** list, for example, allows that group only to be used in policy but excludes all other groups. Groups in the **Excluded Groups and Users** and the users they contain are excluded from user awareness and control. All other groups and users *are* available. For more information, see Realm directory and synchronize fields, on page 2285 .

Configure the Realm

Before you begin

You must have created a new realm and its groups and users, as described in the prior procedure.

Procedure

Step 1 Click the **Realm Configuration** tab.

Step 2 Enter **Group Attribute** , and (if you use Kerberos authentication for captive portal) enter **AD Join Username** and **AD Join Password** . For more information, see Realm directory and synchronize fields, on page 2285 .

Step 3 If you use Kerberos authentication, click **Test** . If the test fails, wait a short time and try again.

Step 4 Enter user session timeout values, in minutes, for **ISE/ISE-PIC Users** , **Terminal Server Agent Users** , **Captive Portal Users** , **Failed Captive Portal Users** , and **Guest Captive Portal Users** .

Step 5 When you're finished configuring the realm, click **Save** .

Connect securely to Active Directory or LDAP

To create a secure connection between an Active Directory or LDAP server and the Cloud-Delivered Firewall Management Center (which we strongly recommend), you must perform all of the following tasks:

- Export the server's *root* certificate.
- Import the root certificate into the Cloud-Delivered Firewall Management Center as a trusted CA certificate (**Objects** > **Object Management** > **PKI** > **Trusted CAs**).
- Find the server's fully qualified name.
- Create the realm directory.

Related Topics

Export the active directory server's root certificate, on page 2329
Find the active directory server's name, on page 2328
Create an LDAP realm or an Active Directory realm and realm directory, on page 2325

Find the active directory server's name

Find the fully qualified server name in Microsoft Active Directory that you need to configure a realm directory.

To configure a realm directory in the Cloud-Delivered Firewall Management Center, you must know the fully qualified server name, which you can find as discussed in the procedure that follows.

These tasks apply to Microsoft Active Directory only. If you use LDAP, consult an appropriate reference for the procedure.

Before you begin

You must log in to the Active Directory server as a user with sufficient privileges to view the computer's name.

Follow these steps to find the Active Directory server's name:

Procedure

Step 1 Log in to the Active Directory server.

Step 2 Click **Start**.

Step 3 Right-click **This PC**.

Step 4 Click **Properties**.

Step 5 Click **Advanced System Settings**.

Step 6 Click the **Computer Name** tab.

Step 7 Note the value of **Full computer name**.
You must enter this exact name when you configure the realm directory in the Cloud-Delivered Firewall Management Center.

What to do next

Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Related Topics

Export the active directory server's root certificate, on page 2329

Export the active directory server's root certificate

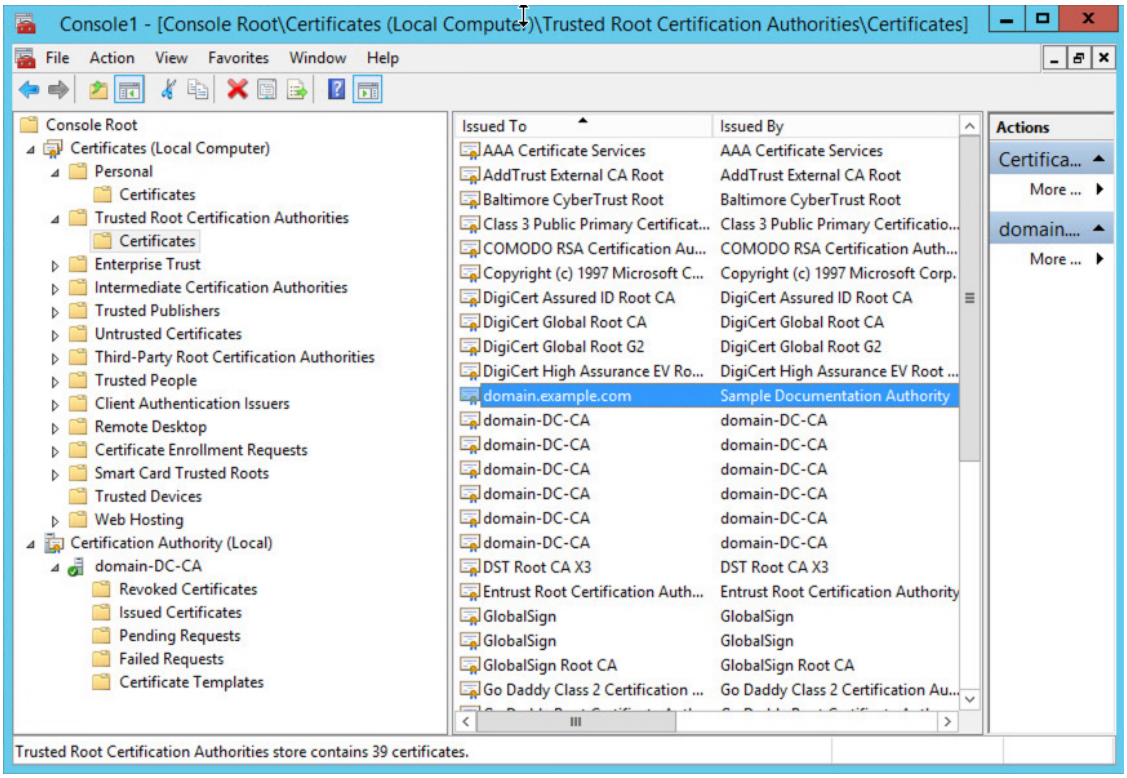
Export the Active Directory server's root certificate to enable secure connection to the Cloud-Delivered Firewall Management Center for obtaining user identity information and authentication purposes.

The task that follows discusses how to export the Active Directory server's root certificate, which is required to connect securely to the Cloud-Delivered Firewall Management Center to obtain user identity information.

These tasks apply to Microsoft Active Directory only. If you use LDAP, consult an appropriate reference for the procedure.

Before you begin

You must know the name of your Active Directory server's root certificate. The root certificate might have the same name as the domain or the certificate might have a different name. The procedure that follows shows one way you can find the name; there could be other ways, however.



Follow these steps to export the Active Directory server's root certificate:

Procedure

Step 1 Find the name of the Active Directory Server's root certificate using the Microsoft Management Console.

This is one way to find the name of the Active Directory Server's root certificate; consult Microsoft documentation for more information:

a) Log in to the Active Directory server as a user with privileges to run the Microsoft Management Console.
b) Click **Start** and enter **mmc**.
c) Click **File** > **Add/Remove Snap-in**
d) From the Available Snap-ins list in the left pane, click **Certificates (local)**.
e) Click **Add**.
f) At the Certificates snap-in dialog box, click **Computer Account** and click **Next**.
g) At the Select Computer dialog box, click **Local Computer** and click **Finish**.
h) *Windows Server 2012 only*. Repeat the preceding steps to add the Certification Authority snap-in.
i) Click **Console Root** > **Trusted Certification Authorities** > **Certificates**.
The server's trusted certificates are displayed in the right pane. The following figure is only an example for Windows Server 2012; yours will probably look different.

Step 2 Export the certificate using the **certutil** command.

This is only one way to export the certificate. It is a convenient way to export the certificate, especially if you can run a web browser and connect to the Cloud-Delivered Firewall Management Center from the Active Directory server.

a) Click **Start** and enter **cmd**.
b) Enter the command **certutil -CA.cert** *certificate-name*.
The server's certificate is displayed on the screen.
c) Copy the entire certificate to the clipboard, starting with **-----BEGIN CERTIFICATE-----** and ending with **-----END CERTIFICATE-----** (including those strings).

What to do next

Import the Active Directory server's certificate into the Cloud-Delivered Firewall Management Center as a trusted CA certificate as discussed in Add a trusted CA object, on page 2993.

Related Topics

Find the active directory server's name, on page 2328

Synchronize users and groups

This task synchronizes users and groups from Active Directory domains to enable their use in identity policies.

Synchronizing users and groups means the Cloud-Delivered Firewall Management Center queries the realms and directories you configured for groups and users in those groups. All users the Cloud-Delivered Firewall Management Center finds can be used in identity policies.

If issues are found, you most likely need to add a realm that contains users and groups the Cloud-Delivered Firewall Management Center cannot load. For details, see Realms and trusted domains, on page 2275.

Before you begin

Create a Cloud-Delivered Firewall Management Center *realm* for each Active Directory domain and a Cloud-Delivered Firewall Management Center *directory* for each Active Director domain controller in each forest. See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

You must create a realm only for domains that have users you want to use in user control.

You can nest Microsoft AD groups and the Cloud-Delivered Firewall Management Center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

You must create the realm with the original domain name of the domain and not any alternative user principal name (UPN) suffixes of the domain. Otherwise, users and groups fail to download and identity policies will not be enforced. For example, if the original domain is `domain.example.com` and the alternative UPN name is`domain2.mydomain.com`, you must configure the realm to use `domain.example.com`. For more information about configuring an alternative UPN suffix, see a resource like Configuring Alternate Login ID on learn.microsoft.com.

Follow these steps to synchronize users and groups:

Procedure

Step 1 Log in to the Security Cloud Control.

Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 3 Next to each realm, click **Download** ( ).

Step 4 To see the results, click the **Sync Results** tab.
The Realms column indicates whether or not there were issues synchronizing users and groups in Active Directory forests. Look for the following indicators next to each realm.

Indicator in Realms column	Meaning
(nothing)	All users and groups synchronized without error. No action is necessary.
Yellow Triangle ( )	There were issues synchronizing users and groups. Make sure you added a realm for each Active Directory domain and a directory for each Active Directory domain controller. For more details, see Troubleshoot cross-domain trust, on page 2345.

Create a realm sequence

Creating a realm sequence provides an ordered list of realms the system searches when it applies identity policy, allowing you to specify the priority order for user authentication across multiple Active Directory servers.

The following procedure enables you to create a realm sequence, which is an ordered list of realms the system searches when it applies identity policy. You add a realm sequence to an identity rule exactly the same way as you add a realm; the difference is that the system searches all the realms in the order specified in the realm sequence when applying an identity policy.

Before you begin

You must create and enable at least two realms, each corresponding to a connection with an Active Directory server. You cannot create realm sequences for LDAP realms.

Create a realm as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Follow these steps to create a realm sequence:

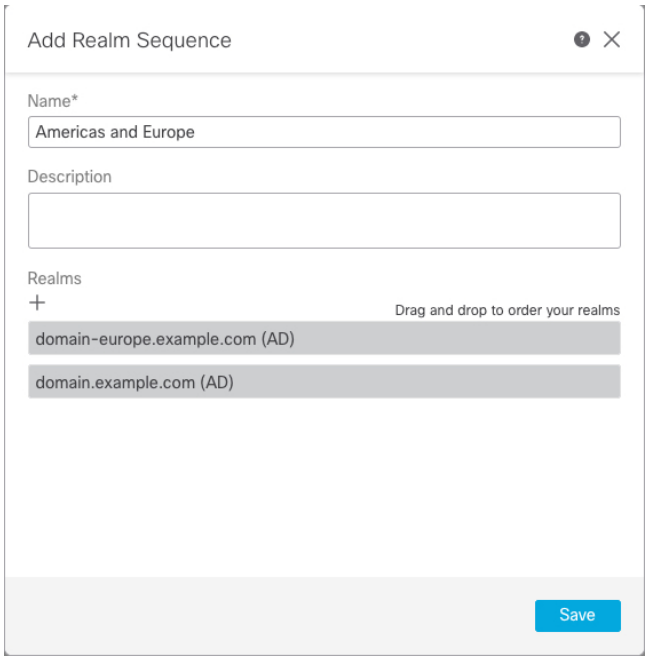
Procedure

Step 1 Log in to the Security Cloud Control and click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 2 Under the **Realm Sequences** tab, click **Add Sequence**.

Step 3 In the **Name** field, enter a name to identify the realm sequence.

Step 4 (Optional.) In the **Description** field, enter a description for the realm sequence.



Step 5 Under Realms, click **Add** (+).

Step 6 Click the name of each realm to add to the sequence.

To narrow your search, enter all or part of a realm name in **Filter** field.

Click **OK**.

Step 7 In the Add Realm Sequence dialog box, drag and drop the realms in the order in which you want the system to search for them.
The following figure shows an example of a realm sequence consisting of two realms. The **domain-europe.example.com** realm will be searched for users before the **domain.example.com** realm.

Step 8 Click **Save**.

What to do next

See Create an identity policy, on page 2507.

Cross-domain trust setups with Cloud-Delivered Firewall Management Center

A cross-domain trust setup allows discovery and use of users and groups from multiple domains in access control policies.

This is an introduction to several topics that walk you through configuring the Cloud-Delivered Firewall Management Center with two realms having cross-domain trust.

Example setup configuration

This step-by-step example involves two forests: **forest.example.com** and **eastforest.example.com**. The forests are configured so that certain users and groups in each forest can be authenticated by Microsoft AD in the other forest.

The example setup uses this configuration:

Using this example, you would set up the Cloud-Delivered Firewall Management Center with these components:

- Realm and directory for any domain in **forest.example.com** that contains users you want to control with access control policy
- Realm and directory for any domain in **eastforest.example.com** that contains users you want to control with access control policy

Each realm in the example has one domain controller, which is configured in the Cloud-Delivered Firewall Management Center as a directory. The directories in this example are configured as follows:

- **forest.example.com**
  - Base distinguished name (DN) for users: **ou=UsersWest,dc=forest,dc=example,dc=com**
  - Base DN for groups: **ou=EngineringWest,dc=forest,dc=example,dc=com**
- **eastforest.example.com**
  - Base DN for users: **ou=EastUsers,dc=eastforest,dc=example,dc=com**
  - Base DN for groups: **ou=EastEngineering,dc=eastforest,dc=example,dc=com**

Related Topics

Configure Security Cloud Control for cross-domain-trust step 1: Configure realms and directories, on page 2334

Configure Security Cloud Control for cross-domain-trust step 1: Configure realms and directories

This task configures the Cloud-Delivered Firewall Management Center to recognize Active Directory servers in a cross-domain trust relationship, enabling the discovery and use of users and groups from multiple domains in access control policies.

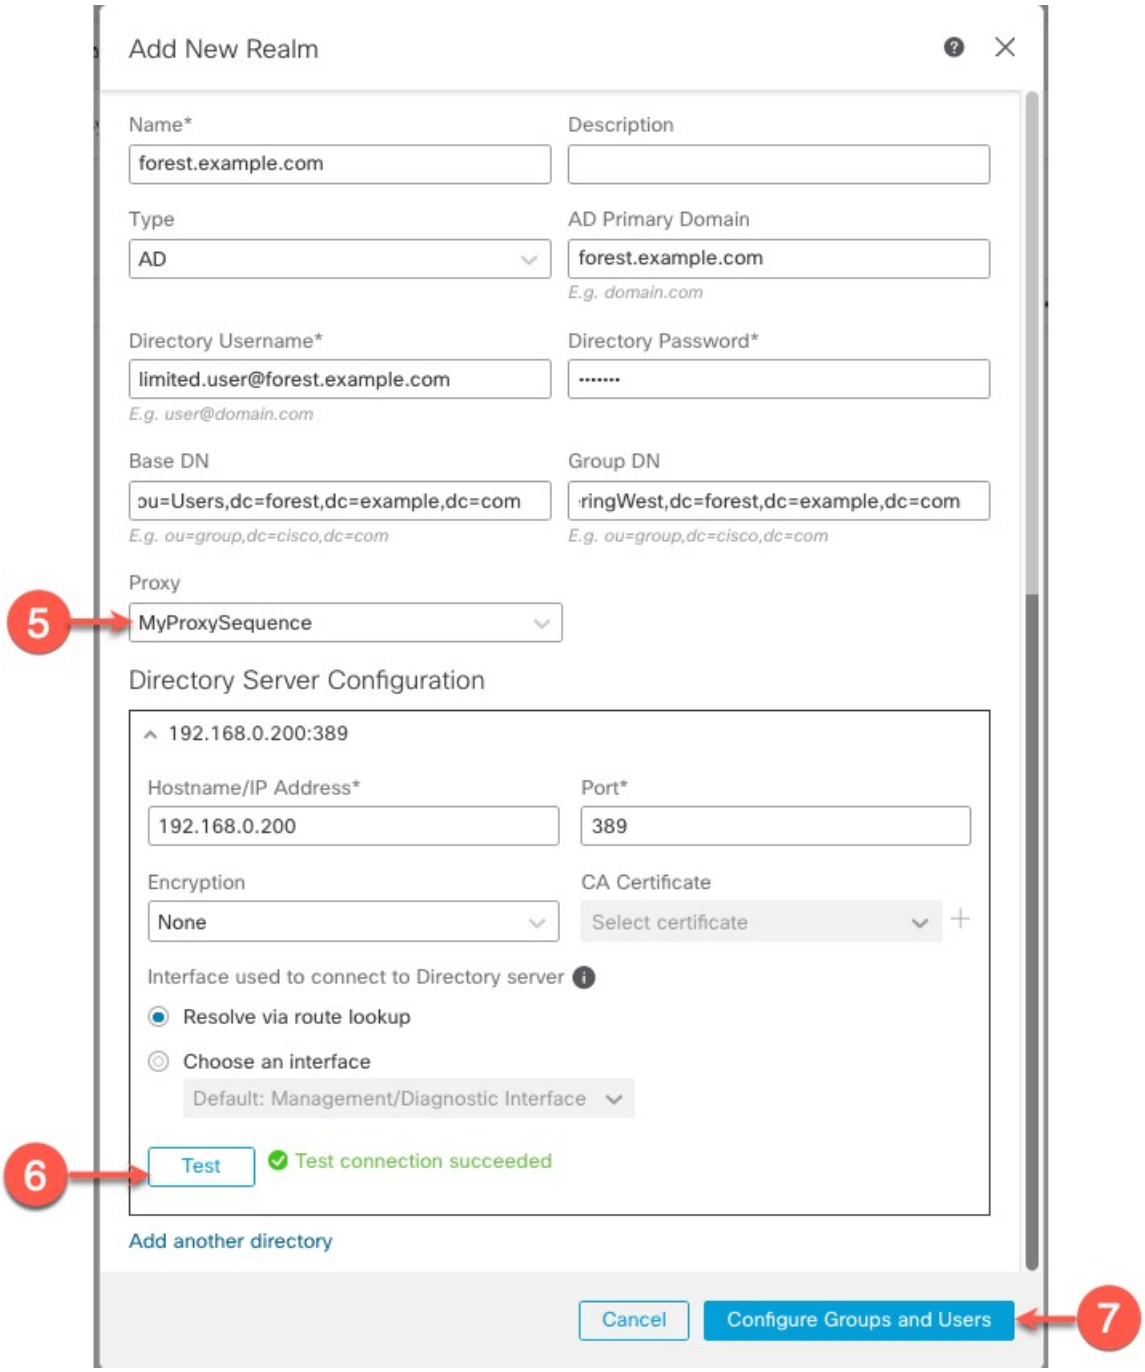
This is the first task in a step-by-step procedure that explains how to configure the Cloud-Delivered Firewall Management Center to recognize Active Directory servers configured in a cross-domain trust relationship, which is an increasingly common configuration for enterprise organizations. For an overview of this sample configuration, see Cross-domain trust setups with Cloud-Delivered Firewall Management Center, on page 2333.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 foreign security principals (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

Before you begin

You must configure Microsoft Active Directory servers in a cross-domain trust relationship; see Realms and trusted domains, on page 2275 for more information.

If you authenticate users with LDAP, you *cannot* use this procedure.



Procedure

Step 1 Log in to the Security Cloud Control.

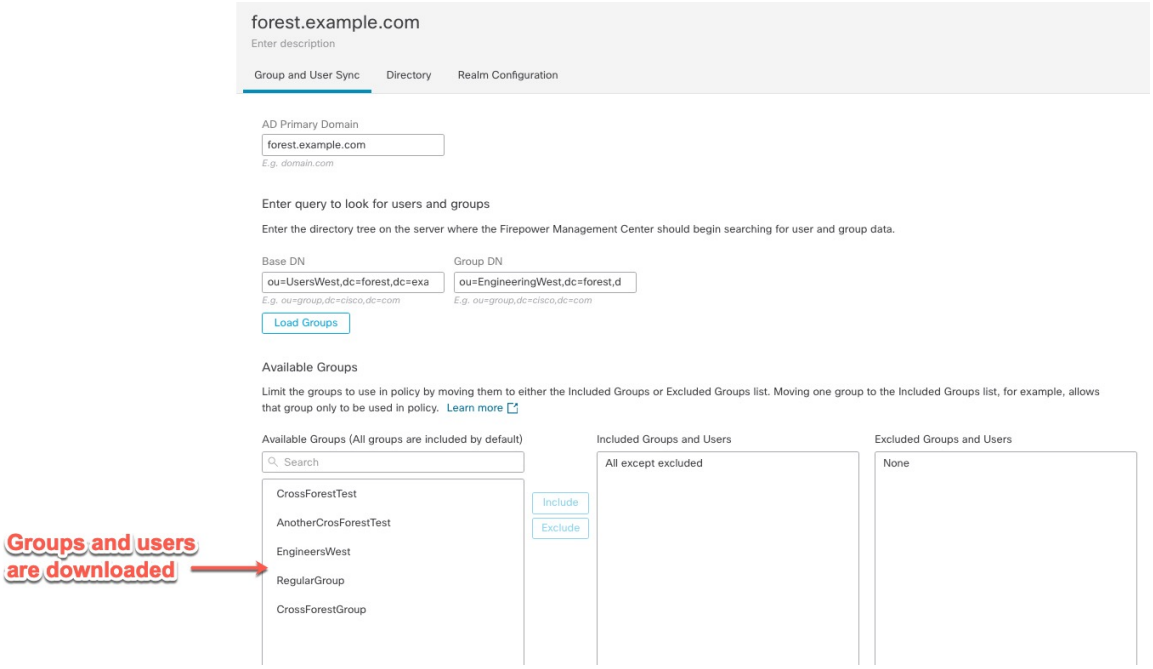
Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 3 Click **Add Realm** > **Active Directory/LDAP**.

Step 4 Enter the following information to configure **forest.example.com**.

Note
The **Directory Username** can be any user in the Active Directory domain; no special permissions are required.

The **Interface used to connect to Directory server** can be any interface that can connect to the Active Directory server.



Step 5 **Proxy** is an optional managed device or proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so.

For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

Step 6 Click **Test** and make sure the test succeeds before you continue.

Step 7 Click **Configure Groups and Users**.

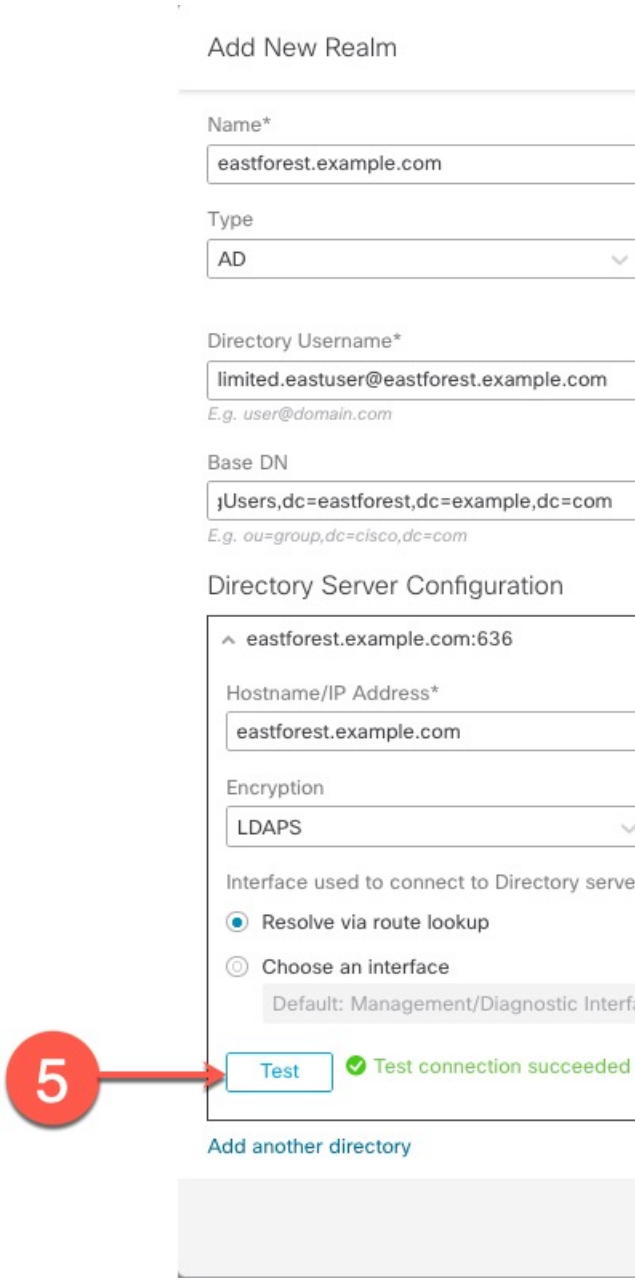
Step 8 Verify your configuration was successful by checking that the next page is displayed similar to the following.

Note
If groups and users were not downloaded, verify the values in the **Base DN** and **Groups DN** fields and click **Load Groups**.

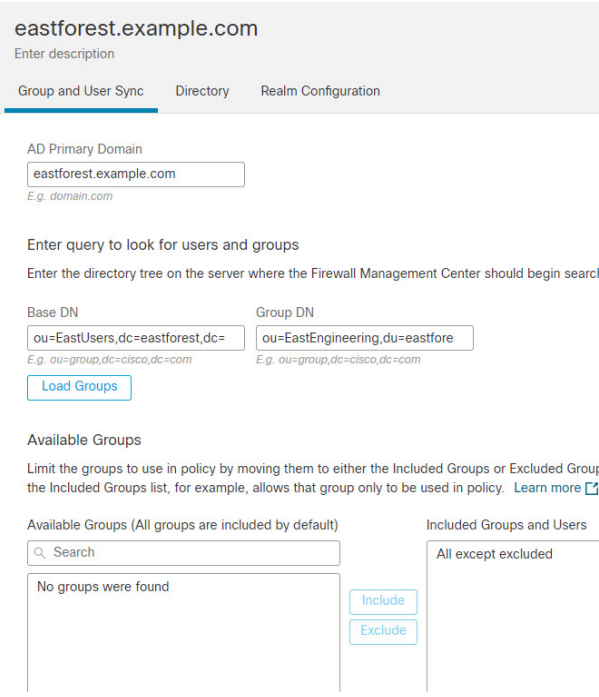
There are other optional configurations available on this page; for more information about them, see Realm fields, on page 2281 and Realm directory and synchronize fields, on page 2285.

Step 9 If you made changes on this page or tab pages, click **Save**.

Create another realm



Before you begin



Complete the configuration of your first realm as in the prior task.

Follow these steps to create another realm.

Procedure

	Command or Action	Purpose
Step 1	Click **Integration** > **Other Integrations** > **Realms** > **Realms**.	

	Command or Action	Purpose
Step 2	Click **Add Realm**.	
Step 3	Enter the following information to configure **eastforest.example.com**.	
Step 4	Click **Test** and make sure the test succeeds before you continue.	
Step 5	Click **Configure Groups and Users**.	

	Command or Action	Purpose
Step 6	Verify your configuration was successful by checking that the next page is displayed similar to the following.	

You have successfully configured two realms (**forest.example.com** and **eastforest.example.com**) with their respective directories.

Configure the Security Cloud Control for cross-domain trust Step 2: Synchronize users and groups

This task allows you to download users and groups from Active Directory servers with cross-domain trust relationships to synchronize identity data in the Secure Firewall Management Center and resolve download issues by verifying directory setup and device communication.

After you configure two or more Active Directory servers that have a cross-domain trust relationship, you must download users and groups. That process exposes possible issues with the Active Directory configuration (for example, groups or users downloaded for one Active Directory domain but not the other).

Before you begin

Make sure you have performed the tasks discussed in Configure Security Cloud Control for cross-domain-trust step 1: Configure realms and directories, on page 2334.

Procedure

Step 1 Log in to the Security Cloud Control.

Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 3 At the end of the row of any realm in the cross-domain trust, click **Download Now**( ), then click **Yes**.

Step 4 Click **Check Mark** ( ) (Notifications) > **Tasks**.

If groups and users fail to download, try again. If subsequent attempts fail, review your realm and directory setup as discussed in Realm fields, on page 2281 and Realm directory and synchronize fields, on page 2285.

If you're using a proxy or proxy sequence, make sure all managed devices can communicate with Active Directory or ISE/ISE-PIC. If more than one managed device can communicate with ISE/ISE-PIC, we strongly recommend you set up a proxy sequence for the realm as discussed in Create a proxy sequence, on page 2288

Step 5 Click **Integration** > **Other Integrations** > **Realms** > **Sync Results**.

Related Topics

Configure the Security Cloud Control for cross-domain trust step 3: Resolve issues, on page 2340

Configure the Security Cloud Control for cross-domain trust step 3: Resolve issues

This task enables you to make sure users and groups are downloaded without errors during cross-domain trust setup.

The final step in setting up cross-domain trust in the Cloud-Delivered Firewall Management Center is to make sure users and groups are downloaded without errors. A typical reason why users and groups do not download properly is that the realms to which they belong have not been downloaded to the Cloud-Delivered Firewall Management Center.

This topic discusses how to diagnose that a group referred in one forest to cannot be downloaded because the realm is not configured to find the group in the domain controller hierarchy.

Procedure

Step 1 Log in to the Security Cloud Control.

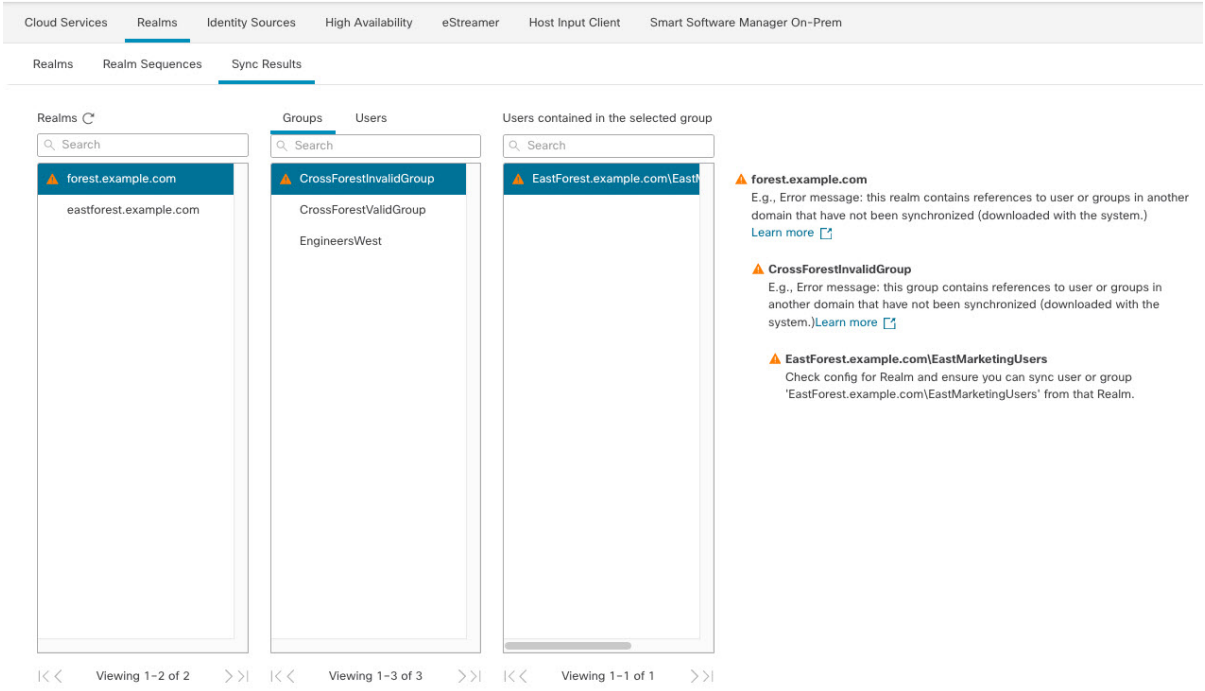
Step 2 Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

In the Realms column, if **Yellow Triangle** ( ) is displayed next to the name of a realm, you have issues that must be resolved. If not, your results are configured properly and you can quit.

Step 3 Download users and groups again from the realms that display issues.

a) Click the **Realms** tab.

b) Click (Download Now), then click **Yes**.



Step 4 Click the **Sync Results** tab page.

If the **Yellow Triangle** ( ) is displayed in the Realms column, click **Yellow Triangle** ( ) next to the realm that has issues.

Step 5 In the middle column, click either **Groups** or **Users** to find more information.

Step 6 In the Groups or Users tab page, click **Yellow Triangle** ( ) to display more information.

The right column should display enough information you can isolate the source of the issue.

In the preceding example, **forest.example.com** includes a cross-domain group **CrossForestInvalidGroup** that contains another group **EastMarketingUsers** that was not downloaded by the Cloud-Delivered Firewall Management Center. If, after synchronizing the **eastforest.example.com** realm again, the error does not resolve, it likely means that the Active Directory domain controller does not include **EastMarketingUsers**.

To resolve this issue, you can:

- Remove the **EastMarketingUsers** from **CrossForestInvalidGroup**, synchronize the **forest.example.com** realm again, and recheck.
- Remove the **ou=EastEngineering** value from the **Group DN** of the **eastforest.example.com** realm, which causes the Cloud-Delivered Firewall Management Center to retrieve groups from the highest level in the Active Directory hierarchy, synchronize **eastforest.example.com**, and recheck.

Manage a realm

This task enables you to perform various maintenance operations on realms to manage authentication and user access control.

This section discusses how to perform various maintenance tasks for a realm using controls on the Realms page:

Procedure

Step 1 Log in to the Security Cloud Control. Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 2 To delete a realm, click **Delete** ( ).

Step 3 To edit a realm, click **Edit** ( ) next to the realm and make changes as described in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Step 4 To enable a realm, slide **State** to the right; to disable a realm, slide it to the left.

Step 5 To download users and user groups, click **Download** ( ).

Step 6 To copy a realm, click **Copy** ( ).

Step 7 To compare realms, see Compare realms, on page 2342.

Compare realms

Use this task to compare identity realms in the Secure Firewall Management Center to review differences between selected realms, generate comparison reports, and analyze changes to support identity integration management.

You must be an Admin, Access Admin, Network Admin, or Security Approver to perform this task.

Procedure

Step 1 Log in to the Security Cloud Control. Click **Policies** > **Firewall Threat Defense** > **Integrations** > **Other Integrations** > **Realms**.

Step 2 Click **Compare Realms**.

Step 3 Choose **Compare Realm** from the **Compare Against** list.

Step 4 Choose the realms you want to compare from the **Realm A** and **Realm B** lists.

Step 5 Click **OK**.

Step 6 To navigate individually through changes, click **Previous** or **Next** above the title bar.

Step 7 (Optional.) Click **Comparison Report** to generate the realm comparison report.

Step 8 (Optional.) Click **New Comparison** to generate a new realm comparison view.

Troubleshoot realms and user downloads

If you notice unexpected server connection behavior, consider tuning your realm configuration, device settings, or server settings. For other related troubleshooting information, see:

- Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues, on page 2399
- Troubleshoot the TS agent identity source, on page 2502
- Troubleshoot the captive portal identity source, on page 2369
- Troubleshooting guidelines for remote access VPN identity source, on page 2497
- Troubleshoot user control, on page 2526

Users are not downloaded

Possible causes include:

- If you have the realm **Type** configured incorrectly, users and groups cannot be downloaded because of a mismatch between the attribute the system expects and what the repository provides. For example, if you configure **Type** as **LDAP** for a Microsoft Active Directory realm, the system expects the `uid` attribute, which is set to `none` on Active Directory. (Active Directory repositories use `sAMAccountName` for the user ID.)

  Solution: Set the realm **Type** field appropriately: **AD** for Microsoft Active Directory or **LDAP** for another supported LDAP repository.

- Users in Active Directory groups that have special characters in the group or organizational unit name might not be available for identity policy rules. For example, if a group or organizational unit name contains the characters asterisk (*), equals (=), or backslash (\), users in those groups are not downloaded and can't be used for identity policies.

  Solution: Remove special characters from the group or organizational unit name.

- If your managed device connects to Cloud-Delivered Firewall Management Center through its data interface, and a LDAP or Active Directory (AD) server is behind this managed device, the managed device acts as a proxy for the AD server traffic. Because the AD server is in the internal network, it might drop some request packets. This can cause realm download or test connection to fail.

  Solution: Create a flex config object with **ip-clien** *interface-name* and deploy it to to the device. Then download the users and groups.

Important To reduce latency between the Cloud-Delivered Firewall Management Center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the Cloud-Delivered Firewall Management Center.

For example, if your Cloud-Delivered Firewall Management Center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

Not all users in a realm are downloaded

Possible causes include:

- If you attempt to download more than the maximum number of users in any one realm, the download stops at the maximum number of users and a health alert is displayed. User download limits are set per Cloud-Delivered Firewall Management Center model.

- Every user must be a member of a group. Users that are members of no groups do not get downloaded.

Access control policy doesn't match group membership

This solution applies to an AD domain that is in a trust relationship with other AD domains. In this discussion, *external domain* means a domain other than the one to which the user logs in.

If a user belongs to a group defined in a trusted external domain, the Cloud-Delivered Firewall Management Center doesn't track membership in the external domain. For example, consider this scenario:

- Domain controllers 1 and 2 trust each other
- Group A is defined on domain controller 2
- User `mparvinder` in controller 1 is a member of Group A

Even though user `mparvinder` is in Group A, the Cloud-Delivered Firewall Management Center access control policy rules specifying membership Group A don't match.

Solution: Create a similar group in domain controller 1 that contains has all domain 1 accounts that belong to group A. Change the access control policy rule to match any member of Group A or Group B.

Access control policy doesn't match child domain membership

If a user belongs to a domain that is child of parent domain, Firepower doesn't track the parent/child relationships between domains. For example, consider this scenario:

- Domain `child.parent.com` is child of domain `parent.com`
- User `mparvinder` is defined in `child.parent.com`

Even though user `mparvinder` is in a child domain, the Firepower access control policy matching the `parent.com` don't match `mparvinder` in the `child.parent.com` domain.

Solution: Change the access control policy rule to match membership in either `parent.com` or `child.parent.com`.

Realm or realm directory test fails

The **Test** button on the directory page sends an LDAP query to the hostname or IP address you entered. If it fails, check these items:

- The **Hostname** you entered resolves to the IP address of an LDAP server or Active Directory domain controller.
- The **IP Address** you entered is valid.

The **Test AD Join** button on the realm configuration page verifies these items:

- DNS resolves the **AD Primary Domain** to an LDAP server or Active Directory domain controller's IP address.
- The **AD Join Username** and **AD Join Password** are correct.

  AD Join Username must be fully qualified (for example, **`administrator@mydomain.com`**, *not* **`administrator`**).

- The user has sufficient privileges to create a computer in the domain and join the Cloud-Delivered Firewall Management Center to the domain as a Domain Computer.

User timeouts are occurring at unexpected times

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC server is synchronized with the time on the Cloud-Delivered Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC, or TS Agent server is synchronized with the time on the Cloud-Delivered Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

User data for previously-unseen ISE/ISE-PIC users is not displaying in the web interface

After the system detects activity from an ISE/ISE-PIC or TS Agent user whose data is not yet in the database, the system retrieves information about them from the server. In some cases, the system requires additional time to successfully retrieve this information from Microsoft Windows servers. Until the data retrieval succeeds, activity seen by the ISE/ISE-PIC, or TS Agent user is *not* displayed in the web interface.

Note that this can also prevent the system from handling the user's traffic using access control rules.

User data in events is unexpected

If you notice user or user activity events contain unexpected IP addresses, check your realms. The system does not support configuring multiple realms with the same **AD Primary Domain** value.

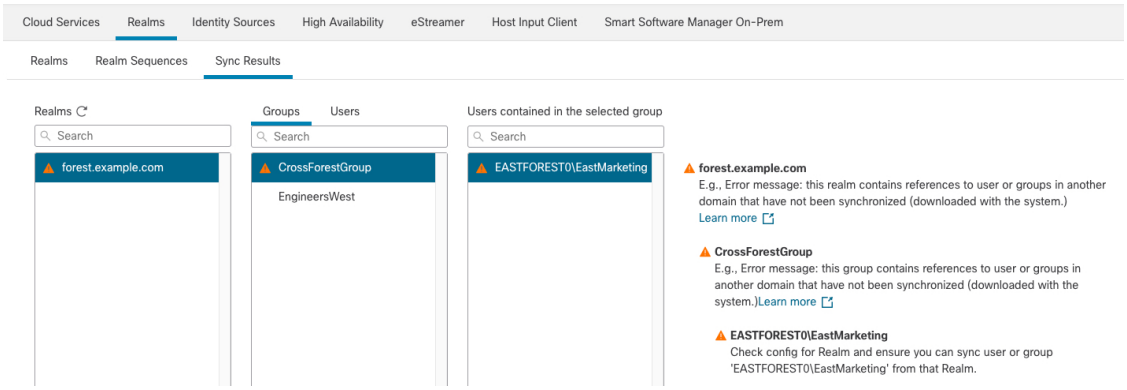
Users originating from terminal server logins are not uniquely identified by the system

If your deployment includes a terminal server and you have a realm configured for one or more servers connected to the terminal server, you must deploy the Cisco Terminal Services (TS) Agent to accurately report user logins in terminal server environments. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users in the web interface.

For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

Troubleshoot cross-domain trust

Troubleshoot user and group synchronization issues in the Cloud-Delivered Firewall Management Center configuration for cross-domain trust. This reference provides information on typical issues, error interpretation, and resolution steps for Active Directory forest synchronization problems.



Typical issues

Typical issues with troubleshooting the Cloud-Delivered Firewall Management Center configuration for cross-domain trust include these items:

- Not adding realms or directories for all forests that have shared groups.
- Configure a realm to exclude users from being downloaded and those users are referenced in a group in a different realm.
- Certain temporary issues.

Understand the issues

If there are issues with the Firewall Management Center being able to synchronize users and groups with your Active Directory forests, the Sync Results tab page is displayed similar to this.

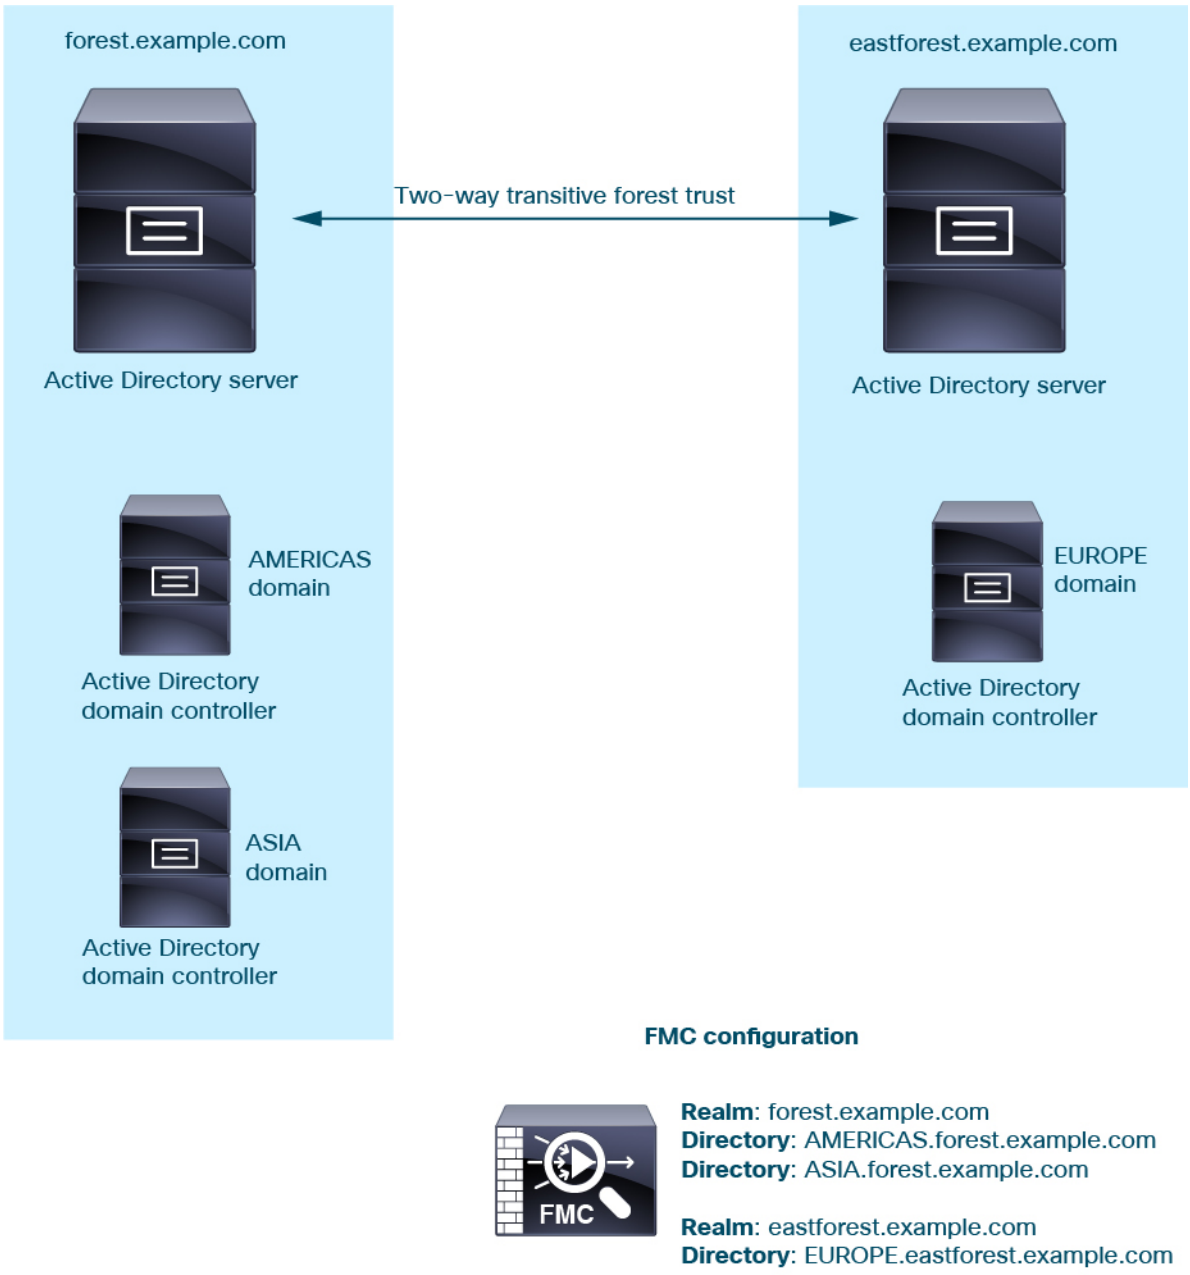
This table explains how to interpret the information.

Column	Meaning
Realms	Displays all realms configured in the system. Click **Refresh** ( ) to update the list of realms. **Yellow Triangle** ( ) is displayed to indicate issues in the realm. Nothing is displayed next to a realm if all users and groups synchronized successfully.
Groups	Click **Groups** to display all groups in the realm. As with realms, **Yellow Triangle** ( ) is displayed to indicate issues. Click **Yellow Triangle** ( ) to see more detail about the issue.
Users	Click **Users** to display all users, sorted by group.
Users contained in the selected group	Displays all users in the group you selected in the Groups column. Clicking **Yellow Triangle** ( ) displays more information to the right of the table.
Groups that contain selected user	Displays all groups the selected user belongs to. Clicking **Yellow Triangle** ( ) displays more information to the right of the table.

Column	Meaning
Error detail information (displayed to the right of the table).	The system displays the NetBIOS forest name and group name it could not synchronize. Typical reasons the system cannot synchronize these users and groups follow: • **Problem**: The forest containing the groups and users do not have corresponding realms configured in the Firewall Management Center. **Solution**: Add a realm for the forest that contains the group as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325. • **Problem**: You excluded groups from being downloaded to the Firewall Management Center. **Solution**: Click the **Realms** tab page, click **Edit** (), then move the indicated group or user from the **Excluded Groups and Users** list.

Try downloading users and groups again

If there is a possibility the issues are temporary, download users and groups for all realms.



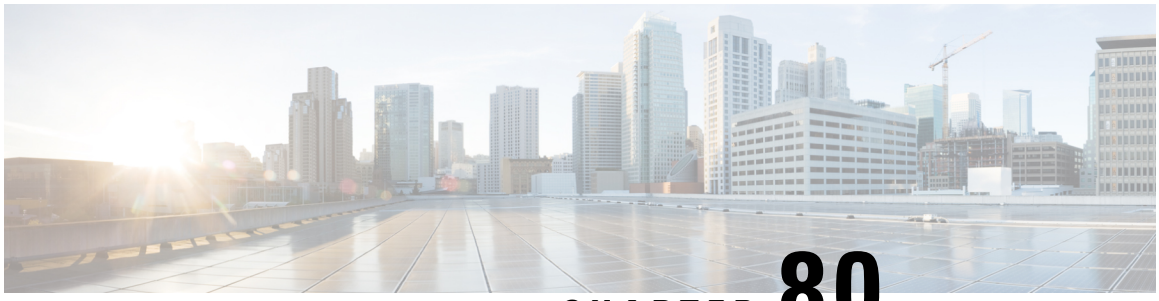
1. If you haven't done so already, log in to the Firewall Management Center.
2. Click **Integration** > **Other Integrations** > **Realms** > **Realms**.
3. Click **Download** ().
4. Click the **Sync Results** tab page.
5. If no indicator is displayed for entries in the Realms column, the issues have been resolved.

Add a realm for all forests

Make sure you configured:

- Firewall Management Center realm for each forest that has users you want to use in identity policies.
- Firewall Management Center directory for each domain controller in that forest with users you want to use in identity polices.

This figure shows an example.



History for realms

This reference provides the version history and implementation details for realm-related features across different versions of the Cisco security platform.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Microsoft Azure Active Directory (SAML) realms.	November 8, 2024	7.4.0	You can now use Microsoft Azure Active Directory (AD) realms for active and passive authentication: • Active authentication using Azure AD: Use Azure AD as a captive portal. • Passive authentication using Cisco ISE (introduced in Version 7.4.0): The Cloud-Delivered Firewall Management Center gets groups from Azure AD and logged-in user session data from ISE. We use SAML (Security Assertion Markup Language) to establish a trust relationship between a service provider (the devices that handle authentication requests) and an identity provider (Azure AD). For upgraded Cloud-Delivered Firewall Management Centers, existing Azure AD realms are displayed as SAML - Azure AD realms. **Upgrade impact**. If you had a Microsoft Azure AD realm configured before the upgrade, it is displayed as a SAML - Azure AD realm configured for passive authentication. All previous user session data is preserved. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Add Realm** > **SAML - Azure AD** New/modified CLI commands: none See: Create a Microsoft Azure AD (SAML) Realm.
Microsoft Azure Active Directory (AD) realms.	January 18, 2023	7.4.0	You can use a Microsoft Azure Active Directory (AD) realm with ISE to authenticate users and get user sessions for user control. New/modified screens: **System** > **Integration** > **Realms** > **Add Realm** > **Azure AD**
Proxy sequences.	Any	7.2.0	Similar to a realm sequence, a proxy sequence is one or more managed devices that can communicate with Security Cloud Control in the event Security Cloud Control cannot communicate with the LDAP or Active Directory server. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Proxy Sequence**
Cross-domain trust for Active Directory domains.	Any	7.0.0	A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B. The Cloud-Delivered Firewall Management Center can get users from Active Directory forests for identity rules.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Realm sequences.	Any	6.7.0	A *realm sequence* is an ordered list of two or more realms to which to apply identity rules. When you associate a realm sequence with an identity policy, the Firepower System searches the Active Directory domains in order from first to last as specified in the realm sequence. New/modified screens: **Integration** > **Other Integrations** > **Realms** > **Realm SequencesSystem** > **Integration** > **Realms** > **Realm Sequences**
Realms for user control.	Any	Any	A realm is a connection between the Cloud-Delivered Firewall Management Center either an Active Directory or LDAP user repository.

CHAPTER 80

Identity Source: Captive Portal

- Captive portal identity source, on page 2351
- License requirements for captive portal, on page 2352
- Requirements and prerequisites for captive portal, on page 2352
- Best practices for captive portal guidelines and limitations, on page 2353
- Configure the captive portal for user control, on page 2355
- Troubleshoot the captive portal identity source, on page 2369
- History for captive portal, on page 2370

Captive portal identity source

A captive portal identity source is an active authentication method that

- presents a login page to users and authenticates HTTP and HTTPS traffic to enable secure access to network resources
- requires authentication to access the internet or to access restricted internal resources
- differs from passive authentication by presenting users with a login page on the managed device rather than querying the authentication realm.

You typically use captive portal to require authentication to access the internet or to access restricted internal resources; you can optionally configure guest access to resources. After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only.

Captive portal authentication details

Captive portal is one of the authoritative identity sources supported by the system. Active authentication differs from passive authentication in that the user is presented with a login page by the managed device, whereas passive authentication queries the authentication realm (for example, Microsoft AD) to authenticate the user.

After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only. You can optionally configure guest access to resources.

Note To use a Microsoft Azure AD (SAML) realm for captive portal, see Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal), on page 2310.

Note HTTPS traffic must be decrypted before captive portal can perform authentication.

Captive portal also records failed authentication attempts. A failed attempt does not add a new user to the list of users in the database. The user activity type for failed authentication activity reported by captive portal is **Failed Auth User**.

The authentication data gained from captive portal can be used for user awareness and user control.

Hostname redirect

A hostname redirect uses the managed device's fully-qualified domain name (FQDN) instead of an IP address for authentication redirections.

(Snort 3 only) An active authentication identity rule redirects to the captive portal port using its configured interface. Because the redirect is typically done to an IP address, the user gets an untrusted certificate error. As this behavior is similar to a man-in-the-middle attack, users might be reluctant to accept the untrusted certificate.

To avoid this problem, you can configure the captive portal to use the managed device's fully-qualified domain name (FQDN). With a properly configured certificate, users will not get an untrusted certificate error, and the authentication will be more seamless and appear to be more secure.

License requirements for captive portal

This reference provides the license requirements for captive portal functionality.

Best practices for captive portal guidelines and limitations

Captive portal and policies

You configure captive portal in your identity policy and invoke active authentication in your identity rules. Identity policies are associated with access control policies and access control policies define access to resources in the network. For example, you might exclude users in the US-West/Finance group to access Engineering servers or you can prohibit users from accessing nonsecure applications on the network.

You configure some captive portal identity policy settings on the identity policy's **Active Authentication** tab page and configure the rest in the identity rule associated with the access control policy.

An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected. In each case the system transparently enables or disables TLS/SSL decryption, which restarts the Snort process.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

Microsoft Azure AD SAML realm configuration

To use a Microsoft Azure AD (SAML) realm as a captive portal, see Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal), on page 2302.

Routed interface requirements

Ensure that captive portal active authentication is performed only by a device with a routed interface configured. If you are configuring an identity rule for captive portal and your captive portal device contains inline and routed interfaces, you must configure interface rule conditions in the access control policy to target only the routed interfaces on the device.

If the identity policy associated with your access control policy contains one or more captive portal identity rules and you deploy the policy on the Security Cloud Control that manages one or more devices with routed interfaces configured, the policy deployment succeeds and the routed interfaces perform active authentication.

For more information about synchronizing users and groups, see Synchronize users and groups, on page 2330.

Required certificates and certificate authorities

Before you can use the captive portal for user control and awareness, you must have all of the following:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Security Cloud Control as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

Captive portal requirements and limitations

Note the requirements and limitations when configuring captive portal:

- Captive portal does not support HTTP/3 QUIC connections.
- The system supports up to 20 captive portal logins per second.
- A failed login attempt is counted toward the maximum login attempts only if it occurs within five minutes of the previous failed attempt. The five minute limit is not configurable.

  Connection events show the number of maximum login attempts. To view connection events, click **Analysis** > **Unified Events**.

  If more than five minutes elapse between failed logins, the user is redirected to captive portal for authentication and will not be designated a failed login user or a guest user, and will not be reported to the Security Cloud Control.
- Captive portal does not negotiate TLS v1.0 connections. Only TLS v1.1, v1.2, and TLS 1.3 connections are supported.
- You *cannot* use a realm sequence with the captive portal.
- If a realm is created for a parent domain and the managed device detects a login to a child of that parent domain, the user's subsequent logout is not detected by the managed device.
- To limit the amount of non-HTTP or HTTPS traffic that is allowed through the managed device, you should enter typical HTTP and HTTPS ports in the identity policy's **Ports** tab page.
- Your access control rule must allow traffic destined for the IP address and port of the device you plan to use for captive portal.
- To perform captive portal active authentication on HTTPS traffic, you must use a decryption policy to decrypt the traffic from the users you want to authenticate. You cannot decrypt the traffic in the connection between a captive portal user's web browser and the captive portal daemon on the managed device; this connection is used to authenticate the captive portal user.
- The managed device changes a previously unseen user from **`Pending`** to **`Unknown`** when it determines that the incoming request does not use the HTTP or HTTPS protocol. As soon as the managed device changes a user from **`Pending`** to another state, access control, Quality of Service, and decryption policies

can be applied to that traffic. If your other policies don't permit non-HTTP or HTTPS traffic, configuring ports on the captive portal identity policy can prevent undesired traffic from being allowed through the managed device.

Kerberos prerequisites

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.

Configure the captive portal for user control

Configure captive portal active authentication to enable user authentication through the portal by setting up the necessary components and associating them with access control policies.

To use the captive portal for active authentication, you must set up an LDAP realm; or a Microsoft AD realm or realm sequence; Microsoft Azure AD (SAML) realm; access control policy; an identity policy; a decryption policy; and associate the identity and decryption policies with the same access control policy. Finally, you must deploy the policies to managed devices. This topic provides a high-level summary of those tasks.

Note To use a Microsoft Azure AD (SAML) realm as a captive portal, see Create a Microsoft Azure AD (SAML) realm for active authentication (captive portal), on page 2302.

Before you begin

Perform these tasks first:

- Confirm that your Security Cloud Control manages one or more devices with a *routed* interface configured.
- To use encrypted authentication with the captive portal, either create a PKI object for the authenticating managed device or have your certificate data and key available on the machine from which you're accessing the Security Cloud Control. To create a PKI object, see PKI objects, on page 2986.

Follow these steps to configure the captive portal for user control:

Procedure

Step 1 Create and enable an LDAP realm; or a Microsoft AD realm and optionally realm sequence as discussed in these topics:

- Create an LDAP realm or an Active Directory realm and realm directory, on page 2325
- (Optional.) Create a realm sequence, on page 2332
- Synchronize users and groups, on page 2330

A realm sequence is not supported for the captive portal.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information, see Synchronize users and groups, on page 2330.

Step 2 Get required certificates and certificate authorities.

You must have all of these:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Cloud-Delivered Firewall Management Center as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

Step 3 Create a network object with an associated trusted certificate authority.

See Create a network object, on page 2357.

Step 4 Create identity policy with an active authentication rule.

The identity policy enables selected users in your realm access resources after authenticating with the captive portal.

For more information, see Create an identity policy and active authentication rule, on page 2358.

Step 5 Configure an access control rule for the captive portal that allows traffic on the captive portal port (by default, TCP 885).

You can choose any available TCP port for the captive portal to use. Whatever your choice, you must create a rule that allows traffic on that port.

For more information, see Create a TCP port access control rule, on page 2360.

Step 6 Add another access control rule to allow users in the selected realm or realm sequence to access resources using the captive portal.

For more information, see Create a user access control rule, on page 2362.

Step 7 Configure a decryption policy with a **Decrypt - Resign** rule for the **Unknown** user so captive portal users can access web pages using the HTTPS protocol.

The captive portal can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the captive portal. The captive portal itself is seen by the system as the **Unknown** user.

Create a decryption policy with an outbound rule, on page 2362

Step 8 Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the captive portal.

For more information, see Associate Identity and decryption policies with the access control policy, on page 2366.

What to do next

See Create a network object, on page 2357.

Create a network object

Create a network object to enable access using a fully qualified domain name for captive portal authentication.

This task discusses how to start configuring the captive portal as an identity source.

Before you begin

(Snort 3 only.) Create a fully-qualified host name (FQDN) using your DNS server and upload the Firewall Threat Defense's internal certificate to the Firewall Management Center. You can consult a resource such as this one if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your Firewall Management Center.

For more information about the network object, see Redirect to host name network rule conditions, on page 2510.

Procedure

Step 1 If you haven't already done so, log in to your Firewall Management Center and click **Objects** > **Object Management**..

Step 2 Expand **PKI**.

Step 3 Click **Internal Certs**.

Step 4 Click **Add Internal Cert**.

a) In the **Name** field, enter a name to identify the internal cert (for example, **`MyCaptivePortal`**).

b) In the **Certificate Data** field, either paste the certificate or use the **Browse** button to locate it.

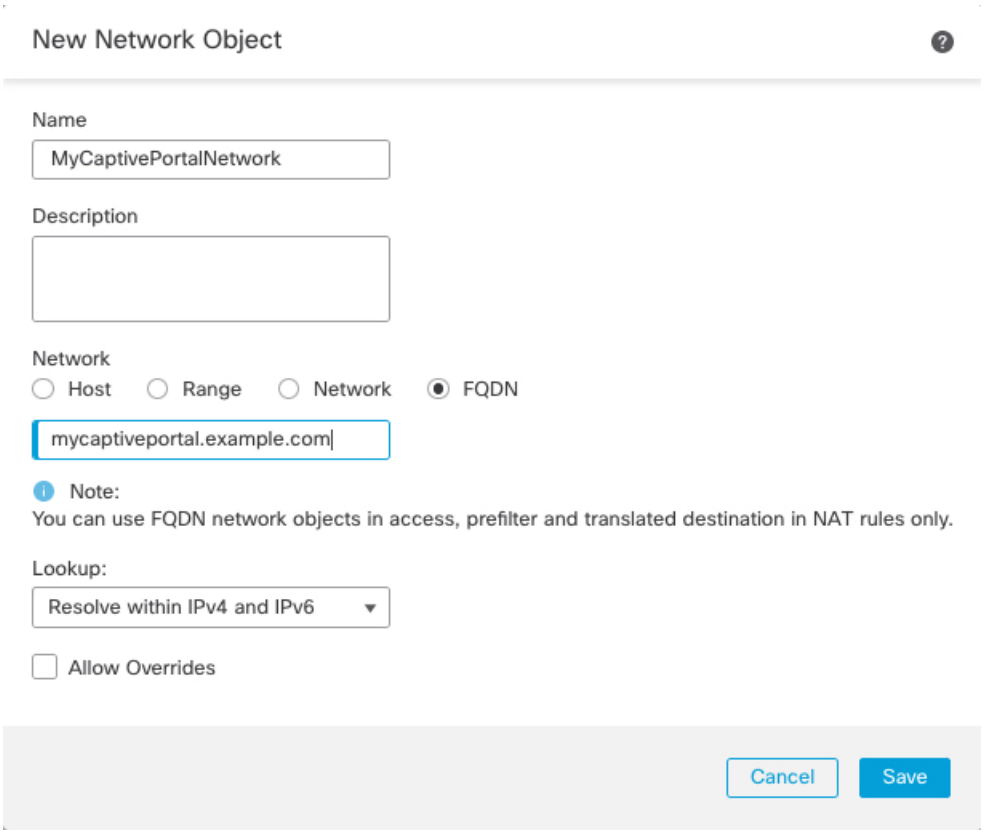
The certificate Common Name must exactly match the FDQN with which you want captive portal users to authenticate.

c) In the **Key** field, either paste the certificate's private key or use the **Browse** button to locate it.

d) If the certificate is encrypted, select the **Encrypted** check box and enter the password in the adjacent field.

e) Click **Save**.

Step 5 Click **Network**.



Step 6 Click **Add Network** > **Add Object**.

a) In the **Name** field, enter a name to identify the object (for example, **`MyCaptivePortalNetwork`**).

b) Click **FDQN** and, in the field, enter the name of the captive portal's FDQN.

c) Click an option for **Lookup**.

The following figure shows an example.

d) Click **Save**.

What to do next

Create an identity policy and active authentication rule, on page 2358.

Create an identity policy and active authentication rule

This procedure enables captive portal to perform active authentication for users in your domains using the Secure Firewall Management Center.

This multi-part procedure shows how to set up the captive portal using the default TCP port 885 and using a Cloud-Delivered Firewall Management Center server certificate for both the captive portal and for TLS/SSL decryption. Each part of this example explains one task required to enable the captive portal to perform active authentication.

If you follow all the steps in this procedure, you can configure captive portal to work for users in your domains. You can optionally perform additional tasks, which are discussed in each part of the procedure.

For an overview of the entire procedure, see Configure the captive portal for user control, on page 2355.

Procedure

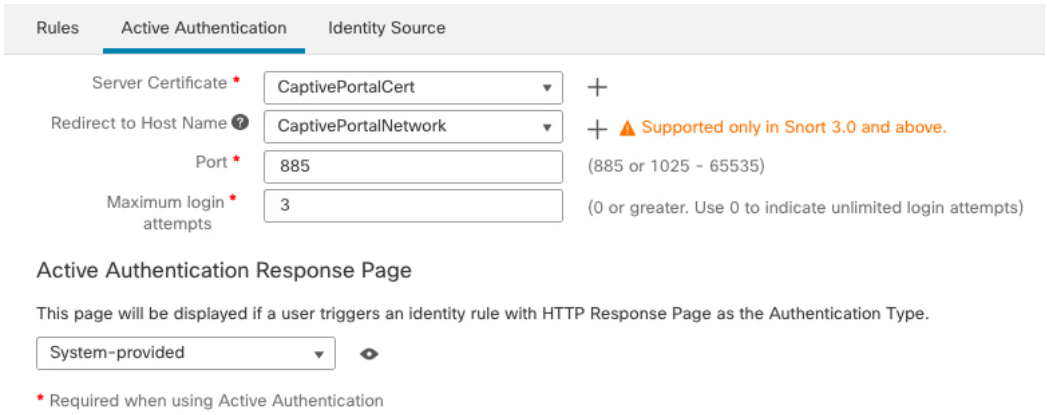
Step 1 In the Firewall Management Center, click **Policies** > **Access Control heading** > **Identity** and create or edit an identity policy.

Step 2 (Optional.) Click **Add Category** to add a category for the captive portal identity rules and enter a **Name** for the category.

Step 3 Click the **Active Authentication** tab.

a) Choose the appropriate *root* **Server Certificate** from the list or click **Add** (+) to add a certificate.

For more information, see Connect securely to Active Directory or LDAP, on page 2328.



Note
Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

b) From the **Redirect to Host Name** field, click the network object you previously created or click **Add** (+).

c) Enter **885** in the **Port** field and specify the **Maximum login attempts**.

d) (Optional.) Choose an **Active Authentication Response Page** as described in Captive portal fields, on page 2367.

This figure shows an example.

Step 4 Click **Save**.

Step 5 Click the **Rules** tab.

Step 6 Click **Add Rule** to add a new captive portal identity policy rule, or click **Edit** (✎) to edit an existing rule.

In the **Add Rule** page,

a) Enter a **Name** for the rule.

b) From the **Action** list, choose **Active Authentication**.

c) Click **Realm & Settings**.

d) From the **Realms** list, choose a realm to use for user authentication

A realm sequence is not supported.

e) (Optional.) Check **Identify as Guest if authentication cannot identify user**. For more information, see Captive portal fields, on page 2367.
f) Choose an **Authentication Protocol** from the list.
g) (Optional.) To exempt specific application traffic from captive portal, see Exclude applications from captive portal, on page 2368.
h) Add conditions to the rule (port, network, and so on) as discussed in Identity rule conditions, on page 2509.
i) Click **Add**.

Step 7 At the top of the page, click **Save**.

What to do next

Continue with Create a TCP port access control rule, on page 2360.

Update a custom authentication form

Allow users to see a list of domains when they authenticate with captive portal by adding a custom realm selection to your authentication form.

After you upgrade to version 7.4.1 (or later) from an earlier release, you must update custom authentication forms for users to see available domains during authentication. This task is always required if you use the HTTP Response Page authentication type; if users authenticate with a realm using another authentication type, this task is optional.

Procedure

Step 1 On the **Active Authentication** tab page of your identity rule, click **Edit** ( ).

Step 2 Enter the following code in the part of the form that requires the user to log in:

Example:

```
<select name="realm" id="realm"></select>
```

Users can now view and select from available domains during captive portal authentication.

Create a TCP port access control rule

Create an access control rule that allows the captive portal to communicate with clients using TCP port 885, enabling secure user authentication.

This part of the procedure shows how to create an access control rule that allows the captive portal to communicate with clients using TCP port 885, which is the captive portal's default port. You can choose another port if you wish, but the port must match the one you chose in Create an identity policy and active authentication rule, on page 2358.

Before you begin

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 2355.

Follow these steps to create a TCP port access control rule:

Procedure

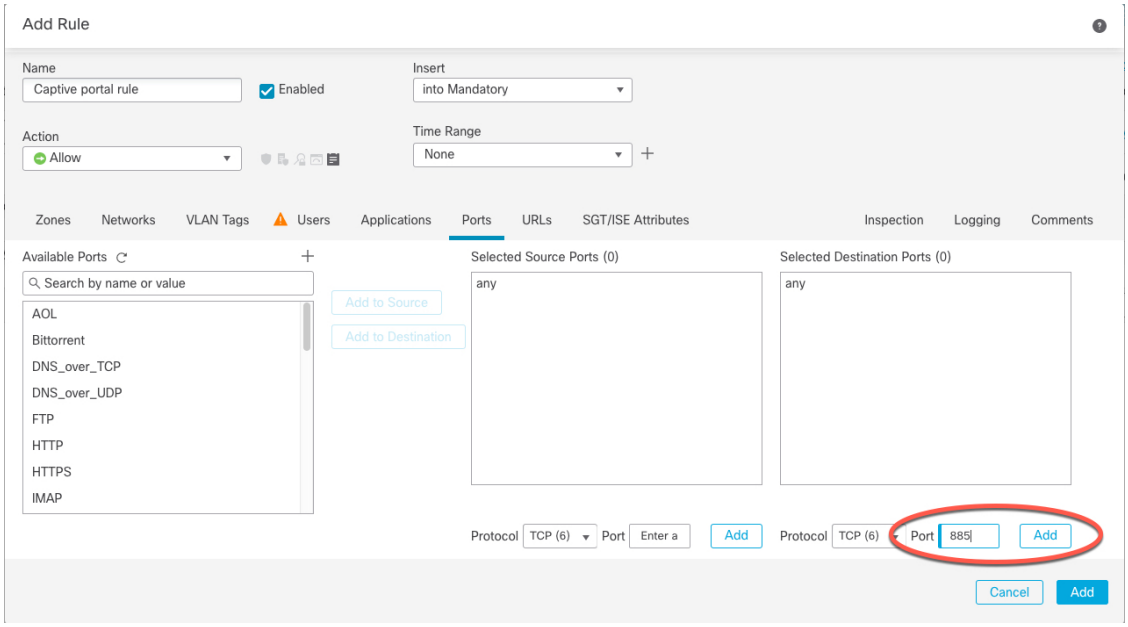
Step 1 Log in to the Firewall Management Center if you have not already done so.

If you haven't done so already, create a certificate for the captive portal as discussed in PKI objects, on page 2986.

Step 2 Click **Policies** > **Access Control heading** > **Access Control** and create or edit an access control policy.

Step 3 Click **Add Rule**.

Step 4 Enter a **Name** for the rule.



Step 5 Choose **Allow** from the **Action** list.

Step 6 Click **Ports**.

Step 7 From the **Protocol** list under the **Selected Destination Ports** field, choose **TCP**.

Step 8 In the **Port** field, enter **885** and click **Add** next to the **Port** field.

The following figure shows an example.

Step 9 Click **Add** at the bottom of the page.

What to do next

Continue with Create a user access control rule, on page 2362.

Create a user access control rule

Configure an access control rule to allow users in a specified realm to authenticate using captive portal, then adjust rule order in the policy editor to optimize traffic handling and resource use.

This part of the procedure discusses how to add an access control rule that enables users in a realm to authenticate using captive portal.

Before you begin

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 2355.

Procedure

Step 1 In the rule editor, click **Add Rule**.

Step 2 Enter a **Name** for the rule.

Step 3 Choose **Allow** from the **Action** list.

Step 4 Click **Users**.

Step 5 In the **Available Realms** list, click the realms to allow.

If no realms display, click **Refresh** ( ).

Step 6 In the **Available Users** list, choose the users to add to the rule and click **Add to Rule**.

Step 7 (Optional.) Add conditions to the access control policy as discussed in Identity rule conditions, on page 2509.

Step 8 Click **Add**.

Step 9 On the access control rule page, click **Save**.

In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption

What to do next

Create a decryption policy with an outbound rule, on page 2362

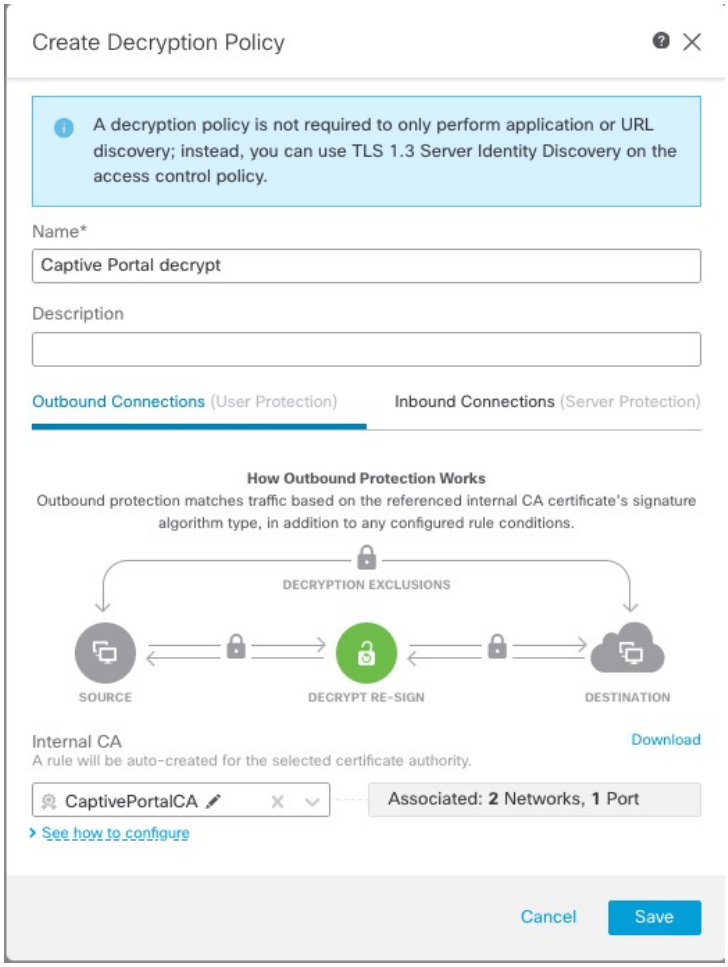
Create a decryption policy with an outbound rule

Create a decryption policy to decrypt and resign outbound traffic before captive portal authentication in the Secure Firewall Management Center.

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

Before you begin

You must have an internal certificate authority (CA) for your outbound server; in other words, the managed device that decrypts the traffic for captive portal users to authenticate. This certificate must be different from the *internal certificate* you use to authenticate the captive portal with the managed device.



Procedure

Step 1 Click **Policies** > **Access Control heading** > **Decryption**.

Step 2 Click **New Policy**.

Step 3 Give the policy a unique **Name** and, optionally, a **Description**.

Step 4 Click the **Outbound Connections** tab.

Step 5 Upload or choose certificates for the rules.

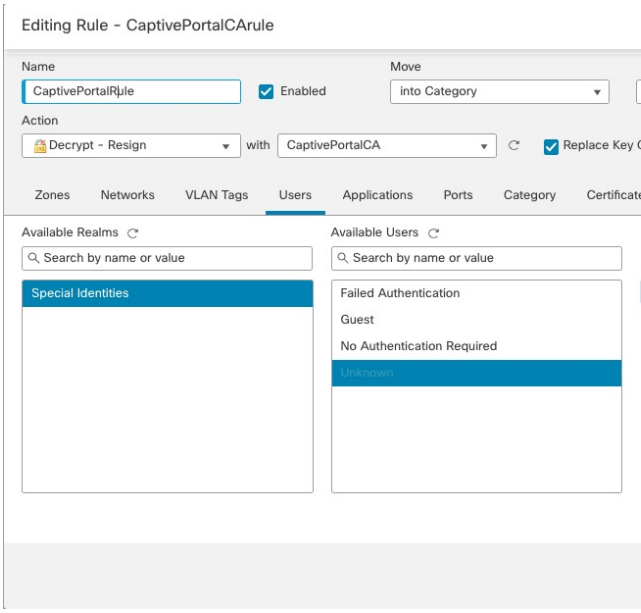
The system creates one rule per combination of CA and networks/ports.

Step 6 (Optional.) Choose networks and ports.

For more information:

- Rule-based decryption rule conditions, on page 2201

- Network rule conditions, on page 1701
- Best practice: use application-based rules over port-based rules, on page 1703



Step 7 Click **Save**.

What to do next

Configure the decryption rule.

Configure a decryption rule

Procedure

	Command or Action	Purpose
Step 1	Click **Edit** ( ) next to the decryption policy you just created.	
Step 2	Click **Edit** ( ) next to the decryption rule for captive portal.	
Step 3	Click **Users**.	
Step 4	Above the **Available Realms** list, click **Refresh** ( ).	
Step 5	In the **Available Realms** list, click **Special Identities**.	
Step 6	In the **Available Users** list, click **Unknown**.	
Step 7	Click **Add to Rule**.	The following figure shows an example. 

	Command or Action	Purpose
Step 8	(Optional.) Set other options as discussed in Rule-based decryption rule conditions, on page 2201.	
Step 9	Click **Add**.	

Create A decryption policy with a Decrypt-Resign rule

Create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal.

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

Before you begin

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 2355.

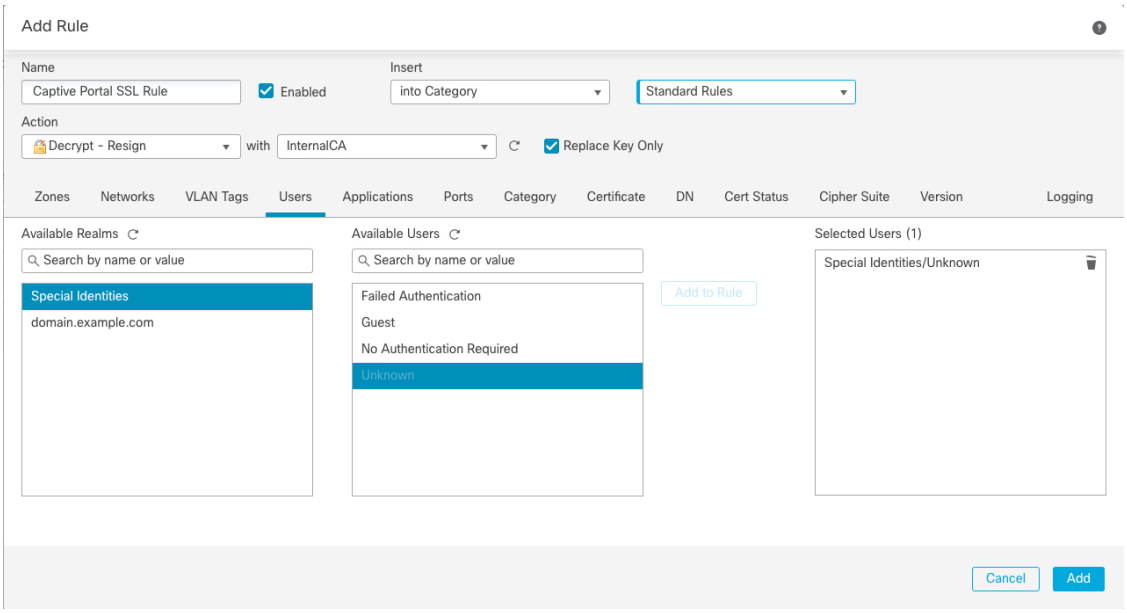
Follow these steps to create A decryption policy with a Decrypt-Resign rule:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center and create a certificate object to decrypt TLS/SSL traffic as discussed in PKI objects, on page 2986.

Step 2 Click **Policies** > **Access Control heading** > **Decryption**.

Step 3 Click **New Policy**.



Step 4 Enter a **Name** and choose a **Default Action** for the policy. Default actions are discussed in Rule-based decryption policy default actions, on page 2179.

Step 5 Click **Save**.

Step 6 Click **Add Rule**.

a) Enter a **Name** for the rule.
b) From the **Action** list, choose **Decrypt - Resign**.
c) From the **with** list, choose your PKI object.
d) Under the **Users** tab, refresh the **Available Realms**list by clicking **Refresh** ( ).
e) In the **Available Realms** list, click **Special Identities**.
f) In the **Available Users** list, click **Unknown**.
g) Click **Add to Rule**.

The following figure shows an example.

Step 7 (Optional.) Set other options as discussed in Rule-based decryption rule conditions, on page 2201.

Step 8 Click **Add**.

Step 9 At the top of the page, click **Save**.

What to do next

Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the captive portal.

For more information, see Associate Identity and decryption policies with the access control policy, on page 2366.

Associate Identity and decryption policies with the access control policy

Associate the identity policy and TLS/SSL **Decrypt - Resign** rule with your access control policy to enable captive portal authentication.

This part of the procedure discusses how to associate the identity policy and TLS/SSL **Decrypt - Resign** rule with the access control policy you created earlier. After this, users can authenticate using the captive portal.

For an overview of the entire captive portal configuration, see Configure the captive portal for user control, on page 2355.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **Access Control** and edit the access control policy you created as discussed in Create a TCP port access control rule, on page 2360. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Either create a new access control policy or edit an existing policy.

Step 3 At the top of the page, click the word **Identity**.

Step 4 From the list, choose the name of your identity policy and, at the top of the page, click **Save**.

Step 5 Repeat the preceding steps to associate your captive portal decryption policy with the access control policy.

Step 6 If you haven't done so already, target the policy at managed devices as discussed in Assign access control policy to devices, on page 2014.

What to do next

- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity .

Captive portal fields

Use these fields to configure captive portal on the **Active Authentication** tab page of your identity policy. See also Identity rule fields, on page 2517 and Exclude applications from captive portal, on page 2368.

Server Certificate

An internal certificate presented by the captive portal daemon.

Note Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

Port

The port number to use for the captive portal connection. You must set up your access control rule with a TCP port to use for the captive portal, then associate the identity policy with that access control policy. For more information, see Create a TCP port access control rule, on page 2360.

Maximum login attempts

The maximum allowed number of failed login attempts before the system denies a user's login request.

Active Authentication Response Page

The system-provided or custom HTTP response page you want to display to captive portal users. After you select an **Active Authentication Response Page** in your identity policy active authentication settings, you also must configure one or more identity rules with **`HTTP Response Page`** as the **Authentication Protocol**.

The system-provided HTTP response page includes **Username** and **Password** fields, a list of realms if you chose to authenticate with a realm sequence, as well as a **Login as guest** button to allow users to access the network as guests. To display a single login method, configure a custom HTTP response page.

An example of what users see when logging in with a response page is shown in Create a sample identity policy with an active authentication rule, on page 2520.

Choose these options:

- To use a generic response, click **System-provided**. You can click **View** ( ) to view the HTML code for this page.
- To create a custom response, click **Custom**. A window with system-provided code is displayed that you can replace or modify. When you are done, save your changes. You can edit a custom page by clicking **Edit** ( ).

Exclude applications from captive portal

This task allows you to exempt specific applications from captive portal active authentication, enabling their traffic to pass through the identity policy without requiring authentication.

You can select applications (identified by their HTTP `User-Agent` strings) and exempt them from captive portal active authentication. This allows traffic from the selected applications to pass through the identity policy without authenticating.

Note Only applications with the **`User-Agent Exclusion` Tag** are displayed in this list.

Before you begin

Follow these steps to exclude applications from captive portal authentication:

Procedure

Step 1 If you haven't done so already, log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Edit the identity policy that contains the captive portal rule.

Step 4 On **Realm & Settings** tab page, expand **HTTP User Agent Exclusions**.

- In the first column, select the check box next to each item to filter applications, then one or more applications, and click **Add to Rule**.

  Check boxes are ANDed together.

- To narrow the filters that are displayed, type a search string in the **Search by name** field; this is especially useful for categories and tags. To clear the search, click **Clear** ( ).
- To refresh the filters list and clear any selected filters, click **Reload** ( ).

Note

The list displays 100 applications at a time.

Step 5 Choose the applications that you want to add to the filter from the **Available Applications** list:

- To narrow the individual applications that appear, enter a search string in the **Search by name** field. To clear the search, click **Clear** ( ).
- Use paging at the bottom of the list to browse the list of individual available applications.
- To refresh the applications list and clear any selected applications, click **Reload** ( ).

Step 6 Add the selected applications to exclude from external authentication. You can click and drag, or you can click **Add to Rule**. The result is the combination of the application filters you selected.

What to do next

- Continue configuring the identity rule as described in Create an identity rule, on page 2515.

Troubleshoot the captive portal identity source

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 2342 and Troubleshoot user control, on page 2526.

If you experience issues with captive portal, check these items:

- The time on your captive portal managed device must be synchronized with the time on the Cloud-Delivered Firewall Management Center.
- If you have DNS resolution configured and you create an identity rule to perform **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) captive portal, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the hostname you provided when configuring DNS.

  For more information, see Hostname redirect, on page 2352.
- If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: Naming conventions in Active Directory for computers, domains, sites, and OUs.

  DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in RFC 6891 section-6.2.5.
- If the device you want to use for captive portal contains both inline and routed interfaces, you must configure a zone condition in your captive portal identity rules to target only the routed interfaces on the captive portal device.
- If the captive portal is configured correctly but the redirect to an IP address or fully-qualified domain name (FQDN) fails, disable endpoint security software. This type of software can interfere with the redirection.

- The ERR_CONNECTION_TIMED_OUT error during active authentication occurs when the redirect URL fails to resolve to the managed device's IP address. This error could prevent the client from receiving a user authentication prompt after redirection, cause client traffic on port 885 to be missing from managed device packet captures, or lead to other connection issues. To mitigate connection issues, ensure that the redirect URL resolves to the managed device's IP address on the client's ingress path, where active portal authentication is configured. Verify the configuration by using the `system support captive-portal-debug` command.
- To securely log a user out of captive portal and prevent the user from logging in again, an administrator can close their session: **Analysis** > **Users heading** > **Active Sessions**. If the user closes their browser, the browser does not reauthenticate automatically.
- If you select **`Kerberos`** (or **`HTTP Negotiate`**, if you want Kerberos as an option) as the **Authentication Type** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

  If you select **`HTTP Basic`** as the **Authentication Type** in an identity rule, users on your network might not notice their sessions time out. Most web browsers cache the credentials from **`HTTP Basic`** logins and use the credentials to seamlessly begin a new session after an old session times out.
- If the connection between your Cloud-Delivered Firewall Management Center and a managed device fails, no captive portal logins reported by the device can be identified during the downtime, unless the users were previously seen and downloaded to the Cloud-Delivered Firewall Management Center. The unidentified users are logged as Unknown users on the Cloud-Delivered Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 959.

  When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

  To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

  For more information, see Synchronize users and groups, on page 2330.

History for captive portal

This reference provides the development history and version information for the captive portal feature across different software releases.

Feature	Minimum Cloud-Delivered Firewall Management Center/Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Hostname redirect.	Any	7.1.0 with Snort 3	You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.
Guest login.	Any	6.1.0	Users can log in as guest using captive portal.
Captive portal.	Any	6.0.0	Feature introduced. You can use the captive portal to require users to enter their credentials when prompted in a browser window. The mapping also allows policies to be based on a user or group of users.

CHAPTER 81

Identity Source: ISE/ISE-PIC

The following topics discuss how to perform user awareness and user control with ISE/ISE-PIC:

- The ISE/ISE-PIC identity source, on page 2373
- License requirements for ISE/ISE-PIC, on page 2375
- Requirements and prerequisites for ISE/ISE-PIC, on page 2375
- Best practices for ISE/ISE-PIC integration, on page 2376
- ISE/ISE-PIC configurations for user control , on page 2379
- ISE/ISE-PIC configuration, on page 2382
- Configure ISE for user control, on page 2387
- Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390
- Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues, on page 2399
- History for ISE/ISE-PIC, on page 2401

The ISE/ISE-PIC identity source

The ISE/ISE-PIC identity source is an authoritative identity source that

- provides user awareness data for users who authenticate using Active Directory (AD), LDAP, RADIUS, or RSA
- enables passive authentication and user control on Active Directory users
- integrates with the system to manage network access and classify traffic in a Cisco TrustSec environment, and
- supports security group tags (SGT) for access control.

ISE/ISE-PIC integration capabilities

You can integrate your Cisco Identity Services Engine (ISE) or ISE Passive Identity Connector (ISE-PIC) deployment with the system to use ISE/ISE-PIC for passive authentication.

In addition to user awareness and control, if you use ISE Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects. Also see Best practices for ISE/ISE-PIC integration, on page 2376.

ISE/ISE-PIC does not report failed login attempts or the activity of ISE Guest Services users.

Note The system does not parse IEEE 802.1x machine authentication but it *does* parse 802.1x user authentication. If you are using 802.1x with ISE, you must include user authentication. 802.1x machine authentication will not provide a user identity to the Cloud-Delivered Firewall Management Center that can be used in policy.

For more information on Cisco ISE/ISE-PIC, see the Identity Services Engine Passive Identity Connector administrator guides or the Identity Services Engine administrator guides.

Note We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set and the most number of issue fixes.

Source and destination security group tag (SGT) matching

If you use Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects.

You can also use source SGT matching in DNS rules, as explained in Controlling traffic based on security group tag or dynamic attributes, on page 2572.

Benefits and implementation details

Matching on SGT tags provides these benefits:

- The Cloud-Delivered Firewall Management Center can subscribe to Security Group Tag eXchange Protocol (SXP) mappings from ISE.

  ISE uses SXP to propagate the IP-to-SGT mapping database to managed devices. When you configure Cloud-Delivered Firewall Management Center to use an ISE server, you enable the option to listen to the SXP topic from ISE. This causes the Cloud-Delivered Firewall Management Center to learn about the security group tags and mappings directly from ISE. The Cloud-Delivered Firewall Management Center then publishes SGTs and mappings to managed devices.

  The SXP Topic receives security group tags based on static and dynamic mappings learned through the SXP protocol between ISE and other SXP compliant devices (like switches).

  You can create security group tags in ISE and assign host or network IP addresses to each tag. You can also assign SGTs to user accounts, and the SGT is assigned to the user's traffic. If the switches and routers in the network are configured to do so, these tags then get assigned to packets as they enter the network controlled by ISE, the Cisco TrustSec cloud.

  SXP is *not* supported by ISE-PIC.

- The Cloud-Delivered Firewall Management Center and managed devices can learn about SGT mappings without deploying additional policy. (In other words, you can view connection events for SGT mappings without deploying an access control policy.)

- Supports Cisco TrustSec, which enables you to segment your network to protect critical business assets.

- When a managed device evaluates SGT as a traffic matching criteria for a rule, it uses this priority:
  1. The source SGT tag defined in the packet, if any.

     For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

     For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.
  2. The SGT assigned to the user session, as downloaded from the ISE session directory. The SGT can be matched to source or destination.
  3. The SGT-to-IP address mapping downloaded using SXP. If the IP address is in the range for an SGT, then the traffic matches the rule that uses the SGT. The SGT can be matched to source or destination.

SGT matching examples

- In ISE, create an SGT tag named Guest Users and associate it with the 192.0.2.0/24 network.

  For example, you could use Guest Users as a source SGT condition in your access control rule and restrict access to certain URLs, web site categories, or networks from anyone who accesses your network.
- In ISE, create an SGT tag named Restricted Networks and associate it with the 198.51.100.0/8 network.

  For example, you could use Restricted Networks as a destination SGT rule condition and block access from Guest Users and other networks that have users who are not authorized to access the network.

Best practices for ISE/ISE-PIC integration

ISE/ISE-PIC version and configuration compatibility

Ensure your ISE/ISE-PIC version and configuration supports proper integration with the Cloud-Delivered Firewall Management Center.

- Use the latest version of ISE/ISE-PIC to get the latest feature set.
- Synchronize the time on the ISE/ISE-PIC server and the Cloud-Delivered Firewall Management Center. Otherwise, the system might perform user timeouts at unexpected intervals.
- Configure and enable a realm for the ISE server assuming the pxGrid persona to implement user control using ISE or ISE-PIC data as described in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
- Ensure each Cloud-Delivered Firewall Management Center host name that connects to an ISE server is unique; otherwise, the connection to one of the Cloud-Delivered Firewall Management Centers will be dropped.
- If you use ISE 3.4 Patch 4 or later as an identity source for in a hybrid deployment, where authorization can use either Microsoft Entra ID (Azure) or on-prem Active Directory, ensure that your ISE authorization policy rule order evaluates on-premises Active Directory external identity source rules before any Entra ID-based authorization rules. This guideline applies to hybrid deployments in which remote access VPN users can authenticate with Microsoft Entra ID, and uses the on-premises Microsoft Active Directory realm for user identity and user-based access control.

For the specific versions of ISE/ISE-PIC that are compatible with this version of the system, see the Cisco Firepower Compatibility Guide.

If you configure ISE/ISE-PIC to monitor a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected.

For any device running version 6.7 or later, you can optionally use the **configure identity-subnet-filter** command to limit the subnets that the managed device monitors. For more information, see the *Cisco Secure Firewall Threat Defense Command Reference*.

Alternatively, you can configure a network object and apply that object as an Identity Mapping Filter in the identity policy. See Create an identity policy, on page 2507.

IPv6 support

Verify IPv6 compatibility between ISE/ISE-PIC and your managed devices.

- Compatible versions of ISE/ISE-PIC version 2.x include support for IPv6-enabled endpoints.

- Version 3.0 (patch 2) and later of ISE/ISE-PIC enables IPv6 communication between ISE/ISE-PIC and the Cloud-Delivered Firewall Management Center.

Proxy sequence configuration

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

Because of its limited capacity, we recommend you *do not* use a Secure Firewall 220 as a proxy sequence.

Client approval in ISE

Manually approve clients in ISE before the connection between the ISE server and the Cloud-Delivered Firewall Management Center succeeds. Typically, there are two clients: one for the connection test and another for ISE agent.

You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the *Cisco Identity Services Engine Administrator Guide*.

Unreachable session management

If a user session in ISE/ISE-PIC is reported as unreachable, the system prunes that session so another user with the same IP cannot match the unreachable user's identity rules.

You can control this behavior in ISE/ISE-PIC by going to **Providers** > **Endpoint Probes** and clicking one of these options:

- **Enabled** to cause ISE/ISE-PIC to monitor endpoint connections and therefore to cause the Cloud-Delivered Firewall Management Center prune a session from an unreachable user.
- **Disabled** to cause ISE/ISE-PIC to ignore endpoint connections.

Security group tags (SGT) implementation

A Security Group Tag (SGT) specifies the privileges of a traffic source within a trusted network. Cisco ISE and Cisco TrustSec use a feature called Security Group Access (SGA) to apply SGT attributes to packets as they enter the network. These SGTs correspond to a user's assigned security group within ISE or TrustSec. If you configure ISE as an identity source, the Firepower System can use these SGTs to filter traffic.

Security Group Tags can be used both as source and destination matching criteria in access control and DNS rules.

Note

- To implement user control using only the ISE SGT attribute tag, you do not need to configure a realm for the ISE server. ISE SGT attribute conditions can be configured in policies with or without an associated identity policy.
- In some rules, custom SGT conditions can match traffic tagged with SGT attributes that were *not* assigned by ISE. This is not considered user control, and works only if you are not using ISE/ISE-PIC as an identity source.

To match destination SGT tags in addition to source SGT tags, verify these requirements:

Required ISE version: 2.6 patch 6 or later, 2.7 patch 2 or later

Router support: Any Cisco router that supports SGT inline tagging over Ethernet. For more information, consult a reference such as the Cisco Group Based Policy Platform and Capability Matrix Release

Limitations:

- Quality of Service (QoS) policy uses source SGT matching only; it does *not* use destination SGT matching
- RA-VPN does not receive SGT mappings directly through RADIUS

ISE and high availability

When the primary ISE/ISE-PIC server fails, understand the impact on operations.

As a result of the integration with pxGrid v2, the Cloud-Delivered Firewall Management Center round-robins between both configured ISE hosts until one accepts the connection.

If the connection is lost, the Cloud-Delivered Firewall Management Center resumes round-robin attempts to the connected hosts.

Endpoint location (or location IP)

An Endpoint Location attribute is the IP address of the network device that used ISE to authenticate the user, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Location (Location IP)**.

ISE attributes

Configuring an ISE connection populates the Cloud-Delivered Firewall Management Center database with ISE attribute data. You can use ISE attributes for user awareness and user control. This is not supported with ISE-PIC.

Endpoint profile (or device type)

An Endpoint Profile attribute is the user's endpoint device type, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Profile (Device Type)**.

ISE/ISE-PIC configurations for user control

An ISE/ISE-PIC configuration uses realms, identity policies, and access control policies to control user access to network resources.

Configuration options

You can use ISE/ISE-PIC in any of these configurations:

- With a realm, identity policy, and associated access control policy: Use a realm to control *user* access to network resources in policy. You can still use ISE/ISE-PIC Security Group Tags (SGT) metadata in your policies.
- With an access control policy only. No realm or identity policy are necessary: Use this method to control network access using SGT metadata alone.

Configure ISE/ISE-PIC without a realm

Configure ISE to allow or block access to the network using SGT tags for enhanced network security and access control.

This topic provides a high-level overview of tasks you must complete to configure ISE to be able to allow or block access to the network using SGT tags.

Procedure

Step 1 SGT matching: Enable SXP on ISE.

This enables the Cloud-Delivered Firewall Management Center to receive updates from ISE when SGT metadata changes.

Step 2 Export system certificates from ISE/ISE-PIC.

The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the Cloud-Delivered Firewall Management Center. See Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center, on page 2384

Step 3 Import the certificates in the Cloud-Delivered Firewall Management Center.

The certificates must be imported as follows:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Step 4 Create the ISE/ISE-PIC identity source.

The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC.

Step 5 Create an access control rule.

The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Access control rules, on page 2041.

Step 6 Deploy the access control policy to managed devices.

Before your policy can take effect, it must be deployed to managed devices. See Deploy configuration changes, on page 202.

What to do next

Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center, on page 2384

Configure ISE/ISE-PIC for user control using a realm

This task enables you to configure ISE/ISE-PIC for user control and to allow or block user or group access to the network. Users and groups can be stored in any server listed in Supported servers for realms, on page 2278.

This topic provides a high-level overview of tasks you must complete to configure ISE/ISE-PIC for user control and to be able to allow or block user or group access to the network.

Procedure

Step 1 Enable SXP on ISE for destination SGT only.

This enables the Cloud-Delivered Firewall Management Center to receive updates from ISE when SGT metadata changes.

Step 2 Export system certificates from ISE/ISE-PIC.

The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the Cloud-Delivered Firewall Management Center. See the following:

- pxGrid server and MNT server certificate: Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center, on page 2384
- pxGrid client certificate: Generate a self-signed certificate, on page 2386

Step 3 Import the certificates in the Cloud-Delivered Firewall Management Center.

The certificates must be imported as follows:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Step 4 Create a proxy sequence for use with the realm and also with ISE/ISE-PIC (optional).

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

Step 5 Create a realm.

You must create a realm only to control access to the network by the users and groups you choose.

See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

a) Download users and groups, and enable the realm.

Downloading users and groups enables you to use them in access control rules. See Synchronize users and groups, on page 2330.

Step 6 Create the ISE/ISE-PIC identity source.

The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC.

Step 7 Create an identity policy.

An identity policy is a container for one or more identity rules. See Create an identity policy, on page 2507.

a) Create an identity rule.

An identity rule specifies how a realm is used to control access to the network by users and groups. See Create an identity rule, on page 2515.

Step 8 Associate the identity policy with an access control policy.

This enables the access control policy to use users and groups in the realm.

a) Create an access control rule.

The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See Access control rules, on page 2041.

Step 9 Deploy the access control policy to managed devices.

Before your policy can take effect, it must be deployed to managed devices. See Deploy configuration changes, on page 202.

What to do next

Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center, on page 2384

ISE/ISE-PIC configuration

This section explains how to configure the ISE/ISE-PIC server for use with identity policies in the Cloud-Delivered Firewall Management Center, including:

- export certificates from the ISE/ISE-PIC server to authenticate with the Cloud-Delivered Firewall Management Center
- publish SXP topics so the Cloud-Delivered Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server.

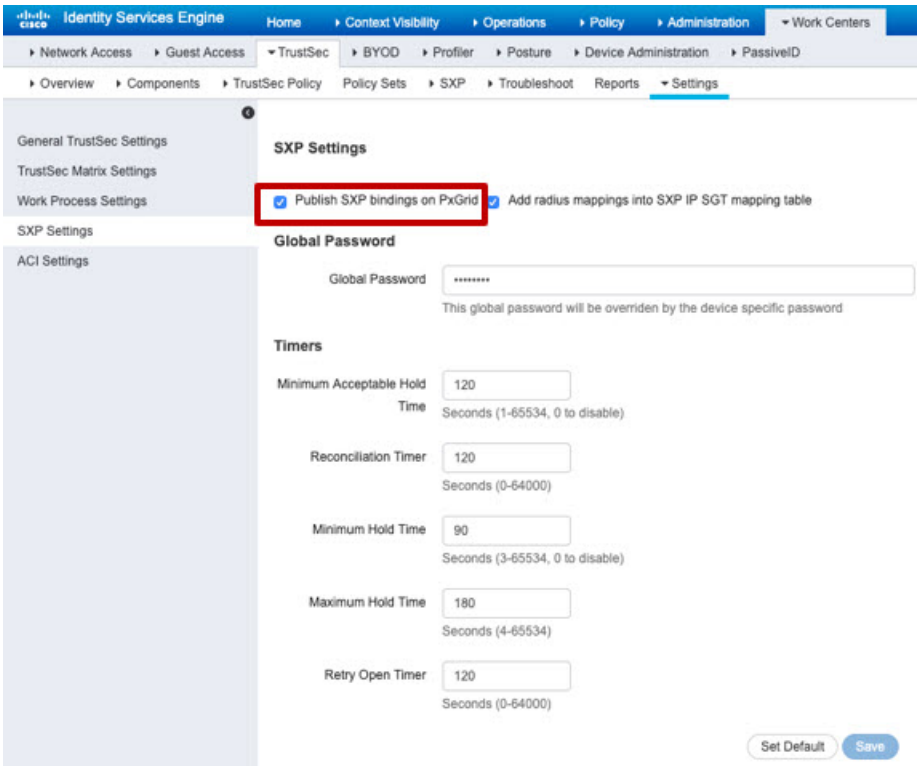
Configure security groups and SXP publishing in ISE

This task enables static SGT-to-IP address mappings for Secure Firewall Threat Defense devices, allowing TrustSec policies and access control based on source and destination security group tags (SGT).

There is a lot of configuration that you must do in Cisco Identity Services Engine (ISE) to create the TrustSec policy and security group tags (SGT). Please look at the ISE documentation for more complete information on implementing TrustSec.

The following procedure picks out the highlights of the core settings you must configure in ISE for the Firewall Threat Defense device to be able to download and apply static SGT-to-IP address mappings, which can then be used for source and destination SGT matching in access control rules. See the ISE documentation for detailed information.

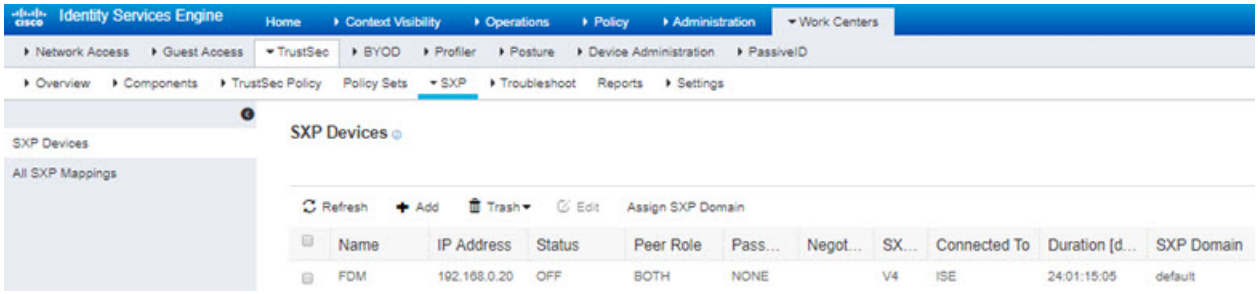
The figures in this procedure are based on ISE 2.4. The exact paths to these features might change in subsequent releases, but the concepts and requirements will be the same. Although ISE 2.4 or later is recommended, and preferably 2.6 or later, the configuration should work starting with ISE 2.2 patch 1.



Before you begin

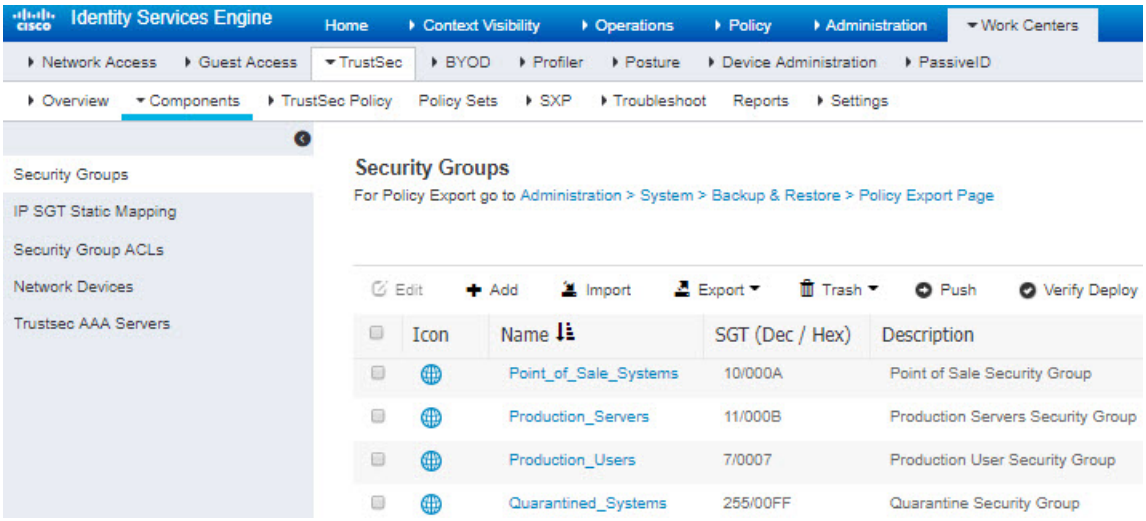
You must have the ISE Plus license to publish SGT-to-IP address static mappings and to get user session-to-SGT mappings so that the Firewall Threat Defense device can receive them.

Procedure



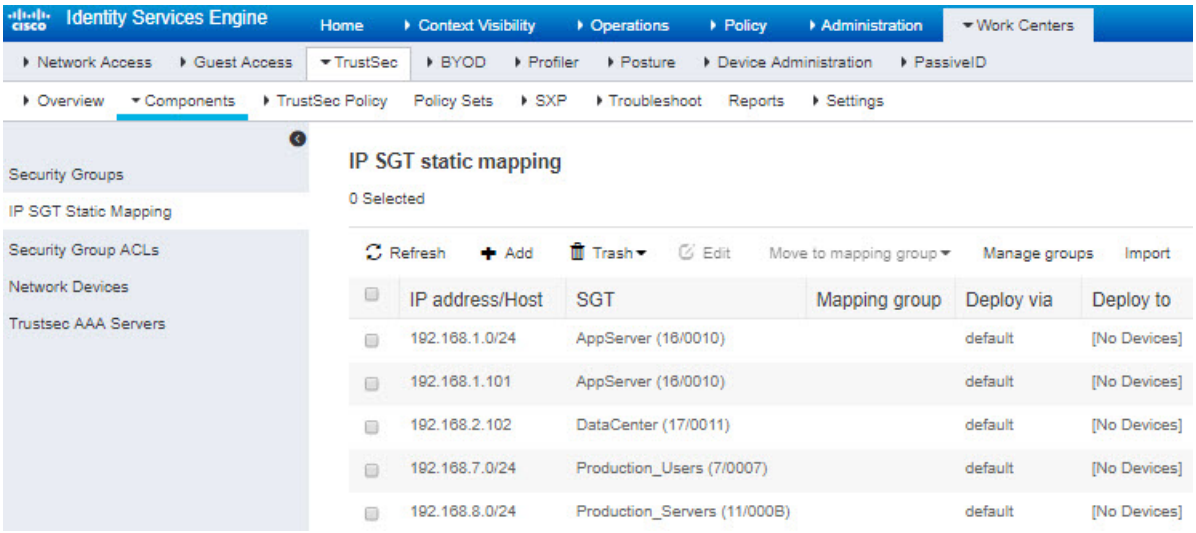
Step 1 Choose **Work Centers** > **TrustSec** > **Settings** > **SXP Settings**, and select the **Publish SXP Bindings on PxGrid** option.

This option makes ISE send the SGT mappings out using SXP. You must select this option for the Firewall Threat Defense device to "hear" anything from listing to the SXP topic. This option must be selected for the Firewall Threat Defense device to get static SGT-to-IP address mapping information. It is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.



Step 2 Choose **Work Centers** > **TrustSec** > **SXP** > **SXP Devices**, and add a device.

This does not have to be a real device, you can even use the management IP address of the Firewall Threat Defense device. The table simply needs at least one device to induce ISE to publish the static SGT-to-IP address mappings. This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.



Step 3 Choose **Work Centers** > **TrustSec** > **Components** > **Security Groups** and verify there are security group tags defined. Create new ones as necessary.

Step 4 Choose **Work Centers** > **TrustSec** > **Components** > **IP SGT Static Mapping** and map host and network IP addresses to the security group tags.

This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

You have configured ISE with the necessary security groups, SXP publishing settings, and static SGT-to-IP mappings required for Secure Firewall Threat Defense devices to receive and apply TrustSec policies.

Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center

Certificate exported from Identity Services Engine (ISE) / Identity Services Engine - Passive Identity Connector (ISE-PIC) servers enables secure authentication between the Cloud-Delivered Firewall Management Center and ISE systems.

You might need to export one, or as many as three, certificates, depending on how your ISE system is set up:

- One certificate for the pxGrid server
- One certificate for the monitoring (MNT) server
- One certificate, including the private key, for the pxGrid client (that is, the Cloud-Delivered Firewall Management Center)

  Unlike the first two certificates, this is a self-signed certificate.

These certificates are then imported into the Cloud-Delivered Firewall Management Center:

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Export a system certificate

Export a system certificate or a certificate with its associated private key for backup or transfer to another system.

You can export a system certificate or a certificate and its associated private key. If you export a certificate and its private key for backup purposes, you can reimport them later if needed.

Before you begin

To perform the following task, you must be a Super Admin or System Admin.

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration** > **System** > **Certificates** > **System Certificates**.

Step 2 Check the check box next to the certificate that you want to export and click **Export**.

Step 3 Choose whether to export only the certificate, or the certificate and its associated private key.

Tip
We do not recommend exporting the private key that is associated with a certificate because its value may be exposed. If you must export a private key (for example, when you export a wildcard system certificate to be imported into the other Cisco ISE nodes for inter-node communication), specify an encryption password for the private key. You must specify this password while importing this certificate into another Cisco ISE node to decrypt the private key.

Step 4 Enter the password if you have chosen to export the private key. The password should be at least eight characters long.

Step 5 Click **Export** to save the certificate to the file system that is running your client browser.

If you export only the certificate, the certificate is stored in the PEM format. If you export both the certificate and private key, the certificate is exported as a .zip file that contains the certificate in the PEM format and the encrypted private key file.

Generate a self-signed certificate

Generate a self-signed certificate to add a new local certificate for internal testing and evaluation purposes in Cisco ISE.

Add a new local certificate by generating a self-signed certificate. Cisco recommends that you only employ self-signed certificates for your internal testing and evaluation needs. If you plan to deploy Cisco ISE in a production environment, use CA-signed certificates whenever possible to ensure more uniform acceptance around a production network.

Note If you use a self-signed certificate and you want to change the hostname of your Cisco ISE node, log in to the administration portal of the Cisco ISE node, delete the self-signed certificate that has the old hostname, and generate a new self-signed certificate. Otherwise, Cisco ISE continues to use the self-signed certificate with the old hostname.

Before you begin

To perform this task, you must be a Super Admin or System Admin.

Follow these steps to generate a self-signed certificate:

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration** > **System** > **Certificates** > **System Certificates**.

To generate a self-signed certificate from a secondary node, choose **Administration** > **System** > **Server Certificate**.

Step 2 In the ISE-PIC GUI, click the **Menu** icon (☰) and choose **Certificates** > **System Certificates**.

Step 3 Click **Generate Self Signed Certificate** and enter the details in the window displayed.

Step 4 Check the check boxes in the **Usage** area based on the service for which you want to use this certificate.

Step 5 Click **Submit** to generate the certificate.

To restart the secondary nodes, from the CLI, enter these commands in this order:

a) **application stop ISE**
b) **application start ISE**

Import ISE/ISE-PIC certificates

Import certificates and keys from your ISE or ISE-PIC server to the firewall to enable secure pxGrid and MNT integration for cloud-delivered firewall management.

This procedure is optional.

- pxGrid client certificate: internal certificate with key (**Objects** > **Object Management** > **PKI** > **Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects** > **Object Management** > **PKI** > **Trusted CAs**)
- MNT certificate: trusted CA

Before you begin

Export certificates from the ISE/ISE-PIC server as discussed in Export a system certificate, on page 2385. The certificates and key must be present on the machine from which you log in to the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center if you have not already done so.
Step 2 Click **Objects** > **Object Management** > **PKI** > **Internal Certs**.
Step 3 Click **Add Internal Cert**.
Step 4 Follow the prompts on your screen to import the certificate and private key.
Step 5 Click **Trusted CAs**.
Step 6 Click **Add Trusted CA**.
Step 7 Follow the prompts on your screen to import the pxGrid server certificate.
Step 8 Repeat the preceding steps, if necessary, to import the MNT server's trusted CA.

Configure ISE for user control

Configure ISE/ISE-PIC identity source to enable user session retrieval from Microsoft Active Directory or LDAP servers for identity-based access control.

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

Firewall Threat Defense Feature History:

7.2—Optionally add a proxy, which is a connection to one or more cSecurity Cloud Control in the event Security Cloud Control cannot communicate with the ISE/ISE-PIC server. .

Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the Cisco ISE server, assuming the pxGrid persona, as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in Create and edit access control rules, on page 2066. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
  - To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.
- (Advanced configuration only.) Export certificates from the ISE/ISE-PIC server and optionally import them into the Cloud-Delivered Firewall Management Center as discussed in Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center, on page 2384.
- To publish SXP topics so the Cloud-Delivered Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server, see ISE/ISE-PIC configuration, on page 2382.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note
To disable the connection, click **None**.

Step 4 Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.

Step 5 Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **pxGrid Client Certificate** list. You can also click **Add** (+) to add a certificate.

Note
The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

Step 6 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 7 In the Subscribe To section, check the following:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

Step 8 (Optional.) From the **Proxy** list, click either a managed device or a proxy sequence.
If Security Cloud Control cannot communicate with your ISE/ISE-PIC server, you can choose either a managed device or proxy sequence to do it. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

Step 9 To test the connection, click **Test**.

If the test fails, click **Additional Logs** for more information about the connection failure.

Note
If you set up load balancing with ISE, the node that responds to the test should be the currently active node. For more information, see Cisco pxGrid Node.

What to do next

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity .

ISE/ISE-PIC configuration fields

The fields in this reference are used to configure a connection to ISE/ISE-PIC.

Connection and certificate configuration fields for ISE/ISE-PIC integration:

- **Primary and Secondary Host Name/IP Address**: The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers. The ports used by the host names you specify must be reachable by both ISE and the Cloud-Delivered Firewall Management Center.
- **pxGrid Server CA**: The trusted certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.
- **MNT Server CA**: The trusted certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.
- pxGrid Client Certificate: The internal certificate and key that the Cloud-Delivered Firewall Management Center must provide to /ISE-PIC to connect to /ISE-PIC or to perform bulk downloads.

Note The **pxGrid Client Certificate** must include the clientAuth extended key usage value, or it must not include any extended key usage values.

Data filtering, subscription, and proxy configuration fields:

- **ISE Network Filter**: An optional filter you can set to restrict the data that ISE reports to the Cloud-Delivered Firewall Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in these ways:
  - Leave the field blank to specify **`any`**.

- Enter a single IPv4 address block using CIDR notation.
- Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

- **Subscribe to**: **Session Directory Topic**: Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata. **SXP Topic**: Check this box to subscribe to SXP mappings from the ISE server.
- **Proxy**: You can optionally choose either a managed device or a proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

Note This version of the system does not support filtering using IPv6 addresses, regardless of your ISE version.

Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source

Cisco ISE identity source configuration methods are approaches that

- enable authentication and certificate management for the firewall
- provide quick or advanced setup options based on integration requirements, and
- support different ISE deployment types including ISE-PIC.

Configuration methods

You can configure the Cisco ISE identity source in these ways:

- Quick configuration (new): *Cisco ISE only; not supported for ISE-PIC*. Enter the user name and password of a user in at least the External RESTful Services (ERS) Operator group. The Cloud-Delivered Firewall Management Center logs into the Cisco ISE Primary Authentication Node (PAN), downloads the certificates, and configures the identity source. You have the option of saving the ISE configuration for later use.

  For more information about groups, see the section on Cisco ISE Administrator Groups in the Identity Services Engine administrator guides.

  For details, see Quick configuration, on page 2392.

- Advanced configuration (old): Same as previous Cloud-Delivered Firewall Management Center releases and works for both Cisco ISE and ISE-PIC. You must get certificates and other information from your ISE/ISE-PIC server as discussed in ISE/ISE-PIC configuration, on page 2382.

  For details about advanced configuration, see Configure Cisco ISE advanced configuration, on page 2396.

Cisco ISE quick configuration

Cisco ISE quick configuration lets you configure ISE using only the user name and password of a user in the External RESTful Services (ERS) Operator group. (This feature is available for ISE only, not ISE-PIC.)

Prerequisites and requirements

Complete these tasks first: Configure prerequisites for Cisco ISE quick configuration, on page 2391.

You must have the following information:

- the fully qualified domain name or IP address of the policy administration node (PAN) and
- the user name and password of a user in at least the External RESTful Services (ERS) Operator group.

Note the following about SGT-to-IP mappings and SXP:

- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in Create and edit access control rules, on page 2066. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
  - To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.

Configure prerequisites for Cisco ISE quick configuration

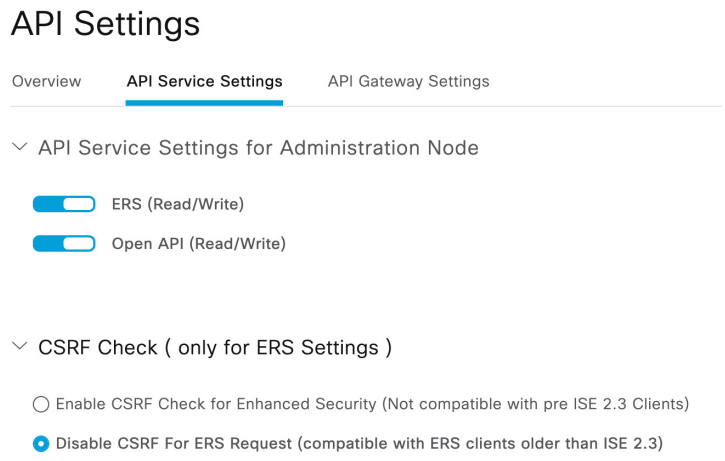
Configure the necessary ISE settings to enable quick configuration functionality through API services and certificate authority features.

As an ISE administrator, you must configure specific API and certificate authority settings to ensure ISE quick configuration works properly.

Before you begin

You must have ISE administrator privileges.

Follow these steps to configure prerequisites for Cisco ISE quick configuration:



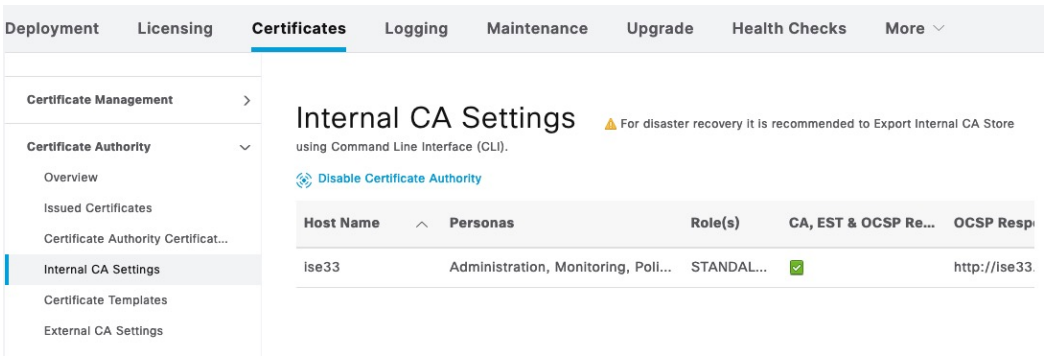
Procedure

Step 1 Enable External RESTful Services (ERS) (read/write), Open API (read/write), and *disable* the Cross-Site Request Forgery (CSRF) check.

Go to  > **Administration** > **System** > **Settings** > **API Settings** > **API Service Settings**

For more information, see Enable API Service in the Identity Services Engine administrator guides.

The following figure shows an example.



Step 2 Slide **ERS (Read/Write)** to **Enabled**.

Step 3 Enable the certificate authority.

Go to > **Administration** > **System** > **Certificates** > **Certificate Authority** > **Internal CA Settings**

For more information, see Internal CA Settings in the Identity Services Engine administrator guides.

The following figure shows an example.

ISE quick configuration is now enabled with the proper API services and certificate authority settings configured.

Quick configuration

Configure Cisco ISE integration with the firewall to authenticate applications and enable identity-based access control.

This task discusses how to configure Cisco ISE (but not ISE-PIC) by entering a user name and password. The Cloud-Delivered Firewall Management Center then logs in to ISE and downloads the necessary certificates to authenticate the two applications.

Firewall Threat Defense Feature History:

7.6—This feature is introduced.

Before you begin

See these topics first:

- Cisco ISE quick configuration, on page 2391
- Configure prerequisites for Cisco ISE quick configuration, on page 2391

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center. Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**

Step 2 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note
To disable the connection, click **None**.

Step 3 Click **Quick Configuration (New)**.

a) In the **Primary PAN FQDN/IP Address** field, enter the fully qualified domain name or IP address of the policy administration node (PAN). Do *not* enter a scheme (such as **https://**).

b) In the **Username** field, enter the user name of a user in at least the ERS Operator group.

For more information about groups, see the section on Cisco ISE Administrator Groups in the Identity Services Engine administrator guides.

c) In the **Password** field, enter the user's password.

Step 4 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 5 In the Subscribe To section, check both options:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

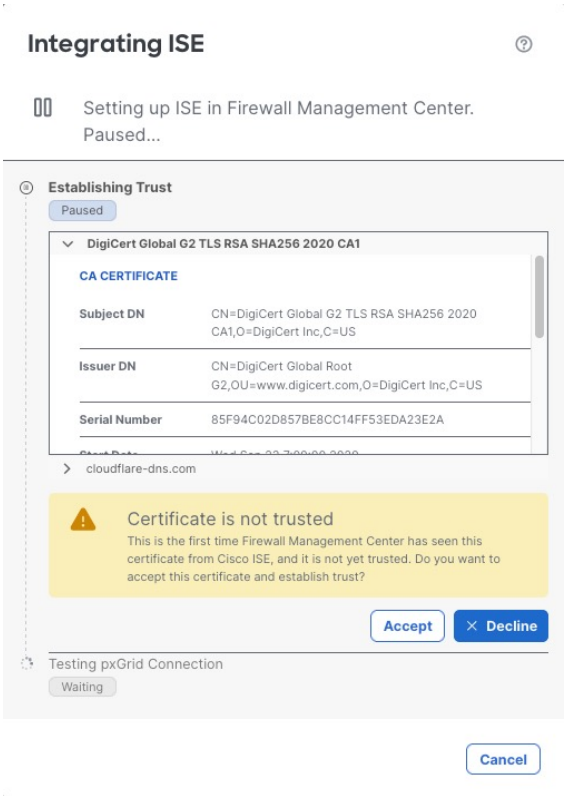
Step 6 (Optional.) From the **Proxy** list, click either a managed device or a proxy sequence.
If Security Cloud Control cannot communicate with your ISE/ISE-PIC server, you can choose either a managed device or proxy sequence to do it. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

Step 7 To test the connection, click **Test**.

Step 8 (Optional.) After a successful test, click **Save this Config** at the top of the page to save the configuration on the Cloud-Delivered Firewall Management Center.

What to do next

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.



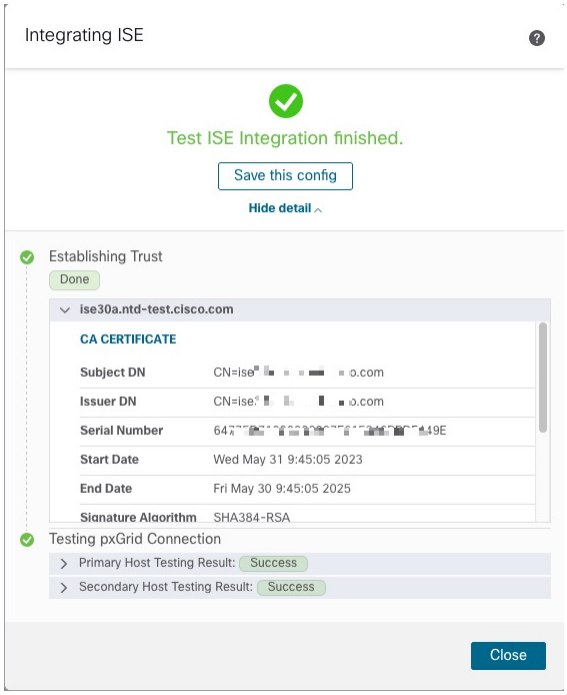
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity .

Cisco Identity Services Engine (Cisco ISE) quick configuration results

This reference provides information about the different results that can occur during Cisco Identity Services Engine (Cisco ISE) quick configuration integration with the firewall, including certificate trust prompts and authentication outcomes.

Initial information page for an untrusted certificate

When you enter required information in the **Quick Configuration (New)** tab page, the system first checks to see if the certificate was signed by a trusted authority. If not, a page similar to this is displayed.



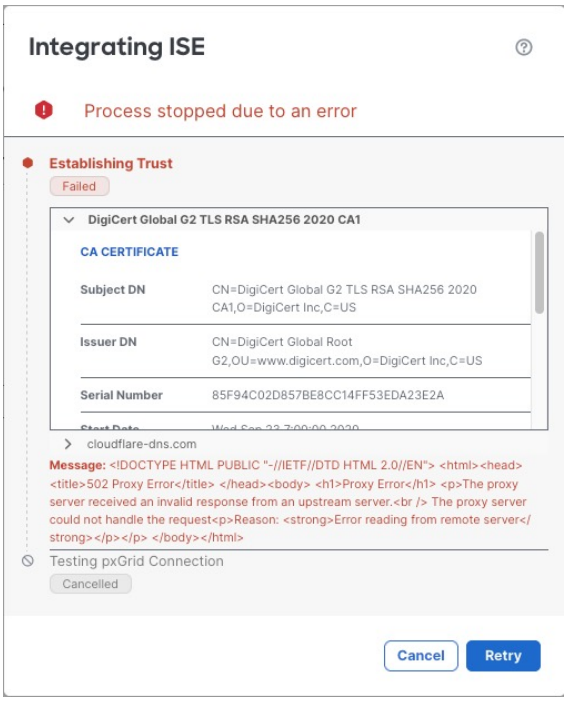
You have these options:

- Click **Accept** for the > to trust the certificate and continue authenticating with ISE.
- Click **Decline** to quit without authenticating with ISE.

  You can then verify the ISE configuration on the **Quick Configuration (New)** tab page and try again.

Successful ISE integration

If the Cloud-Delivered Firewall Management Center was able to authenticate successfully with the information you provided, a page similar to this is displayed.



Click **Save this Config** to save it and be able to use the identity source in the future.

Optionally expand one of the lists under Testing pxGrid Connection to display certificates downloaded from those sources.

Unsuccessful ISE integration

If the Cloud-Delivered Firewall Management Center fails to authenticate with ISE for any reason, a page similar to this is displayed.

The error messages are displayed in red text.

You have these options:

- If the error is temporary (for example, a temporarily network issue), click **Retry**.
- To try again with different ISE credentials, click **Cancel**.

Configure Cisco ISE advanced configuration

This task configures ISE/ISE-PIC identity source integration with the firewall to enable advanced security policies based on user identity.

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

Firewall Threat Defense Feature History:

7.2—Optionally add a proxy, which is a connection to one or more cSecurity Cloud Control in the event Security Cloud Control cannot communicate with the ISE/ISE-PIC server. .

Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the Cisco ISE server, assuming the pxGrid persona, as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:

- To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in Create and edit access control rules, on page 2066. Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
- To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.

- (Advanced configuration only.) Export certificates from the ISE/ISE-PIC server and optionally import them into the Cloud-Delivered Firewall Management Center as discussed in Export certificates from the ISE/ISE-PIC server for use in the Cloud-Delivered Firewall Management Center, on page 2384.
- To publish SXP topics so the Cloud-Delivered Firewall Management Center can be updated with Security Group Tags (SGT) on the ISE server, see ISE/ISE-PIC configuration, on page 2382.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Integration** > **Other Integrations** > **Identity Sources**.

Step 3 Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.

Note
To disable the connection, click **None**.

Step 4 Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.

Step 5 Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **pxGrid Client Certificate** list. You can also click **Add** (+) to add a certificate.

Note
The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

Step 6 (Optional.) Enter an **ISE Network Filter** using CIDR block notation.

Step 7 In the Subscribe To section, check the following:

- **Session Directory Topic** to receive ISE user session information from the ISE server.
- **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.

Step 8 (Optional.) From the **Proxy** list, click either a managed device or a proxy sequence.
If Security Cloud Control cannot communicate with your ISE/ISE-PIC server, you can choose either a managed device or proxy sequence to do it. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

Step 9 To test the connection, click **Test**.

If the test fails, click **Additional Logs** for more information about the connection failure.

Note

If you set up load balancing with ISE, the node that responds to the test should be the currently active node. For more information, see Cisco pxGrid Node.

What to do next

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity .

ISE/ISE-PIC configuration fields

The fields in this reference are used to configure a connection to ISE/ISE-PIC.

Connection and certificate configuration fields for ISE/ISE-PIC integration:

- **Primary and Secondary Host Name/IP Address**: The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers. The ports used by the host names you specify must be reachable by both ISE and the Cloud-Delivered Firewall Management Center.
- **pxGrid Server CA**: The trusted certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.
- **MNT Server CA**: The trusted certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.
- pxGrid Client Certificate: The internal certificate and key that the Cloud-Delivered Firewall Management Center must provide to /ISE-PIC to connect to /ISE-PIC or to perform bulk downloads.

Note The **pxGrid Client Certificate** must include the clientAuth extended key usage value, or it must not include any extended key usage values.

Data filtering, subscription, and proxy configuration fields:

- **ISE Network Filter**: An optional filter you can set to restrict the data that ISE reports to the Cloud-Delivered Firewall Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in these ways:
  - Leave the field blank to specify **`any`**.
  - Enter a single IPv4 address block using CIDR notation.

- Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

- **Subscribe to**: **Session Directory Topic**: Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata. **SXP Topic**: Check this box to subscribe to SXP mappings from the ISE server.
- **Proxy**: You can optionally choose either a managed device or a proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

Note This version of the system does not support filtering using IPv6 addresses, regardless of your ISE version.

Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues

This reference helps you troubleshoot issues with Cisco TrustSec, ISE, or ISE-PIC integration to ensure Security Group Tag propagation, user mapping, and certificate requirements are correctly configured for Cloud-Delivered Firewall Management Center and Secure Firewall Management Center deployments.

Troubleshoot Cisco TrustSec issues

A device interface can be configured to propagate Security Group Tags (SGTs) either from ISE/ISE-PIC or from a Cisco device on the network (referred to as Cisco TrustSec.) On the device management page (**Devices** > **Device Management**), the **Propagate Security Group Tag** check box for an interface is checked after a device reboot. If you do not want the interface to propagate TrustSec data, uncheck the box.

Troubleshoot ISE/ISE-PIC issues

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 2342 and Troubleshoot user control, on page 2526.

If you experience issues with the ISE or ISE-PIC connection, check these items:

- The pxGrid Identity Mapping feature in ISE must be enabled before you can successfully integrate ISE with the system.
- When the primary server fails, you must manually promote the secondary to primary; there is no automatic failover.
- Before a connection between the ISE server and the Cloud-Delivered Firewall Management Center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

  You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the Identity Services Engine administrator guides.
- The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

- The time on your ISE server must be synchronized with the time on the Cloud-Delivered Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.
- If your deployment includes a primary and a secondary pxGrid node,
  - The certificates for both nodes must be signed by the same certificate authority.
  - The ports used by the host name must be reachable by both the ISE server and by the Cloud-Delivered Firewall Management Center.
- If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

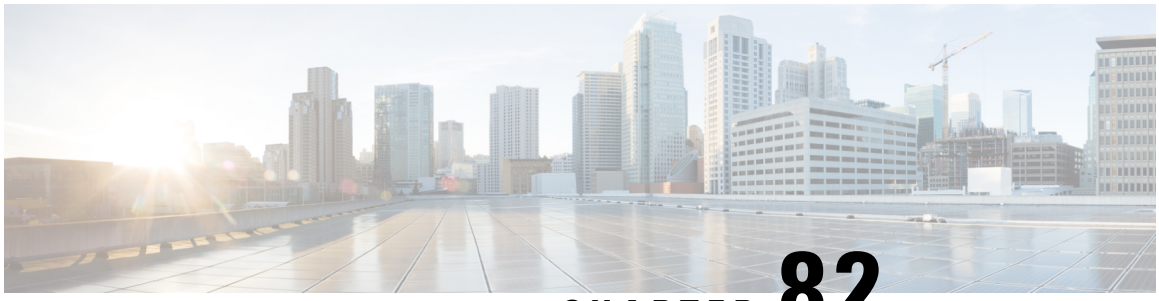
To exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE, use the **configure identity-subnet-filter** {**add** | **remove**} command. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

If you experience issues with user data reported by ISE or ISE-PIC, note these items:

- After the system detects activity from an ISE user whose data is not yet in the database, the system retrieves information about them from the server. Activity seen by the ISE user is *not* handled by access control rules, and is *not* displayed in the web interface until the system successfully retrieves information about them in a user download.
- You cannot perform user control on ISE users who were authenticated by an LDAP, RADIUS, or RSA domain controller.
- The Cloud-Delivered Firewall Management Center does not receive user data for ISE Guest Services users.
- If ISE monitors the same users as TS Agent, the Cloud-Delivered Firewall Management Center prioritizes the TS Agent data. If the TS Agent and ISE report identical activity from the same IP address, only the TS Agent data is logged to the Cloud-Delivered Firewall Management Center.
- Your ISE version and configuration impact how you can use ISE in the system. For more information, see The ISE/ISE-PIC identity source, on page 2373.
- If you have Cloud-Delivered Firewall Management Center high availability configured and the primary fails, see the section on ISE and high availability in Best practices for ISE/ISE-PIC integration, on page 2376.
- ISE-PIC does not provide ISE attribute data.
- ISE-PIC cannot perform ISE ANC remediations.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, refer to RFC 959.

If you experience issues with supported functionality, see The ISE/ISE-PIC identity source, on page 2373 for more information about version compatibility.

ISE/ISE-PIC user timeout



If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the Cloud-Delivered Firewall Management Center.

History for ISE/ISE-PIC

This reference provides the historical development of ISE and ISE-PIC integration features across different software versions.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Quick configuration	20241127	7.6.0	You can optionally configure ISE using only the user name and password of a user in the External RESTful Services (ERS) Operator group. (*This feature is available for ISE only, not ISE-PIC.*) **Upgrade impact**. Any ISE or ISE-PIC identity source you created before upgrade is still available on the **Advanced Configuration (Old)** tab page. Quick configuration affects only new ISE identity sources created after the upgrade. New/modified screens: **Integration** > **Other Integrations** > **Identity Sources** > **Identity Services Engine**. There are two tab pages: **Quick Configuration (New)** and **Advanced Configuration (Old)**. New/modified CLI commands: none
Proxy	Any	7.2.0	One or more managed devices that can communicate with Security Cloud Control in the event Security Cloud Control cannot communicate with the ISE/ISE-PIC server. **New/updated screen**: **Integration** > **Other Integrations** > **Realms** > **Proxy Sequence**
pxGrid 2.0 is the default for supported ISE/ISE-PIC versions	Any	6.7.0	Note: • Supported ISE/ISE-PIC versions: 2.6 patch 6 or later, 2.7 patch 2 or later • Adaptive Network Control (ANC) policies replace Endpoint Protection Service (EPS) remediations. If you have EPS policies configured in the Cloud-Delivered Firewall Management Center, you must migrate them to use ANC.
Optionally exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.	Any	6.7.0	New command: **configure identity-subnet-filter** {**add** | **remove**}

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Destination Security Group Tag matching (SGT)	Any	6.5.0	Feature introduced. Enables you to use ISE SGT tags for both source and destination matching criteria in access control rules. SGT tags are tag-to-host/network mappings obtained by ISE. New/modified screens: • New options to configure Destination SGT matching: **System** > **Integration** > **Identity Sources** > **ISE/ISE-PIC** • **Session Directory Topic**: Subscribe to ISE user session information. • **SXP Topic**: Subscribe to SGT tag updates on the ISE server. • New and renamed columns in **Analysis** > **Connections** > **Events** • Renamed: Security Groups Tags renamed to Source SGT • New: Destination SGT
Integration with ISE-PIC	Any	6.2.1	You can now use data from ISE-PIC.
SGT tags for user control.	Any	6.2.0	You no longer need to create a realm or identity policy to perform user control based on ISE Security Group Tag (SGT) data.
Integration with ISE.	Any	6.0	Feature introduced. By subscribing to Cisco's Platform Exchange Grid (PxGrid), the Firepower Management Center can download additional user data, device type data, device location data, and Security Group Tags (SGTs) —a method used by ISE to provide network access control).

CHAPTER 82

Identity Source: Passive Identity Agent

The following topics discuss how to configure and use the passive identity agent.

- The passive identity agent identity source, on page 2403
- Deploy the passive identity agent, on page 2404
- How to configure a passive identity agent identity source, on page 2409
- Configure the passive identity agent, on page 2410
- Monitor the passive identity agent, on page 2426
- Manage the passive identity agent, on page 2427
- Troubleshoot the passive identity agent, on page 2429
- Security requirements for the passive identity agent, on page 2430
- Internet access requirements for the passive identity agent, on page 2431
- History for the passive identity agent, on page 2431

The passive identity agent identity source

The passive identity agent identity source sends session data from Microsoft Active Directory (AD) to the Cloud-Delivered Firewall Management Center. All you need is a supported Microsoft AD setup as described in Realms and realm sequences, on page 2273.

Passive identity agent roles

The passive identity agent supports these roles: Standalone, Primary, and Secondary.

Note You do not need to configure the Cisco Identity Services Engine (ISE) to use this identity source.

For more information on these roles, refer to About passive identity agent roles.

Passive identity agent system requirements

The passive identity agent supports Windows Server 2016, 2019, 2022, and 2025 on Active Directory servers, and Windows 11 or later on domain-joined Windows clients. The system time must be synchronized across the Cloud-Delivered Firewall Management Center, domain controllers, and the agent host.

Refer to Passive identity agent system requirements for more information.

Passive identity agent limitations

The passive identity agent has these limitations:

- Up to 10 agents simultaneously
- A single passive identity agent identity source monitors up to 50 AD directories
- Up to 300,000 concurrent user sessions
- IPv6 addresses are *not* supported (passive identity agent 1.0)
- IPv6 addresses are supported (passive identity agent 1.1)
- Cloud-Delivered Firewall Management Center receives user login information from the Passive Identity Agent but does not track or process user logoff events. As a result, Cloud-Delivered Firewall Management Center does not detect user session termination and continues to show user information until either the realm times out or the administrator deletes the user session.

Deploy the passive identity agent

For information about deployment options, see Deploy the passive identity agent, on page 2404.

Note We recommend you use the latest version of the passive identity agent.

To see the available versions, go to software.cisco.com.

To upgrade the passive identity agent, see Upgrade the passive identity agent software, on page 2426.

Deploy the passive identity agent

Deploy the passive identity agent software on any machine that is part of a Microsoft Active Directory (AD) domain that you want to use for user awareness and control.

Installation locations and agent types

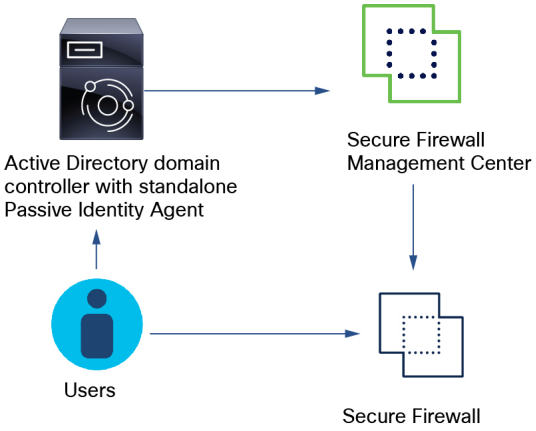
You can install the passive identity agent software on any of the following machines:

- The Microsoft Active Directory server
- A domain controller
- A client connected to the network that is neither the directory server nor a domain controller

Any particular passive identity agent can monitor one or several Active Directory domain controllers in the same domain.

The machine on which the passive identity agent is installed must communicate with the Cloud-Delivered Firewall Management Center using the TLS/SSL protocol. For more information, see Internet access requirements for the passive identity agent, on page 2431.

You can configure the following types of agents on the Microsoft AD directory server, domain controller, or on any client connected to the domain:



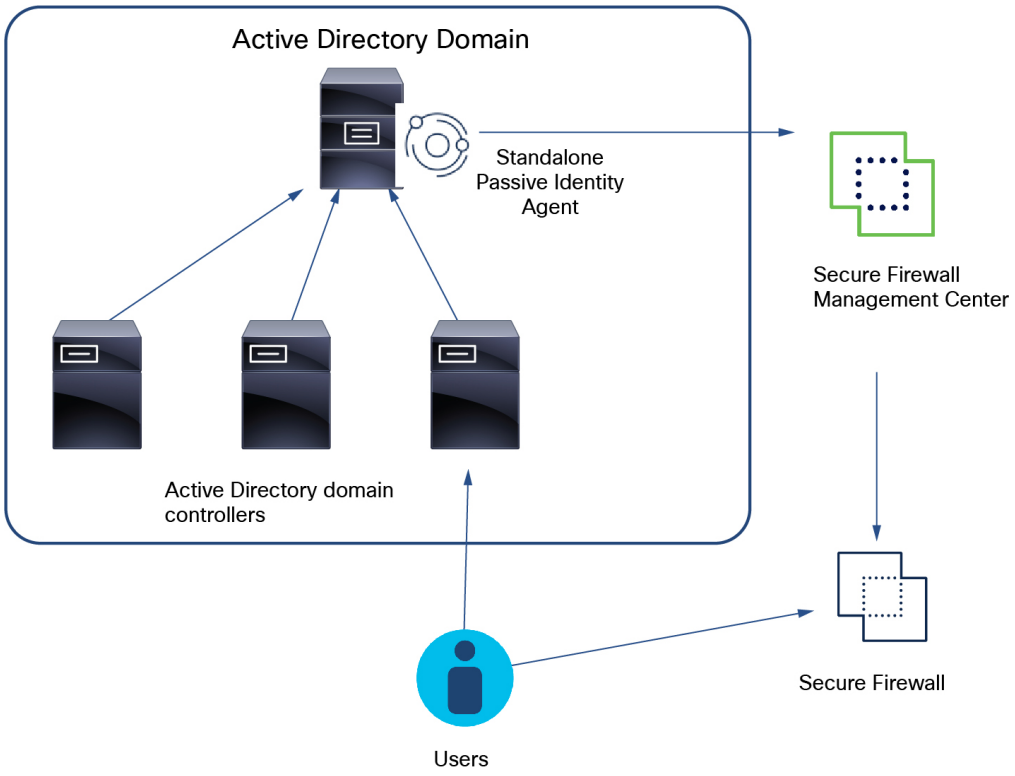
- Standalone agent: One agent that can monitor one or several Active Directory domain controllers in the same domain.
- Primary agent and secondary agent: Both can monitor one or several AD domain controllers in the same domain. To provide redundancy, you can install a primary agent and a secondary agent on different machines. The primary agent is responsible for communicating with the Cloud-Delivered Firewall Management Center. If communication fails, the secondary agent takes over.

Related Topics

Simple passive identity agent deployment, on page 2405
Single passive identity agent monitoring multiple domain controllers, on page 2405
Multiple passive identity agents monitoring multiple domain controllers, on page 2406
Configure Passive identity agent primary and secondary agent deployments, on page 2408

Simple passive identity agent deployment

The following diagram shows the simplest passive identity agent deployment.



Deployment architecture

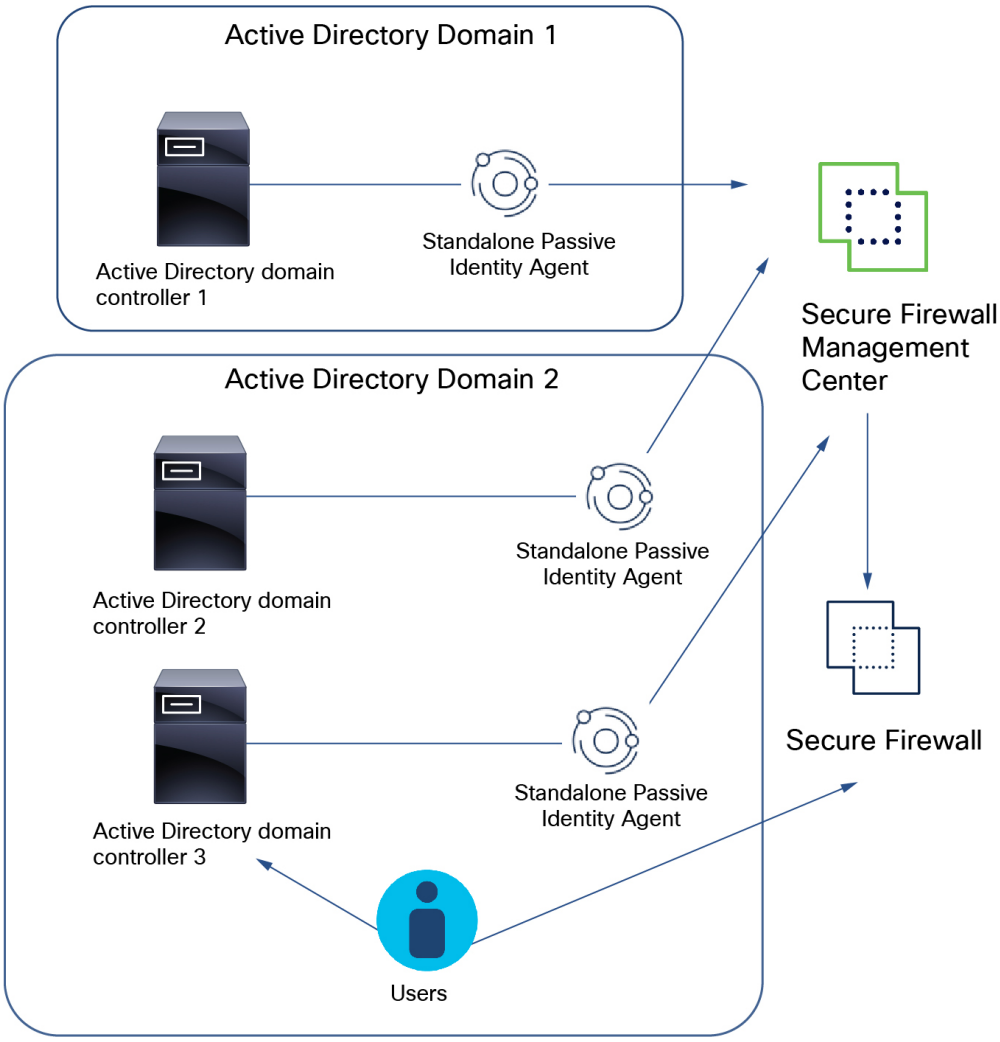
In this example, a standalone passive identity agent is installed on the AD domain controller. Users log in and out of the AD domain. The agent sends user name and IP address information to the Cloud-Delivered Firewall Management Center. As users access the network, access control and identity policies deployed to the Secure Firewall Threat Defense determine whether or not access is allowed and how access is granted.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

Single passive identity agent monitoring multiple domain controllers

The diagram shows a standalone passive identity agent that monitors several AD domain controllers.

Architecture details



In this diagram, the standalone passive identity agent is installed on a client attached to the AD domain (or on the domain controller itself). Users log in to any domain controller and the agent sends user and IP address information to the Cloud-Delivered Firewall Management Center. As users access the network, access control and identity policies deployed to the Secure Firewall Threat Defense determine whether access is allowed and how access is permitted.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

Multiple passive identity agents monitoring multiple domain controllers

This figure illustrates how standalone agents monitor multiple AD domain controllers.

- In AD domain 1, a standalone passive identity agent installed on a machine attached to AD domain controller 1 sends user and IP address mapping data to the .
- In AD domain 2, standalone agents installed on domain controllers 1 and 2 send user and IP address mapping data to the .

You can install a passive identity agent on an AD domain controller, a directory server, or on any client connected to the domain you want to monitor.

Deployment steps

The preceding figure shows three passive identity agents, each configured as a standalone. To do this:

1. Create two Microsoft AD realms: one for each AD domain.

   See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

2. For AD domain 2, create two directories, one for each domain controller.
3. Install the Passive Identity Agent software on a client that can log in to the domain.

   Configure each passive identity agent individually to communicate with the on which you configure the passive identity agent source.

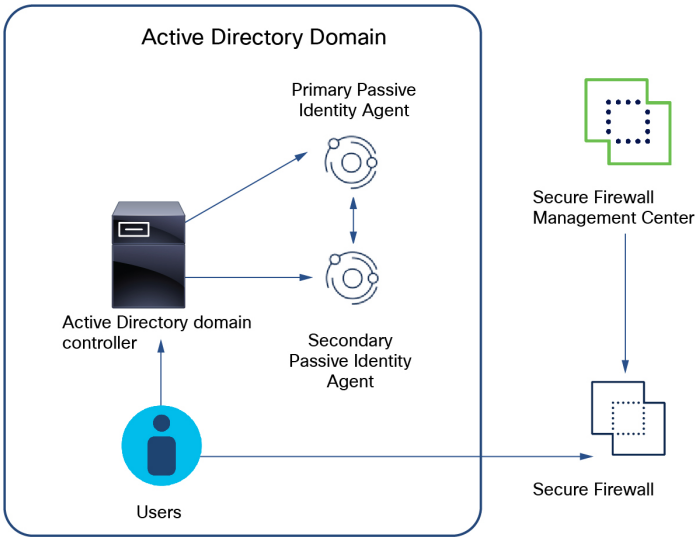
   See Install the passive identity agent software, on page 2422.

4. Create the passive identity agent identity source.

See Create a primary or secondary passive identity agent identity source, on page 2414.

Configure Passive identity agent primary and secondary agent deployments

Configure primary and secondary passive identity agents to provide redundancy and avoid a single point of failure in user identity monitoring.



To provide redundancy and to avoid a single point of failure, you can configure primary and secondary passive identity agents in any of the ways shown in this topic.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

Procedure

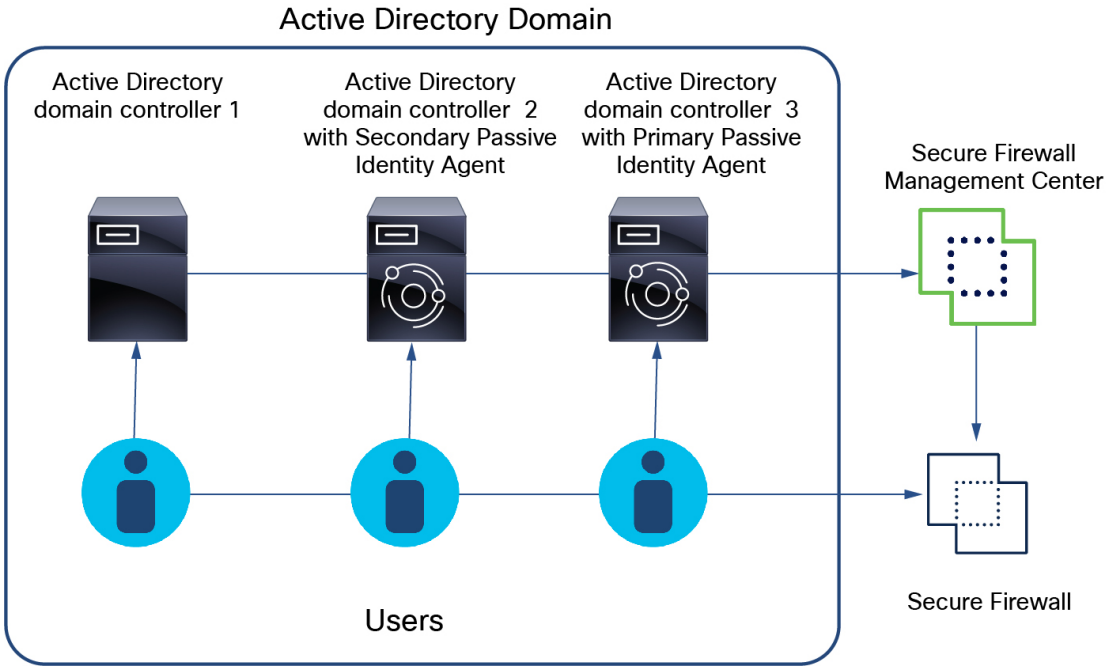
Step 1 For a single AD domain controller with primary and secondary agents deployment:

The following figure shows how to set up primary and secondary passive identity agents on one AD domain controller. If the primary agent fails, the secondary takes over.

a) Create a Microsoft AD realm that has one directory for the domain controller.

See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

b) Install the passive identity agent software on any two network machines connected to the domain controller.



Configure each passive identity agent individually to communicate with the Cloud-Delivered Firewall Management Center on which you configure the passive identity agent source.

See Install the passive identity agent software, on page 2422.

c) Create the identity source.

See Create a primary or secondary passive identity agent identity source, on page 2414.

Step 2 For multiple AD domain controllers with primary and secondary agents deployment.

The preceding figure shows how to configure primary and secondary agents to monitor three AD domain controllers. If the primary agent fails, the secondary agent takes over.

a) Create a Microsoft AD realm that has one directory for the domain controller.

See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

b) Install the passive identity agent software on any machine connected to the domain controller.

Configure each passive identity agent individually to communicate with the Cloud-Delivered Firewall Management Center on which you configure the passive identity agent source.

See Install the passive identity agent software, on page 2422.

c) Create the identity source.

See Create a primary or secondary passive identity agent identity source, on page 2414.

How to configure a passive identity agent identity source

Configure the passive identity agent identity source to enable user identity monitoring and enhance access control in your network environment.

This provides high-level tasks required to configure the passive identity agent identity source in the Cloud-Delivered Firewall Management Center and to deploy agent software to your Microsoft Active Directory (AD) servers.

Before you begin

Follow these steps to create a passive identity agent identity source:

Procedure

Step 1 (Optional.) Enable the Dynamic Attributes Connector.

Step 2 Create a realm for your Microsoft AD domain and domain controllers.

Realms are connections between the Cloud-Delivered Firewall Management Center and the user accounts on the servers you monitor. They specify the connection and authentication filter settings for the server.

For more information, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Step 3 Create a passive identity agent identity source.

The identity source allows the Cloud-Delivered Firewall Management Center and passive identity agent to communicate with each other. Create standalone, primary, or secondary agents, to match your requirements.

For more information, refer to:

- Passive identity agent roles, on page 2417
- Create a passive identity agent identity source, on page 2411

Step 4 Get the API token for the passive identity agent to authenticate with Cloud-Delivered Firewall Management Center.

Refer to Get an API token for the passive identity agent, on page 2418.

Step 5 Install the passive identity agent software.

The installation method for the agent varies according to your deployment.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

For more information, see:

- Deploy the passive identity agent, on page 2404
- Install the passive identity agent software, on page 2422

What to do next

Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Configure the passive identity agent

These topics discuss how to configure the passive identity agent.

Related Topics

Create an LDAP realm or an Active Directory realm and realm directory, on page 2325

Create a passive identity agent identity source, on page 2411
Install the passive identity agent software, on page 2422

Enable the dynamic attributes connector

Enable the dynamic attributes connector to allow objects from cloud networking products to be used in Cloud-Delivered Firewall Management Center access control and DNS rules.

This task discusses how to enable the dynamic attributes connector in the Cloud-Delivered Firewall Management Center. The dynamic attributes connector is an integration that enables objects from cloud networking products to be used in Cloud-Delivered Firewall Management Center access control and DNS rules.

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center if you have not done so already.

Step 2 Click **Administration** > **Dynamic Attributes Connector**.

Step 3 Slide to **Enabled**.

Step 4 The system displays messages when the dynamic attributes connector is enabled.

In the event of errors, try again. If errors persist, contact Cisco TAC.

See Connectors, on page 2631.

Create a Microsoft Active Directory realm

passive identity agent requires you to create a Microsoft Active Directory (AD) realm and directories in the Cloud-Delivered Firewall Management Center.

Additional information

For detailed instructions on creating a Microsoft Active Directory realm and directories, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Create a passive identity agent identity source

This task creates a passive identity agent that sends user session activity to the Cloud-Delivered Firewall Management Center.

Use this task to configure agent details, assign roles, and integrate with Microsoft AD for identity management and monitoring.

Before you begin

Complete the following:

- Review passive identity agent roles as discussed in Passive identity agent roles, on page 2417.
- Create a Microsoft AD realm as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

Follow these steps to create a passive identity agent identity source:

Procedure

Step 1 Log in to the Security Cloud Control.

Step 2 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 3 Click **Passive Identity Agent**.

Step 4 If the dynamic attributes connector has not been enabled yet, you are prompted to do so.

For more information about enabling the dynamic attributes connector, see Enable the dynamic attributes connector, on page 2411.

Step 5 Click **Create Agent**.

Step 6 In the Configure Agent dialog box, enter the following information:

Item	Description
Name	Enter a unique name to identify this passive identity agent.
Description	Enter an optional description.
Role	Click one of the following: • **Primary**: The agent responsible for communicating with the Cloud-Delivered Firewall Management Center. Not available if you choose **Standalone**. • **Secondary**: Becomes the primary if the primary loses contact with the Cloud-Delivered Firewall Management Center. Not available if you choose **Standalone**. • **Standalone**: If there is only one passive identity agent. For more information about roles, see Passive identity agent roles, on page 2417.

Step 7 Continue with:

- Create a standalone passive identity agent identity source, on page 2412
- Create a primary or secondary passive identity agent identity source, on page 2414

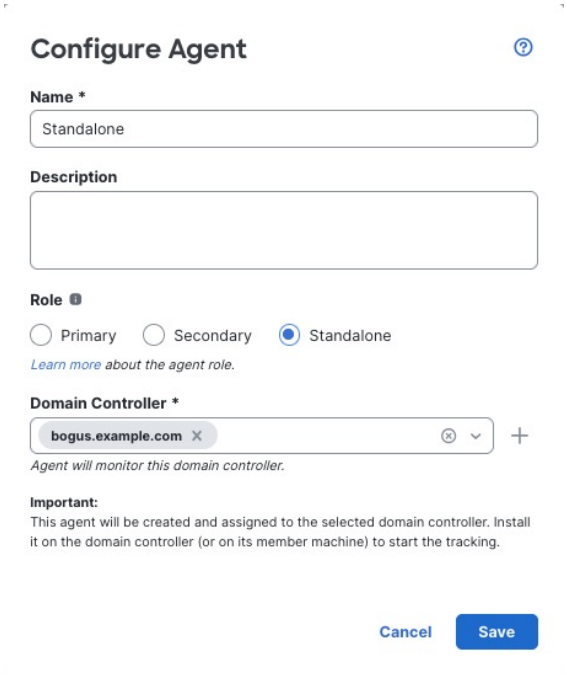
Create a standalone passive identity agent identity source

Configure a standalone passive identity agent to enable identity management and user control.

This task discusses how to configure a standalone passive identity agent.

Before you begin

Complete the tasks discussed in Create a passive identity agent identity source, on page 2411.

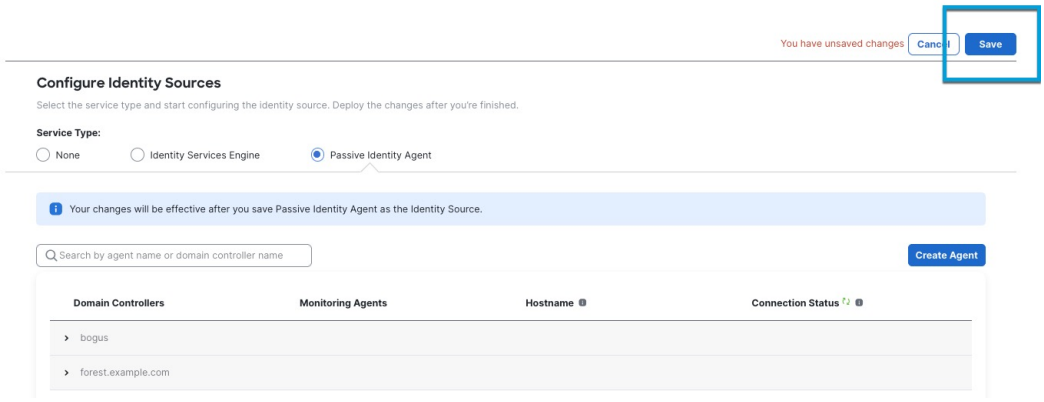


Follow these steps to create a standalone passive identity agent identity source:

Procedure

Step 1 In the Configure Agent dialog box, enter the following information:

Item	Description
Role	Click **Standalone**.
Domain Controller	From the list, select the check box next to each domain controller that has a passive identity agent you wish to use for identity management and user control. (Optional.) Click **Add** (+) to add a new one.



This figure shows an example of a standalone passive identity agent identity source.

Step 2 In the Configure Agent dialog box, click **Save**.

Step 3 In the top right corner of the page, click **Save**.

This figure shows an example.

Note
The passive identity agent won't be active until you create a user and install the software.

What to do next

- See Get an API token for the passive identity agent, on page 2418
- See Passive identity agent installation, on page 2418

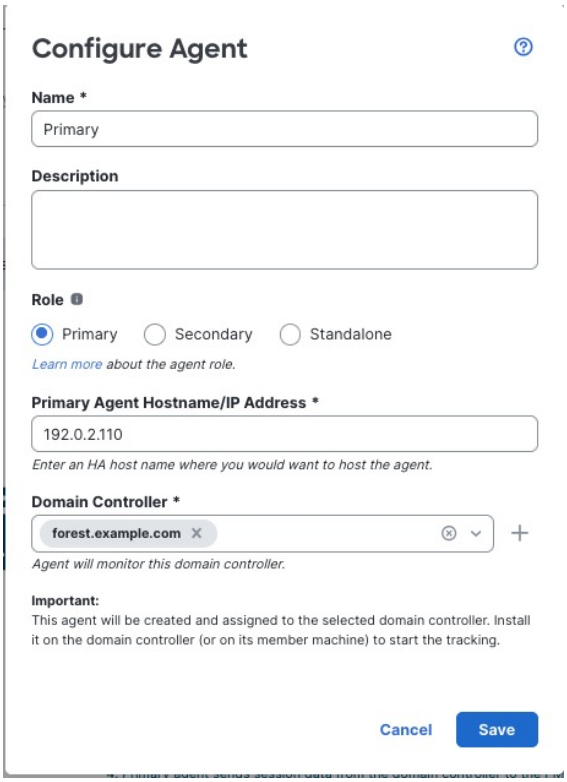
Create a primary or secondary passive identity agent identity source

This task enables you to configure a primary and secondary passive identity agent to manage user identities and ensure continuous communication with the firewall. You will assign agent roles, specify host details, and enable domain controller monitoring for identity management.

The following task continues from Create a passive identity agent identity source, on page 2411.

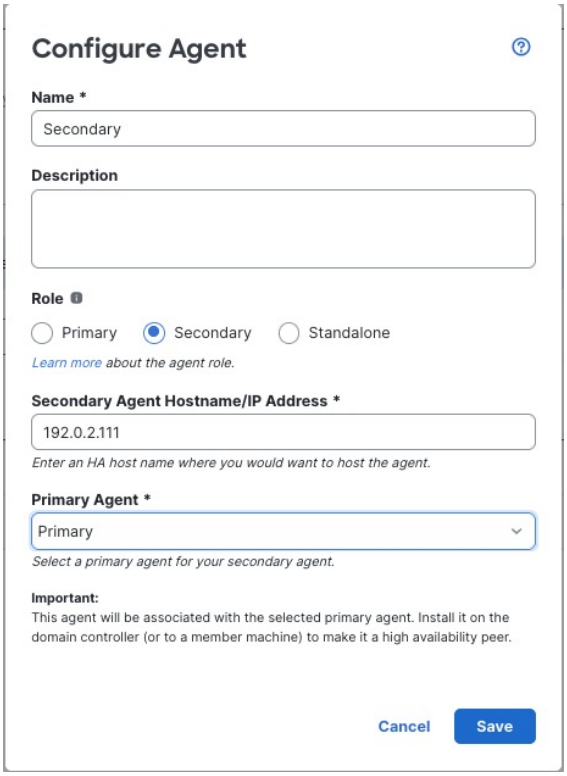
Before you begin

Complete the tasks discussed in Create a passive identity agent identity source, on page 2411.



Follow these steps to create a primary or secondary passive identity agent identity source:

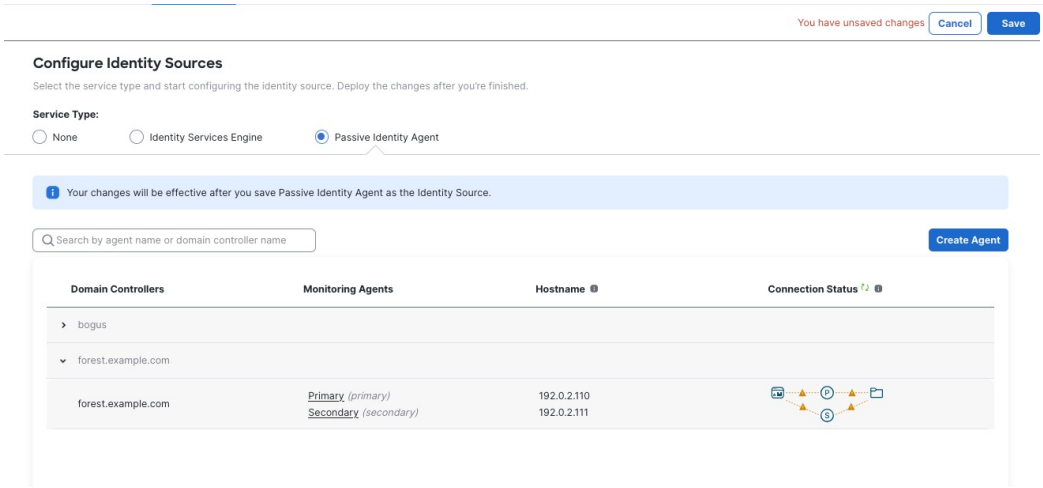
Procedure



Step 1 In the Configure Agent dialog box, enter the following information:

Item	Description
Role	Click one of the following: • **Primary**: The agent responsible for communicating with the Cloud-Delivered Firewall Management Center. • **Secondary**: Becomes the primary if the primary loses contact with the Cloud-Delivered Firewall Management Center. For more information about roles, see Passive identity agent roles, on page 2417.
Primary Agent Hostname/IP Address	(Primary agent only.) Enter the fully qualified domain name or IP address of the server on which the primary passive identity agent is installed. The passive identity agent version 1.0 supports IPv4 addresses and fully qualified domain names only. Version 1.1 supports IPv4, IPv6, and fully qualified domain names.
Secondary Agent Hostname/IP Address	(Secondary agent only.) Enter the fully qualified host name or IP address of the server on which the secondary passive identity agent is installed. The passive identity agent version 1.0 supports IPv4 addresses and fully qualified domain names only. Version 1.1 supports IPv4, IPv6, and fully qualified domain names.
Primary Agent	(Secondary agent only.) From the list, click the name of the primary passive identity agent.
Domain Controller	(Primary agent only.) From the list, select the check box next to each domain controller that has a passive identity agent you wish to use for identity management and user control.

The following figure shows an example of a primary agent:



The following figure shows an example of a secondary agent:

Step 2 In the Configure Agent dialog box, click **Save**.

Step 3 In the top right corner of the page, click **Save**.

The following figure shows an example.

Note
The passive identity agent won't be active until you create a user and install the software.

What to do next

- See Get an API token for the passive identity agent, on page 2418
- See Passive identity agent installation, on page 2418

Passive identity agent roles

A passive identity agent role determines how the agent functions in Active Directory environments for user and group monitoring.

Role types

The passive identity agent has the following roles:

- Standalone: A passive identity agent that is not part of a redundant pair. A standalone agent can read users and groups from multiple Active Directory servers and domain controllers, provided the software is installed on all of them.
- Primary: (Primary agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

  Handles all communication with the Cloud-Delivered Firewall Management Center unless it stops communicating, in which case communication is handled by secondary agents.
- Secondary: (Secondary, or backup, agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

Monitors the health of the primary agent and takes over if the primary agent stops communicating with the Cloud-Delivered Firewall Management Center.

The passive identity agent can monitor several AD domain controllers that are part of the same domain.

Get an API token for the passive identity agent

Use this procedure to obtain the API token that enables the passive identity agent to authenticate with the Cloud-Delivered Firewall Management Center.

This task applies *only* to using the passive identity agent with the Cloud-Delivered Firewall Management Center.

Required role:

- Super Admin
- Admin

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Administration** > **Firewall Management Center**.

Step 3 Check the box next to the Cloud-Delivered Firewall Management Center with which you want to use the passive identity agent.

Step 4 In the right pane, click **Passive Identity**.

Step 5 Copy the token to the clipboard.

What to do next

Install the passive identity agent software, on page 2422.

Passive identity agent installation

The passive identity agent installation process requires specific prerequisites and tasks to deploy the agent in your environment.

Installation requirements

These topics discuss prerequisites and tasks required to install the passive identity agent.

Note We recommend you use the latest version of the passive identity agent. To see the available versions, go to software.cisco.com. To upgrade the passive identity agent, see Upgrade the passive identity agent software, on page 2426

Prerequisites to install the passive identity agent

You must complete all of the tasks before you install the passive identity agent software.

Passive identity agent system requirements

This reference provides the system and software requirements for installing the passive identity agent, including supported Windows versions, synchronized system clocks, and necessary firewall software versions.

- If you install the passive identity agent on a Windows Active Directory server, the server must run one of the following versions:
  - Microsoft Windows Server 2016
  - Microsoft Windows Server 2019
  - Microsoft Windows Server 2022
- If you install the passive identity agent on a Windows client attached to the domain, the client must run Windows 11 or later.
- The system clock on all systems must be synchronized. We strongly recommend using the same NTP servers on all of them. This means:
  - The Security Cloud Control.

    For more information, see Configure NTP Server.
  - All Windows Active Directory servers and domain controllers.
  - The machine on which the passive identity agent is installed.
- Security Cloud Control must run November 8, 2024 or later.
- You must enable Snort 3 on the Secure Firewall Threat Defense devices.

Enable the windows event viewer to log kerberos authentication attempts

This task enables the Windows Event Viewer to log successful and unsuccessful Kerberos authentication attempts so that the passive identity agent can function properly by reading user sessions from the Event Viewer.

The passive identity agent reads user sessions from the Event Viewer so this setting is required for the passive identity agent to function properly.

For more information, see System audit policy recommendations on learn.microsoft.com.

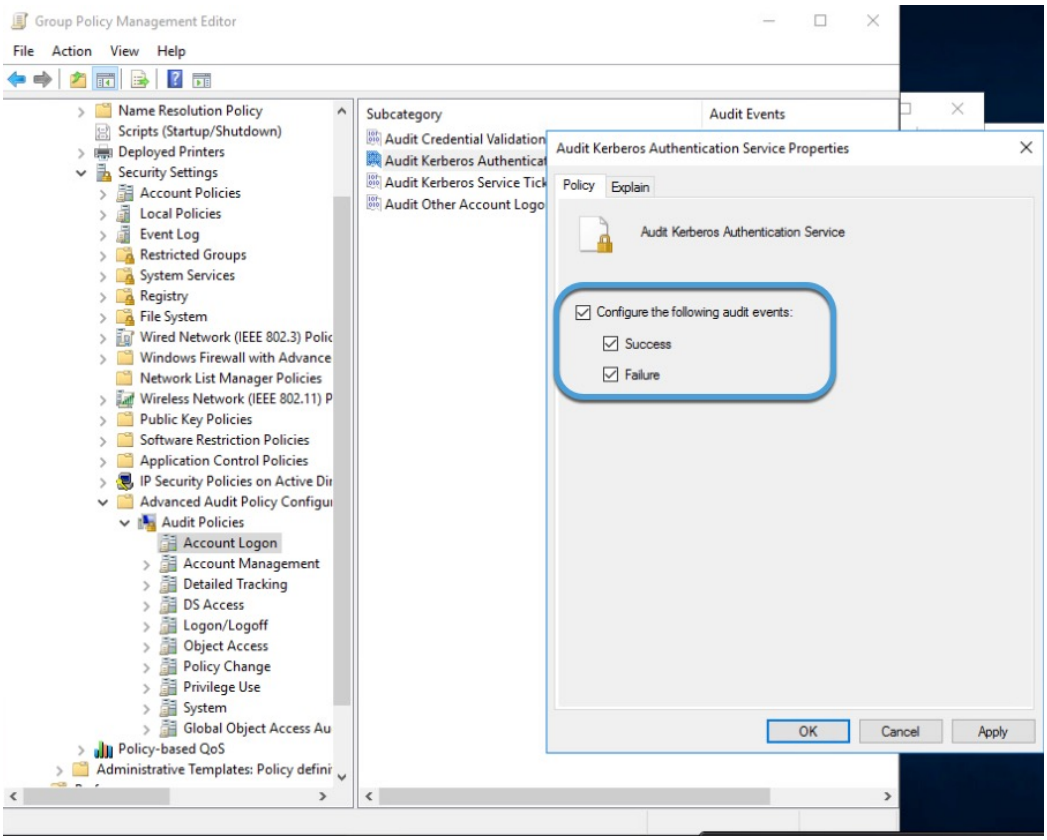
Procedure

Step 1 Log in to the Active Directory Server as an administrator and open a DOS command prompt.

Step 2 Enter `gpmc.msc` to start the Group Policy Management Editor.

Step 3 If necessary, create a new Group Policy Object (GPO); if one already exists, edit it.

For more information about creating a GPO, see a resource like Create a Group Policy Object on learn.microsoft.com.



Step 4 In your GPO, expand **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Advanced Policy Configuration** > **Audit Policies**.

Step 5 Click **Account Logon**.

Step 6 In the right pane, double-click **Audit Kerberos Authentication Service**.

Step 7 In the dialog box that is displayed, select all checkboxes which enables the system to log successes and failures.

The following figure shows an example.

Step 8 Follow the prompts on your screen to save the changes.

Step 9 (Optional.) To update GPO immediately, enter **`gpupdate /force`** in your DOS command prompt window.

What to do next

See Add the Active Directory user to groups, on page 2420.

Add the Active Directory user to groups

Use this procedure to give the Active Directory and passive identity agent service user sufficient privileges to Active Directory.

To function normally, the passive identity agent must be able to connect to the domain and to read the Windows Event Log. This topic discusses how to give the proper privileges to:

- The passive identity agent service user.

- Active Directory user (namely, the **Directory Username** user in the Active Directory realm on the Cloud-Delivered Firewall Management Center).

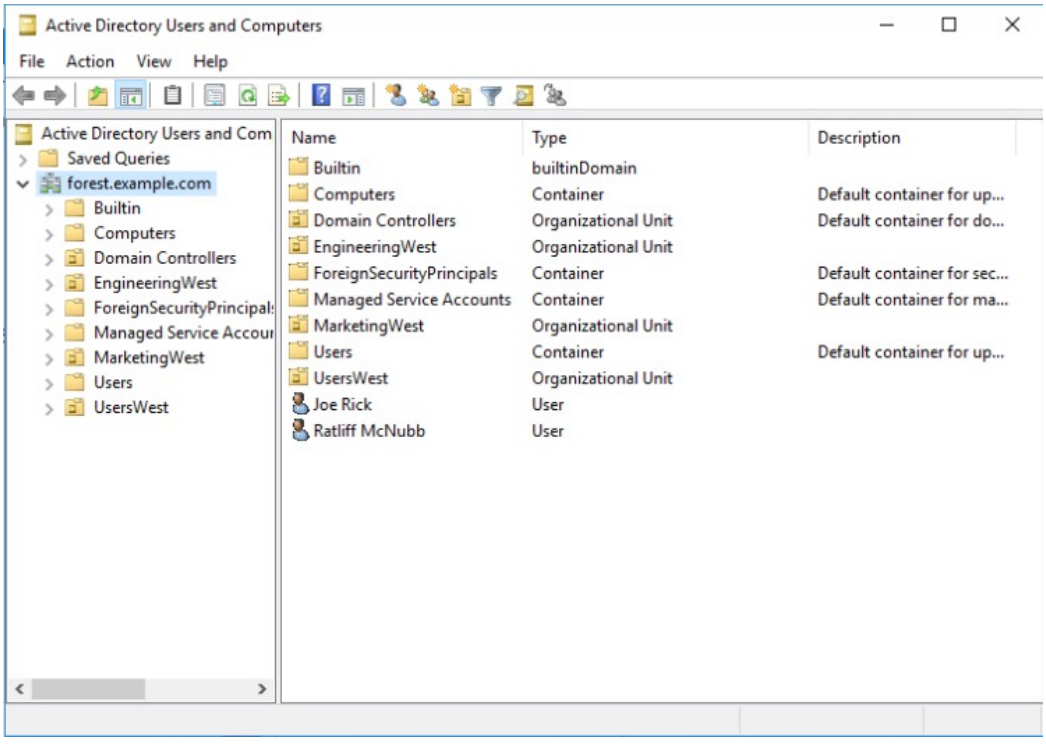
Before you begin

You must be a Microsoft Server administrator familiar with how to add a user to a group and how to set a Windows service to run as a specific user.

Procedure

Step 1 Log in as an administrator to the system on which the passive identity agent is running.

You can log in to any of the following:



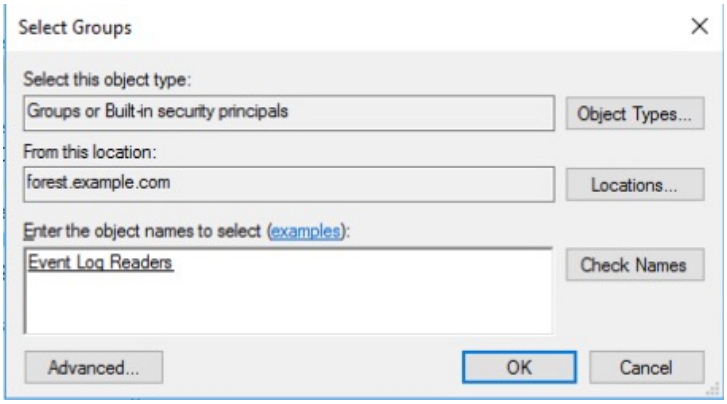
- The domain controller.
- The Active Directory server.

Step 2 Start the Server Manager.

Step 3 Click **Tools** > **Active Directory Users and Computers**.

Step 4 Under Active Directory Users and Computers, expand the forest in which the directory user is defined.

The following figure shows an example.



Step 5 Expand the organization unit or group to reveal the directory user. (You can create a new user by clicking **New** > **User**).

Step 6 Right-click the directory user and click **Add to a group**.

Step 7 In the Select Groups dialog box, enter **`Event Log Readers`** and click **Check Names**.

The following figure shows an example.

Step 8 Repeat the preceding tasks to add the user to the Domain Users group.

Step 9 In the Add Groups dialog box, click **OK**.

What to do next

See Install the passive identity agent software, on page 2422.

Install the passive identity agent software

Install the passive identity agent software to enable user identity monitoring and integration with your firewall management center.

This task discusses how to install the passive identity agent software. For a simple installation, you can install it on your Microsoft Active Directory (AD) domain controller; for other options, see Deploy the passive identity agent, on page 2404.

Note We recommend you use the latest version of the passive identity agent. To see the available versions, go to software.cisco.com. To upgrade the passive identity agent, see Upgrade the passive identity agent software, on page 2426

Before you begin

See Get an API token for the passive identity agent, on page 2418.

Complete all of these tasks:

- Enable the windows event viewer to log kerberos authentication attempts, on page 2419
- Add the Active Directory user to groups, on page 2420
- Add Log On to the Passive Identity Agent Service, on page 2424

Follow these steps to install the Passive Identity Agent Software:

Procedure

Step 1 Download the passive identity agent from software.cisco.com.

Step 2 Log in as a member of the Administrators group to the machine on which to install the passive identity agent.

Step 3 Double-click **CiscoPassiveIdentityAgentInstaller-1.1.1.msi** and click **Next**.

Step 4 Choose a folder in which to install the passive identity agent and click **Next**.

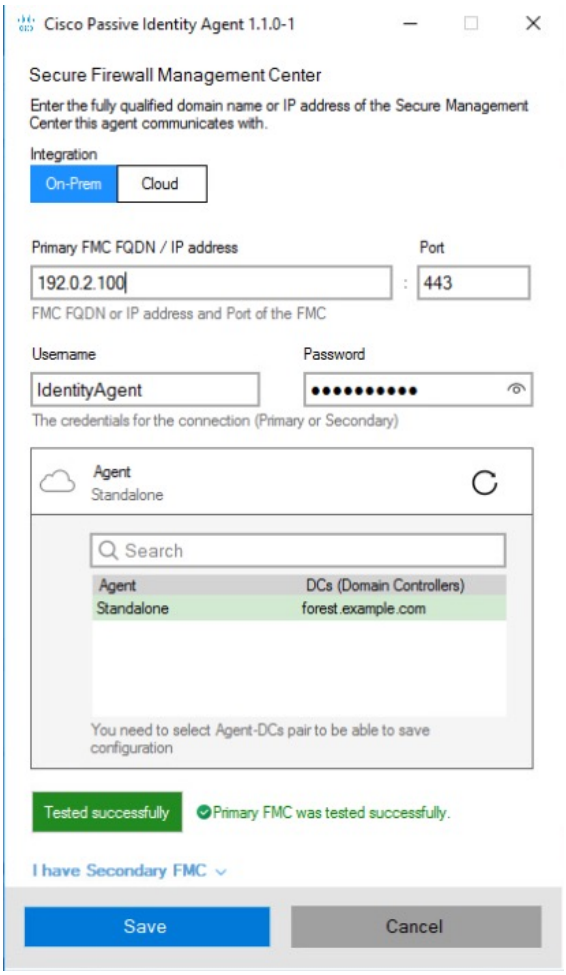
The default installation folder is **Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Step 5 Click **Install**.

Step 6 When the installation is done, click **Finish** and optionally check the box to start the passive identity agent.

Step 7 When the passive identity agent starts, click the **On-Prem** tab if you are using the agent with an on-premises Cloud-Delivered Firewall Management Center (physical or virtual) or click the **Cloud** tab if you are using the agent with Cloud-Delivered Firewall Management Center.

Step 8 In the Cisco Passive Agent dialog box, enter the following information:



Item	Description
FMC FQDN / IP Address	Enter the fully qualified domain name, IPv4, or IPv6 address of the Cloud-Delivered Firewall Management Center on which you created the passive identity agent identity source.
Token	Enter the API token you found in Get an API token for the passive identity agent, on page 2418.
Agent	Click the list to locate the domain controller of the passive identity agent you created previously on the Cloud-Delivered Firewall Management Center.

Step 9 Click the **Agent** list.

a) From the list, click the name of the domain controller to monitor.

b) Click **Test**.

The following figure shows an example.

c) Only if the test succeeds, click **Save**.

What to do next

See Add Log On to the Passive Identity Agent Service, on page 2424.

Add Log On to the Passive Identity Agent Service

Use this procedure to enable the passive identity agent service to run as the Active Directory user. This user is the **Directory Username** user in the Active Directory realm on the Cloud-Delivered Firewall Management Center.

This task is optional but recommended. It ensures that the passive identity agent service runs with the minimal permissions required to send login information to the Cloud-Delivered Firewall Management Center.

Before you begin

Complete the tasks in Add the Active Directory user to groups, on page 2420.

You must be a Microsoft Server administrator who knows how to add a user to a group and set a Windows service to run as a specific user.

Procedure

Step 1 Log in as an administrator to the system on which the passive identity agent is running.

You can log in to any of these:

- the domain controller
- the Active Directory server

Step 2 In the Windows search bar, enter **`Services`**.

Step 3 In the Services window, right-click **Cisco Passive Identity Agent**.

Step 4 Click **Properties**.

Step 5 In the Properties dialog box, click the **Log On** tab.

Step 6 Click **This account**.

Step 7 Click **Browse**. Follow the prompts on your screen to select the directory user.

Step 8 Enter the user's password in the provided fields.

Step 9 Click **Apply**.

What to do next

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity .

Uninstall the passive identity agent software

Remove the passive identity agent software from Microsoft AD servers when it is no longer needed or requires replacement.

This task discusses how to uninstall the passive identity agent software from your Microsoft AD servers.

Procedure

Step 1 Log in as an administrator to the machine on which the passive identity agent is installed.

Step 2 Search for Add or Remove Programs.

Step 3 Click **Cisco Passive Identity Agent**.

Step 4 Click **Uninstall**.

Step 5 You are required to confirm the uninstallation.

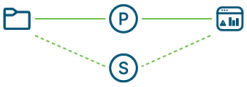
Upgrade the passive identity agent software

To upgrade to a newer version of the passive identity agent, first uninstall the earlier version. Then install the later version.

Refer to this information:

- Uninstall the passive identity agent software, on page 2425
- Passive identity agent installation, on page 2418

Monitor the passive identity agent



The passive identity agent indicates whether or not it can communicate with the Security Cloud Control and other agents if it's configured as primary-secondary. View the status at **Integration** > **Other Integrations** > **Identity Sources**.

Deployments

A standalone passive identity agent is represented as follows.

A primary-secondary pair is represented as follows.

This table explains the meaning of the indicators.

Object	Meaning
	Cloud-Delivered Firewall Management Center
	Standalone Passive Identity Agent
	Active Directory domain controller
	Primary agent
	Secondary agent

Status indicators and colors

The passive identity agent indicates status using lines (that indicate whether communication with the Cloud-Delivered Firewall Management Center is active or standby) and colors (that indicate whether or not communication is successful).

This table explains the meanings of lines and colors:

Object	Meaning
Solid line	The agent that is responsible for communicating with the Cloud-Delivered Firewall Management Center.
Dashed line	Primary/secondary configuration only. The agent that is acting as the backup agent. In the event of a communication failure between the active (solid line) agent, this agent communicates with the Cloud-Delivered Firewall Management Center.
Green	Agent communication is normal.
Amber 	Agent has never successfully communicated with the Cloud-Delivered Firewall Management Center. A newly created agent line is amber and remains so until configuration is complete.
Red 	Communication is failing. To resolve the issues: • Verify the network connections between agents and the Cloud-Delivered Firewall Management Center. • Complete the configuration for the system (Microsoft AD server, domain controllers, and the Cloud-Delivered Firewall Management Center). For more information, see How to configure a passive identity agent identity source, on page 2409.

Manage the passive identity agent

passive identity agent management includes editing previously configured agents and deleting existing agent configurations.

Platform-specific management options

Related Topics

Edit passive identity agents, on page 2428
Delete a standalone passive identity agent, on page 2428

Delete primary and secondary passive identity agents, on page 2428
Uninstall the passive identity agent software, on page 2425

Edit passive identity agents

Edit passive identity agents to update configuration settings and maintain accurate identity source integration for your network security environment.

This task discusses how to edit passive identity agents you previously configured in the Security Cloud Control.

Procedure

Step 1 Log in to the Security Cloud Control.

Step 2 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 3 Click **Passive Identity Agent**.

Step 4 Click **Edit** (✎) next to the agent to edit.

Step 5 Make the desired changes.

Step 6 Click **Save**.

Delete a standalone passive identity agent

Delete a standalone passive identity agent to remove its association from the Secure Firewall Management Center and Security Cloud Control for enhanced identity source management.

This task discusses how to delete a standalone passive identity agent.

Procedure

Step 1 Log in to the Security Cloud Control.

Step 2 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 3 Click **Passive Identity Agent**.

Step 4 Click **Edit** (✎) next to the agent to delete.

Step 5 Click **Delete**.

Step 6 Confirm the action when prompted.

Delete primary and secondary passive identity agents

This task allows you to remove unwanted or unused passive identity agents from your system configuration.

You must delete a secondary agent before you can delete a primary agent.

Procedure

Step 1 Log in to the Security Cloud Control.

Step 2 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 3 Click **Passive Identity Agent**.

Step 4 Click **Edit** ( ) next to a secondary agent to delete.

Step 5 Click **Delete**.

Step 6 Confirm the action when prompted.

Step 7 If you wish to delete a primary agent, first delete all secondary agents.

Troubleshoot the passive identity agent

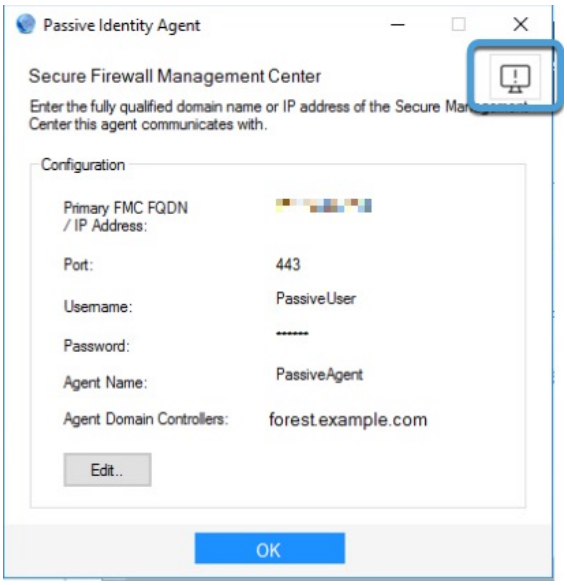
Troubleshoot the passive identity agent software on your Windows AD domain controller or directory server.

This task helps you investigate and resolve user session issues with the passive identity agent by utilizing various troubleshooting methods including log analysis and event viewer investigation.

Procedure

Step 1 Set the log level by opening **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config** in a text editor, save the file, and restart the Cisco Passive Identity Agent service.

By default, the passive identity agent logs at the INFO level.



Do not rename **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config**; otherwise, the passive identity agent will stop generating log files. Do not remove or change the **.exe.config** file extension.

Step 2 Generate troubleshooting files by logging in to the Microsoft Active Directory domain controller.

Step 3 Start the passive identity agent software.

Step 4 Click the Troubleshooting button in the top right corner of the window.

The following figure shows an example.

The system displays a confirmation message and generates a .zip file containing troubleshooting files.

Your troubleshoot logs are saved to your system's Downloads folder; the file name starts with **TroubleshootLogs**.

Step 5 Manually view log files stored in plain text format in the agent's installation directory: **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Use Notepad or another text editor to view these files. Log files rotate after reaching 10MB in size.

Step 6 Use the Microsoft Active Directory event viewer to look for Kerberos-related events if you are not seeing user sessions in the Cloud-Delivered Firewall Management Center.

Look for the following Kerberos-related events:

- 4770
- 4768

For general information about audit policy, see Audit Policy Recommendations on learn.microsoft.com.

For more information about Windows Group Policy Object settings, see Group Policy Objects on learn.microsoft.com.

Security requirements for the passive identity agent

To safeguard the system, you should install the passive identity agent on a protected internal network. Although the passive identity agent is configured to have only the necessary services and ports available, you must make sure that attacks cannot reach it.

If the passive identity agent and the Security Cloud Control reside on the same network, you can connect the Security Cloud Control to the same protected internal network as the passive identity agent.

Regardless of how you deploy your appliances, inter-system communication is encrypted. You must ensure that communications between appliances are not interrupted, blocked, or tampered with; for example, with a distributed denial of service (DDoS) or man-in-the-middle attack.

Internet access requirements for the passive identity agent

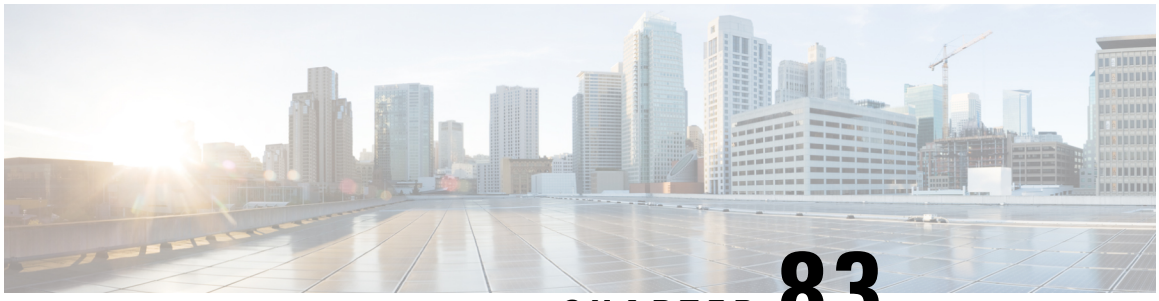
By default, the passive identity agent is configured to communicate with the Firepower System over the internet using HTTPS on port 443/tcp (HTTPS). If you do not want the passive identity agent to have direct access to the internet, you can configure a proxy server.

If your Cloud-Delivered Firewall Management Center cannot communicate with the machine on which the passive identity agent is installed, you must use a proxy with the HTTPS protocol enabled.

You can choose how to set up the proxy. For example, you can use a commercial proxy and a Windows system proxy with HTTPS enabled to communicate with it.

This section lists the ports the passive identity agent uses to communicate with other agents, the Security Cloud Control, and Microsoft Active Directory.

Table 130: Passive Identity Agent port requirements



Port	Reason
443	Communicate with the Security Cloud Control.
135	Communicate with Microsoft Active Directory using the MSRPC protocol.
9095	Communicate with other agents using the UDP protocol.

History for the passive identity agent

This reference provides the version history and feature introduction timeline for the passive identity agent.

Table 131: History for the passive identity agent

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
Passive Identity Agent	November 8, 2024	7.1	This feature is introduced. Passive identity agent version 1.1 is compatible with 7.6.0 and later and adds the following: • You can use either FQDN, IPv4, or IPv6 to connect from the Passive Identity Agent to the Cloud-Delivered Firewall Management Center or Security Cloud Control. • Sends both IPv4 and IPv6 user sessions from Microsoft Active Directory (AD) to the Cloud-Delivered Firewall Management Center. • You can zip troubleshooting logs. • When you start the passive identity agent software, a list of prerequisites is displayed. The passive identity agent identity source sends session data from Microsoft Active Directory (AD) to the Cloud-Delivered Firewall Management Center. Passive identity agent software is supported on: • Microsoft AD server (Windows Server 2008 or later) • Microsoft AD domain controller (Windows Server 2008 or later) • Any client connected to the domain you want to monitor (Windows 8 or later) See: User Control With the Passive Identity Agent.

CHAPTER 83

Identity Source: pxGrid Cloud Identity (ISE 3.3 and Earlier)

This document discusses how to configure and use the pxGrid Cloud Identity Source with Cisco ISE version 3.3 and earlier.

- pxGrid Cloud identity source, on page 2433
- pxGrid Cloud identity source configuration, on page 2436
- Enable the pxGrid Cloud service in Cisco ISE, on page 2439
- Register Cisco ISE with the Catalyst Cloud Portal, on page 2439
- Register the pxGrid Cloud connection with Cisco ISE, on page 2442
- Create a pxGrid Cloud identity source, on page 2443
- Create dynamic attributes filters, on page 2455
- Create access control rules or DNS rules using dynamic attributes filters, on page 2456
- Troubleshoot the pxGrid Cloud identity source, on page 2457
- Deactivating and deleting the pxGrid Cloud identity source, on page 2459

pxGrid Cloud identity source

The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud identity source enables you to use subscription and user data from Cisco ISE in Cloud-Delivered Firewall Management Center access control rules. Also, the identity source uses constantly changing dynamic objects from Cisco ISE in access control policies in the Cloud-Delivered Firewall Management Center.

Integration technologies

The pxGrid Cloud identity source also uses:

- The Cisco Platform Exchange Grid (pxGrid), which enables multivendor, cross-platform network system collaboration in things like security monitoring and detection systems, network policy platforms, asset and configuration management, identity, and access management. pxGrid Cloud is the cloud-based interface to Cisco ISE.

  More information about pxGrid is available in resources such as What is PxGrid? on devnet.

- The Cisco Digital Network Architecture (Cisco DNA) delivers automation, security, predictive monitoring, and a policy-driven approach. It provides end-to-end network visibility and uses network insights to optimize network performance and deliver the best user and application experience.

To use the pxGrid Cloud identity source with the Security Cloud Control, you must Create a Cisco Account.

- What is pxGrid? on devnet
- Cisco Platform Exchange Grid Cloud on devnet

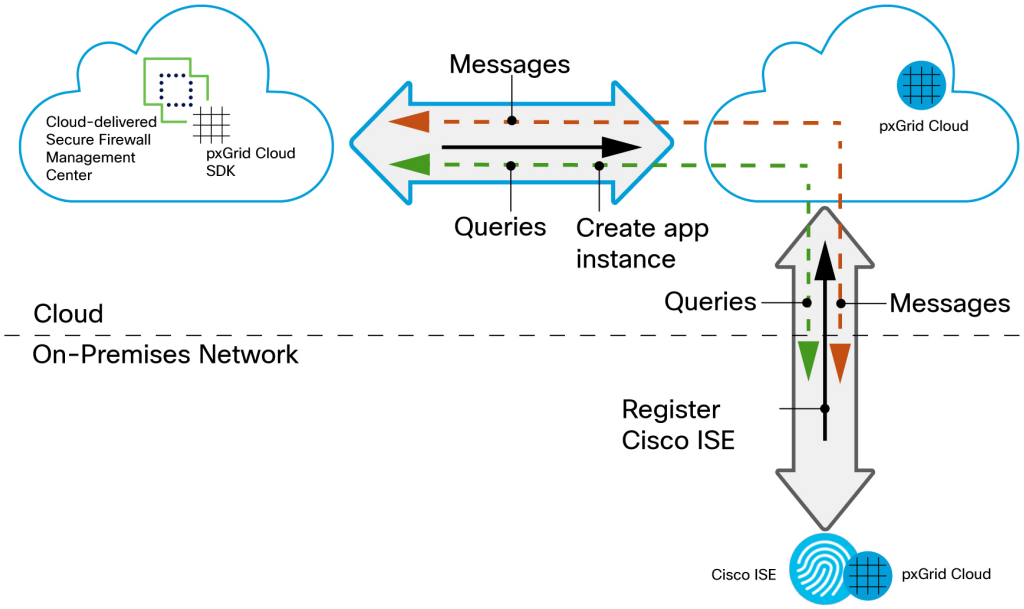
Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier), on page 2436

Restrictions for the pxGrid Cloud identity source

Before you set up the pxGrid Cloud identity source, note these restrictions:

- pxGrid Cloud suppports these regions: `us-west-2`, `eu-central-1`, and `ap-southeast-1`.



How the pxGrid Cloud identity source works

Summary

The key components involved in the pxGrid Cloud identity source are:

- Cloud-Delivered Firewall Management Center: Uses the pxGrid Cloud SDK to programmatically retrieve user information
- Cisco ISE: Provides user information, SGT, endpoint profile, and other details
- pxGrid Cloud: Facilitates secure data exchange between the management center and ISE
- Authentication process: Requires one-time passwords (OTP) to establish trusted communication

Workflow

These stages describe how the pxGrid Cloud identity source works:

1. In Cisco ISE, the administrator enables the use of pxGrid Cloud.
2. The administrator registers Cisco ISE as a product in pxGrid Cloud, which authenticates Cisco ISE and pxGrid Cloud and enables them to communicate with each other.

   The authentication process requires you to paste a one-time password (OTP) from pxGrid Cloud into Cisco ISE.
3. In pxGrid Cloud, the administrator creates an "app instance" that generates an OTP for use in the Cloud-Delivered Firewall Management Center to authenticate the two with each other.
4. After completing all the preceding tasks, the Cloud-Delivered Firewall Management Center (which includes the pxGrid Cloud SDK) can query Cisco ISE using pxGrid Cloud and retrieve sessions containing user information, SGT, endpoint profile, and other details.
5. Many types of dynamic objects can be filtered and sent to the Cloud-Delivered Firewall Management Center as dynamic objects to be used in access control rules. These include: SGT, endpoint profile, posture status, and machine authentication.

   User information is retrieved from Cisco ISE and group information is retrieved from either Microsoft Active Directory or Azure Active Directory.

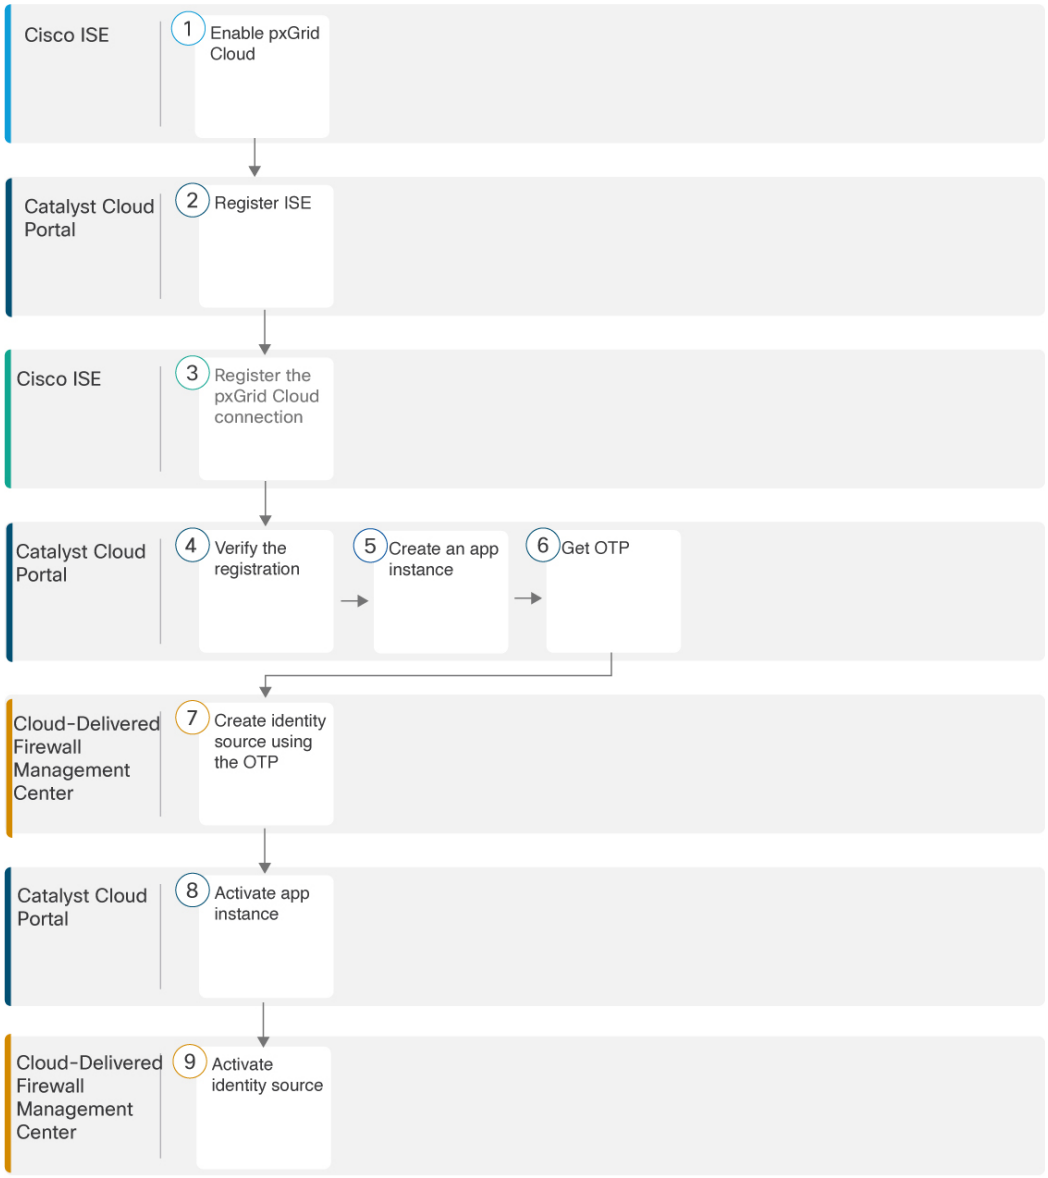
Activate the app instance, on page 2446
Activate the pxGrid Cloud identity source, on page 2448

Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier)

Before you begin, create a Cisco Account.

Important *This topic applies to Cisco ISE version 3.3 or earlier*. If you are using a later version, see Configuring a pxGrid Cloud identity source, on page 2468 instead.

Summary



The key components involved in configuring a pxGrid Cloud identity source are:

- Cisco ISE: Enables pxGrid Cloud for secure data exchange and provides the data source for user information
- Catalyst Cloud Portal: Manages registration and authentication between components, creates application instances, and provides one-time passwords for secure connection
- Cloud-Delivered Firewall Management Center: Creates and activates the identity source connection to receive user data from Cisco ISE

This process establishes a secure cloud-based connection that enables the Cloud-Delivered Firewall Management Center to receive user and group information from Cisco ISE through the pxGrid Cloud service.

Workflow

Figure 390: Configure a pxGrid Cloud identity source

Lorem ipsum

1 Enable the pxGrid Cloud service in Cisco ISE, on page 2439
2 Register Cisco ISE with the Catalyst Cloud Portal, on page 2439
3 Register Cisco ISE with the Catalyst Cloud Portal, on page 2439
4 Create an app instance, on page 2443
5 Create the identity source, on page 2445

6 Activate the app instance, on page 2446
7 Activate the app instance, on page 2446

These stages describe configuring a pxGrid Cloud identity source:

1. Cisco ISE enables pxGrid Cloud functionality.
   - pxGrid Cloud enables you to subscribe to offers and to register apps (in this case, the Cloud-Delivered Firewall Management Center) for secure data exchange in a cloud environment

   For more information, see Enable the pxGrid Cloud service in Cisco ISE, on page 2439.
2. The administrator registers Cisco ISE in the Catalyst Cloud Portal and authenticates communication between Cisco ISE and the Catalyst Cloud Portal.

   For more information, see Register Cisco ISE with the Catalyst Cloud Portal, on page 2439.
3. The administrator registers the pxGrid Cloud with Cisco ISE and verifies the registration.

   For more information, see Register the pxGrid Cloud connection with Cisco ISE, on page 2442.
4. The administrator creates an application instance in the Catalyst Cloud Portal and gets the one-time password (OTP).
   - The application instance enables the Cloud-Delivered Firewall Management Center to authenticate with Cisco ISE using the pxGrid Cloud service
   - The OTP, required for the next step, expires in 60 minutes
5. The administrator creates the pxGrid Cloud identity source using the OTP from the previous step.
   - Linking the app enables the Cloud-Delivered Firewall Management Center to authenticate with Cisco ISE and the Catalyst Cloud Portal so it can receive user data from Cisco ISE

   For more information, see Create the identity source, on page 2445.
6. The administrator activates the app instance in the Catalyst Cloud Portal.

   For more information, see Activate the app instance, on page 2446.
7. The administrator activates the pxGrid Cloud identity source in the Cloud-Delivered Firewall Management Center.

   For more information, see Activate the pxGrid Cloud identity source, on page 2448

What's next

After you have completed all the preceding tasks, you can:

- Test the pxGrid Cloud identity source to make sure it's working properly. For more information, see Test the pxGrid Cloud identity source, on page 2450.
- Create dynamic attributes filters, which define what dynamic objects are sent to the Cloud-Delivered Firewall Management Center. For more information, see Create dynamic attributes filters, on page 2455.
- After you configure the pxGrid Cloud identity source, you can use dynamic objects, Microsoft AD user and groups, and Azure AD users and groups in access control rules.

Enable the pxGrid Cloud service in Cisco ISE

Enable the pxGrid Cloud service to establish outbound connections to Cisco pxGrid Cloud for cloud-based integration capabilities.

The pxGrid Cloud service allows Cisco ISE to connect to cloud-based services and share identity information securely. This service can be enabled on multiple nodes for high availability.

Before you begin

- Ensure that you install and activate the Advantage license tier in your Cisco ISE deployment.
- The pxGrid Cloud agent creates an outbound HTTPS connection to Cisco pxGrid Cloud. Therefore, you must configure Cisco ISE proxy settings if the customer network uses a proxy to reach the internet. To configure proxy settings in Cisco ISE, click the **Menu** icon (☰) and choose **Administration > System > Settings > Proxy**.
- The Cisco ISE Trusted Certificates Store must include the root CA certificate required to validate the server certificate presented by pxGrid Cloud. Ensure that the **Trust for Authentication of Cisco Services** option is enabled for this root CA certificate. To enable **Trust for Authentication of Cisco Services**, navigate to **Administration** > **System** > **Certificates**.

Follow these steps to enable the pxGrid Cloud service:

Procedure

Step 1 In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration > System > Deployment**.

Step 2 Click the node on which you want to enable the pxGrid Cloud service.

Step 3 In the **General Settings** tab, enable the **pxGrid** service.

Step 4 Check the **Enable pxGrid Cloud** check box.

The pxGrid Cloud service can be enabled on two nodes to enable high availability.

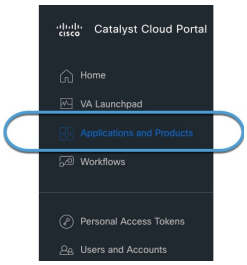
Note
You can enable the **pxGrid Cloud** option only when the **pxGrid** service is enabled on that node.

Register Cisco ISE with the Catalyst Cloud Portal

Register Cisco ISE as an app in the Catalyst Cloud Portal to authenticate communication between the systems.

This task discusses how to register Cisco ISE as an app in the Catalyst Cloud Portal and to authenticate communication between the Catalyst Cloud Portal and Cisco ISE.

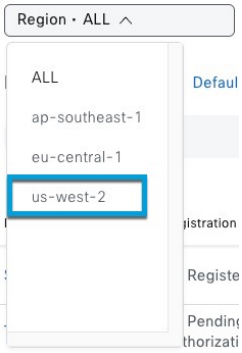
Also refer to Register Cisco ISE in the *pxGrid Cloud Solution Guide*.



Procedure

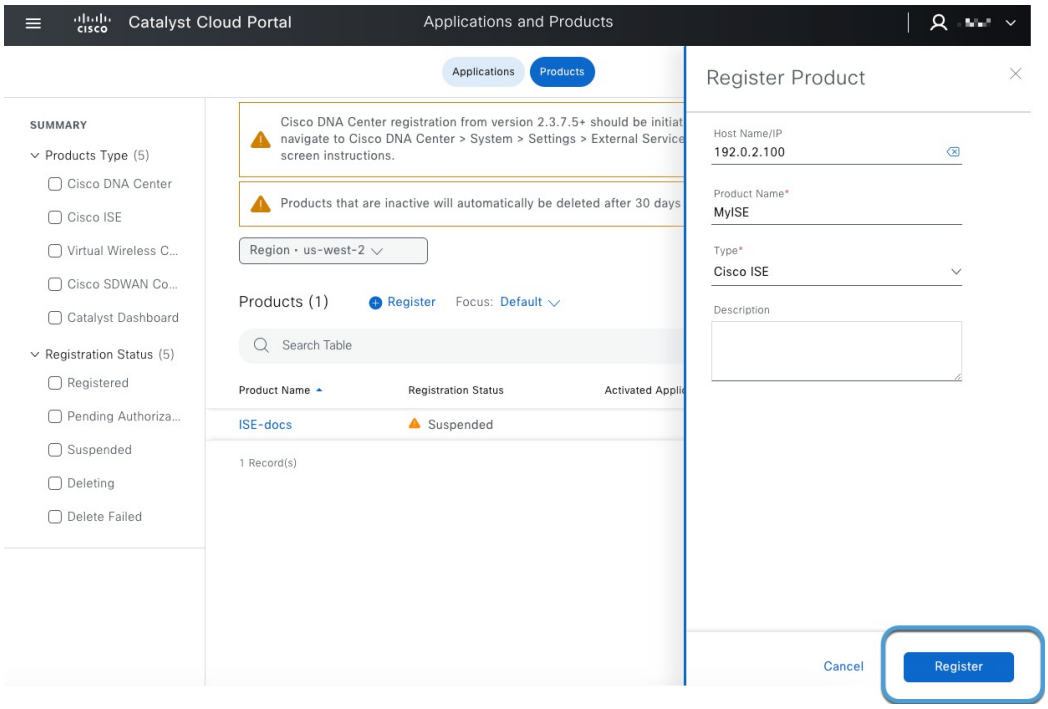
Step 1 Log in to the Cisco Cloud Catalyst Portal.

If prompted, choose an account to use.



Step 2 Click **Register**.

Step 3 In the Catalyst Cloud Portal, click ☰ > **Applications and Products**.



Step 4 At the top of the page, click **Products**.

Step 5 From the **Region** list, click **us-west-2**, **eu-central-1**, or **ap-southeast-1**.

Step 6 Click **Register**.

The registration page appears.

Step 7 Enter the required information.

- **Host Name/IP**: (Optional.) Enter the ISE server's fully qualified domain name or IP address. If you enter an IP address, omit the scheme (for example, **https://**) and the port, if any.
- **Product Name**: Enter a unique name to identify this server.
- **Type**: From the list, click **Cisco ISE**.
- **Description**: Enter an optional description.

Step 8 Click **Register**.

Step 9 Generate a one-time password (OTP).

- If you've previously registered ISE apps and see yours listed, click **Generate OTP** in the **Actions** column; you'll need it in the next part of this procedure.
- If you're registering your app now, the OTP is displayed. Click to copy it to the clipboard; you'll need it in the next part of this procedure.

What to do next

See Register the pxGrid Cloud connection with Cisco ISE, on page 2442.

Register the pxGrid Cloud connection with Cisco ISE

This task registers the pxGrid Cloud connection with Cisco ISE to enable pxGrid Cloud to send user data to the pxGrid Cloud identity source in Security Cloud Control.

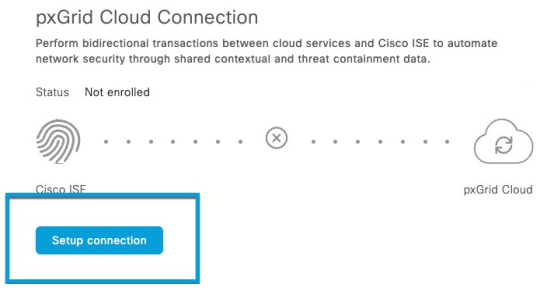
Registering this connection enables communication between your identity services and cloud security services, facilitating the exchange of user authentication and authorization data.

Before you begin

Complete the tasks discussed in Register Cisco ISE with the Catalyst Cloud Portal, on page 2439.

Follow these steps to register the pxGrid Cloud connection with Cisco ISE:

Procedure

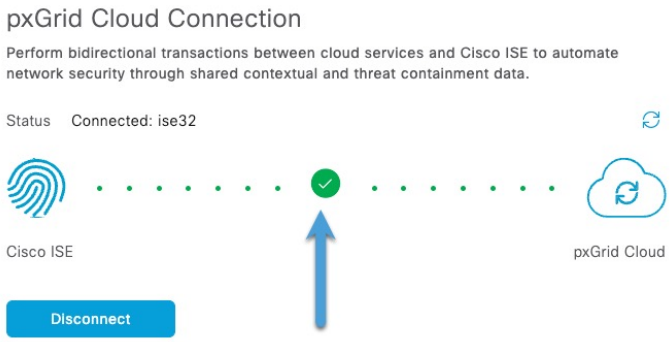


Step 1 Log in to Cisco ISE as an administrator.

Step 2 Click ☰ > **Administration** > **pxGrid Services** > **Client Management** > **pxGrid Cloud Connection**.

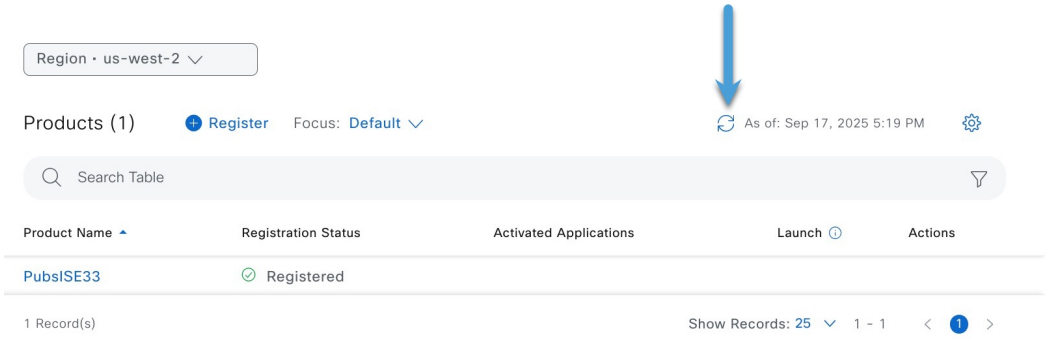
Step 3 Make sure all services are enabled with read/write privileges.

Step 4 In the left navigation bar, click **pxGrid Cloud Connection**.



Step 5 Click **Setup Connection**.

Step 6 Paste the OTP value in the provided field.



Step 7 Click **Connect**.

A green check mark confirms that connection was successful.

Step 8 Confirm the setup has been successful:

a) Log in to the Catalyst Cloud Portal.
b) Click the **Products** tab.
c) Click **Refresh**.

d) Verify that **Registered** is displayed as the status of your product.

What to do next

Continue with Create the identity source, on page 2445.

Create a pxGrid Cloud identity source

The tasks discuss how to create a pxGrid Cloud identity source using Cisco ISE, the Catalyst Cloud Portal, and Security Cloud Control. You must complete all tasks in the order shown; in some cases, there is a time limit due to the expiration of a required One-Time Password (OTP).

Related Topics

Create an app instance, on page 2443
Create the identity source, on page 2445
Activate the app instance, on page 2446
Activate the pxGrid Cloud identity source, on page 2448
Test the pxGrid Cloud identity source, on page 2450

Create an app instance

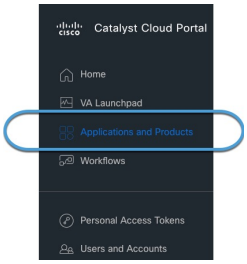
Create an application instance in the Catalyst Cloud Portal to establish a pxGrid Cloud identity source.

This task is one of several tasks you must perform to create a pxGrid Cloud identity source to send user session data to the Cloud-Delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. You do not need to log in to Cisco ISE.

Before you begin

Complete all of these tasks first:



- Enable the pxGrid Cloud service in Cisco ISE, on page 2439

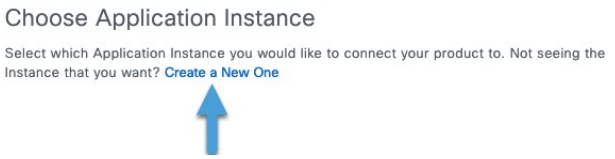
- Register Cisco ISE with the Catalyst Cloud Portal, on page 2439
- Register the pxGrid Cloud connection with Cisco ISE, on page 2442

Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

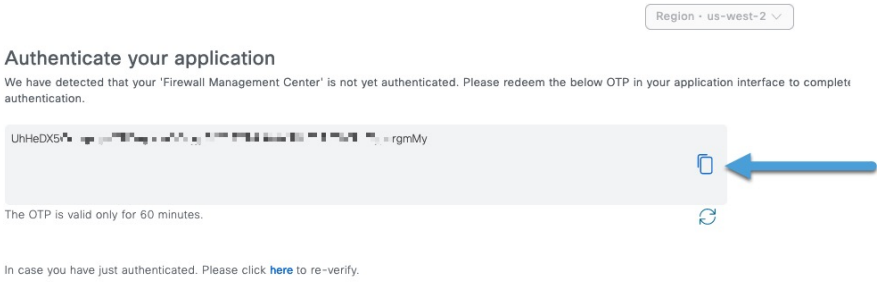
Step 2 In the Catalyst Cloud Portal, click ☰ > **Applications and Products**.

Step 3 At the top of the page, click **Applications**.



Step 4 From the **Regions** list, click **us-west-2**, **eu-central-1**, or **ap-southeast-1**.

Step 5 Click **Manage** (or **Activate**) next to **Firepower Management Center**.



Step 6 Click **Add**.

Step 7 Click **Create a New One**.

The following figure shows an example.

Step 8 Click the copy button next to the displayed OTP.

Copy the OTP to a text file; it expires in 60 minutes.

Step 9 Continue with Create the identity source, on page 2445.

Create the identity source

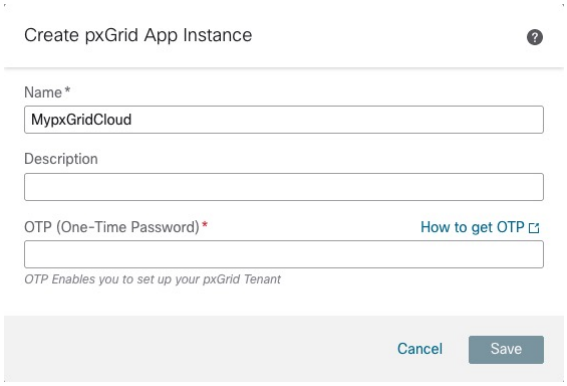
This task creates a pxGrid Cloud identity source to send user session data to the Cloud-Delivered Firewall Management Center.

This task is one of several required to create a pxGrid Cloud identity source to send user session data to the Cloud-Delivered Firewall Management Center.

Before you begin

Complete the task discussed in Create an app instance, on page 2443.

Procedure



Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Step 2 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**

Step 3 Click **Identity Services Engine (pxGrid Cloud)**.

Step 4 Click **Create pxGrid Application Instance**.

This figure shows an example.

Step 5 Enter the required information.

Value	Description
Name	Enter a name to uniquely identify this connector.
Description	Optional description.
OTP (One-Time Password)	Enter the OTP.

Step 6 Click **Create**.

Step 7 At the top of the page, click **Save**.

What to do next

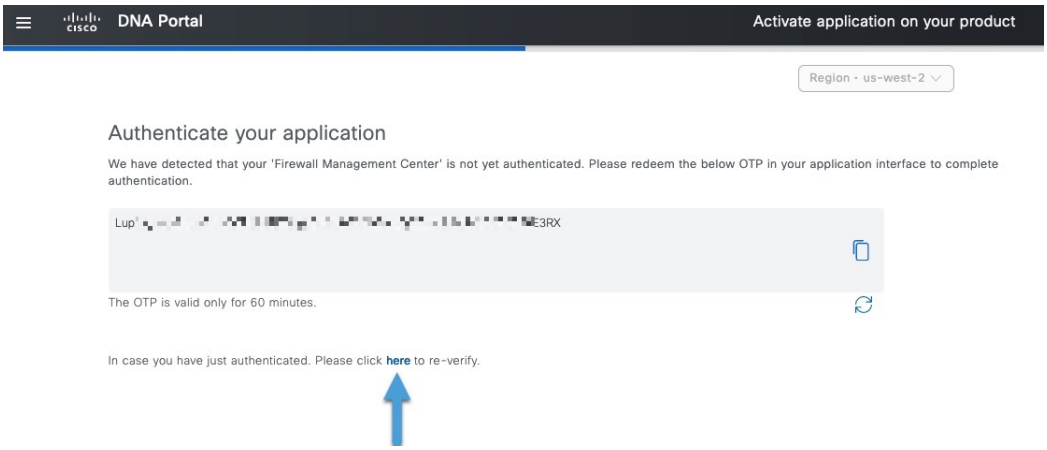
Continue with Activate the app instance, on page 2446.

Activate the app instance

Activate an app instance to create a pxGrid Cloud identity source that sends user session data to the Cloud-Delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. You do not need to log in to Cisco ISE.

Before you begin

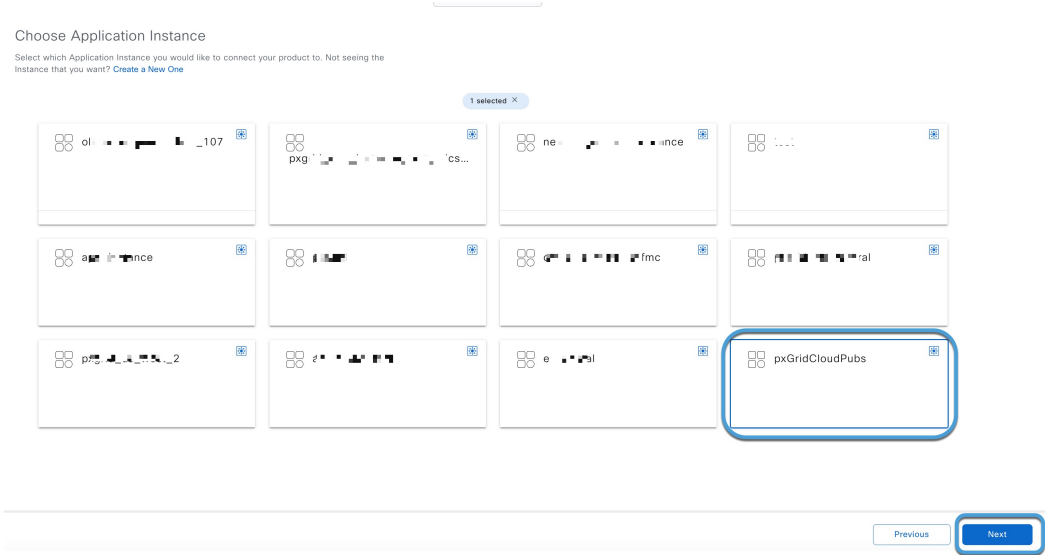


Complete the task discussed in Create the identity source, on page 2445.

Follow these steps to activate the app instance:

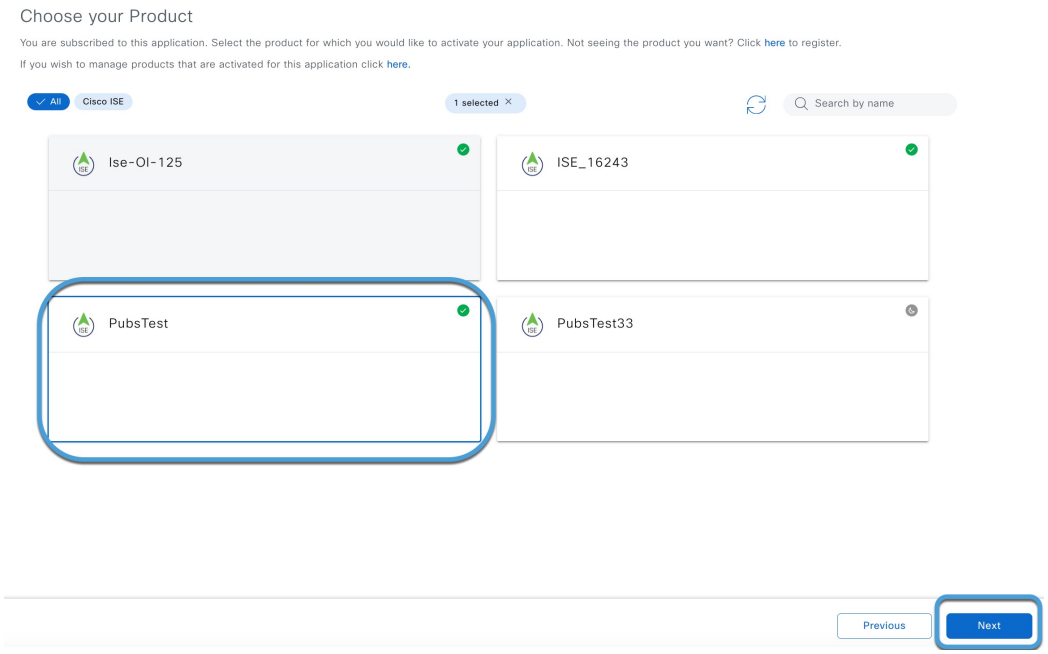
Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.



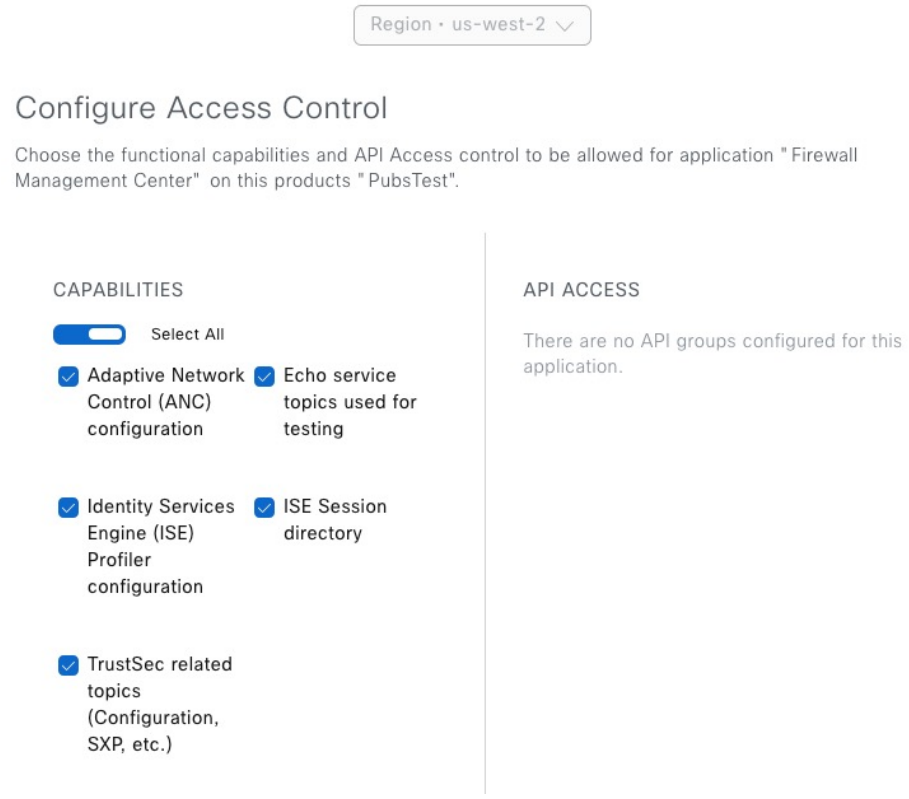
Step 2 Reverify the app by clicking the word **here** as the following figure shows.

Step 3 Click the name of the application instance you just created in Cloud-Delivered Firewall Management Center.



Step 4 Click **Next**.

Example:



Step 5 On the Choose Product page, click the name of the Cisco ISE product and click **Next**.

Example:

Step 6 Select the check box next to each scope.
The following figure shows an example.

Step 7 Click **Next**.

Step 8 Review the displayed information for accuracy. Make sure all scopes are selected.

Step 9 Click **Activate**.

It can take several minutes for the app instance to be activated.

Continue with Activate the pxGrid Cloud identity source, on page 2448.

Activate the pxGrid Cloud identity source

This task activates the pxGrid Cloud identity source to enable identity services integration in your security infrastructure.

This task explains how to activate the pxGrid Cloud identity source in the Security Cloud Control.

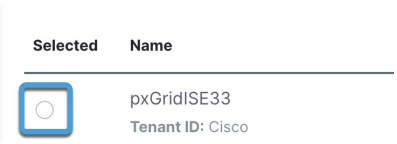
Before you begin

Complete the tasks discussed in Activate the app instance, on page 2446.

Note Only one pxGrid Cloud identity source can be active at a time.

Procedure

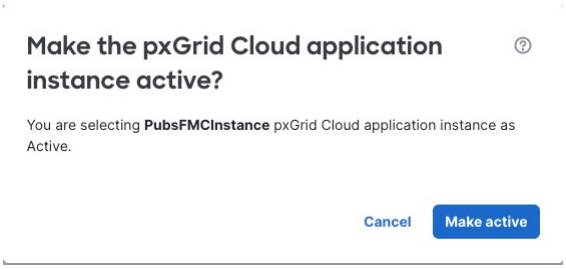
Step 1 Log in to Security Cloud Control as a user with the Super Admin role.



Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 2 Click **Identity Services Engine (pxGrid Cloud)**.

Step 3 Click **Save** at the top of the page.



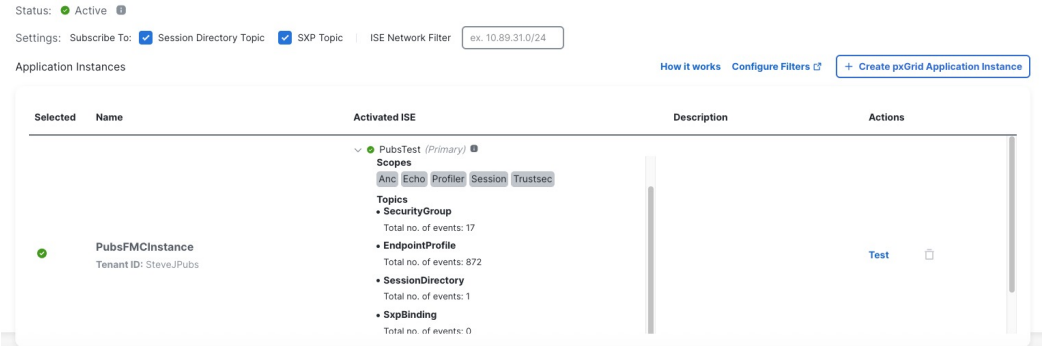
Step 4 If a green check mark is *not* displayed next to the name of the identity source, select it.

Example:

Step 5 Click **Make Active**.

Example:

Step 6 (Optional.) Select the following options if desired:



- **Session Directory Topic**: Select the check box to receive ISE user session information from the Cisco ISE server.
- **SXP Topic**: Select the check box to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.
- **ISE Network Filter**: Optional filter you can set to restrict the data that Cisco ISE reports. If you provide a network filter, Cisco ISE reports data from the networks in that filter.

  You have the following options:

  - Leave the field blank to specify **`any`**.
  - Enter a single IPv4 address block using CIDR notation.
  - Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

Step 7 Under Activated ISE, expand the identity source.

Example *normal* result:

Example *error* result:

In the event of an error, see Test the pxGrid Cloud identity source, on page 2450.

Step 8 Verify the status is Active and that all scopes and topics are displayed.

Wait a few minutes for data to be downloaded.

What to do next

See Test the pxGrid Cloud identity source, on page 2450.

Test the pxGrid Cloud identity source

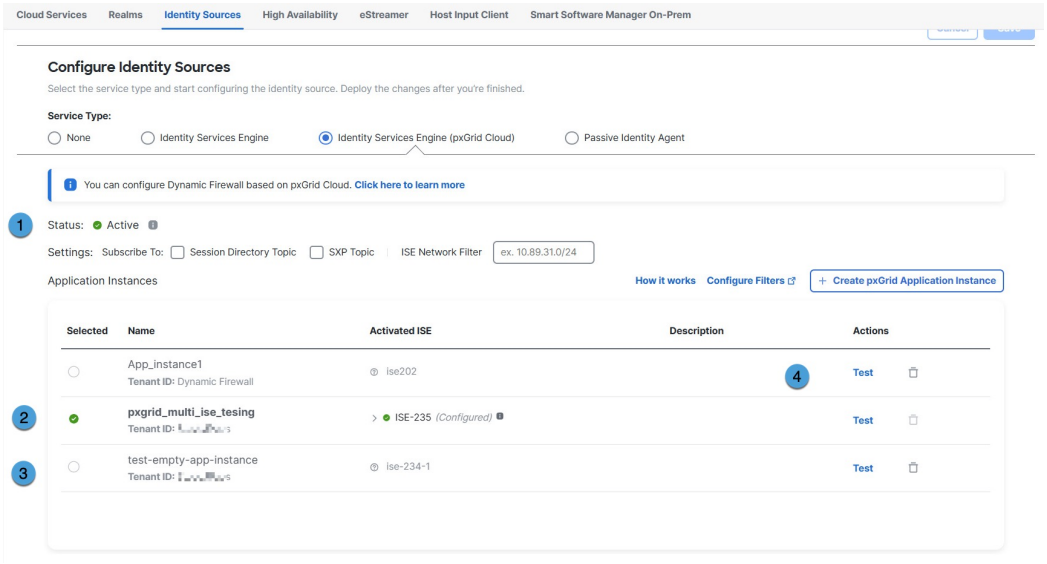
This task enables you to perform diagnostics using the Security Cloud Control to determine if the identity source is working.

Errors might include communication with Cisco ISE, or with the Cisco ISE configuration with Catalyst Cloud Portal.

Procedure

Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Step 2

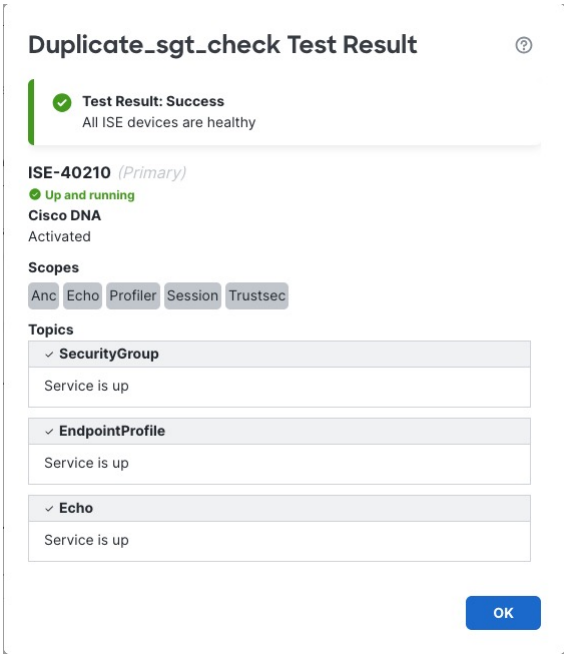


Step 3 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

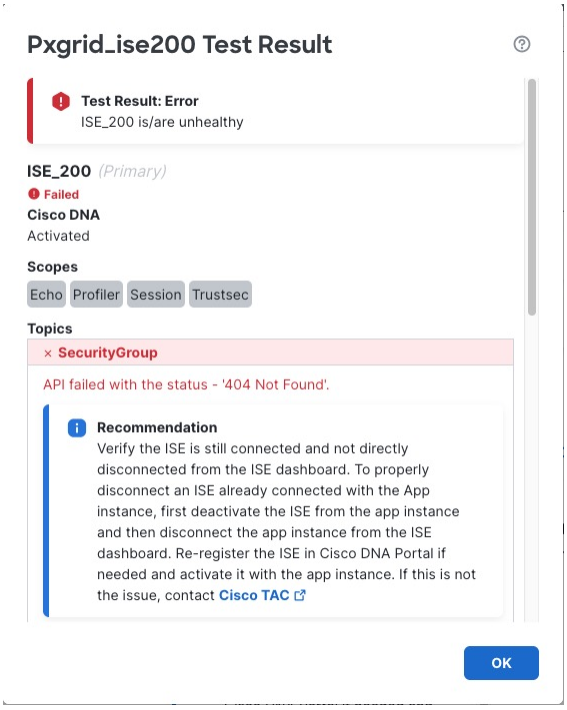
Step 4

Step 5 Click **Identity Services Engine (pxGrid Cloud)**.

Step 6 Review the configuration status information.



The following figure shows an example configuration.



The following table has more information about the numbered areas in the figure.

Number	Meaning
1	Overall status Any errors in the overall status of the Cisco ISE app instances are displayed. In that case, scroll to that instance and either expand the error message or click **Test** for more information.
2	Active A green check mark indicates the app is active.
3	Inactive A dimmed app instance is inactive. You can activate it by selecting the check box next to its name and then clicking **Make active**.
4	**Test** button Click **Test** to perform diagnostic tests that show more detailed status of the app instance.

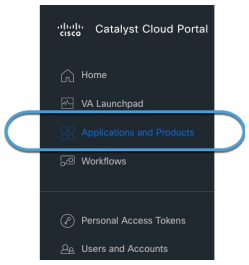
The following figure shows a sample success message.

The following figure shows an example error result.

Step 7 Click **Test** to perform diagnostic tests.

If errors occur, use the following error code reference to help diagnose and solve issues with Cisco ISE, pxGrid Cloud, and the Catalyst Cloud Portal. If these suggestions do not work, or if you have a different issue, contact Cisco TAC.

Table 132: Error code troubleshooting

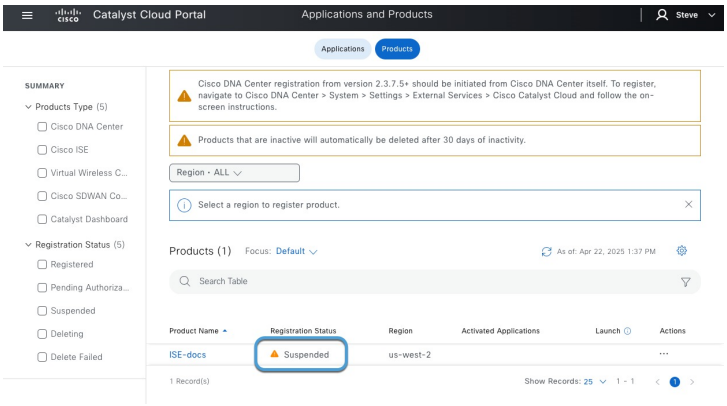


Error Code	Troubleshooting Steps
403 – Forbidden	Verify the Cisco ISE product is not in a **Pending** or **Suspended** state in the Catalyst Cloud Portal. If suspended, verify that Cisco ISE is registered as discussed in Enable pxGrid Cloud service in Cisco ISE and register your device. Additionally, verify pxGrid Cloud services are publicly available.
404 – Not Found	Verify the Cisco ISE server is not directly disconnected from the Cisco ISE dashboard. To properly disconnect Cisco ISE already connected with the app instance, first deactivate Cisco ISE from the app instance and then disconnect the app instance from the Cisco ISE dashboard.
408 – Request Timeout	Check whether there are any general connectivity issues with Cisco ISE and verify pxGrid Cloud connectivity status is **Connected** in the ISE dashboard under ☰ > **Administration** > **pxGrid Services** > **Client Management** > **pxGrid Cloud Connection**. Verify the Cisco ISE server is not directly disconnected from the Cisco ISE dashboard.
413 – Content Too Large	Review the pxGrid Cloud API limitations on GitHub. If needed, consider upgrading your Cisco ISE version to fully utilize pxGrid Cloud support.
500 – Internal Server Error	Check that the Cisco ISE server is operational and that pxGrid Cloud services are active (verify MNT, SXP, pxGrid nodes, and so on). For more information, see Monitoring and debugging in the Cisco pxGrid chapter in the *Cisco Identity Services Engine Administrator Guide*.

Step 8 If the product is in a **Pending** or **Suspended** state, verify that it is active.

a) Log in to the Catalyst Cloud Portal.

b) In the Catalyst Cloud Portal, go to ☰ > **Applications and Products**.

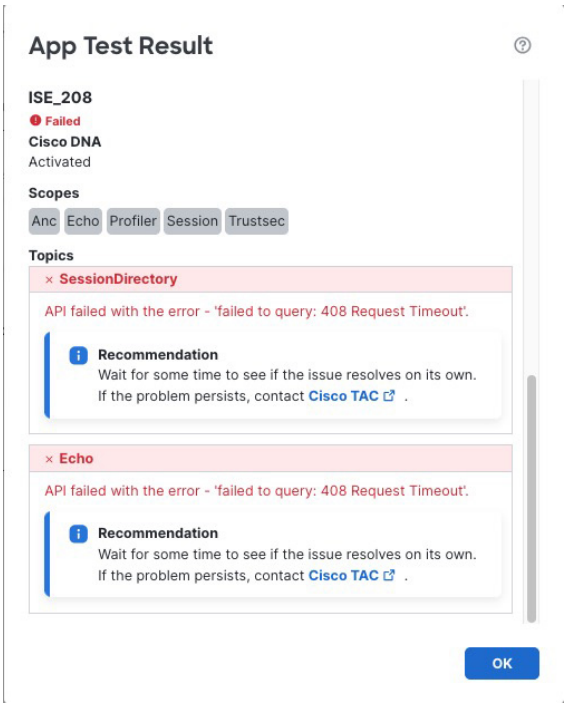


Example:

c) Click the **Products** tab.

Example:

The following figure shows an example of a suspended product.



d) To correct the issue, in the Actions column, click ••• and click **Generate OTP**.

e) Use the OTP as discussed in Create the identity source, on page 2445.

Step 9 If you encounter a cluster member not reachable error, find what node is not reachable.

If a member of the Cisco ISE cluster is not reachable, a page like this is displayed:

To find what node is not reachable, log in to Cisco ISE primary administration node as an administrator and click click the **Menu** icon (☰) and choose **Administration** > **System** > **Deployment**, then see Node Status in a Cisco ISE Deployment.

Create dynamic attributes filters

Create dynamic attributes filters to expose them as dynamic objects in Security Cloud Control for use in access control policies.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Security Cloud Control as dynamic objects that can be used in access control policies. For example, restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules or DNS rules using dynamic attributes filters, on page 2456.

Before you begin

Connectors, on page 2631

Procedure

Step 1 Log in to Security Cloud Control.

a) Click **Firewall**.

b) Click **Administration** > **Dynamic Attributes Connector** > **Dynamic Attributes Filters**.

Step 2 Do any of the following:

- Add a new filter: click **Add** ( ).
- Edit or delete a filter: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 3 Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in a policy and in the Security Cloud Control Object Manager (**External Attributes** > **Dynamic Object**).
Connector	From the list, click the name of a connector to use.
Query	Click Add .

Step 4 To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: • **Equals** to exactly match the key to the value. • **Contains** to match the key to the value if any part of the value matches.
Values	Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 5 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

Step 6 When you're finished, click **Save**.

Step 7 (Optional.) Verify the dynamic object in the Security Cloud Control.

a) Log in to the Security Cloud Control.

b) Click **Policies** > **Firewall Threat Defense**.

c) Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.

The dynamic attribute query you created should be displayed as a dynamic object.

Create access control rules or DNS rules using dynamic attributes filters

Create access control rules using dynamic objects that are based on dynamic attributes filters you have previously configured.

This topic discusses how to create access control rules using dynamic objects (these dynamic objects are named after the dynamic attributes filters you created previously).

To add dynamic attributes filters to DNS policies, see Create basic DNS policies, on page 2561.

To add dynamic attributes filters to DNS policies, see Creating Basic DNS Policies.

Before you begin

Create dynamic attributes filters as discussed in Create dynamic attributes filters, on page 2455.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

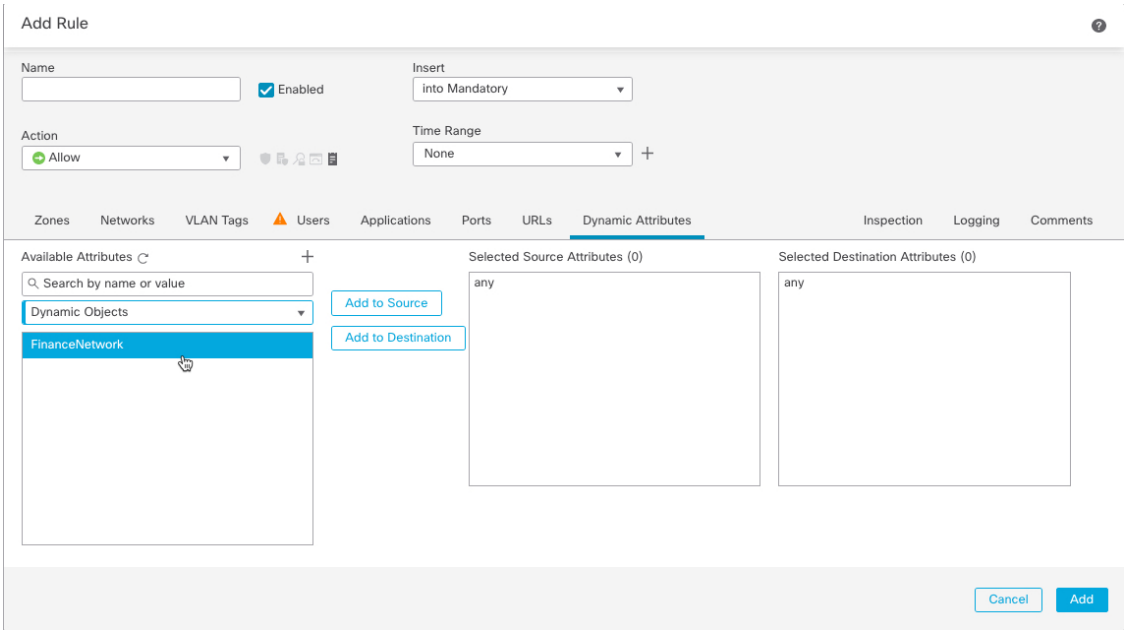
Follow these steps to create access control rules or DNS rules using dynamic attributes filters:

Procedure

Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Click **Policies** > **Firewall Threat Defense** > **Access Control heading** > **Access Control**.

Step 2 Click **Firewall**.



Step 3 Click **Edit** ( ) next to an access control policy.

Step 4 Click **Add Rule**.

Step 5 Click the **Dynamic Attributes** tab.

Step 6 In the Available Attributes section, from the list, click **Dynamic Objects**.

The following figure shows an example.

This example shows a dynamic object named `APIC Dynamic Attribute` that corresponds to the dynamic attribute filter created in the dynamic attributes connector.

Step 7 Add the desired object to source or destination attributes.

Step 8 Add other conditions to the rule if desired.

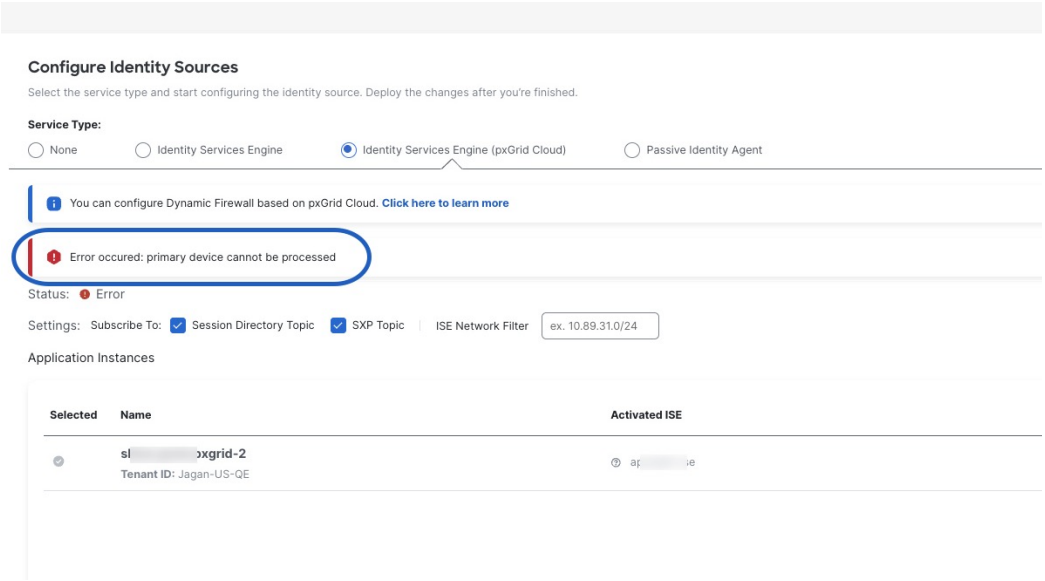
See Dynamic attributes rule conditions, on page 2681.

Troubleshoot the pxGrid Cloud identity source

These topics describe troubleshooting the pxGrid Cloud identity source.

Related Topics

Primary device cannot be processed, on page 2458
Primary device cannot be processed, on page 2458



Primary device cannot be processed

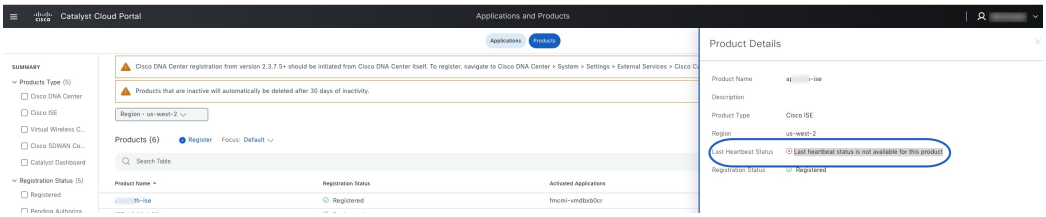
This task resolves the error "primary device cannot be processed" or "ISE is unhealthy" that occurs when a Cisco ISE cluster is associated with more than one app instance.

Each Cisco ISE cluster must be associated with one and only one app instance, typically in a single dedicated tenant.

If you associate a Cisco ISE with more than one app instance, an error such as `Error occured: primary device cannot be processed` or `ISE is unhealthy` is displayed for the identity source.

Example:

The solution is to deactivate the ISE properly from other app instances for that tenant, before using it in any other tenant or app instance



Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

Step 2 At the top of the page, click **Applications**.

Step 3 Locate a Cisco ISE product that is activated and verify it is the one causing the issue.

Example:

Step 4 Wait for the product to be removed.

Step 5 Deactivate the app instance as described in Deactivate the pxGrid Cloud app instance, on page 2459.

Deactivating and deleting the pxGrid Cloud identity source

Deactivating the FMC app instance in the Catalyst Cloud Portal is an optional task to troubleshoot issues with the Cisco ISE integration.

You should delete the pxGrid Cloud identity source from the Security Cloud Control when you are certain you don't want to use it again.

Related Topics

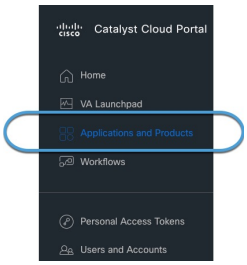
Deactivate the pxGrid Cloud app instance, on page 2459
Delete the pxGrid Cloud identity source, on page 2462

Deactivate the pxGrid Cloud app instance

This task explains how to deactivate a pxGrid Cloud app instance using the Catalyst Cloud Portal when your Cisco ISE or pxGrid Cloud stops working or you need to update it.

This is an optional task. You should do this only if your Cisco ISE or pxGrid Cloud stops working or you need to update it.

Before you begin



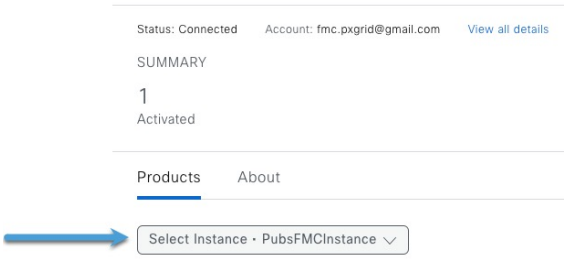
Make sure your current pxGrid Cloud identity source is active as discussed in Activate the pxGrid Cloud identity source, on page 2448.

Follow these steps to deactivate the pxGrid Cloud app instance:

Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

Step 2 In the Catalyst Cloud Portal, click ☰ > **Applications and Products** as the following figure shows:



Step 3 Click **Applications**.

Step 4 Click **Manage** for Firewall Management Center.

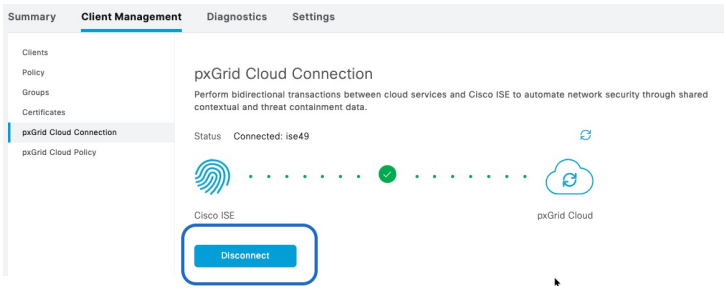
From the **Select Instance** list, click the name of the firewall application you created earlier.

Example:

Step 5 In the Actions column, click More icon (···) > **Deactivate**.

Step 6 Wait until the product is removed.

You can click **Refresh** ( ) to see updated status if necessary.



Step 7 ISE 3.3 or earlier: Disconnect the app instance:

a) Log in to Cisco ISE as an administrator.

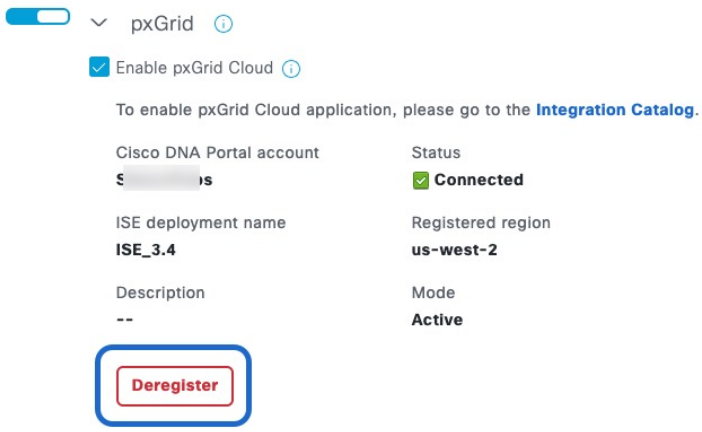
b) Click **Administration** > **pxGrid Services** > **Client Management** > **pxGrid cloud connection**.

c) Click **Disconnect**.

Example:

Step 8 ISE 3.4 or later: Deregister the app instance:

a) Log in to Cisco ISE as an administrator.

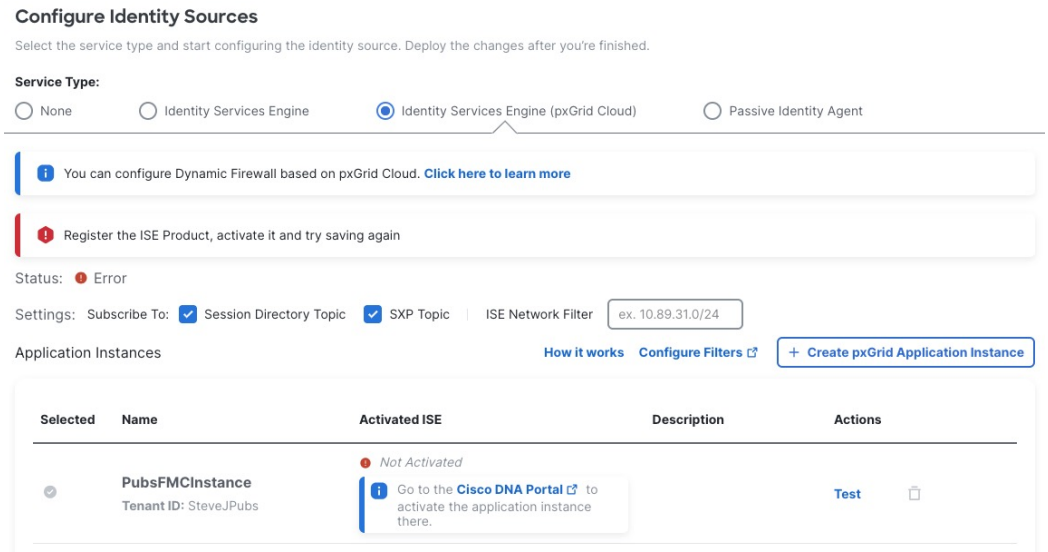


b) Click **Administration** > **System** > **Deployment**.

c) Expand **Deployment**.

d) Click the name of the ISE node.

e) In the **General Settings** tab page, scroll to locate **pxGrid**.
f) Click **Deregister**.



Example:

Step 9 To verify the app instance is deactivated in Security Cloud Control:

a) Log in to Security Cloud Control.
b) Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**
c) Click **Identity Services Engine (pxGrid Cloud)**.
d) Verify that **Not Activated** is displayed in the Activated ISE column.

Example:

What to do next

- To register Cisco ISE with pxGrid Cloud and activate the app instance, see:

- ISE 3.3 and earlier: Register Cisco ISE with the Catalyst Cloud Portal, on page 2439.
- ISE 3.4 and later: Create an app instance, on page 2473.

- To completely remove the identity source, see Delete the pxGrid Cloud identity source, on page 2462.

Delete the pxGrid Cloud identity source

Delete the pxGrid Cloud identity source from Security Cloud Control when you no longer need it.

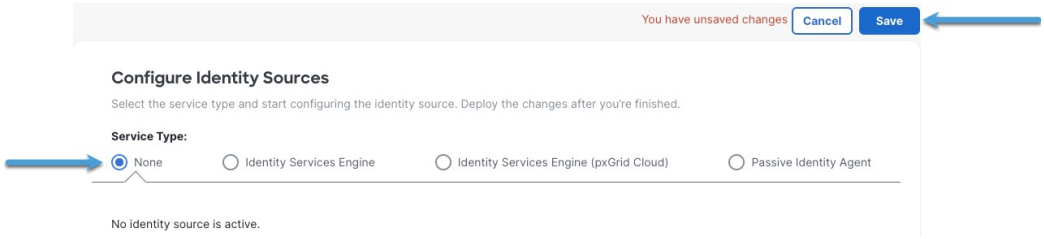
This task explains how to delete the pxGrid Cloud identity source from Security Cloud Control, which is necessary if you do not want to use it again.

Before you begin

Deactivate the FMC app instance from the Catalyst Cloud Portal as discussed in Deactivate the pxGrid Cloud app instance, on page 2459.

Follow these steps to delete the pxGrid Cloud identity source:

Procedure



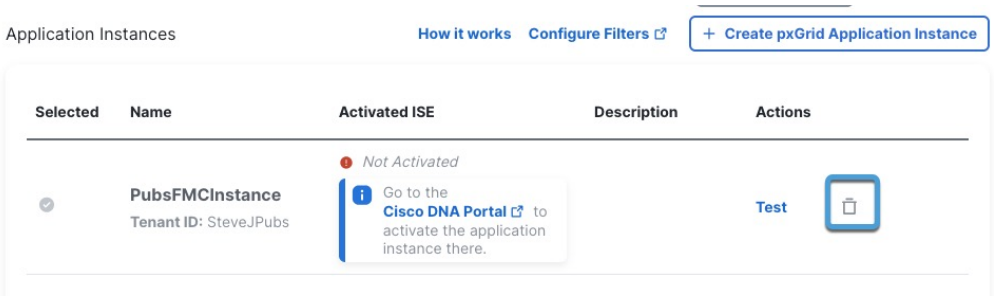
Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 2 Click **Identity Services Engine (pxGrid Cloud)**.

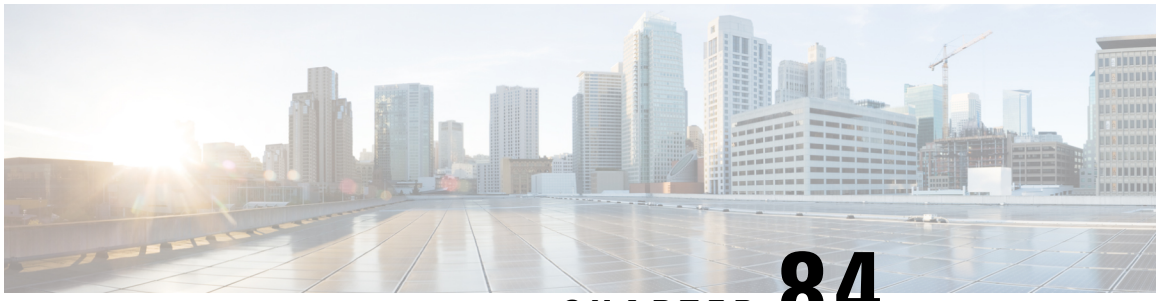
Step 3 For Service Type, click **None**.

Example:



Step 4 Click **Save**.

Step 5 Confirm your choice when prompted.



Step 6 Click **Identity Services Engine (pxGrid Cloud)**.

Step 7 Click **Delete** ( ).

Example:

Step 8 Confirm the action when prompted.

CHAPTER 84

Identity Source: pxGrid Cloud Identity (ISE 3.4 and Later)

The following topics discuss how to configure and use the pxGrid Cloud Identity Source with Cisco ISE version 3.4 and later.

- pxGrid Cloud identity source, on page 2465
- pxGrid Cloud identity source configuration, on page 2468
- Enable the pxGrid Cloud service in Cisco ISE, on page 2470
- Create an app instance, on page 2473
- Create the identity source, on page 2474
- Activate the app instance, on page 2475
- Activate the pxGrid Cloud identity source, on page 2478
- Test the pxGrid Cloud identity source, on page 2480
- Troubleshoot the pxGrid Cloud identity source, on page 2485
- Create dynamic attributes filters, on page 2486
- Create access control rules or DNS rules using dynamic attributes filters, on page 2487
- Deactivating and deleting the pxGrid Cloud identity source, on page 2489

pxGrid Cloud identity source

The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud identity source enables you to use subscription and user data from Cisco ISE in Cloud-Delivered Firewall Management Center access control rules. Also, the identity source uses constantly changing dynamic objects from Cisco ISE in access control policies in the Cloud-Delivered Firewall Management Center.

Integration technologies

The pxGrid Cloud identity source also uses:

- The Cisco Platform Exchange Grid (pxGrid), which enables multivendor, cross-platform network system collaboration in things like security monitoring and detection systems, network policy platforms, asset and configuration management, identity, and access management. pxGrid Cloud is the cloud-based interface to Cisco ISE.

  More information about pxGrid is available in resources such as What is PxGrid? on devnet.

- The Cisco Digital Network Architecture (Cisco DNA) delivers automation, security, predictive monitoring, and a policy-driven approach. It provides end-to-end network visibility and uses network insights to optimize network performance and deliver the best user and application experience.

  To use the pxGrid Cloud identity source with the Security Cloud Control, you must Create a Cisco Account.

  - What is pxGrid? on devnet
  - Cisco Platform Exchange Grid Cloud on devnet

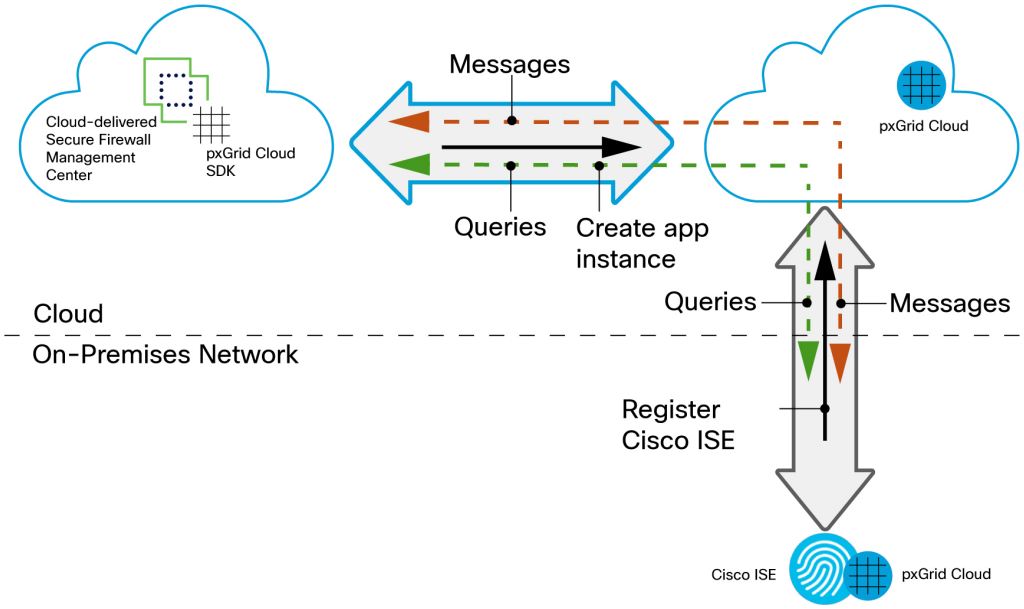
Configuring a pxGrid Cloud identity source, on page 2468
Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier), on page 2436

Restrictions for the pxGrid Cloud identity source

Before you set up the pxGrid Cloud identity source, note these restrictions:

- pxGrid Cloud suppports these regions: `us-west-2`, `eu-central-1`, and `ap-southeast-1`.



How the pxGrid Cloud identity source works

Summary

The key components involved in the pxGrid Cloud identity source are:

- Cloud-Delivered Firewall Management Center: Uses the pxGrid Cloud SDK to programmatically retrieve user information
- Cisco ISE: Provides user information, SGT, endpoint profile, and other details
- pxGrid Cloud: Facilitates secure data exchange between the management center and ISE
- Authentication process: Requires one-time passwords (OTP) to establish trusted communication

Workflow

These stages describe how the pxGrid Cloud identity source works:

1. In Cisco ISE, the administrator enables the use of pxGrid Cloud.
2. The administrator registers Cisco ISE as a product in pxGrid Cloud, which authenticates Cisco ISE and pxGrid Cloud and enables them to communicate with each other.

   The authentication process requires you to paste a one-time password (OTP) from pxGrid Cloud into Cisco ISE.
3. In pxGrid Cloud, the administrator creates an "app instance" that generates an OTP for use in the Cloud-Delivered Firewall Management Center to authenticate the two with each other.
4. After completing all the preceding tasks, the Cloud-Delivered Firewall Management Center (which includes the pxGrid Cloud SDK) can query Cisco ISE using pxGrid Cloud and retrieve sessions containing user information, SGT, endpoint profile, and other details.
5. Many types of dynamic objects can be filtered and sent to the Cloud-Delivered Firewall Management Center as dynamic objects to be used in access control rules. These include: SGT, endpoint profile, posture status, and machine authentication.

   User information is retrieved from Cisco ISE and group information is retrieved from either Microsoft Active Directory or Azure Active Directory.

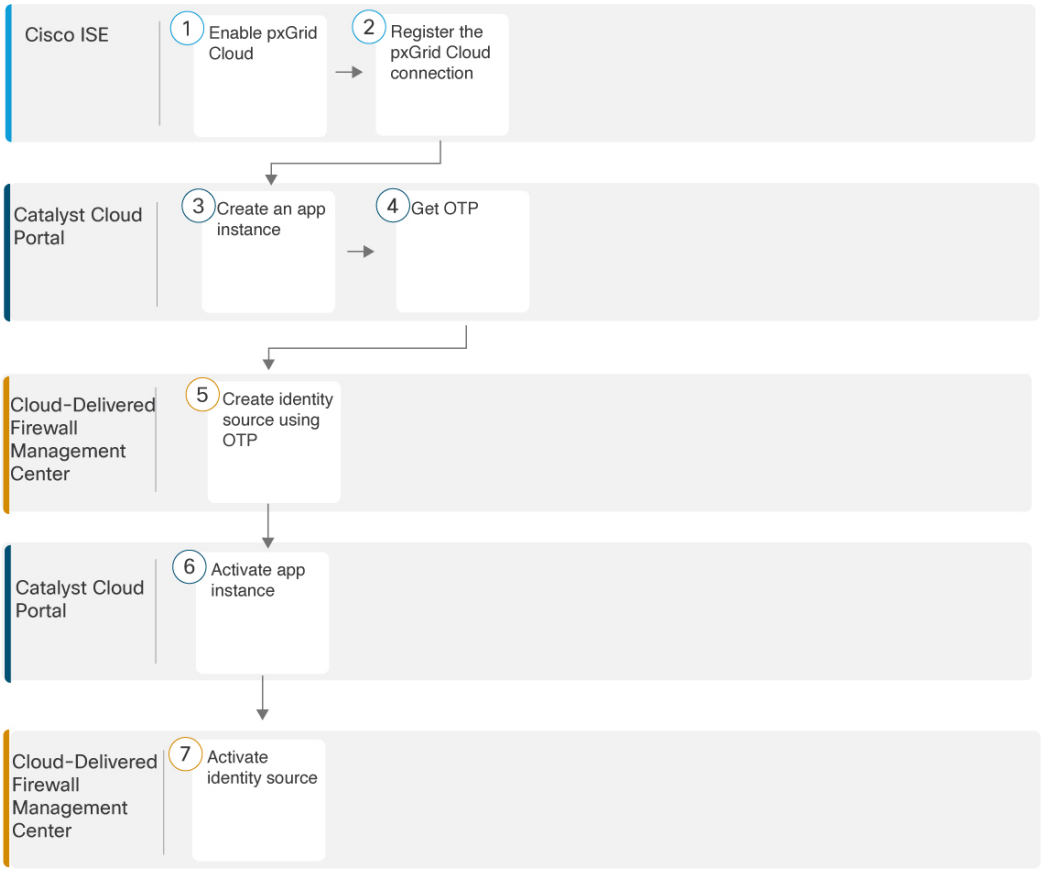
Create the identity source, on page 2445
Activate the app instance, on page 2446
Activate the pxGrid Cloud identity source, on page 2448

Configuring a pxGrid Cloud identity source

Before you begin, create a Cisco Account.

Important *This topic applies to Cisco ISE version 3.4 or later*. If you are using an earlier version, see Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier), on page 2436 instead.



Summary

The key components involved in configuring a pxGrid Cloud identity source are:

- Cisco ISE: Enables pxGrid Cloud service and creates the connection
- Catalyst Cloud Portal: Creates and manages app instances for authentication
- Cloud-Delivered Firewall Management Center: Receives user data and creates identity sources for policy enforcement

Workflow

Figure 391: Configure a pxGrid Cloud identity source

1 Enable the pxGrid Cloud service in Cisco ISE, on page 2470
2 Register the pxGrid Cloud connection with Cisco ISE, on page 2442
3 Create an app instance, on page 2473
4 Create an app instance, on page 2473
5 Create a pxGrid Cloud identity source, on page 2443
6 Activate the app instance, on page 2446
7 Activate the pxGrid Cloud identity source, on page 2448

These are the stages of configuring a pxGrid Cloud identity source using Cisco ISE, the Catalyst Cloud Portal, and Cloud-Delivered Firewall Management Center:

1. Enable pxGrid Cloud in Cisco ISE.

   pxGrid Cloud enables you to subscribe to offers and to register apps (in this case, the Cloud-Delivered Firewall Management Center) for secure data exchange in a cloud environment.

   For more information, see Enable the pxGrid Cloud service in Cisco ISE, on page 2470.

2. Create an app instance and get the one-time password (OTP) required to create the pxGrid Cloud identity source in the Catalyst Cloud Portal.

   For more information, see Create an app instance, on page 2473.

3. Create the pxGrid Cloud identity source in the Cloud-Delivered Firewall Management Center.

   The identity source enables the Cloud-Delivered Firewall Management Center to authenticate with Cisco ISE and the Catalyst Cloud Portal so it can receive user data from Cisco ISE.

   For more information, see Create the identity source, on page 2445.

4. Activate the app instance in the Catalyst Cloud Portal.

   For more information, see Activate the app instance, on page 2446.

5. Activate the pxGrid Cloud identity source in the Cloud-Delivered Firewall Management Center.

   For more information, see Activate the pxGrid Cloud identity source, on page 2448.

What's next

After you complete this configuration process, you can:

- Test the pxGrid Cloud identity source to make sure it's working properly. For more information, see Test the pxGrid Cloud identity source, on page 2450.
- Create dynamic attributes filters, which define what dynamic objects are sent to the Cloud-Delivered Firewall Management Center. For more information, see Create dynamic attributes filters, on page 2455.
- Use the pxGrid Cloud identity source to enable dynamic objects, Microsoft AD user and groups, and Azure AD users and groups in access control rules.

Enable the pxGrid Cloud service in Cisco ISE

This task enables the pxGrid Cloud service in Cisco ISE, which allows your ISE deployment to connect to cloud-based pxGrid services for enhanced security and visibility.

This task explains how to enable pxGrid Cloud in Cisco ISE.

Before you begin

- Install and activate the Advantage license tier in your Cisco ISE deployment.
- The pxGrid Cloud agent creates an outbound HTTPS connection to Cisco pxGrid Cloud. Therefore, you must configure Cisco ISE proxy settings if the customer network uses a proxy to reach the internet. To configure proxy settings in Cisco ISE, click the **Menu** icon (☰) and choose **Administration > System > Settings > Proxy**.
- The Cisco ISE Trusted Certificates Store must include the root CA certificate required to validate the server certificate presented by Cisco pxGrid Cloud. Ensure that the **Trust for Authentication of Cisco Services** option is enabled for this root CA certificate. To enable this option, navigate to **Administration** > **System** > **Certificates**.

Follow these steps to enable the pxGrid Cloud service in Cisco ISE:

Procedure

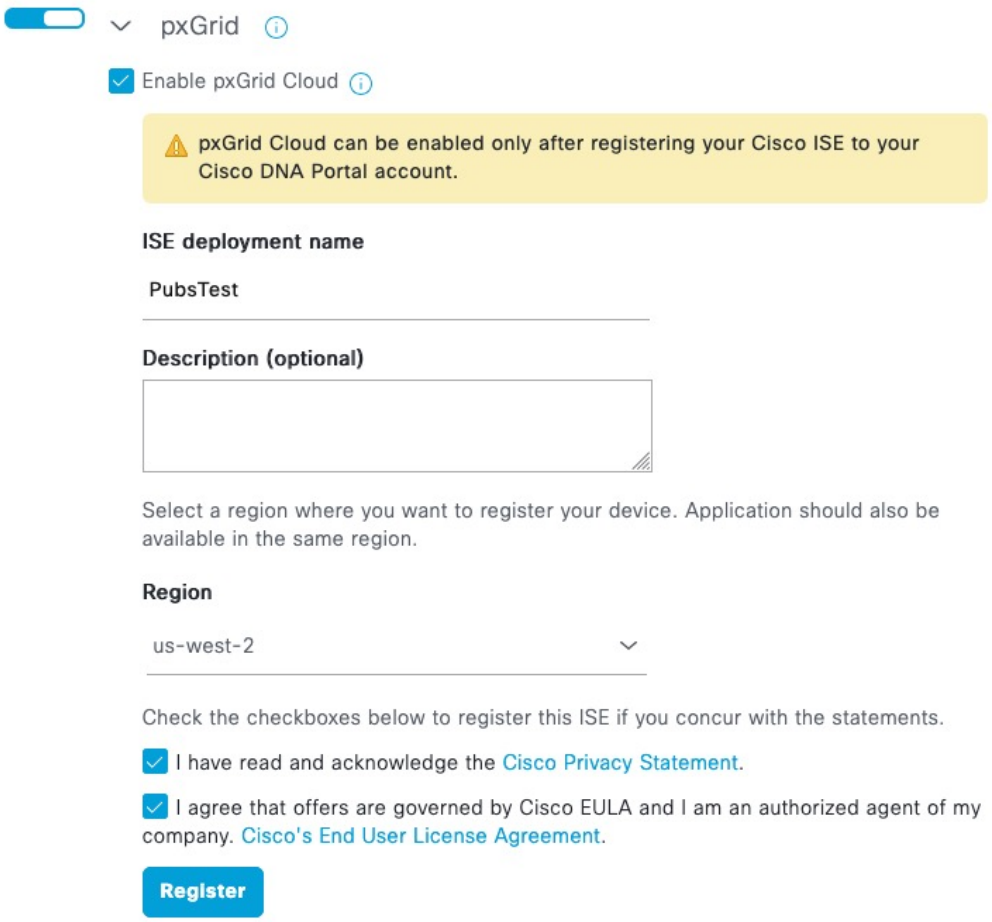
Step 1 Log in as an administrator to Cisco ISE.

If your Cisco ISE server is part of a cluster, log in to the Primary Administration Node (PAN).

Step 2 Click the **Menu** icon (☰), then click **Administration** > **Deployment**.

Under Deployment Nodes, click the name of the deployment node.

Step 3 On the next page, scroll down to locate the **pxGrid** node.



Select the **Enable pxGrid Cloud** check box.

Step 4 Enter the following information:

Option	Description
ISE Deployment Name	Enter a unique name to identify your ISE deployment.
Description (Optional)	Enter an optional description.
Region	Click the region you're in (**us-west-2**, **eu-central-1**, or **ap-southeast-1**). This is the only valid region at this time.
License agreements	You are required to select both check boxes to continue.

Step 5 Click **Register**.

Example:

Step 6 When prompted with an activation code for the Catalyst Cloud Portal, click **Next**.

Step 7 When prompted, log in to the Catalyst Cloud Portal.

Step 8 At the Select an Account dialog box, click the name of an account with which to register Cisco ISE.

Step 9 Click **Register ISE**.

What to do next

See Verify Cisco ISE registration in the Catalyst Cloud Portal, on page 2472.

Verify Cisco ISE registration in the Catalyst Cloud Portal

This task allows you to confirm that Cisco ISE is properly registered with the Catalyst Cloud Portal.

This task explains how to verify that Cisco ISE is registered with the Catalyst Cloud Portal.

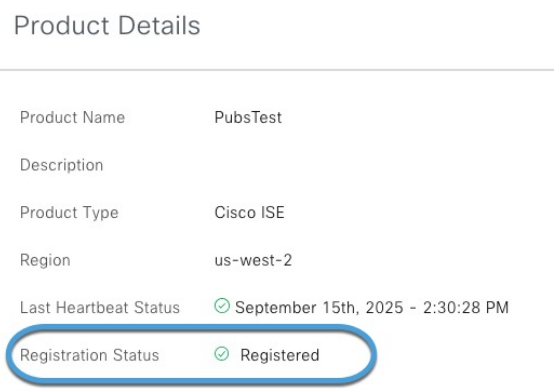
Before you begin

Complete the tasks discussed in Enable the pxGrid Cloud service in Cisco ISE, on page 2470.

Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

Step 2 If prompted, select the account.



Step 3 In the left navigation, click ☰ > **Applications and Products**.

Step 4 At the top of the page, click **Products**.

Step 5 Click the name of the Cisco ISE deployment you created previously.

Step 6 Make sure that **Registered** is displayed for its status.

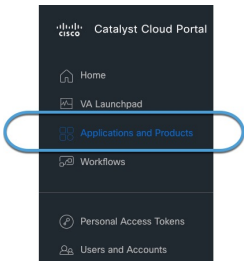
Example:

Create an app instance

Create an app instance to enable pxGrid Cloud identity source functionality for sending user session data to the Cloud-Delivered Firewall Management Center.

This task is one of several tasks you must perform to create a pxGrid Cloud identity source to send user session data to the Cloud-Delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. You do not need to log in to Cisco ISE.



Before you begin

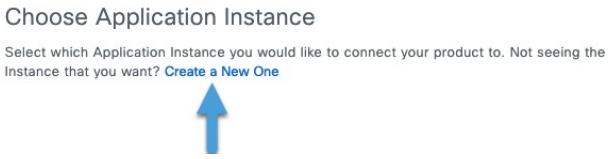
Verify Cisco ISE registration in the Catalyst Cloud Portal, on page 2472.

Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

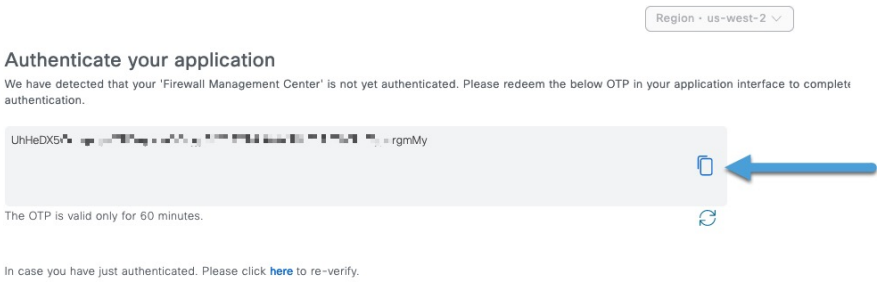
Step 2 In the Catalyst Cloud Portal, click ☰ > **Applications and Products**.

Step 3 At the top of the page, click **Applications**.



Step 4 From the **Regions** list, click **us-west-2**, **eu-central-1**, or **ap-southeast-1**.

Step 5 Click **Manage** (or **Activate**) next to **Firepower Management Center**.



Step 6 Click **Add**.

Step 7 Click **Create a New One**.

The following figure shows an example.

Step 8 Click the copy button next to the displayed OTP.

Copy the OTP to a text file; it expires in 60 minutes.

Step 9 Continue with Create the identity source, on page 2445.

Create the identity source

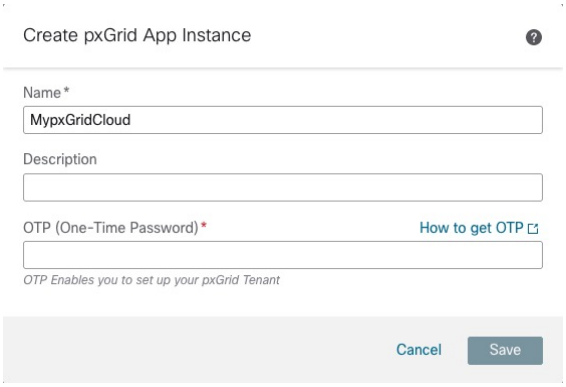
This task creates a pxGrid Cloud identity source to send user session data to the Cloud-Delivered Firewall Management Center.

This task is one of several required to create a pxGrid Cloud identity source to send user session data to the Cloud-Delivered Firewall Management Center.

Before you begin

Complete the task discussed in Create an app instance, on page 2443.

Procedure



Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Step 2 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**

Step 3 Click **Identity Services Engine (pxGrid Cloud)**.

Step 4 Click **Create pxGrid Application Instance**.

This figure shows an example.

Step 5 Enter the required information.

Value	Description
Name	Enter a name to uniquely identify this connector.
Description	Optional description.
OTP (One-Time Password)	Enter the OTP.

Step 6 Click **Create**.

Step 7 At the top of the page, click **Save**.

What to do next

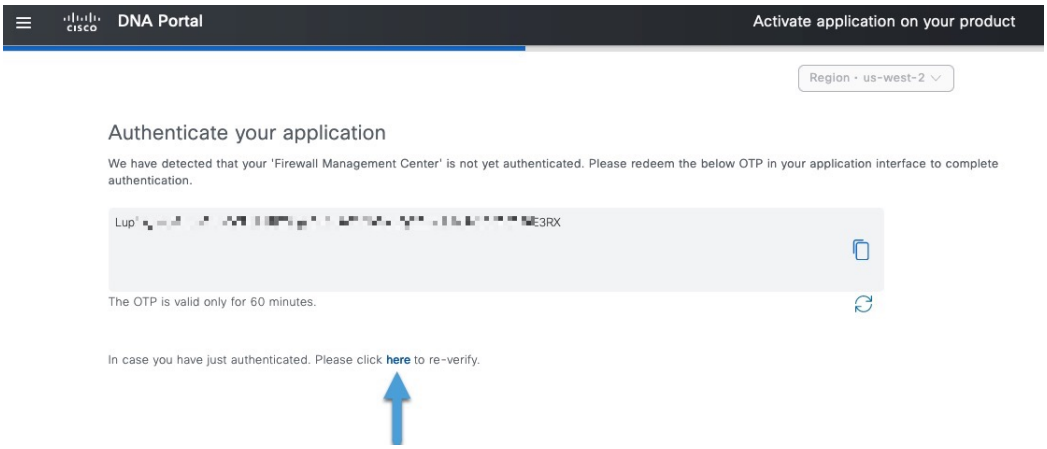
Continue with Activate the app instance, on page 2446.

Activate the app instance

Activate an app instance to create a pxGrid Cloud identity source that sends user session data to the Cloud-Delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. You do not need to log in to Cisco ISE.

Before you begin

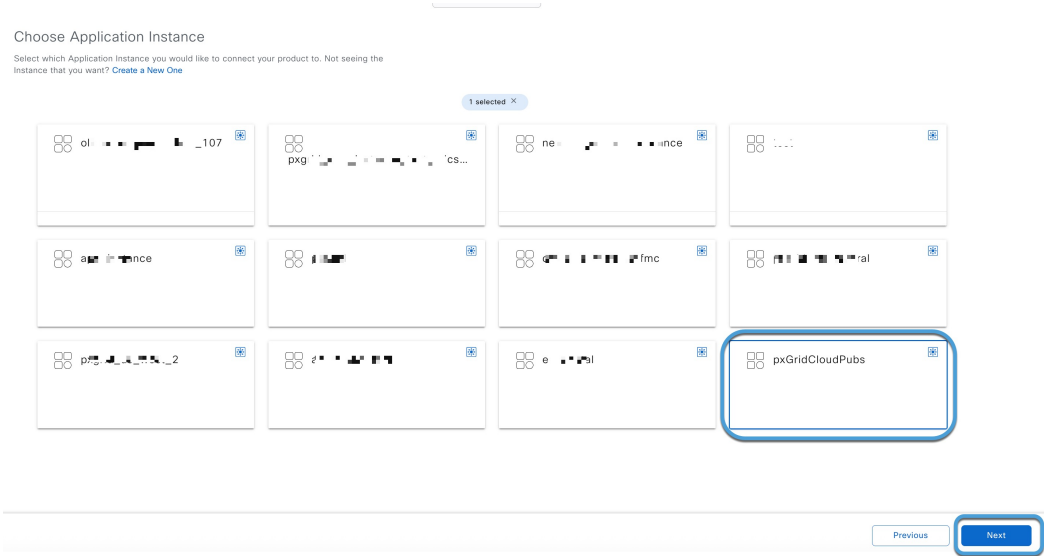


Complete the task discussed in Create the identity source, on page 2445.

Follow these steps to activate the app instance:

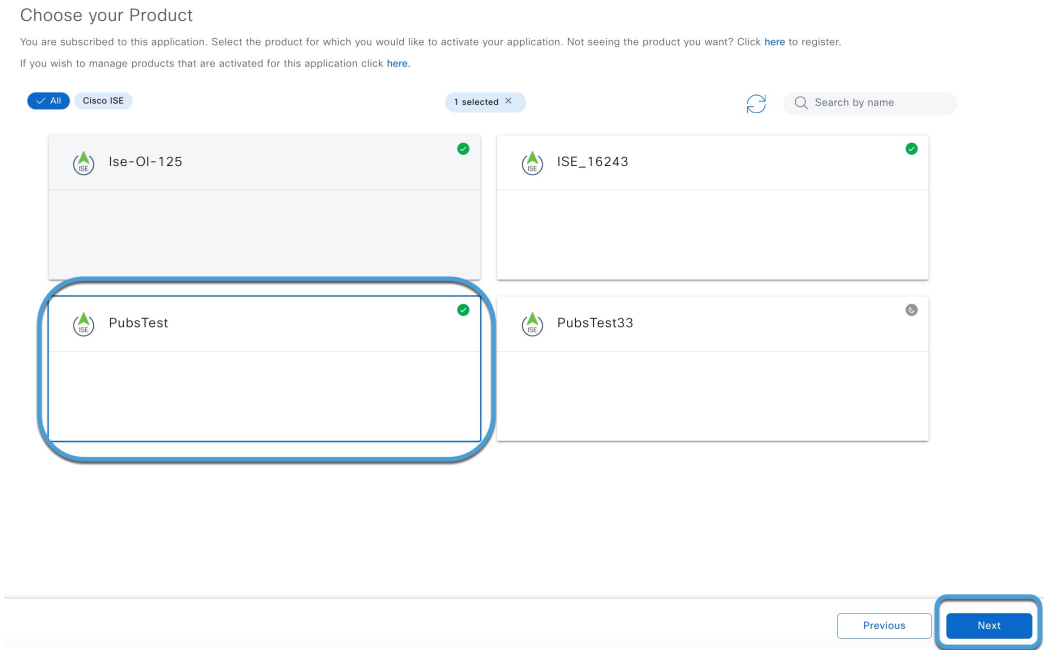
Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.



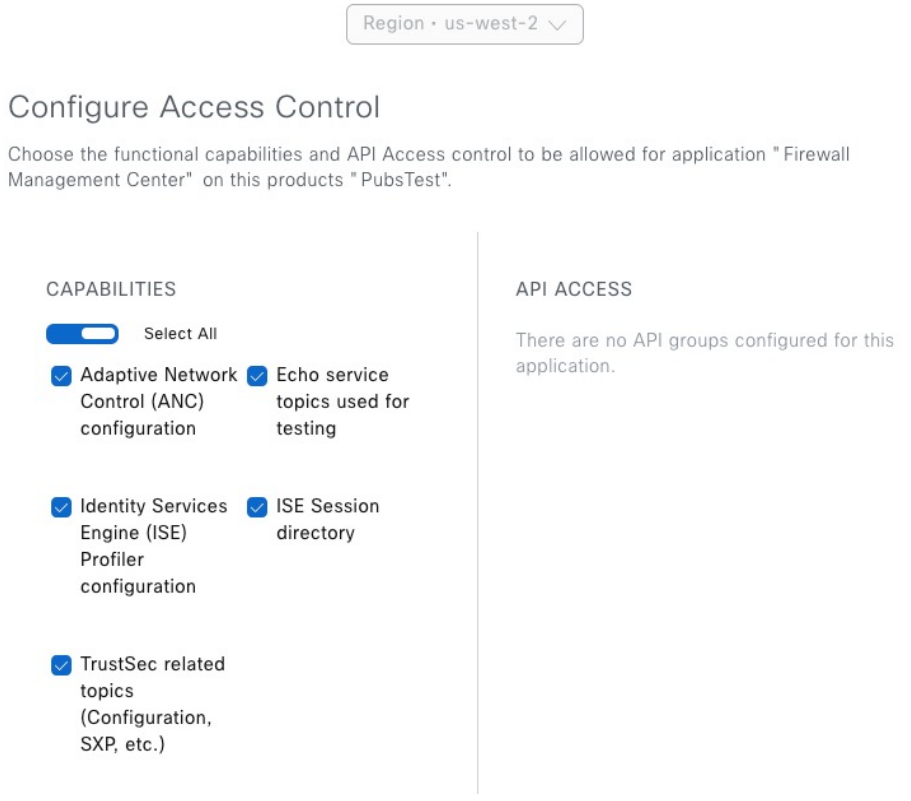
Step 2 Reverify the app by clicking the word **here** as the following figure shows.

Step 3 Click the name of the application instance you just created in Cloud-Delivered Firewall Management Center.



Step 4 Click **Next**.

Example:



Step 5 On the Choose Product page, click the name of the Cisco ISE product and click **Next**.

Example:

Step 6 Select the check box next to each scope.
The following figure shows an example.

Step 7 Click **Next**.

Step 8 Review the displayed information for accuracy. Make sure all scopes are selected.

Step 9 Click **Activate**.

It can take several minutes for the app instance to be activated.

Continue with Activate the pxGrid Cloud identity source, on page 2448.

Activate the pxGrid Cloud identity source

This task activates the pxGrid Cloud identity source to enable identity services integration in your security infrastructure.

This task explains how to activate the pxGrid Cloud identity source in the Security Cloud Control.

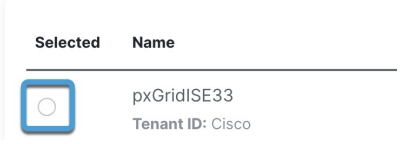
Before you begin

Complete the tasks discussed in Activate the app instance, on page 2446.

Note Only one pxGrid Cloud identity source can be active at a time.

Procedure

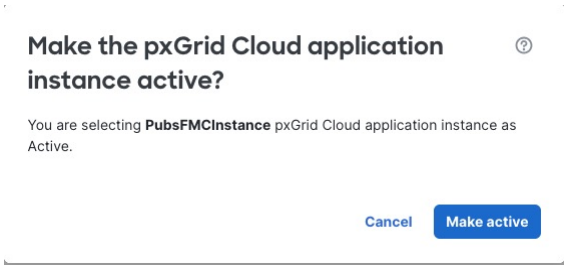
Step 1 Log in to Security Cloud Control as a user with the Super Admin role.



Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 2 Click **Identity Services Engine (pxGrid Cloud)**.

Step 3 Click **Save** at the top of the page.



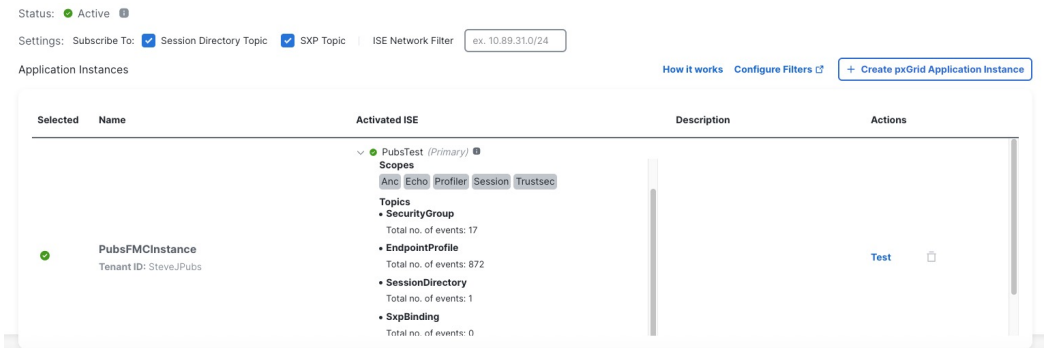
Step 4 If a green check mark is *not* displayed next to the name of the identity source, select it.

Example:

Step 5 Click **Make Active**.

Example:

Step 6 (Optional.) Select the following options if desired:



- **Session Directory Topic**: Select the check box to receive ISE user session information from the Cisco ISE server.
- **SXP Topic**: Select the check box to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.
- **ISE Network Filter**: Optional filter you can set to restrict the data that Cisco ISE reports. If you provide a network filter, Cisco ISE reports data from the networks in that filter.

  You have the following options:

  - Leave the field blank to specify **`any`**.
  - Enter a single IPv4 address block using CIDR notation.
  - Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

Step 7 Under Activated ISE, expand the identity source.

Example *normal* result:

Example *error* result:

In the event of an error, see Test the pxGrid Cloud identity source, on page 2450.

Step 8 Verify the status is Active and that all scopes and topics are displayed.

Wait a few minutes for data to be downloaded.

What to do next

See Test the pxGrid Cloud identity source, on page 2450.

Test the pxGrid Cloud identity source

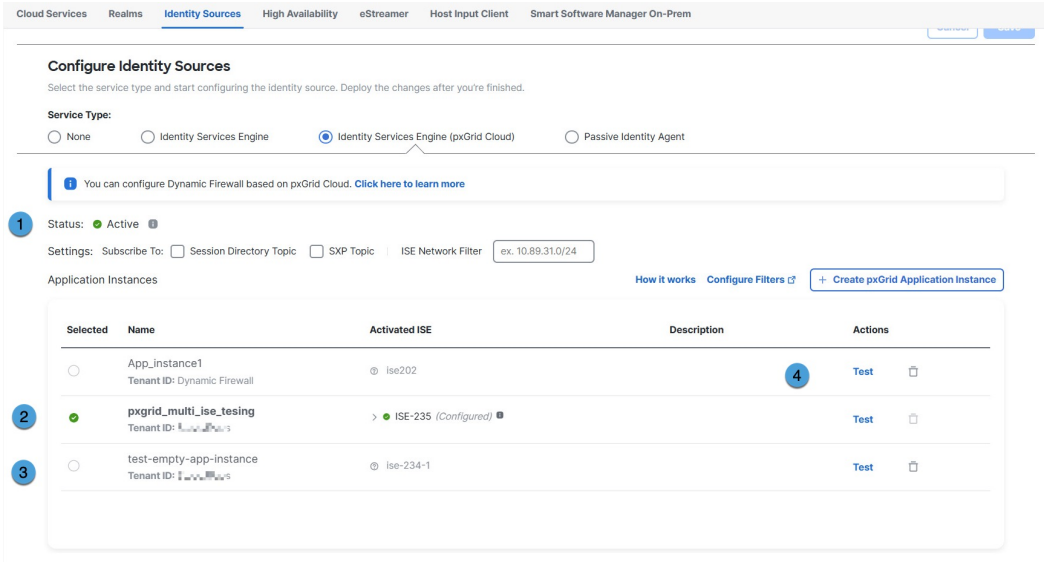
This task enables you to perform diagnostics using the Security Cloud Control to determine if the identity source is working.

Errors might include communication with Cisco ISE, or with the Cisco ISE configuration with Catalyst Cloud Portal.

Procedure

Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Step 2

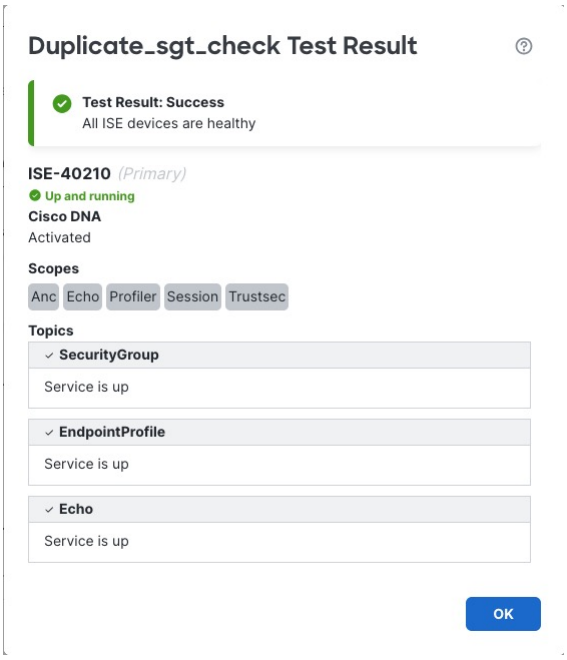


Step 3 Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

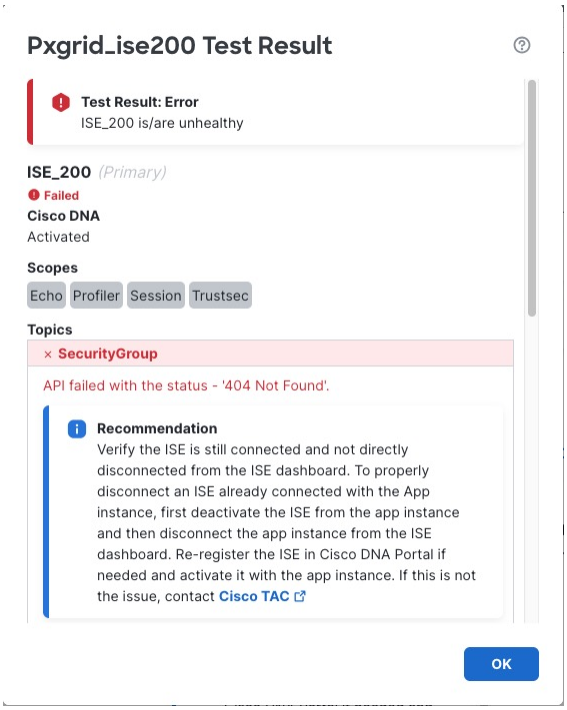
Step 4

Step 5 Click **Identity Services Engine (pxGrid Cloud)**.

Step 6 Review the configuration status information.



The following figure shows an example configuration.



The following table has more information about the numbered areas in the figure.

Number	Meaning
1	Overall status Any errors in the overall status of the Cisco ISE app instances are displayed. In that case, scroll to that instance and either expand the error message or click **Test** for more information.
2	Active A green check mark indicates the app is active.
3	Inactive A dimmed app instance is inactive. You can activate it by selecting the check box next to its name and then clicking **Make active**.
4	**Test** button Click **Test** to perform diagnostic tests that show more detailed status of the app instance.

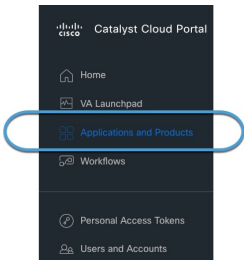
The following figure shows a sample success message.

The following figure shows an example error result.

Step 7 Click **Test** to perform diagnostic tests.

If errors occur, use the following error code reference to help diagnose and solve issues with Cisco ISE, pxGrid Cloud, and the Catalyst Cloud Portal. If these suggestions do not work, or if you have a different issue, contact Cisco TAC.

Table 133: Error code troubleshooting

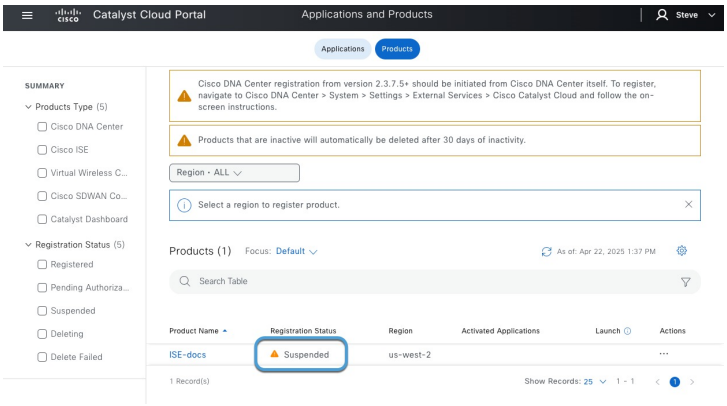


Error Code	Troubleshooting Steps
403 – Forbidden	Verify the Cisco ISE product is not in a **Pending** or **Suspended** state in the Catalyst Cloud Portal. If suspended, verify that Cisco ISE is registered as discussed in Enable pxGrid Cloud service in Cisco ISE and register your device. Additionally, verify pxGrid Cloud services are publicly available.
404 – Not Found	Verify the Cisco ISE server is not directly disconnected from the Cisco ISE dashboard. To properly disconnect Cisco ISE already connected with the app instance, first deactivate Cisco ISE from the app instance and then disconnect the app instance from the Cisco ISE dashboard.
408 – Request Timeout	Check whether there are any general connectivity issues with Cisco ISE and verify pxGrid Cloud connectivity status is **Connected** in the ISE dashboard under ☰ > **Administration** > **pxGrid Services** > **Client Management** > **pxGrid Cloud Connection**. Verify the Cisco ISE server is not directly disconnected from the Cisco ISE dashboard.
413 – Content Too Large	Review the pxGrid Cloud API limitations on GitHub. If needed, consider upgrading your Cisco ISE version to fully utilize pxGrid Cloud support.
500 – Internal Server Error	Check that the Cisco ISE server is operational and that pxGrid Cloud services are active (verify MNT, SXP, pxGrid nodes, and so on). For more information, see Monitoring and debugging in the Cisco pxGrid chapter in the *Cisco Identity Services Engine Administrator Guide*.

Step 8 If the product is in a **Pending** or **Suspended** state, verify that it is active.

a) Log in to the Catalyst Cloud Portal.

b) In the Catalyst Cloud Portal, go to ☰ > **Applications and Products**.

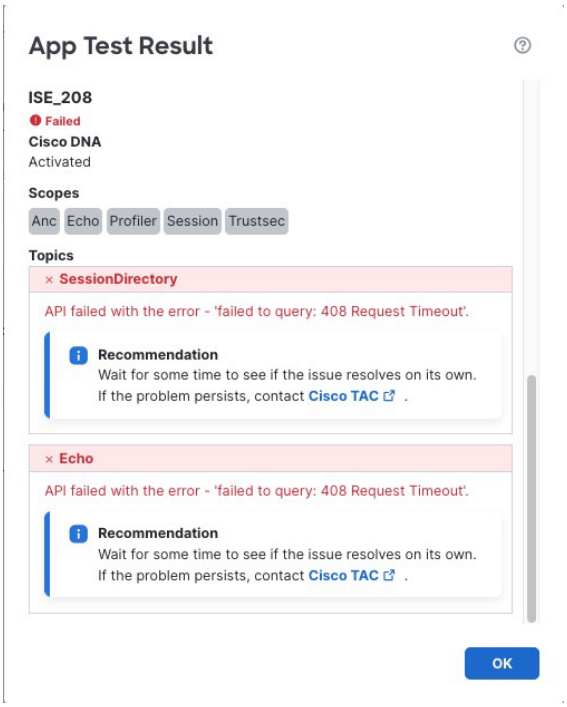


Example:

c) Click the **Products** tab.

Example:

The following figure shows an example of a suspended product.



d) To correct the issue, in the Actions column, click ••• and click **Generate OTP**.

e) Use the OTP as discussed in Create the identity source, on page 2445.

Step 9 If you encounter a cluster member not reachable error, find what node is not reachable.

If a member of the Cisco ISE cluster is not reachable, a page like this is displayed:

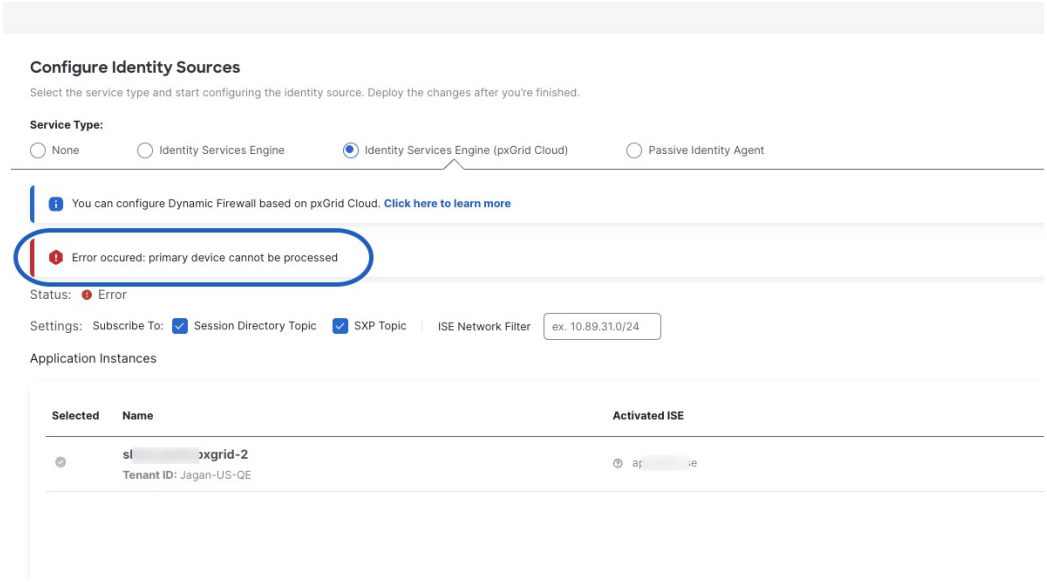
To find what node is not reachable, log in to Cisco ISE primary administration node as an administrator and click click the **Menu** icon (☰) and choose **Administration** > **System** > **Deployment**, then see Node Status in a Cisco ISE Deployment.

Troubleshoot the pxGrid Cloud identity source

These topics describe troubleshooting the pxGrid Cloud identity source.

Related Topics

Primary device cannot be processed, on page 2458
Primary device cannot be processed, on page 2458



Primary device cannot be processed

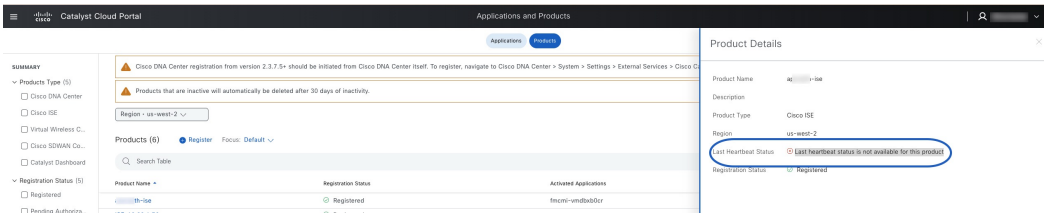
This task resolves the error "primary device cannot be processed" or "ISE is unhealthy" that occurs when a Cisco ISE cluster is associated with more than one app instance.

Each Cisco ISE cluster must be associated with one and only one app instance, typically in a single dedicated tenant.

If you associate a Cisco ISE with more than one app instance, an error such as `Error occured: primary device cannot be processed` or `ISE is unhealthy` is displayed for the identity source.

Example:

The solution is to deactivate the ISE properly from other app instances for that tenant, before using it in any other tenant or app instance



Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

Step 2 At the top of the page, click **Applications**.

Step 3 Locate a Cisco ISE product that is activated and verify it is the one causing the issue.

Example:

Step 4 Wait for the product to be removed.

Step 5 Deactivate the app instance as described in Deactivate the pxGrid Cloud app instance, on page 2459.

Create dynamic attributes filters

Create dynamic attributes filters to expose them as dynamic objects in Security Cloud Control for use in access control policies.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Security Cloud Control as dynamic objects that can be used in access control policies. For example, restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules or DNS rules using dynamic attributes filters, on page 2456.

Before you begin

Connectors, on page 2631

Procedure

Step 1 Log in to Security Cloud Control.

a) Click **Firewall**.

b) Click **Administration** > **Dynamic Attributes Connector** > **Dynamic Attributes Filters**.

Step 2 Do any of the following:

- Add a new filter: click **Add** ( ).
- Edit or delete a filter: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 3 Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in a policy and in the Security Cloud Control Object Manager (**External Attributes** > **Dynamic Object**).
Connector	From the list, click the name of a connector to use.
Query	Click Add .

Step 4 To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: • **Equals** to exactly match the key to the value. • **Contains** to match the key to the value if any part of the value matches.
Values	Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 5 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

Step 6 When you're finished, click **Save**.

Step 7 (Optional.) Verify the dynamic object in the Security Cloud Control.

a) Log in to the Security Cloud Control.

b) Click **Policies** > **Firewall Threat Defense**.

c) Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.

The dynamic attribute query you created should be displayed as a dynamic object.

Create access control rules or DNS rules using dynamic attributes filters

Create access control rules using dynamic objects that are based on dynamic attributes filters you have previously configured.

This topic discusses how to create access control rules using dynamic objects (these dynamic objects are named after the dynamic attributes filters you created previously).

To add dynamic attributes filters to DNS policies, see Create basic DNS policies, on page 2561.

To add dynamic attributes filters to DNS policies, see Creating Basic DNS Policies.

Before you begin

Create dynamic attributes filters as discussed in Create dynamic attributes filters, on page 2455.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

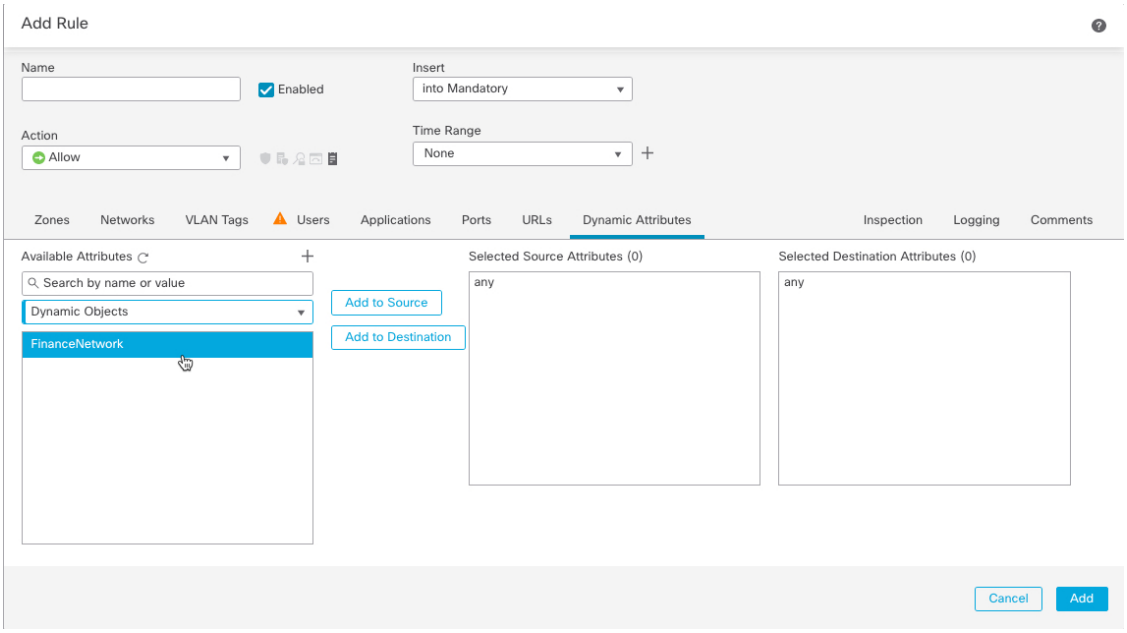
Follow these steps to create access control rules or DNS rules using dynamic attributes filters:

Procedure

Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Click **Policies** > **Firewall Threat Defense** > **Access Control heading** > **Access Control**.

Step 2 Click **Firewall**.



Step 3 Click **Edit** ( ) next to an access control policy.

Step 4 Click **Add Rule**.

Step 5 Click the **Dynamic Attributes** tab.

Step 6 In the Available Attributes section, from the list, click **Dynamic Objects**.

The following figure shows an example.

This example shows a dynamic object named `APIC Dynamic Attribute` that corresponds to the dynamic attribute filter created in the dynamic attributes connector.

Step 7 Add the desired object to source or destination attributes.

Step 8 Add other conditions to the rule if desired.

See Dynamic attributes rule conditions, on page 2681.

Deactivating and deleting the pxGrid Cloud identity source

Deactivating the FMC app instance in the Catalyst Cloud Portal is an optional task to troubleshoot issues with the Cisco ISE integration.

You should delete the pxGrid Cloud identity source from the Security Cloud Control when you are certain you don't want to use it again.

Related Topics

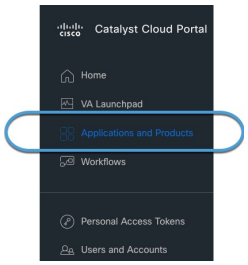
Deactivate the pxGrid Cloud app instance, on page 2459
Delete the pxGrid Cloud identity source, on page 2462

Deactivate the pxGrid Cloud app instance

This task explains how to deactivate a pxGrid Cloud app instance using the Catalyst Cloud Portal when your Cisco ISE or pxGrid Cloud stops working or you need to update it.

This is an optional task. You should do this only if your Cisco ISE or pxGrid Cloud stops working or you need to update it.

Before you begin



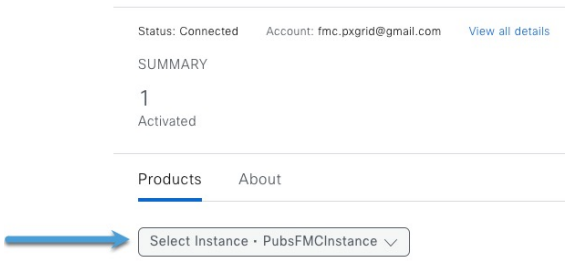
Make sure your current pxGrid Cloud identity source is active as discussed in Activate the pxGrid Cloud identity source, on page 2448.

Follow these steps to deactivate the pxGrid Cloud app instance:

Procedure

Step 1 Log in to the Cisco Catalyst Cloud Portal.

Step 2 In the Catalyst Cloud Portal, click ☰ > **Applications and Products** as the following figure shows:



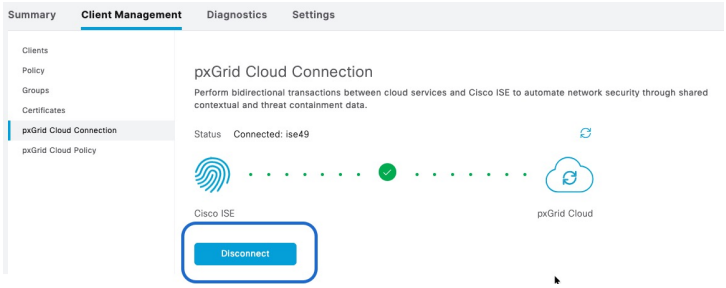
Step 3 Click **Applications**.

Step 4 Click **Manage** for Firewall Management Center.

From the **Select Instance** list, click the name of the firewall application you created earlier.

Example:

Step 5 In the Actions column, click More icon (···) > **Deactivate**.

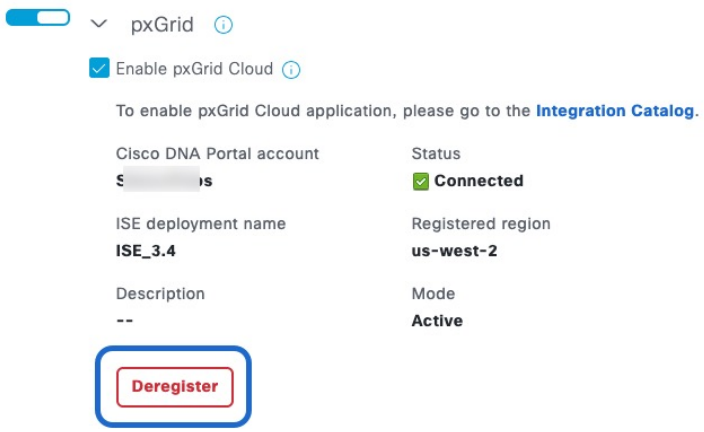


Step 6 Wait until the product is removed.

You can click **Refresh** ( ) to see updated status if necessary.

Step 7 ISE 3.3 or earlier: Disconnect the app instance:

a) Log in to Cisco ISE as an administrator.
b) Click **Administration** > **pxGrid Services** > **Client Management** > **pxGrid cloud connection**.
c) Click **Disconnect**.



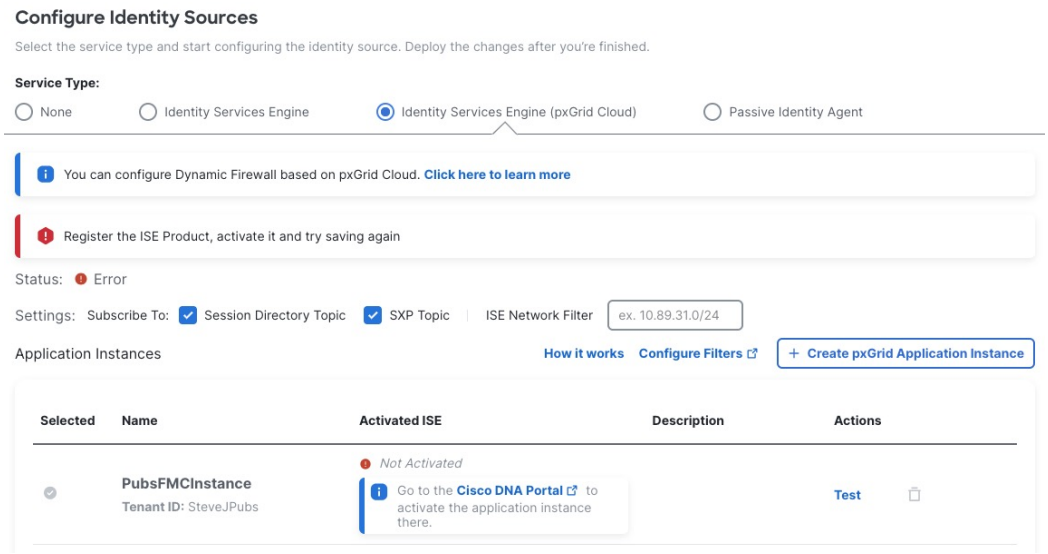
Example:

Step 8 ISE 3.4 or later: Deregister the app instance:

a) Log in to Cisco ISE as an administrator.
b) Click **Administration** > **System** > **Deployment**.
c) Expand **Deployment**.
d) Click the name of the ISE node.
e) In the **General Settings** tab page, scroll to locate **pxGrid**.
f) Click **Deregister**.

Example:

Step 9 To verify the app instance is deactivated in Security Cloud Control:



a) Log in to Security Cloud Control.

b) Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**

c) Click **Identity Services Engine (pxGrid Cloud)**.

d) Verify that **Not Activated** is displayed in the Activated ISE column.

Example:

What to do next

- To register Cisco ISE with pxGrid Cloud and activate the app instance, see:
  - ISE 3.3 and earlier: Register Cisco ISE with the Catalyst Cloud Portal, on page 2439.
  - ISE 3.4 and later: Create an app instance, on page 2473.
- To completely remove the identity source, see Delete the pxGrid Cloud identity source, on page 2462.

Delete the pxGrid Cloud identity source

Delete the pxGrid Cloud identity source from Security Cloud Control when you no longer need it.

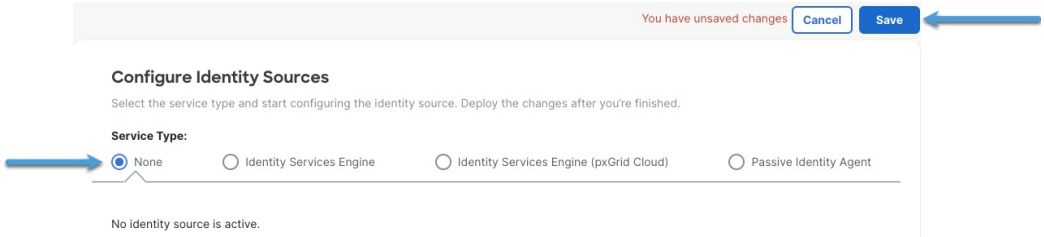
This task explains how to delete the pxGrid Cloud identity source from Security Cloud Control, which is necessary if you do not want to use it again.

Before you begin

Deactivate the FMC app instance from the Catalyst Cloud Portal as discussed in Deactivate the pxGrid Cloud app instance, on page 2459.

Follow these steps to delete the pxGrid Cloud identity source:

Procedure



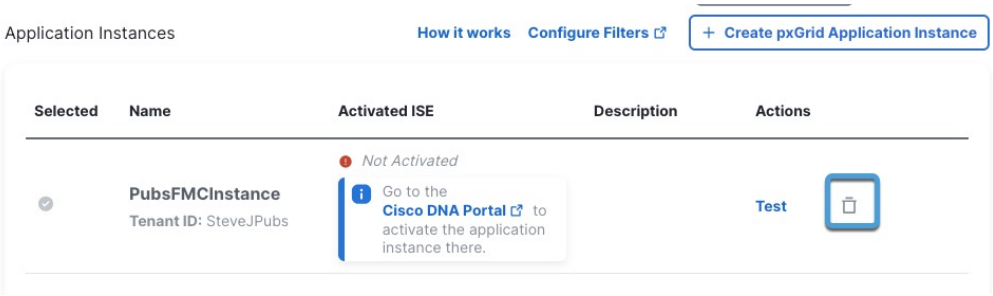
Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Click **Policies** > **Threat Defense** > **Integration** > **Other Integrations** > **Identity** > **Identity Sources**.

Step 2 Click **Identity Services Engine (pxGrid Cloud)**.

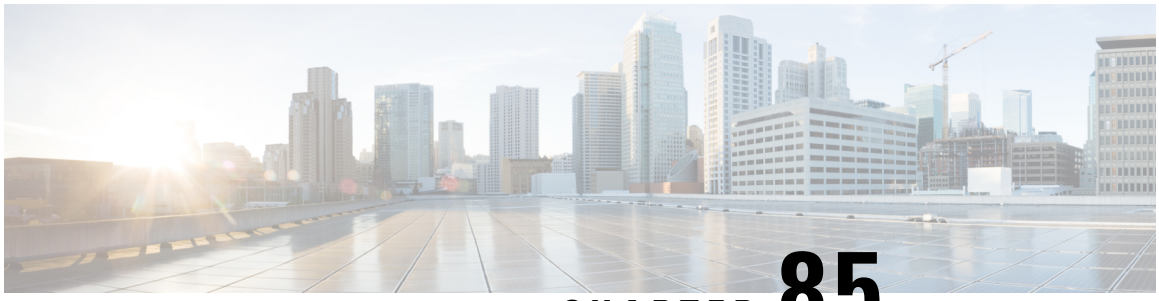
Step 3 For Service Type, click **None**.

Example:



Step 4 Click **Save**.

Step 5 Confirm your choice when prompted.



Step 6 Click **Identity Services Engine (pxGrid Cloud)**.

Step 7 Click **Delete** ( ).

Example:

Step 8 Confirm the action when prompted.

CHAPTER 85

Identity Source: Remote Access VPN

The following topics discuss how to perform user awareness and user control with Remote Access VPN:

- Remote access VPN identity sources, on page 2495
- Configure Remote Access VPN for AD-authenticated users, on page 2496
- Hybrid Entra ID and on-premises AD deployments, on page 2497
- Troubleshooting guidelines for remote access VPN identity source, on page 2497

Remote access VPN identity sources

A remote access VPN identity source authenticates a user before establishing secure remote connection to the network. It requires the user to provide credentials through a client to verify the identity.

Identity source configuration

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to Firewall Threat Defense devices.

When you set up a secure VPN gateway as discussed in Configure a remote access VPN policy, you can set up an identity policy for those users and associate the identity policy with an access control policy, provided your users are in an Active Directory repository.

Note If you use remote access VPN with User Identity and RADIUS as the identity source, you must configure the realm (**Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**).

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

Note If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format domain\username or username@domain fails. (Active Directory refers to this username as the logon name or sometimes as sAMAccountName.) For more information, see User Naming Attributes on MSDN.

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

Once authenticated through a VPN connection, the remote user takes on a VPN identity. This VPN identity is used by identity policies on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that a remote user blocked or allowed to access your network resources.

Related Topics

Secure Connections Overview, on page 1709
Remote access VPN
VPN basics, on page 1710
Configure a remote access VPN policy

Configure Remote Access VPN for AD-authenticated users

Configure remote access VPN for Active Directory-authenticated users. Manage VPN connections and apply identity-based policies to control user access and traffic filtering.

Remote access VPN user control allows you to implement identity-based policies that manage and monitor VPN user connections, providing enhanced security and access control for your network environment.

Before you begin

- Create a realm as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
- To use authentication, authorization, and auditing (AAA), set up a RADIUS server group as discussed in Add a RADIUS server group, on page 2943.

Follow these steps to configure RA VPN for user control:

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Devices** > **VPN** > **Remote Access**.

Step 3 See Configure a remote access VPN policy.

Step 4 Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.

Step 5 Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Step 6 Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.

What to do next

Monitor VPN user traffic .

Hybrid Entra ID and on-premises AD deployments

The hybrid Entra ID and on-premises AD deployment model enables secure, flexible authentication and authorization for remote access users, provided the correct policy order and rule configuration are maintained.

In a hybrid deployment, remote access VPN users can authenticate with Microsoft Entra ID (formerly Azure AD). Cisco ISE authorizes the session and Firewall Management Center uses an on-premises Microsoft Active Directory realm for user identity and user-based access control. In this deployment model:

- Remote access VPN (RA VPN) is configured on Firewall Threat Defense
- Microsoft Entra ID or Azure is used as the SAML identity provider for VPN authentication
- Cisco ISE is used for session authorization
- Cisco ISE authorization policies may include both Microsoft Entra ID/Azure and on-premises AD rules or conditions
- Firewall Management Center uses the on-premises AD domain as the realm for user identity and user enforcement

Best practice: ISE authorization policy order for hybrid deployments

Beginning with Cisco ISE Release 3.4 Patch 4, when ISE evaluates an Entra ID identity source during authorization, it associates Entra ID attributes with the session. If Firewall Management Center uses an on-premises AD realm, the presence of Entra ID attributes may prevent correct user-to-IP mapping for RA VPN sessions. Identity-based access control rules that depend on user or group identity might not match as expected.

To prevent this issue:

Place ISE authorization rules that use the on-premises AD external identity source before rules that evaluate Entra ID or Azure conditions for the same users. This ensures that the session attributes published to FMC through pxGrid align with the configured on-premises AD realm.

After configuring the authorization policy order, verify that new RA VPN sessions create user mappings in Firewall Management Center and that user-based or group-based access control rules match as expected.

Note This behavior applies to Cisco ISE Release 3.4 Patch 4 and later. If user mappings stopped appearing after an ISE upgrade, review the ISE authorization policy order as described in this section.

Troubleshooting guidelines for remote access VPN identity source

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 2342 and Troubleshoot user control, on page 2526.

If you experience issues with Remote Access VPN, check the connection between your Cloud-Delivered Firewall Management Center and a managed device. If the connection fails, all Remote Access VPN logins

reported by the device cannot be identified during the downtime, unless the users were previously seen and downloaded to the Cloud-Delivered Firewall Management Center.

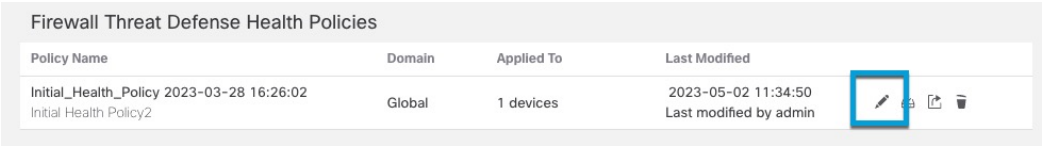
The unidentified users are logged as Unknown users on the Cloud-Delivered Firewall Management Center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.

Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see RFC 95

Not Observing Correct Settings for VPN Statistics

This task ensures that managed devices receive the correct health policy settings after modifying VPN statistics configurations.



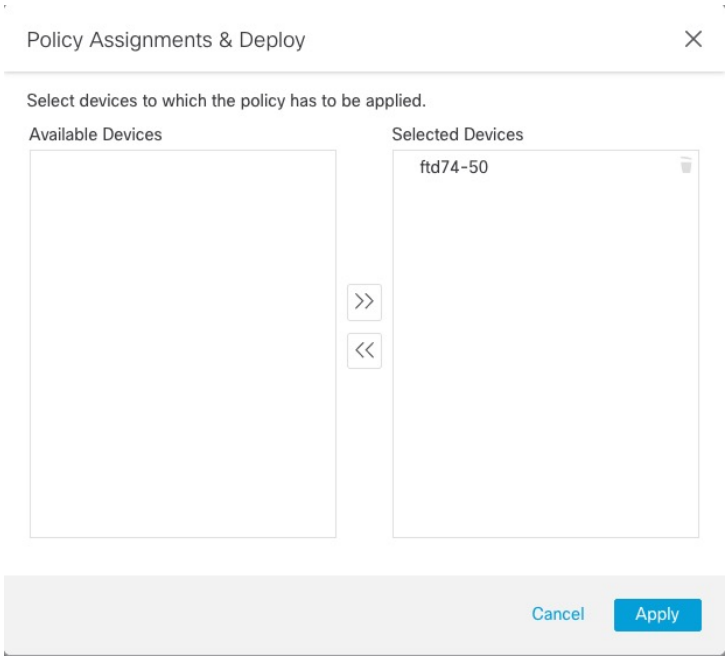
This task discusses steps you must take after either enabling or disabling the **VPN Statistics** setting in a health policy. Failure to perform this task means managed devices have a health policy with incorrect settings.

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center if you haven't already done so.

Step 2 Click **System** (⚙) > **Health** > **Policy**.

Step 3 Under Firewall Threat Defense Health Policies, click **Edit** (✎) next to a policy to edit.



Step 4 On the **Health Modules** tab page, scroll down to locate **VPN Statistics**.

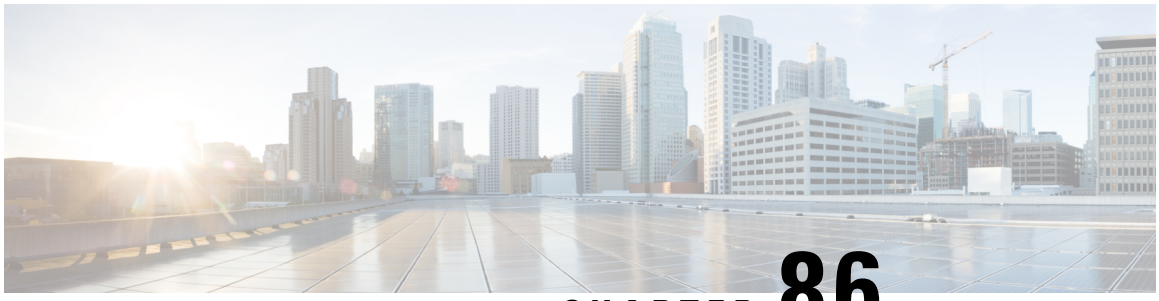
Step 5 Verify the VPN statistics setting is correct or change it if necessary.

Step 6 If you changed the setting, click **Save**, then click **Cancel** to return to the health policy.

Step 7 Under Firewall Threat Defense Health Policies, click **Deploy health policy** (⬇) to apply the policy.

Step 8 In the **Policy Assignments & Deploy** dialog box, move the devices to which to deploy the health policy to the **Selected Devices** field.

Step 9 Click **Apply**.
A message is displayed when the health policy is deployed.



Step 10 After the health policy has finished deploying, click **Policies** > **Access Control heading** > **Access Control** to edit an access control policy.

Step 11 Click **Edit** (✎) next to a policy to edit.

Step 12 Make a minor change to the policy, such as changing its name.

Step 13 Save the access control policy.

Step 14 Deploy configuration changes..

CHAPTER 86

Identity source: TS agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the Terminal Services (TS) Agent guides.

What to do next:

- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity.

- Terminal services agent identity source, on page 2501
- Best practices for TS agent configuration, on page 2502
- Identity source: TS agent, on page 2502
- Troubleshoot the TS agent identity source, on page 2502
- History for TS agent, on page 2503

Terminal services agent identity source

The TS Agent is a passive authentication method and one of the authoritative identity sources supported by the system. A Windows Terminal Server performs the authentication, and the TS Agent reports it to a standalone or high availability .

TS agent functionality

When installed on Windows Terminal Servers, the TS Agent assigns a unique port range to individual users as they log in or log out of a monitored network. The Cloud-Delivered Firewall Management Center uses the unique port to identify individual users in the system. You can use one TS Agent to monitor user activity on one Windows Terminal Server and send encrypted data to a Cloud-Delivered Firewall Management Center.

The TS Agent does not report failed login attempts. The data gained from the TS Agent can be used for user awareness and user control.

Best practices for TS agent configuration

Configure the TS Agent on a Windows Terminal Server to monitor user activity and identity realms. The TS Agent enables user awareness in the Cloud-Delivered Firewall Management Center.

- Install and configure the TS Agent on a Windows Terminal Server.
- Configure one or more identity realms targeting the users your server is monitoring.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control. For detailed information about the multi-step TS Agent installation and configuration and a complete discussion of the server and system requirements, see the Terminal Services (TS) Agent guides.

Note If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Cloud-Delivered Firewall Management Center prioritizes the TS Agent data. If the TS Agent and another passive identity source report activity by the same IP address, only the TS Agent data is logged to the Cloud-Delivered Firewall Management Center.

Identity source: TS agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the Terminal Services (TS) Agent guides.

What to do next:

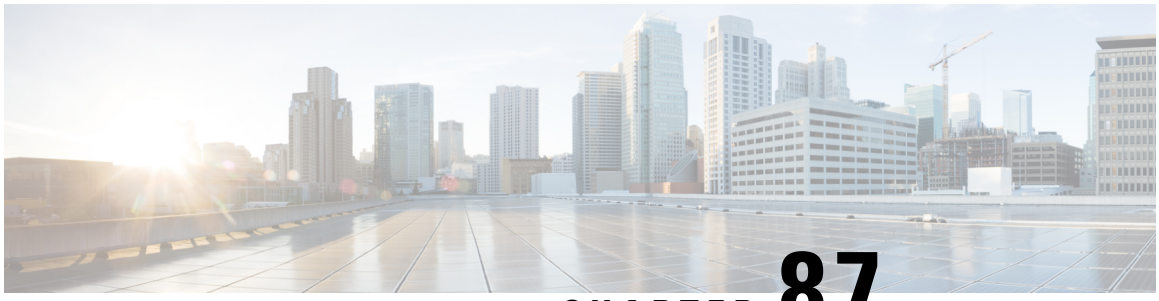
- Specify users to control and other options using an identity policy as described in Create an identity policy, on page 2507.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- Deploy your identity and access control policies to managed devices as discussed in Deploy configuration changes, on page 202.
- Monitor user activity.

Troubleshoot the TS agent identity source

This reference provides troubleshooting guidance for TS Agent integration issues with the Cloud-Delivered Firewall Management Center. It addresses synchronization requirements, user data prioritization, and activity logging for overlapping passive identity sources.

For other related troubleshooting information, see Troubleshoot realms and user downloads, on page 2342 and Troubleshoot user control, on page 2526.

If you experience issues with the TS Agent integration, check:



- You must synchronize the time on your TS Agent server with the time on the Cloud-Delivered Firewall Management Center.
- If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the Cloud-Delivered Firewall Management Center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the Cloud-Delivered Firewall Management Center.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, refer to RFC 959.

For more troubleshooting information, see the Terminal Services (TS) Agent guides.

History for TS agent

This reference provides the historical development timeline and version information for the TS Agent feature, including compatibility details and feature introductions across different Firepower Management Center and Threat Defense versions.

Feature	Minimum Cloud-Delivered Firewall Management Center	Minimum Firewall Threat Defense	Details
TS Agent communicates with the Security Cloud Control	Any	7.2.0	By applying a token from Security Cloud Control, the TS Agent can get user login sessions in the same way as for the Security Cloud Control.
TS Agent for user control.	Any	6.2.0	Feature introduced. Firepower now provides the ability to better identify individual users in shared environments, such as Citrix's Virtual Desktop Infrastructure (VDI), to accurately enforce user-based policy rules on the firewall. Users are identified by ports used. The TS Agent software is updated independently of the Firepower Management Center. For more information, see: • *Cisco Terminal Services (TS) Agent Guide* available on cisco.com • Cisco Firepower Compatibility Guide

CHAPTER 87

Identity Policies

The following topics discuss how to create and manage identity rules and identity policies:

- Identity policies, on page 2505
- License requirements for identity policies, on page 2506
- Requirements and prerequisites for identity policies, on page 2506
- Create an identity policy, on page 2507
- Identity rule conditions, on page 2509
- Create an identity rule, on page 2515
- Sample identity policies and rules, on page 2518
- Manage an identity policy, on page 2524
- Manage an identity rule, on page 2525
- Troubleshoot user control, on page 2526

Identity policies

Identity policies contain identity rules. Identity rules associate sets of traffic with a realm and an authentication method: passive authentication, active authentication, or no authentication.

Configuration requirements

With the exception noted below, you must configure realms and authentication methods you plan to use before you can invoke them in your identity rules:

- You configure realms outside of your identity policy, at **Integration** > **Other Integrations** > **Realms** > **Realms**. For more information, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
- You configure ISE/ISE-PIC, a passive authentication identity source, at **Integration** > **Other Integrations** > **Identity Sources**. For more information, see Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390.
- You configure the TS Agent, a passive authentication identity source, outside the system. For more information, see the *Cisco Terminal Services (TS) Agent Guide*.
- You configure captive portal, an active authentication identity source, within the identity policy. For more information, see Configure the captive portal for user control, on page 2355.

- You configure Remote Access VPN, an active authentication identity source, in Remote Access VPN policies. For more information, see Configure AAA settings for a remote access VPN policy.

After you add multiple identity rules to a single identity policy, order the rules. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles the traffic.

You can also filter traffic by network object, which limits the network each device monitors in the event your devices are at or near their memory limits.

After you configure one or more identity policies, you must associate one identity policy with your access control policy. When traffic on your network matches the conditions in your identity rule, the system associates the traffic with the specified realm and authenticates the users in the traffic using the specified identity source.

If you do not configure an identity policy, the system does not perform user authentication.

Exception to creating an identity policy

An identity policy is not required if all these conditions are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies.

Create an identity policy

Create an identity policy to control user and group access in a realm for access control policies.

This task discusses how to create an identity policy.

Before you begin

An identity policy is required to use users and groups in a realm in access control policies. Create and enable one or more realms as described in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

(Optional.) If a particular managed device monitors a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected. Provided the devices run version 6.7 or later, you can configure the identity rule to monitor traffic by one network or network group object only. To create a network object, see Create a network object, on page 2985.

An identity policy is not required if all these conditions are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity** and click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

Step 5 To add a rule to the policy, click **Add Rule** as described in Create an identity rule, on page 2515.

Step 6 To create a rule category, click **Add Category**.

Step 7 To configure captive portal active authentication, click **Active Authentication** and see Create an identity policy and active authentication rule, on page 2358.

Step 8 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 9 Click **Save** to save the identity policy.

What to do next

- Add rules to your identity policy that specify which users to match and other options; see Create an identity rule, on page 2515.
- Associate the identity policy with an access control policy to allow or block selected users from accessing specified resources; see Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see Deploy configuration changes, on page 202.

If you encounter issues, see Troubleshoot user control, on page 2526.

Related Topics

Create an identity policy and active authentication rule, on page 2358
Captive portal fields, on page 2367
Troubleshoot user control, on page 2526
Create an identity mapping filter, on page 2508

Create an identity mapping filter

An identity mapping filter can be used to limit the networks to which an identity rule applies. For example, if your Firewall Management Center manages FTDs that have a limited amount of memory, you can limit the networks they monitor.

You must create separate identity mapping filters for IPv4 and IPv6 addresses.

You can also optionally exclude subnets from the following:

- Receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE.

You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

Before you begin

Perform the following tasks:

1. Create a realm, which is required for an identity policy. See Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.
2. Create an identity policy. See Create an identity policy, on page 2507.
3. Create a network object or network group object as discussed in Create a network object, on page 2985. The network object or group you create should define the network you want managed devices to monitor in identity policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **Edit** ( ).

Step 4 Click the **Identity Source** tab.

Step 5 From the **Identity Mapping Filter** list, choose the name of a network object to use as a filter .

To create a new network object, see Create a network object, on page 2985.

Note
To restrict traffic to IPv6 addresses, you must add at least one address, network, or group to the filter.

Step 6 Click **Save**.

Step 7 (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see Deploy configuration changes, on page 202.

What to do next

(Not required for Microsoft Azure AD realms.) Associate the identity policy with an access control policy as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

To check or change ISE identity mapping filters (also referred to as *subnet filters*), use these commands:

```
show identity-subnet-filter
configure identity-subnet-filter { add | remove } subnet
```

Identity rule conditions

Identity rule conditions enable you to fine-tune your identity policy to target specific users and networks you want to control. See one of the following topics for more information.

Related Topics

Security zone rule conditions, on page 2202
Network rule conditions, on page 1701
VLAN tag rule conditions, on page 2070
Best practice: use application-based rules over port-based rules, on page 1703
Realm & settings rule conditions, on page 2513

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

Redirect to host name network rule conditions

(Snort 3.0 only)—You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.

The FQDN must resolve to the IP address of one of the interfaces on a managed device. By using an FQDN, you can assign a certificate for active authentication that the client will recognize, thus avoiding the untrusted certificate warning users get when being redirected to a managed device's IP address.

Certificate and redirection behavior

The certificate can specify one FQDN, a wildcard FQDN, or multiple FQDNs in the Subject Alternate Names (SAN) in the certificate.

If an identity rule requires active authentication for a user, but you do not specify a redirect FQDN, the user is redirected to the captive portal port on the managed device interface to which they are connected.

If you do not supply a Redirect to Host Name FQDN, the HTTP Basic, HTTP Response Page, and NTLM authentication methods redirect the user to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name *firewall-hostname.directory-server-domain-name*. If you use HTTP Negotiate without a Redirect to Host Name FQDN, update your DNS server to map this name to the IP addresses of all inside interfaces that require active authentication. If you do not update the DNS server, the redirection does not complete and users cannot authenticate.

We recommend that you always provide a Redirect to Host Name FQDN to ensure consistent behavior regardless of authentication method.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Best practice: use application-based rules over port-based rules

Use application filtering criteria instead of port filtering to target traffic. Applications can be configured to use unique ports to bypass access control blocks.

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

The traditional method targets applications by using port specifications, but applications can manipulate unique ports to bypass these controls

Application filtering is recommended for applications to avoid blocking legitimate applications, like Firewall Threat Defense, that dynamically open separate channels for control and data flow. Port-based access control rules could block such applications, impacting desirable operations.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP).

- For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).
- If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, protocol, and ICMP code rule conditions (concept)

A port, protocol, and ICMP code rule condition is a traffic matching criterion that

- matches traffic based on source and destination ports
- supports TCP, UDP, ICMP, and other protocols that do not use ports, and
- controls traffic flow in access control and other policy rules.

Port condition types

Port conditions match traffic based on the source and destination ports. Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—Control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP (6) /22.
- ICMP—Control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—Control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best practices for port-based rules

Specifying ports is the traditional method used to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Use application filtering criteria when possible; however, note that application filtering is unavailable in prefilter rules.

Use application filtering for FTP and similar applications that open separate channels for control and data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly and could result in blocking desirable connections.

Using source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching non-TCP traffic with port conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although configuring port conditions can match non-TCP traffic, restrictions apply:

- Access control rules—For Classic devices, match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, add only network-based conditions: zone, IP address, port, and VLAN tag. The system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For Firewall Threat Defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support only TCP port conditions.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies, sent in response to ICMP echo requests, are ignored. To match any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

Realm & settings rule conditions

The **Realm & Settings** tab page enables you to choose a realm or realm sequence to which to apply the identity rule. If you are using captive portal, you have additional options.

Authentication realm

From the **Realm** list, click a realm or realm sequence.

The realm or realm sequence containing the users you want to perform the specified **Action** on. You must fully configure a realm or realm sequence before selecting it as the realm in an identity rule.

Note If remote access VPN is enabled and your deployment is using a RADIUS server group for VPN authentication, make sure you specify the realm associated with this RADIUS server group.

Active authentication only: other options

If you either choose **Active Authentication** as the authentication type or if you check the box, **Use active authentication if passive or VPN identity cannot be established**, you have these options.

Use active authentication if passive or VPN identity cannot be established

(Passive authentication rule only.) Selecting this option authenticates users using captive portal active authentication if a passive or a VPN authentication fails to identify them. You must configure an Active Authentication rule in your identity policy in order to select this option. (That is, users must authenticate using the captive portal.)

If you disable this option, users that do not have a VPN identity or that passive authentication cannot identify are identified as Unknown.

Also see the discussion of the **Authentication Realm** list later in this topic,

Identify as Special Identities/Guest if authentication cannot identify user

Selecting this option allows users who fail captive portal active authentication the specified number of times to access your network as a guest. These users appear in the Cloud-Delivered Firewall Management Center identified by their username (if their username exists on the AD or LDAP server) or by **Guest** (if their user name is unknown). Their realm is the realm specified in the identity rule. (By default, the number of failed logins is 3.)

This field is displayed only if you configure **Active Authentication** (that is, captive portal authentication) as the rule **Action**.

Authentication Protocol

The method to use to perform captive portal active authentication. .

The selections vary depending on the type of realm, LDAP or AD:

- Choose **HTTP Basic** if you want to authenticate users using an unencrypted HTTP Basic Authentication (BA) connection. Users log in to the network using their browser's default authentication pop-up window.

  Most web browsers cache the credentials from **HTTP Basic** logins and use the credentials to seamlessly begin a new session after an old session times out.

- Choose **NTLM** to authenticate users using a NT LAN Manager (NTLM) connection. This selection is available only when you select an AD realm. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.

- Choose **Kerberos** to authenticate users using a Kerberos connection. This selection is available only when you select an AD realm for a server with secure LDAP (LDAPS) enabled. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.

Note The **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform Kerberos captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the host name you provided when configuring DNS.

For Firewall Threat Defense devices, the FQDN must resolve to the IP address of the routed interface used for captive portal.

- Choose **HTTP Negotiate** to allow the captive portal server to choose between HTTP Basic, Kerberos, or NTLM for the authentication connection. This type is available only when you select an AD realm.

Note The **Realm** you choose must be configured with an **AD Join Username** and **AD Join Password** for **HTTP Negotiate** to choose Kerberos captive portal active authentication.

Note If you are creating an identity rule to perform **HTTP Negotiate** captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN of the device you are using for captive portal must match the hostname you provided when configuring DNS.

- Choose **HTTP Response Page** to enable users to choose a realm to log in to.

  You can optionally customize the response page; for example, to conform to company style standards.

Create an identity rule

Identity rules enable you to control user authentication and traffic handling by specifying which identity realm should authenticate users for specific network criteria.

For details about configuration options for identity rules, see Identity rule fields, on page 2517.

Before you begin

You must create and enable a realm or realm sequence.

- Create a Microsoft Active Directory realm and realm directory as discussed in Create an LDAP realm or an Active Directory realm and realm directory, on page 2325.

- (Microsoft AD realm only.) Download users and groups and enable the realm as discussed in Synchronize users and groups, on page 2330.
- Create a Microsoft Azure AD (SAML) realm as discussed in Create a Microsoft Azure AD (SAML) realm, on page 2289.
- (Optional.) Create a realm sequence as discussed in Create a realm sequence, on page 2332.
- Rules are evaluated top-down. For a connection that matches the specified network criteria of a given rule, the user is evaluated against the identity realm specified in the rule. If the user is not part of that realm, they will be marked as unknown, and no further rules in the identity policy will be evaluated. Thus, if you have more than one realm that needs to be evaluated, be sure to use realm sequences instead of a single realm.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **Edit** ( ) next to the identity policy to which to add the identity rule.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add Rule**.

a) Enter a **Name**.
b) If the Specified rule is applicable, check the check box of **Enabled**.
c)
d) To add the rule to an existing category, indicate where you want to **Insert** the rule. To add a new category, click **Add Category**.
e) Choose a rule **Action** from the list.
f) If you're configuring captive portal, see Configure the captive portal for user control, on page 2355.
g) (Optional) To add conditions to the identity rule, see Identity rule conditions, on page 2509.
h) Click **Add**.

Step 5 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number.

The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Identity rule fields

Configure identity rules to specify authentication actions for users, including Passive Authentication, Active Authentication, or No Authentication. Learn how VPN identity preference affects authentication and rule processing in remote access scenarios.

Use these fields to configure identity rules.

Enabled

Enabling this option enables the identity rule in the identity policy. Unselecting this option disables the identity rule.

Action

Specify the type of authentication you want to perform on the users in the specified realm: **Passive Authentication** (default), **Active Authentication**, or **No Authentication**. You must fully configure the authentication method, or *identity source*, before selecting it as the action in an identity rule.

Additionally, if VPN is enabled (configured on at least one managed device), remote access VPN sessions are actively authenticated by VPN. Other sessions use the rule action. This means that, if VPN is enabled, VPN identity determination is performed first for all sessions regardless of the selected action. If a VPN identity is found on the specified realm, this is the identity source used. No additional captive portal active authentication is done, even if selected.

If the VPN identity source is not found, the process continues according to the specified action. You cannot restrict the identity policy to VPN authentication only because if the VPN identity is not found, the rule is applied according to the selected action.

Caution Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include an SSL policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

For information about which passive and active authentication methods are supported in your version of the system, see About user identity sources, on page 2256.

Sample identity policies and rules

These sections provide examples of configuring an identity policy with either a passive authentication rule or an active authentication rule. In addition, because you can authenticate users with active authentication using either realms or realm sequences, separate examples are provided.

Authentication types

Active authentication means the user authenticates using the captive portal; the user enters network credentials before being allowed to access allowed resources. (RA-VPN is another type of active authentication but it cannot be used together with captive portal authentication. For more information, see Remote access VPN identity sources, on page 2495.)

Passive authentication covers all other types. Passive authentication includes using Microsoft Active Directory realms, Microsoft Azure Active Directory realms, Cisco Identity Services Engine, and others.

These examples use these assumptions:

- Microsoft Active Directory (AD) realm named forest.example.com with two child domains configured in a trust relationship:
  - US-West
  - US-East
- A realm sequence named US that includes both realms
- Passive authentication rule that authenticates users with a realm sequence
- Two active authentication rules:
  - One rule that authenticates users with a realm and uses the NTLM authentication protocol
  - One rule that authenticates users with a realm sequence and uses the HTTP Response Page authentication protocol
- Each sample identity rule is associated with a different identity policy

When you configure a Passive Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use. For an example, see Create an identity policy with a passive authentication rule, on page 2519.

When you configure an Active Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use.

You can also authenticate users with a Microsoft Active Directory realm sequence except for these authentication types:

- NTLM
- Kerberos
- HTTP Negotiate

For an example, see Create a sample identity policy with an active authentication rule, on page 2520.

Create an identity policy with a passive authentication rule

Create an identity policy that authenticates users using passive authentication with realm sequences for user identification.

This task discusses how to create an identity policy with a passive authentication rule that authenticates users using the US realm sequence. If a user is not found in the first realm in the sequence, the system searches the other realms in the sequence in the order listed in the realm sequence. If a user is still not found in the realm or realm sequence, the user is identified as Unknown.

You can optionally authenticate a user with the captive portal (that is, active authentication) if the user is not found in any realm in the sequence. For more information, see Best practices for captive portal guidelines and limitations, on page 2353.

Procedure

Step 1 Log in to the Firewall Management Center.

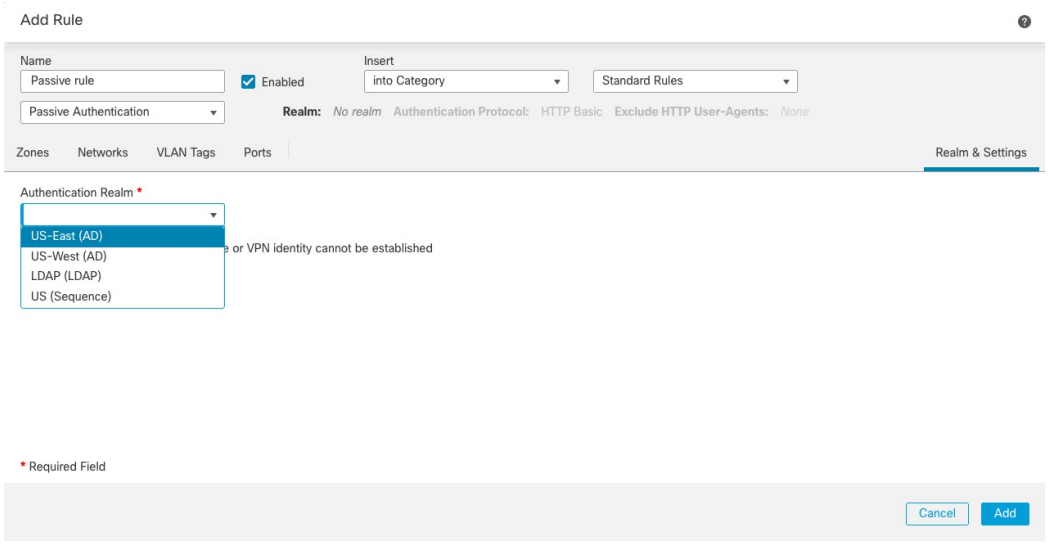
Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **New Policy**.

a) Enter a **Name** for the policy and an optional **Description**.

b) Click **Save**.

Step 4 Click **Add Rule**.



a) Enter a **Name** for the rule.

b) From the list, click **Passive Authentication**.

Step 5 Click the **Realms & Settings** tab page.

a) From the list, click the name of a realm or realm sequence.

The following figure shows an example.

- If you choose a realm (such as **US-East** in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.
- If you choose a realm sequence (**US (Sequence)** in the example), users are searched in every realm in the sequence in the order specified in the sequence. If the user is not found, the user is identified as Unknown.
- You can also choose an LDAP realm.
- For additional ways to authenticate the user, check **Use active authentication if passive or VPN identity cannot be established**. For more information, see Best practices for captive portal guidelines and limitations, on page 2353.

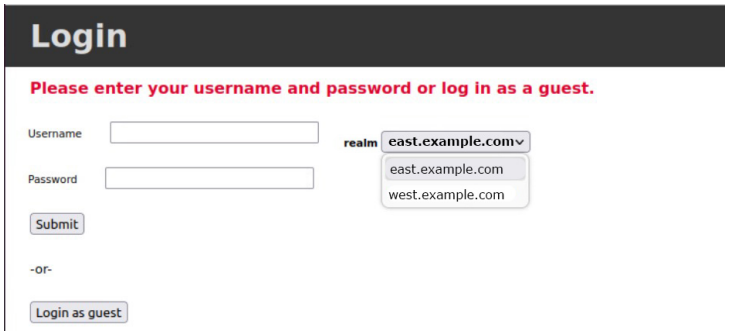
Step 6 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 7 Set identity rule conditions as discussed in Identity rule conditions, on page 2509.

Step 8 Associate the identity rule with an access control rule as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Step 9 Deploy configuration changes to managed devices; see Deploy configuration changes, on page 202.

Create a sample identity policy with an active authentication rule



This task shows you how to configure an identity policy with an Active Authentication rule where authentication is performed using either a realm or a realm sequence. This enables secure network access management through customizable captive portal settings.

The associated tasks show an examples of configuring an identity policy with an **Active Authentication** rule where authentication is performed using either a realm or a realm sequence.

The differences follow:

- *Realm* enables you to use any supported authentication type (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).
- *Realm sequence* limits you to only the **HTTP Basic** or **HTTP Response Page** authentication types.

  Users who authenticate with a realm sequence and the HTTP Response Page authentication type see the following by default:

  The user can authenticate in any of the following ways:

- If a list of realms in the realm sequence is displayed (as shown), the user must enter their user name and password in the provided fields and click the name of their realm from the list.
- If realms are not displayed in a list, the user can enter their credentials in `username@domain` format.

Users who authenticate with a realm and the HTTP Basic authentication page see the following:

The user must enter their user name in `username@domain` format.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **New Policy**.

a) Enter a **Name** for the policy and an optional **Description**.

b) Click **Save**.

Step 4 Click the **Active Authentication** tab.

Enter the following information:

- **Server Certificate**: From the list, click an internal certificate object to use for secure connection to the Firewall Threat Defense device, or click **Add** (+) to add one.
- **Redirect to Host Name**: (Optional.) From the list, click a network object to which to redirect captive portal requests. If you omit this value, requests redirect to the IP address of the managed device. You can click **Add** (+) to create a new network object. For more information, see Redirect to host name network rule conditions, on page 2510.

  Managed devices must have Snort 3 enabled to use this option.
- **Port**: Enter a port for the captive portal to use. This port must be unique for the captive portal and must match an access control rule you set up as discussed in Create a TCP port access control rule, on page 2360. (Default is 885.)
- **Maximum login attempts**: Enter the maximum number of login attempts before login fails. (Default is 3.)

- **Active Authentication Response Page**: Choose a system-provided or custom login page for captive portal users. For more information about your options, see Captive portal fields, on page 2367.

Step 5 Click **Save** to save your changes to the identity policy.

Step 6 Click the **Rules** tab.

Step 7 Click **Add Rule**.

a) Enter a **Name** for the rule.

b) From the list, click **Active Authentication**.

Step 8 Click the **Realms & Settings** tab page. Then configure an active authentication method for the users.

What to do next

Continue with one of the following sections:

- Active authentication using a realm, on page 2522
- Active authentication using a realm sequence, on page 2523

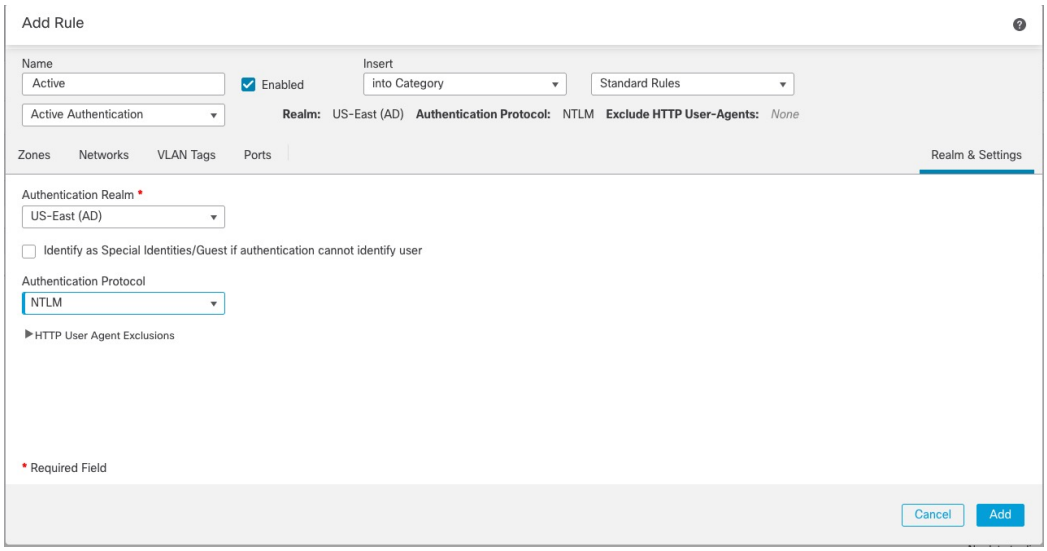
Active authentication using a realm

This task authenticates captive portal users with a realm and any available authentication protocol (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).

Active authentication using a realm provides secure user verification for captive portal access by integrating with your organization's authentication infrastructure.

Before you begin

Complete the task discussed in Create a sample identity policy with an active authentication rule, on page 2520.



Procedure

Step 1 Continue from Create a sample identity policy with an active authentication rule, on page 2520.

Step 2 On the **Realms & Settings** tab page, click **US-East**.

Step 3 From the **Authentication Protocol** list, click **NTLM**.

The following figure shows an example.

If you choose a realm (such as in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.

Step 4 Click **Add**.

Step 5 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 6 Set identity rule conditions as discussed in Identity rule conditions, on page 2509.

Step 7 Associate the identity rule with an access control rule as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Step 8 Deploy configuration changes to managed devices; see Deploy configuration changes, on page 202.

Active authentication using a realm sequence

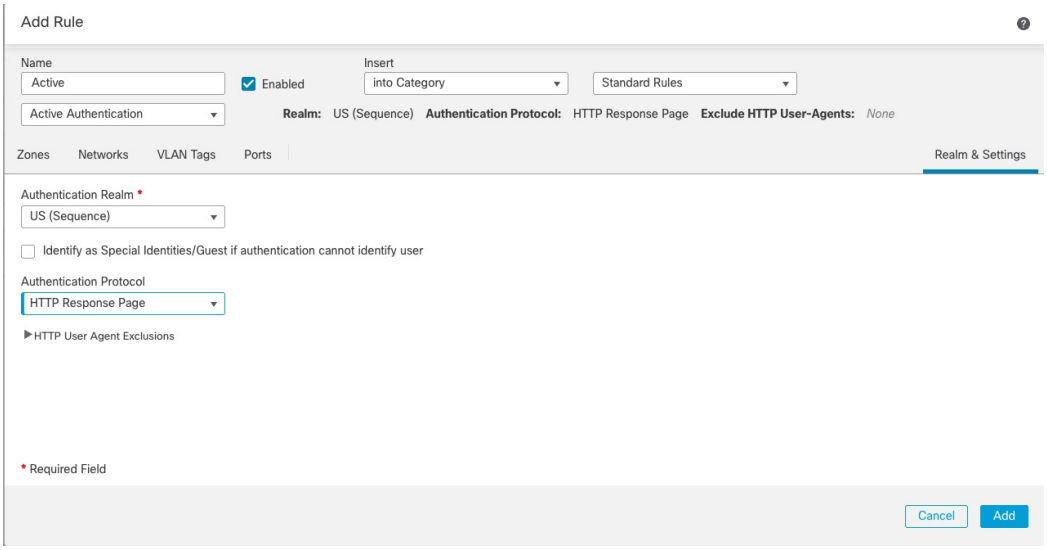
This task enables authentication of captive portal users using a realm sequence, allowing you to control access through HTTP Basic or HTTP Response Page protocols. It helps you select realms, set identity rule conditions, and associate them with access control rules to filter network traffic and manage user identification.

This task discusses how to authenticate captive portal users with a realm sequence, which restricts you to the **HTTP Basic** or **HTTP Response Page** authentication protocols.

Before you begin

Complete the task discussed in Create a sample identity policy with an active authentication rule, on page 2520.

Procedure



Step 1 Continue from Create a sample identity policy with an active authentication rule, on page 2520.

Step 2 On the **Realms & Settings** tab page, click the name of a realm from the list.

Step 3 From the list, click **US-East**.

Step 4 From the **Protocol** list, click **HTTP Response Page**.

The following figure shows an example.

If you choose a realm sequence (such as in the example), the system searches realms in the sequence in the order specified in the realm sequence. The first realm in the sequence can be referred to as the *default* realm; it's the realm that is used if the user does not change it. If a user is not found, the user is identified as Unknown.

(Only if you upgraded to version 7.4.1 from an earlier version.) Edit the HTTP response page so it shows the list of realms in the sequence as discussed in Update a custom authentication form, on page 2360.

Step 5 Click **Add**.

Step 6 (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.

Step 7 Set identity rule conditions as discussed in Identity rule conditions, on page 2509.

Step 8 Associate the identity rule with an access control rule as discussed in Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Step 9 Deploy configuration changes to managed devices; see Deploy configuration changes, on page 202.

Manage an identity policy

This task allows you to manage identity policies by performing various administrative actions including editing, deleting, copying, generating reports, and organizing policies into categories for optimized security policy administration.

Identity policies control access to network resources based on user identity. Managing these policies effectively ensures proper security enforcement and administrative organization within the Secure Firewall Management Center.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 To delete a policy, click **Delete** ( ). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit a policy, click **Edit** ( ) next to the policy and make changes as described in Create an identity policy, on page 2507. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 5 To copy a policy, click **Copy** ( ).

Step 6 To generate a report for the policy, click **Report** ( ) as described in Generate current policy reports, on page 220.

Step 7 To compare policies, see Compare policies, on page 219.

Step 8 To create a folder in which to organize policies, click **Add Category**.

What to do next

Deploy configuration changes.

Manage an identity rule

This task allows you to edit, delete, or organize identity rules in access control policies to manage user access and security within the Secure Firewall Management Center.

Use this procedure to modify existing identity rules, remove unnecessary rules, or organize rules using categories to maintain effective security policies.

Procedure

Step 1 Log in to the Firewall Management Center.

Step 2 Click **Policies** > **Access Control heading** > **Identity**.

Step 3 Click **Edit** ( ) next to the policy you want to edit. If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 To edit an identity rule, click **Edit** ( ) and make changes as described in Create an identity policy, on page 2507.

Step 5 To delete an identity rule, click **Delete** ( ).

Step 6 To create a rule category, click **Add Category** and choose the position and the rule.

Step 7 Click **Save**.

What to do next

- Deploy configuration changes.

Troubleshoot user control

If you notice unexpected user rule behavior, consider tuning your rule, identity source, or realm configurations. For other related troubleshooting information, see:

- Troubleshoot Cisco ISE/ISE-PIC or Cisco TrustSec issues, on page 2399
- Troubleshoot the TS agent identity source, on page 2502
- Troubleshoot the captive portal identity source, on page 2369
- Troubleshoot realms and user downloads, on page 2342

Rules targeting realms, users, or user groups are not matching traffic

If you configure a TS Agent or ISE/ISE-PIC device to monitor a large number of user groups, or if you have a very large number of users mapped to hosts on your network, the system may drop user records due to your Cloud-Delivered Firewall Management Center user limit. As a result, rules with user conditions may not match traffic as expected.

Rules targeting user groups or users within user groups are not matching traffic as expected

If you configure a rule with a user group condition, your LDAP or Active Directory server must have user groups configured. The system cannot perform user group control if the server organizes the users in basic object hierarchy.

Rules targeting users in secondary groups are not matching traffic as expected

If you configure a rule with a user group condition that includes or excludes users who are members of a secondary group on your Active Directory server, your server may be limiting the number of users it reports.

By default, Active Directory servers limit the number of users they report from secondary groups. You must customize this limit so that all of the users in your secondary groups are reported to the Cloud-Delivered Firewall Management Center and eligible for use in rules with user conditions.

Rules are not matching users when seen for the first time

After the system detects activity from a previously-unseen user, the system retrieves information about them from the server. Until the system successfully retrieves this information, activity seen by this user is *not* handled by matching rules. Instead, the user session is handled by the next rule it matches (or the policy's default action, if applicable).

For example, this might explain when:

- Users who are members of user groups are not matching rules with user group conditions.
- Users who were reported by a TS Agent or ISE device are not matching rules, when the server used for user data retrieval is an Active Directory server.

Note that this might also cause the system to delay the display of user data in event views and analysis tools.

Rules are not matching all ISE/ISE-PIC users

This is expected behavior. You can perform user control on ISE/ISE-PIC users who were authenticated by an Active Directory domain controller. You cannot perform user control on ISE/ISE-PIC users who were authenticated by an LDAP, RADIUS, or RSA domain controller.

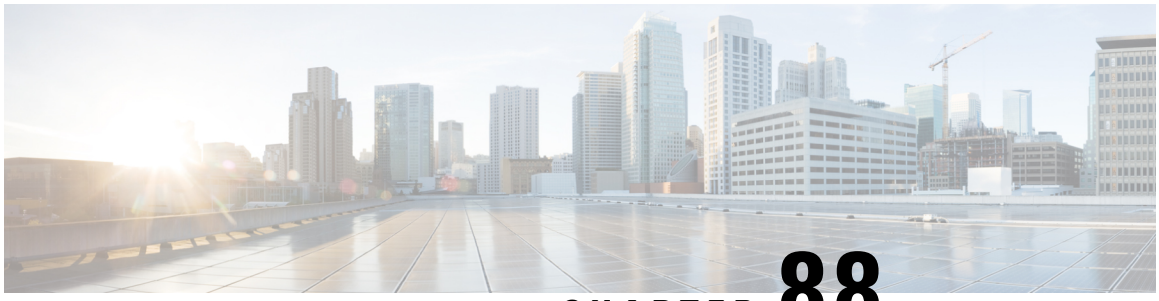
Users and groups using too much memory

If processing users and groups is using too much memory, health alerts are displayed. Remember that all user sessions are propagated to all devices managed by the Cloud-Delivered Firewall Management Center. If your Cloud-Delivered Firewall Management Center manages devices with different amounts of memory, the device with the least amount of memory determines the number of user sessions the system can handle without errors.

It's not possible to tune memory allocated to identity processes; even if a device has available memory, it can report out-of-memory issues. If issues persist, you have these options:

- Segregate lower capacity managed devices on subnets and configure ISE/ISE-PIC to not report passive authentication data to those subnets.

  See the chapter on managing network devices in the *Cisco Identity Services Engine Administrator Guide*.



- Unsubscribe from Security Group Tags (SGTs).
- Upgrade your managed device to a model with more memory.

CHAPTER 88

Prefilter Policies

The prefilter policy is the first security policy applied to incoming connections. Prefilter rules evaluate traffic on layer 3/4 criteria only, that is, protocol and source/destination IP address and port. They give you a chance to make early decisions on connections so you can avoid further processing and improve device performance.

- Prefilter policies, on page 2531
- Requirements and prerequisites for prefilter policies, on page 2540
- Guidelines and limitations for the prefilter policy, on page 2541
- Guidelines and limitations for encapsulated traffic handling, on page 2541
- Best practices for fastpath prefiltering, on page 2542
- Configure prefilter policies, on page 2543
- Examples of prefilter policy, on page 2552

Prefilter policies

A prefilter policy is a security policy that

- serves as the first security policy applied to incoming connections
- evaluates traffic on layer 3/4 criteria only, including protocol and source/destination IP address and port
- enables early decisions on connections to avoid further processing and improve device performance, and
- can fast path connections and make them eligible for flow offload.

Prefilter policy actions

Use prefilter policies to implement these main actions:

- Improve performance—The sooner you exclude traffic that does not require inspection, the better. Specifically, you can perform these actions.
  - Offload trusted flows—If your device supports flow offload, use the prefilter Fastpath action to identify flows you trust to be eligible for offloading to NIC processing. No further processing, including inspection, is needed for these connections. Refer to Best practices for fastpath prefiltering, on page 2542 and Large flow offloads, on page 2535.
  - Block unwanted connections—For example, if you want to block entire subnets, protocols, or TCP/UDP ports, configure this in the prefilter policy.

- Rezone plain text encapsulated tunnels so you can handle them as a unit in the access control policy. Some protocols, such as GRE, create plain-text tunnels that include many connections. By rezoning a tunnel, you assign it a tag, which you can select in access control rules as a source or destination zone. This allows you to apply customized intrusion or other rules to the tunneled traffic and provides granular insight and control.

Note VPN or other encrypted tunnels are not plain-text tunnels and cannot be rezoned.

You must assign each access control policy a prefilter policy. However, the system comes with a pre-defined prefilter policy that might work for you.

Default prefilter policy

A default prefilter policy only analyzes plain-text encapsulated tunnels. It is automatically assigned when you create a new access control policy. It cannot be deleted from the system.

Default prefilter policy characteristics

Every access control policy must have an assigned prefilter policy. For convenience, the system includes a default prefilter policy that is automatically assigned when you create a new access control policy.

You can instead change the default policy to block all plain-text tunnels. See Configuring the default action, on page 2545.

If you want to do any other customization, including adding prefilter or tunnel rules, you must create your own prefilter policy and assign it to the appropriate access control policies, as explained in Assign access control policy to devices, on page 2014.

Prefilter policy rule order

Prefilter policy rule order is a traffic processing mechanism that determines which tunnel rules and prefilter rules handle network traffic first and applies the default action for unmatched tunnels.

Rule processing sequence

In a prefilter policy, tunnel rules, prefilter rules, and a default action handle network traffic:

- Tunnel and prefilter rules—First, rules in a prefilter policy handle traffic in the order you specify. Tunnel rules match specific tunnels only. Prefilter rules have a wider range of constraints.

  Rules are match in top-down order, first match wins. Thus, rule order is critical. For example, you might want to block an entire subnet except for two specific IP addresses on the subnet. In that case:

  - The first rule should specify the two allowable IP addresses as the source network, and the rule action would be Analyze. Connections from these two IP addresses would match this rule, and the next rule would not be processed.
  - The next rule should specify the entire subnet as the source network, with Block for the rule action.

  For more information, see Tunnel vs prefilter rules, on page 2533.

- Default action (tunnels only)—If a tunnel does not match any rules, the default action handles it. The default action can block these tunnels or continue access control on their individual encapsulated connections (Analyze action).

  There is no default action for nonencapsulated traffic. If a nonencapsulated connection does not match any prefilter rules, the system continues with access control. These connections might subsequently be blocked by other policies, or ultimately allowed.

If you need to change rule order, you can:

- Drag and drop the rule to the right location.
- Right click the rule and **Cut**, then find the right location, right click, and select **Paste Above** or **Paste Below**.
- Edit the rule and use the **Insert** control to change its location.

Tunnel vs prefilter rules

Choose to configure a tunnel rule or a prefilter rule based on the type of traffic you want to match and the actions or analysis you intend to perform.

Characteristic	Tunnel Rules	Prefilter Rules
Primary function	Quickly fastpath, block, or rezone plaintext, passthrough tunnels.	Quickly fastpath or block any other connection that benefits from early handling.
Encapsulation and port/protocol criteria	Encapsulation conditions match only plaintext tunnels over selected protocols: GRE, IP-in-IP, IPv6-in-IP, Teredo.	Port conditions can use a wider range of port and protocol constraints than tunnel rules; see Port, protocol, and ICMP code rule conditions (concept), on page 1703.
Network criteria	Tunnel endpoint conditions constrain the endpoints of the tunnels you want to handle.	Network conditions constrain the source and destination hosts in each connection.
Direction	Bidirectional or unidirectional (configurable). Tunnel rules are bidirectional by default, so they can handle all traffic between tunnel endpoints.	Unidirectional only (nonconfigurable). Prefilter rules match source-to-destination traffic only. Return traffic for allowed connections is also permitted.
Rezone sessions for further analysis	Supported, using tunnel zones; see Using tunnel zones to apply access control at the tunnel level, on page 2534.	Not applicable.

How the system processes plain-text tunnels

Some protocols, such as GRE, create plain-text (not encrypted) tunnels that contain (or encapsulate) multiple inner connections. These connections might flow between discontinuous networks. These tunnels are especially useful for routing custom protocols over IP networks, IPv6 traffic over IPv4 networks, and so on.

Summary

A plain-text tunnel has two sets of IP headers:

- Outer headers: Specify tunnel endpoint addresses for prefilter policy handling
- Inner headers: Contain actual connection endpoint addresses for granular inspection

Workflow

The system processes plain-text tunnels through these stages:

1. The system receives a plain-text tunnel with dual IP header structure.
   - Outer header—An outer encapsulation header specifies the source and destination IP addresses of the tunnel endpoints—the routed interfaces of the network devices on either side of the tunnel.
   - Inner headers—Inner payload headers specify the source and destination IP addresses of the encapsulated connections' actual endpoints. There are separate headers for each connection contained within the tunnel.

   For regular, non-tunneled connections, there is only the "outer" header, as the connection does not contain any subordinate connections.
2. The prefilter policy processes the outer tunnel headers to determine handling approach.

   The prefilter policy uses outer headers to handle traffic. You can block or fast path entire plaintext, passthrough tunnels at this stage.

   If you do not want to allow plain-text tunnels at all, you can set the default action in the prefilter policy to block all plain-text tunnels. This block does not apply to encrypted tunnels such as VPN.
3. The system exposes inner headers for tunnels that pass prefilter analysis.

   Any tunnels that you analyze (that is, not block or fast path) have these inner headers exposed for use by the rest of the security policies and other features such as QoS. These features use the innermost detectable level of headers to ensure the most granular level of inspection and handling possible. This ensures that bad actors cannot hide illegitimate traffic within a plain-text tunnel.

   Alternatively, you can use tunnel zones to re-tag tunneled traffic so that you can write access control rules specifically for select tunnels. This lets you customize intrusion inspection or other layer 7 filtering to connections contained with a tunnel. See Using tunnel zones to apply access control at the tunnel level, on page 2534.

Using tunnel zones to apply access control at the tunnel level

A tunnel zone represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis. Although a tunnel zone is not an interface object, you can use it as an interface constraint in some configurations.

Tunnel zone implementation

As explained in How the system processes plain-text tunnels, on page 2533, once a plain-text tunneled connection passes through the prefilter policy, the access control policy applies its rules to each connection contained within the tunnel.

However, you might want to apply the same policy to all the connections within a tunnel. For example, you might have a special intrusion policy you want to use for tunneled connections.

To make it possible to apply access control rules to all connections within a tunnel, you must use the prefilter policy to re-zone the tunnel. Rezoning applies a tunnel zone tag to the plain-text tunnel. You can then use that tunnel zone instead of a security zone when you define the source interface criterion of an access control rule.

Because a tunnel zone does not contain interfaces, the source interface through which the tunnel enters the device is not relevant. You can apply a tunnel zone tag to multiple tunnels that enter the device through different interfaces and access control treats them all in the same way.

Note Connections in rezoned tunnels do not match security zone constraints in an access control rule. After you rezone a tunnel, access control rules match encapsulated connections with their newly assigned tunnel zone, not the original security zone.

See Rezone tunnels for customized inspection, on page 2552 for a walkthrough of a tunnel zone implementation, and a discussion of the implications of rezoning without explicitly handling rezoned traffic.

Large flow offloads

A large flow offload is a hardware-based traffic processing feature that

- handles certain fastpathed traffic in the NIC hardware rather than in the Firewall Threat Defense software
- results in higher throughput and lower latency for data-intensive applications such as large file transfers, and
- includes both static flow offload (based on prefilter policy configuration) and dynamic flow offload (based on trust and other criteria).

Supported models and offload types

For the following models, certain traffic that you configure to be fastpathed by a prefilter policy is handled by the hardware (specifically, in the NIC), not by the Firewall Threat Defense software:

- Firepower 4100/9300
- Secure Firewall 3100 (static only)
- Secure Firewall 4200 (static only)

Offloaded flows continue to receive limited stateful inspection, such as basic TCP flag and option checking. The system can selectively escalate packets to the firewall system for further processing if necessary.

Two types of flow offload are available:

- *Static flow offload*: Offloads flows based on prefilter policy configuration that applies the Fastpath action.
- *Dynamic flow offload*: By default, devices offload flows based on other criteria, including trust.

Applications that can benefit from offloading large flows include:

- High Performance Computing (HPC) Research sites, where the firewall is deployed between storage and high compute stations. When one research site backs up using FTP file transfer or file sync over NFS,

the large amount of data traffic affects all connections. Offloading FTP file transfer and file sync over NFS reduces the impact on other traffic.

- High Frequency Trading (HFT), where the firewall is deployed between workstations and the Exchange, mainly for compliance purposes. Security is usually not a concern, but latency is a major concern.

Flows that can be offloaded include:

- (Static flow offload only.) Connections that are fastpathed by the prefilter policy.
- Standard or 802.1Q tagged Ethernet frames only.
- Cluster asymmetric flows (Secure Firewall 4200). For asymmetric flows, cluster redirect lets the forwarding node offload flows to hardware. When traffic for an existing flow is sent to a different node, then that traffic is redirected to the owner node over the cluster control link. Because asymmetric flows can create a lot of traffic on the cluster control link, letting the forwarder offload these flows can improve performance.
- (Dynamic flow offload only):
  - Inspected flows that the inspection engine decides no longer need inspection. These flows include:
    - Flows handled by access control rules that apply the Trust action and are based on security zone, source and destination network and port matching only.
    - TLS/SSL flows that are not selected for decryption using a decryption policy.
    - Flows that are trusted by the Intelligent Application Bypass (IAB) policy either explicitly or due to exceeding flow bypass thresholds.
    - Flows that match file or intrusion policies that result in trusting the flow.
    - Any allowed flow that no longer needs to be inspected.
  - IPS preprocessor inspected flows:
    - SSH and SMTP.
    - FTP preprocessor secondary connections.
    - Session Initiation Protocol (SIP) preprocessor secondary connections.
  - Intrusion rules that use keywords (also referred to as *options*)

Important For details, exceptions, and limitations to the above, see Restrictions for flow offload implementation, on page 2537.

Static flow offload configuration

To offload eligible traffic to hardware, create a prefilter policy rule that applies the **Fastpath** action. Use prefilter rules for TCP/UDP, and tunnel rules for GRE.

(Not recommended.) To disable flow offload, use FlexConfig:

- Disable static (and thereby dynamic) flow offload: **no flow-offload enable**

- Re-enable flow offload: **flow-offload enable**
- Disable cluster redirection: **no flow-offload cluster-redirect**

For more information, see *Cisco Secure Firewall ASA Series Command Reference*.

Dynamic flow offload configuration

Dynamic flow offload is enabled by default. However, dynamic offload occurs only if static flow offload is enabled, regardless of whether prefiltering is configured.

To disable dynamic flow offload, use the device CLI:

- Disable dynamic offload: **configure flow-offload dynamic whitelist disable**
- Re-enable dynamic offload: **configure flow-offload dynamic whitelist enable**

Restrictions for flow offload implementation

Device limitations

The feature is supported on the following devices:

- Secure Firewall 3100 (static only)
- Secure Firewall 4200 (static only)
- Firepower 4100/9300

Flows that cannot be offloaded

Do not attempt to offload these flow types:

- Any flows that do not use IPv4 addressing, such as IPv6 addressing.
- Flows for any protocol other than TCP, UDP, and GRE.

Note PPTP GRE connections cannot be offloaded.

- Flows on interfaces configured in passive, inline, or inline tap mode. Routed and switched interfaces are the only types supported.
- (3100/4200.) Offload based on inner header for tunnelled flows.
- (3100/4200.) Multi-instance offload.
- Flows that require inspection by Snort or other inspection engines. In some cases, such as FTP, the secondary data channel can be offloaded although the control channel cannot be offloaded.
- IPsec and TLS/DTLS VPN connections that terminate on the device.

Note The Secure Firewall 3100 and Secure Firewall 4200 platforms are exceptions to this restriction. These platforms support flow-offload for IPsec and DTLS VPN connections terminating to the device. For detailed information on this feature and its implementation, please refer to the release notes specific to the Secure Firewall 3100 and Secure Firewall 4200 platforms.

- Flows that require encryption or decryption. For example, connections decrypted due to a decryption policy.
- Multicast flows in routed mode. They are supported in transparent mode if there are only two member interfaces in a bridge group.
- TCP Intercept flows.
- TCP state bypass flows. You cannot configure flow offload and TCP state bypass on the same traffic.
- Flows tagged with security groups.
- Reverse flows that are forwarded from a different cluster node, in the case of asymmetric flows in a cluster.
- Centralized flows in a cluster, if the flow owner is not the control unit.
- Flows that include IP options cannot be dynamically offloaded.

Additional limitations

Consider these operational restrictions when implementing flow offload:

- Flow offload and Dead Connection Detection (DCD) are not compatible. Do not configure DCD on connections that can be offloaded.
- If more than one flow that matches flow offload conditions are queued to be offloaded at the same time to the same location on the hardware, only the first flow is offloaded. The other flows are processed normally. This is called a *collision*. Use the **show flow-offload flow** command in the CLI to display statistics for this situation.
- Dynamic flow offload disables all TCP normalizer checks.
- Although offloaded flows pass through FXOS interfaces, statistics for these flows do not appear on the logical device interface. Thus, logical device interface counters and packet rates do not reflect offloaded flows.

Cluster redirection

When traffic for an existing flow is sent to a different node, then that traffic is redirected to the owner node over the cluster control link. Because asymmetric flows can create a lot of traffic on the cluster control link, offloading these flows can improve performance, for example, for distribited site-to-site VPN mode. This feature is supported for these environments:

- Secure Firewall 4200
- Routed and transparent mode

- Spanned EtherChannel mode

Conditions for reversing offload

After a flow is offloaded, packets within the flow are returned to the firewall operating system for further processing if they meet these conditions:

- They include TCP options other than Timestamp.
- They are fragmented.
- They are subject to Equal-Cost Multi-Path (ECMP) routing, and ingress packets move from one interface to another.
- A change to the routing table applies to the flow. A packet is returned to the device to determine the new route.

Prefilter vs access control policy

Prefilter and access control policies both allow you to block and trust traffic. In a prefilter policy, the "trust" functionality is called "fastpathing" because it skips more inspection. If you do not configure a custom prefilter policy, you can only approximate, but not replicate, prefilter functionality using Block and Trust rules placed early in the access control policy.

Characteristic	Prefilter Policy	Access Control Policy
Primary function	Quickly fastpath or block certain types of plaintext or passthrough tunnels, or tailor subsequent inspection to encapsulated traffic. Fastpath or block any other connections that benefit from early handling.	Inspect and control all network traffic, using simple or complex criteria, including contextual information and deep inspection results.
Sequence within access control	First The system matches traffic to prefilter criteria before all other access control configurations. Thus, fast-pathing in a prefilter policy skips many other policies and inspections.	Last Other policies that might inspect a connection, including Security Intelligence and decryption, are applied before access control rules are evaluated.
Rule actions	Fewer You can stop further inspection (Fastpath and Block) or allow further analysis with the rest of access control (Analyze).	More Access control rules have a larger variety of actions, including monitoring, deep inspection, block with reset, and interactive blocking. See Access control rule actions, on page 2046.

Characteristic	Prefilter Policy	Access Control Policy
Bypass capability	Fastpath rule action Fastpathing traffic in the prefilter stage bypasses all further inspection and handling. This includes: • Security Intelligence • User identity discovery (identity policy) • Decryption • Access control rules • Deep inspection of packet payloads • Discovery • Rate limiting	Trust rule action Traffic trusted by access control rules is only exempt from intrusion inspection and discovery. If another policy that requires inspection is applied to a connection that is eventually trusted, the connection is inspected anyway. Trust means that intrusion and file policies are not applied to the connection.
Rule criteria	Limited Rules in the prefilter policy use simple network criteria: IP address, VLAN tag, port, and protocol. For tunnels, tunnel endpoint conditions specify the IP address of the routed interfaces of the network devices on either side of the tunnel.	Robust Access control rules use network criteria, but also user, application, requested URL, and other contextual information available in packet payloads. Network conditions specify the IP address of source and destination hosts.
IP headers used (tunnel handling)	Outermost Using outer headers allows you to handle entire plaintext, passthrough tunnels. For nonencapsulated traffic, prefiltering still uses "outer" headers—which in this case are the only headers.	Innermost possible For a nonencrypted tunnel, access control acts on its individual encapsulated connections, not the tunnel as a whole. See How the system processes plain-text tunnels, on page 2533.
Rezone encapsulated connections for further analysis	Rezones tunneled traffic Tunnel zones allow you to tailor subsequent inspection to prefiltered, encapsulated traffic.	Uses tunnel zones Access control uses the tunnel zones you assign during prefiltering. See Using tunnel zones to apply access control at the tunnel level, on page 2534.
Connection logging	Fastpathed and blocked traffic only. Allowed connections may still be logged by other configurations.	Any connection

Requirements and prerequisites for prefilter policies

This reference provides the requirements and prerequisites necessary for configuring prefilter policies, including supported models, domain requirements, and required user roles.

Model support

- Admin
- Access Admin
- Network Admin

Guidelines and limitations for the prefilter policy

You can log connections fast pathed and blocked by the prefilter policy. Prefilter connection events contain information on whether and how logged connections—including entire tunnels—were prefiltered. However, because fast pathed and blocked connections are not subject to deep inspection, associated connection events contain limited information.

Access control uses a hierarchical implementation that complements multitenancy. Along with other advanced settings, you can lock a prefilter policy association, enforcing that association in all descendant access control policies. For more information, see Access control policy inheritance, on page 2000.

When you deploy a prefilter policy, its rules are not applied on the existing connections. Hence, traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the rules effectively applied, clear the existing connections, and then deploy the policy.

For a prefilter rule with action as Fastpath and logging options disabled, you might observe that the end-of-flow events are still generated in the system. However, the events are not visible on the management center event pages.

Guidelines and limitations for encapsulated traffic handling

Supported encapsulated traffic types

This topic discusses guidelines for the following types of encapsulated traffic:

- Generic Routing Encapsulation (GRE)
- Point-to-Point Protocol (PPTP). (This protocol is not handled by tunnel rules in the prefilter policy.)
- IPinIP
- IPv6inIP
- Teredo

GRE tunnel limitations

GRE tunnel processing is limited to IPv4 and IPv6 passenger flows. Other protocols, such as PPTP and WCCP, are not supported within the GRE tunnel.

GRE v1 and PPTP bypass restrictions

GRE v1 (sometimes referred to as *stateful GRE*) and PPTP traffic bypass outer flow processing.

- Sessions are over a single tunnel that is not load-balanced.
- There is no HA or clustering replication.
- Primary and secondary flow relationships are not maintained.
- Prefilter policy white and black lists are not supported.

Passenger flow processing is supported for IPv6inIP and Teredo but the following limitations apply:

GRE v0 sequence number field requirement

All endpoints sending traffic on the network must send GREv0 traffic with the sequence number field as optional; otherwise, the sequence number field is removed. RFC 1701 and RFC 2784 both specify the sequence field as optional.

Tunnel interface compatibility

Prefilter and access control policy rules are applied to all tunnel types on routed, transparent, inline-set, inline-tap, and passive interfaces.

Protocol references

For more information about the GRE and PPTP protocols, see the following:

- RFC 1701, RFC 2784, and RFC 2890 (GRE protocol v0)
- RFC 2637 (PPTP and GRE protocol v1)

Best practices for fastpath prefiltering

When you use the fastpath action in a prefilter rule, the matching traffic bypasses inspection and is simply transmitted through the device. Use this action for traffic that you can trust and that would not benefit from any of the security features available.

- VPN traffic that is going through the device. That is, the device is not an endpoint in the VPN topology.
- SQL traffic between trusted endpoints on the internal network.
- Scanner traffic. Scanner probes can create a lot of false-positive responses from intrusion policies.
- Voice/video.
- Backups.
- Management traffic (sftunnel) that traverses Firewall Threat Defense devices. Performing deep inspection on management traffic (using access control policies) can cause issues. You can prefilter based on port TCP/8305 between the management center and managed devices.

Configure prefilter policies

Configure prefilter policies to perform custom prefiltering and to control tunnel traffic analysis on managed devices.

To perform custom prefiltering, configure prefilter policies and assign them to access control policies. It is through the access control policy that prefilter policies get assigned to managed devices.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter**.

At the top of the page, there are convenient links to some related features: object management and access control.

You cannot tell from the prefilter page, or when editing a prefilter policy, whether it is used by an access control policy or which policies use it.

Step 2 Do any of the following:

- Create—Click **New Policy** to create a custom prefilter policy. You are prompted for a name and an optional description. The new policy is opened for edit after you click **Save**. A new prefilter policy has no rules and a default action of Analyze all tunnel traffic.
- Edit—Click **Edit** ( ) to open a policy so that you can add rules or otherwise modify it.
- Copy—Click **Copy** ( ). You are prompted for a name. The copy is added to the list when you click **OK**, but it is not opened for edit.
- Delete—Click **Delete** ( ) to remove a policy. You cannot delete a policy that is currently being used by an access control policy.

Step 3 When editing a prefilter policy, you can do the following:

- Set the default action—Set the default action for tunnels at the bottom of the policy. See Configuring the default action, on page 2545.
- Add prefilter rules—Click **Add Prefilter Rule**. The rule is added to the bottom of the policy. See Configure prefilter rules, on page 2545.
- Add tunnel rules—Click **Add Tunnel Rule**. The rule is added to the bottom of the policy. See Configure tunnel rules, on page 2548.
- Insert rules—Right click the rule before where you want to add the new rule, and select either **Insert New Prefilter Rule** or **Insert New Tunnel Rule**, as appropriate.

- Copy/cut and paste rules—To copy a rule, right-click the rule and select **Copy**. You can also cut the rule (remove it) by selecting **Cut**. Then, select where you want to insert the rule, right click, and select either **Paste Above** or **Paste Below**. When copying, a number in parentheses is added to the rule name; you should edit the rule and change the name and other criteria as needed. Cut rules retain the original name.
- Edit a rule—Click **Edit** ( ) to open the rule editor. You can also click on any element for the rule in the table. See Configure prefilter rules, on page 2545 and Configure tunnel rules, on page 2548.
- Delete rules—Click **Delete** ( ) to remove a rule.
- Move a rule—Click a rule and drag and drop it to the right location. Alternatively, cut the rule and then paste it in the right location. You can also change the rule location while editing it.

  Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules or contain invalid configurations. For more information, see Prefilter policy rule order, on page 2532.
- Move a prefilter rule to an associated access control policy—To move a prefilter rule from the prefilter policy to an associated access control policy, right-click the rule and select **Move to another policy**. You cannot move tunnel rules to an access control policy. See Move prefilter rules to an access control policy, on page 2551.
- View hit counts—To view statistics on how many connections matched each rule, click **Analyze Hit Counts**. See View rule hit counts, on page 2018.
- Search for rules—Use the **Search Rules** box to do a plain text search. Type the string and press enter. The search box shows the number of hits and up/down buttons to move through them.

  Matches are highlighted in the table. Matches include partial hits, but only to explicitly set items. For example, entering "any" does not match the default network, but "any-ipv4" will match because it is a network object and not a passive default. Action and rule type do not match the search string.
- View object details—To see the contents of an object used in a rule, right click the object and select **Object Details**.
- Change the policy description—To modify the description of a policy, click in the description text below the policy name at the top of the page. Click away from the description to save changes.

Be sure to click **Save** to save any changes you make.

Step 4 Use the prefilter policy in the appropriate access control policies.

For each access control policy that should use a custom prefilter policy:

- Edit the access control policy and select the prefilter policy in the **Prefilter Policy** link or in the advanced settings. See Associate prefilter, decryption, and identity policies with an access control, on page 2016.
- If you applied tunnel zone tags in any tunnel rules, create access control rules that use those tunnel zones as source interface criteria.

What to do next

Deploy the changes.

If you deploy time-based rules, specify the time zone of the device to which the policy is assigned. See Configure a time zone for a device, on page 1304.

Configuring the default action

Use the default action to determine how plain-text encapsulated tunnels that do not match any tunnel rules should be handled.

The default action does not apply to non-tunnel traffic. Any other connections that do not match prefilter rules are passed on for processing by subsequent policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter** and create or edit a prefilter policy.

Step 2 Choose a **Default Action: Tunneled Traffic** option:

a. **Analyze all tunnel traffic**—These tunnels are allowed and their encapsulated connections are evaluated by the access control and other policies

Block all tunnel traffic—Tunnels are dropped and no longer evaluated.

Step 3 If you select **Block all tunnel traffic**, click **Logging** ( ) next to the default action.

You can configure default action logging for blocked tunnels only.

Configure prefilter rules

Configure prefilter rules to provide early blocking for unwanted traffic and to fast path traffic that does not benefit from access control inspection.

Use prefilter rules in a non-default prefilter policy to provide early blocking for unwanted traffic, and to fast path traffic that does not benefit from access control inspection.

If your device supports flow offload, fast path traffic is eligible for flow offload if it meets all other criteria. See Large flow offloads, on page 2535.

Before you begin

You cannot create rules in the default prefilter policy. If you have not created a custom prefilter policy, do so now.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter** and create or edit a prefilter policy.

Click **Add Prefilter Rule**.

You can also right-click a rule and select **Insert New Prefilter Rule**.

Select whether the rule should be **Enabled**. A rule must be enabled to affect traffic through the device.

Step 2 Select the **Action** to be taken on matching traffic.

- Fastpath—Exempts matching traffic from all further inspection AND control, including access control, identity requirements, AND rate limiting. These connections are eligible for flow offload if the device supports it.
- Block—Blocks matching traffic without further inspection of any kind.
- Analyze—Allows traffic to continue to be analyzed by the rest of access control. If passed by access control AND any related deep inspection, this traffic may also be rate limited.

Step 3 Select where to **Insert** the rule.

The default is to insert the rule at the end of the policy, but you can select an existing rule and insert the new rule before or after that rule. The action of the first rule that matches a connection is applied to that connection, so order matters.

Step 4 (Optional.) Select the object that defines the **Time Range** for the rule.

You can limit what times of day, or which days, a rule is operational. For example, the rule could apply during business hours only. Select an existing time range object OR create a new one. For more information, see Create a time range object, on page 3036.

Step 5 Configure the traffic matching conditions for the rule.

The rule is applied to connections that match all of the conditions. Within a condition type, separate elements are OR'ed, so that matching any of the selected items counts as a match. For the rule as a whole, all condition types are AND'ed: a connection must match at least one item on each tab to match the rule. You can use these types of conditions:

- **Interface Objects**—Select the security zones OR interface groups that contain the interfaces to which the rule should apply. The default, no objects selected, applies the rule to all interfaces on the device.
- **Networks**—Select the network objects that define the source (**Add to Source**) OR destination (**Add to Destination**) IP addresses, OR both. The default (no objects selected) matches all source AND destination IP addresses.
- **VLAN tags**—Select the objects that define the VLANs to which the rule should apply. For more information, see VLAN tags rule conditions, on page 2547.
- **Ports**—Select the TCP/UDP ports, OR other protocol, for the connections AND add them to the source OR destination criteria. Source criteria is TCP/UDP only, but you can select other protocols for the destination. For more information, see Port rule conditions for prefilter rules, on page 2547.

Step 6 (Fastpath AND Block rules only.) Click **Logging** and configure how matching connections should be logged.

Step 7 (Optional.) Click **Comment** and add comments to the rule. Use comments to help you understand the purpose of the rule and its change history.

Step 8 Click **Add**. If you need to move the rule, do so now.

Step 9 Click **Save** to save the policy.

VLAN tags rule conditions

VLAN tags rule conditions are filtering mechanisms to control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic.

VLAN tag filtering behavior

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Port rule conditions for prefilter rules

Port conditions match traffic based on the source and destination ports.

Port condition types

Depending on the rule type, "port" can represent any of these types:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22. TCP and UDP are the only source ports supported. You can also specify them as destination ports.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3. When you select ICMP as a destination port, you are prompted to specify the type and code.
- Protocol—You can control traffic using other protocols that do not use ports. Not all protocols are supported. You must select the protocol as a destination port.

Source and destination port constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. However, when matching GRE, IP in IP, IPv6 in IP, or Teredo Port 3544, configure tunnel rules instead of port conditions in prefilter rules.

Configure tunnel rules

Configure tunnel rules to control how encapsulated tunnel traffic is processed by the firewall system.

- Provide early blocking for unwanted encapsulated tunnel traffic.
- Fast path tunnels that do not benefit from access control inspection.
- Place encapsulated tunnels into a tunnel zone, called rezoning, so that you can write access control rules to apply inspection to the connections within the tunnel as a whole.

The prefilter policy's default action applies to encapsulated tunnels. Thus, create rules for tunnel traffic only to apply different actions to specific tunnels.

For example, if the default action is to analyze tunnels, this means that all tunnels are passed on to the access control policies AND other policies that inspect, allow, AND potentially block connections, AND these policies will evaluate the inner connections. If that default action is what you want for all tunnels, then you do not need to create any tunnel rules.

If instead:

- The default action is to block encapsulated tunnels, use rules to exempt specific tunnels from blocking AND either pass them to other access control policies (analyze action) OR bypass any additional processing (fastpath).
- There are tunnels where you want to apply access control rules to all encapsulated connections, create rules to rezone the tunnels to the appropriate tunnel zone tag AND also write rules in the access control policy for those tunnel zone tags.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter**. Create or edit a prefilter policy.

Step 2 Click **Add Tunnel Rule**.

You can also right-click a rule AND select **Insert New Tunnel Rule**.

a) Enter a **Name** for the rule.

b) Select whether the rule should be **Enabled**.

A rule must be enabled to affect traffic through the device.

c) Select where to **Insert** the rule.

The default is to insert the rule at the end of the policy, but you can select an existing rule AND insert the new rule before OR after that rule. The action of the first rule that matches a connection is applied to that connection, so order matters.

d) (Optional.) Select the object that defines the **Time Range** for the rule.

You can limit what times of day, OR which days, a rule is operational. For example, the rule could apply during business hours only. Select an existing time range object OR create a new one. For more information, see Create a time range object, on page 3036.

Step 3 Select the **Action** to be taken on matching traffic.

- Fastpath—Exempts matching traffic from all further inspection AND control, including access control, identity requirements, AND rate limiting. Fastpathing a tunnel fastpaths all encapsulated connections. These connections are eligible for flow offload if the device supports it.
- Block—Blocks matching traffic without further inspection of any kind. Blocking a tunnel blocks all encapsulated connections.
- Analyze—Allows traffic to continue to be analyzed by the rest of access control using inner headers.. If passed by access control AND any related deep inspection, this traffic may also be rate limited.

a) (Analyze rules only; when rezoning only.) Select a tunnel zone tag in **Assign Tunnel Zone** if your intention is to rezone the tunnel.

Leave this option blank if you want access control to apply to the encapsulated connections within the tunnel without special processing. For more information about rezoning AND tunnel group tags, see:

- Using tunnel zones to apply access control at the tunnel level, on page 2534
- Creating tunnel zones, on page 2550
- Rezone tunnels for customized inspection, on page 2552

Caution
Exercise caution when assigning tunnel zones. Connections in rezoned tunnels may not match security zone constraints in later evaluation. See Rezone tunnels for customized inspection, on page 2552 for a brief walkthrough of a tunnel zone implementation, AND a discussion of the implications of rezoning without explicitly handling rezoned traffic.

Step 4 Select one of these options to set the direction for the rule:

- **Match tunnels only from source** (unidirectional)—Match source-to-destination traffic only. Matching traffic must originate from one of the specified source interfaces OR tunnel endpoints, AND leave through one of the destination interfaces OR tunnel endpoints. Return traffic for allowed connections is also permitted. (Note that prefilter rules are always unidirectional.)
- **Match tunnels from source AND destination** (bidirectional)—Match both source-to-destination traffic AND destination-to-source traffic. The effect is identical to writing two unidirectional rules, one the mirror of the other. This is the default.

Step 5 Click the **Encapsulation & Ports** tab and select the protocols for this rule.

You must select at least one of these options in a tunnel rule to specify the encapsulation protocol used. The list includes the IP protocol number for the option.

- **GRE** (47)
- **IP-in-IP** (4)
- **IPv6-in-IP** (41)
- **Teredo** (UDP (17)/3455)

Step 6 Configure the traffic matching conditions for the rule.

The rule is applied to connections that match all of the conditions. Within a condition type, separate elements are OR'ed, so that matching any of the selected items counts as a match. For the rule as a whole, all condition types are AND'ed: a connection must match at least one item on each tab to match the rule. You can use these types of conditions:

- **Interface Objects**—Select the security zones OR interface groups that contain the interfaces to which the rule should apply. The default, no objects selected, applies the rule to all interfaces on the device.
- **Tunnel Endpoints**—The network objects that define the source (**Add to Source**) AND destination (**Add to Destination**) IP addresses of the tunnel. The default (no objects selected) matches all source AND destination IP addresses.
- **VLAN tags**—Select the objects that define the VLANs to which the rule should apply. For more information, see VLAN tags rule conditions, on page 2547.

Step 7 (Fastpath AND Block rules only.) Click **Logging** AND configure how matching connections should be logged.

Step 8 (Optional.) Click **Comment** AND add comments to the rule.

Use comments to help you understand the purpose of the rule AND its change history.

Step 9 Click **Add**.

If you need to move the rule, do so now.

Click **Save** to save the policy.

Creating tunnel zones

Create a tunnel zone tag to represent certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis.

A *tunnel zone* represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis. A tunnel zone is not an interface object, even though you can use it as an interface constraint in access control rules, as explained in Using tunnel zones to apply access control at the tunnel level, on page 2534.

You can create zones in the object manager or when editing a tunnel rule.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Tunnel Zone** from the list of object types.

Step 3 Click **Add Tunnel Zone**.

You can also edit an existing tunnel or delete a tunnel zone that is not being used in a tunnel rule.

Step 4 Enter a **Name** and, optionally, a **Description**.

Step 5 Click **Save**.

What to do next

- Assign the tunnel zone to plaintext, passthrough tunnels as part of a tunnel rule. See Configure tunnel rules, on page 2548.
- Use the tunnel zone as source interface criteria in an access control rule.

Move prefilter rules to an access control policy

Moving prefilter rules to an access control policy allows you to reposition rules for better policy organization and effectiveness when the rules would function more appropriately within the access control policy structure.

You can move prefilter rules from a prefilter policy to the associated access control policy.

Before you begin

Note the following conditions before you proceed:

- Only prefilter rules can be moved to an access control policy. Tunnel rules cannot be moved.
- The prefilter rules can be moved only to an access control policy that uses the prefilter policy. Because you can use the same prefilter policy in multiple access control policies, you need to select the policies to which the rule should be moved.
- The prefilter rules that use interface groups to define interface criteria cannot be moved. You can move only those rules that use security zones, or that include no interface criteria.
- The **Action** parameter in the prefilter rule is changed to a suitable action in the access control rule when moved.
  - **Analyze** becomes allow.
  - **Block** becomes block.
  - **Fastpath** becomes trust.
- The logging configuration in the rule is retained.
- The comments in the prefilter rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source prefilter policy.

- While moving rules from the source policy, if another user modifies those rules, you are warned. You can continue with the process after refreshing the page.

Procedure

Step 1 In the prefilter policy editor, select the rules that you want to move with a left-click on your mouse.

Tip
To select multiple rules, use Shift+click.

Step 2 Right-click the selected rules and choose **Move to another policy**.

Step 3 Select the destination access control policies and click **Add** to add them to the list of selected policies.

Step 4 From the **Place Rules** drop-down list, choose where you want to position the moved rules:

- To position as the last set of rules in the **Default** section, choose **At the bottom (within the Default section)**.
- To position as the first set of rules in the **Mandatory** section, choose **At the top (within the Mandatory section)**.

Step 5 Click **Move**.

What to do next

- Deploy configuration changes.

Examples of prefilter policy

These topics provide examples of using the prefilter policy.

Rezone tunnels for customized inspection

Rezone GRE tunnels to enable customized inspection policies for encapsulated traffic while maintaining different inspection policies for other traffic in the same security zone.

This example procedure summarizes how you might rezone GRE tunnels for further analysis, using tunnel zones. You can adapt the concepts described here to other scenarios requiring tailored traffic inspection of connections encapsulated in plaintext or passthrough tunnels.

Consider a situation where your organization's internal traffic flows through the Trusted security zone. The Trusted security zone represents a set of interfaces across multiple managed devices deployed in various locations. Your organization's security policy requires that you allow internal traffic after deep inspection for exploits and malware.

Internal traffic sometimes includes plaintext, passthrough, GRE tunnels between particular endpoints. Because the traffic profile of this encapsulated traffic is different from your "normal" interoffice activity—perhaps it is known and benign—you can limit inspection of certain encapsulated connections while still complying with your security policy.

In this example, after you deploy configuration changes:

- Plaintext, passthrough, GRE-encapsulated tunnels detected in the Trusted zone have their individual encapsulated connections evaluated by one set of intrusion and file policies.
- All other traffic in the Trusted zone is evaluated with a different set of intrusion and file policies.

You accomplish this task by *rezoning* GRE tunnels. Rezoning ensures that access control associates GRE-encapsulated connections with a custom *tunnel* zone, rather than their original Trusted *security* zone. Rezoning is required due to the way access control handles encapsulated traffic; see How the system processes plain-text tunnels, on page 2533 and Using tunnel zones to apply access control at the tunnel level, on page 2534.

Procedure

Step 1 Configure custom intrusion and file policies that tailor deep inspection to encapsulated traffic, and another set of intrusion and file policies tailored to nonencapsulated traffic.

Step 2 Configure custom prefiltering to rezone GRE tunnels flowing through the Trusted security zone.

Create a custom prefilter policy and associate it with access control. In that custom prefilter policy, create a tunnel rule (in this example, **`GRE_tunnel_rezone`**) and a corresponding tunnel zone (**`GRE_tunnel`**). For more information, see Configure tunnel rules, on page 2548.

Table 134: GRE_tunnel_rezone tunnel rule

Rule Component	Description
Interface object condition	Match internal-only tunnels by using the Trusted security zone as both a Source Interface Object and Destination Interface Object constraint.
Tunnel endpoint condition	Specify the source and destination endpoints for the GRE tunnels used in your organization. Tunnel rules are bidirectional by default. If you do not change the **Match tunnels from...** option, it does not matter which endpoints you specify as source and which as destination.
Encapsulation condition	Match GRE traffic.
Assign Tunnel Zone	Create the **`GRE_tunnel`** tunnel zone, and assign it to tunnels that match the rule.
Action	Analyze (with the rest of access control).

Step 3 Configure access control to handle connections in rezoned tunnels.

In the access control policy deployed to your managed devices, ensure that the prefilter policy is used. Then, configure a rule (in this example, **`GRE_inspection`**) that handles the traffic you rezoned. For more information, see Create and edit access control rules, on page 2066.

Table 135: GRE_inspection access control rule

Rule Component	Description
Security zone condition	Match rezoned tunnels by using the GRE_tunnel tunnel zone as a Source Zone constraint.
Action	Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect encapsulated internal traffic.

Caution
If you skip this step, the rezoned connections may match **any** access control rule not constrained by security zone. If the rezoned connections do not match any access control rules, they are handled by the access control policy default action. Make sure this is your intent.

Step 4 Configure access control to handle nonencapsulated connections flowing through the Trusted security zone.

In the same access control policy, configure a rule (in this example, **`internal_default_inspection`**) that handles non-rezoned traffic in the Trusted security zone.

Table 136: Internal_default_inspection access control rule

Rule Component	Description
Security zone condition	Match non-rezoned internal-only traffic by using the Trusted security zone as both a Source Zone and Destination Zone constraint.
Action	Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect nonencapsulated internal traffic.

Step 5 Evaluate the position of the new access control rules relative to preexisting rules. Change rule order if necessary.

If you place the two new access control rules next to each other, it does not matter which you place first. Because you rezoned GRE tunnels, the two rules cannot preempt each other.

Step 6 Save all changes.

What to do next

- Deploy configuration changes.

Offload large flows

This task helps improve performance quickly for large connections that you know you can trust by proactively identifying connections as being offload eligible through matching them to a prefilter fastpath rule.

You can use the prefilter policy to configure static flow offload. If your hardware model supports it, flow offload moves eligible fast path connections to NIC processing, avoiding performance intensive inspection.

Some hardware models will dynamically identify off-loadable connections automatically, but you can proactively identify connections as being offload eligible by matching them to a prefilter fastpath rule. This static configuration helps you improve performance quickly for large connections that you know you can trust.

In the following example, it is assumed that two servers are behind sufficient protection so that you can trust the connections between them. Perhaps one server is using the other for backups. Thus, you can write a fastpath rule for any traffic going from the main server, 10.100.1.20/24, to the backup server, 10.100.2.2/24. The example assumes the servers are accessible through regular, physical routed interfaces.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Prefilter** and create or edit a custom prefilter policy.

Step 2 Click **Add Prefilter Rule**.

You can also right-click a rule and select **Insert New Prefilter Rule**.

Step 3 Enter a **Name** for the rule. For example, Offload_Server_A.

Step 4 In **Action**, select **Fastpath**.

Step 5 In **Insert**, select the rule above or below which the rule should be inserted.

You can also move the rule after you create it.

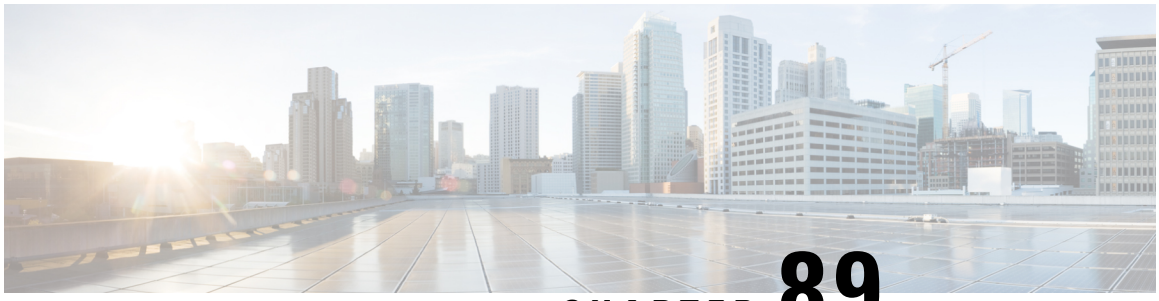
Step 6 Click the **Networks** tab and specify the source and destination servers.

- In the edit box below **Source Networks**, type 10.100.1.20 and click **Add**.
- In the edit box below **Destination Networks**, type 10.100.2.2 and click **Add**.

Step 7 (Optional.) Configure the other traffic matching characteristics for the flow.

Click these tabs to fill in the criteria. Only the Networks tab needs to be configured for this example, so configure these settings only if they make sense for your situation.

- **Interface objects**—The security zones or interface objects that define the source or destination interfaces, or both. This specification is not needed for this example.
- **VLANs**—Because this example uses routed physical interfaces instead of switch interfaces, this setting is not relevant. Even in those circumstances, you do not need to limit the rule based on VLAN.
- **Ports**—If you want to limit the offload to specific TCP/UDP ports, you can specify them. This limits the scope of the rule to these ports only.



Step 8 (Optional.) Click **Logging** and decide whether you want to see syslog events for matching traffic.

Step 9 Click **Add** to add the rule.

Take the time to move the rule to the right location in the policy if it is not already there.

Click **Save** to save the policy.

The next time you deploy the configuration, the rule will be applied to the target devices.

CHAPTER 89

DNS Policies for Security Intelligence

The following topics explain DNS policies, DNS rules, and how to deploy DNS policies to managed devices.

- DNS policies, on page 2557
- Cisco umbrella DNS policies, on page 2558
- DNS policy components, on page 2559
- License requirements for DNS policies, on page 2560
- Requirements and prerequisites for DNS policies, on page 2560
- Managing DNS and Umbrella DNS Policies, on page 2560
- DNS rules, on page 2562
- DNS rules, on page 2569
- Requirement: deploy DNS policy configuration changes, on page 2575
- Cisco umbrella DNS policies, on page 2575

DNS policies

A DNS policy is a security configuration that

- blocks traffic based on the domain name requested by a client, using a Security Intelligence Block list
- uses Cisco-provided domain name intelligence to filter traffic
- supports custom lists and feeds of domain names tailored to your deployment, and
- requires association with an access control policy for deployment to managed devices.

DNS policy behavior

Traffic on a DNS policy Block list is immediately blocked and therefore is not subject to any further inspection—not for intrusions, exploits, malware, and so on, but also not for network discovery. You can use a Security Intelligence Do Not Block list to override a Block list and force access control rule evaluation, and, recommended in passive deployments, you can use a "monitor-only" setting for Security Intelligence filtering. This allows the system to analyze connections that would have been blocked by a Block list, but also logs the match to the Block list and generates an end-of-connection Security Intelligence event.

Note DNS-based Security Intelligence may not work as intended for a domain name unless the DNS server deletes a domain cache entry due to expiration, or a client's DNS cache or the local DNS server's cache is cleared or expires.

You configure DNS-based Security Intelligence using a DNS policy and associated DNS rules. To deploy it to your devices, you must associate your DNS policy with an access control policy, then deploy your configuration to managed devices.

Cisco umbrella DNS policies

A Cisco Umbrella DNS policy is a security mechanism that

- redirects DNS queries to Cisco Umbrella for domain validation and policy enforcement,
- allows or blocks requests based on domain names and applies DNS-based security policies, and
- provides two lines of protection through local DNS inspection and cloud-based Cisco Umbrella policies.

DNS query redirection process

Cisco Umbrella DNS Connection in the management center helps to redirect DNS queries to Cisco Umbrella. This allows Cisco Umbrella to validate requests, allow or block them based on the domain names, and apply DNS-based security policy on the request. If you use Cisco Umbrella, you must configure the Cisco Umbrella Connection (**Integration** > **Other Integrations** > **Cloud Services** and choose the **Cisco Umbrella Connection**) to redirect DNS queries to Cisco Umbrella.

The Umbrella Connector is part of the system's DNS inspection. If your existing DNS inspection policy map decides to block or drop a request based on your DNS inspection settings, the request is not forwarded to Cisco Umbrella. Thus, you have two lines of protection:

- Your local DNS inspection policy
- Your Cisco Umbrella cloud-based policy

When redirecting DNS lookup requests to Cisco Umbrella, the Umbrella Connector adds an EDNS (Extension mechanisms for DNS) record. An EDNS record includes the device identifier information, organization ID, and client IP address. Your cloud-based policy can use those criteria to control access in addition to the reputation of the FQDN. You can also elect to encrypt the DNS request using DNSCrypt to ensure the privacy of usernames and internal IP addresses.

To redirect DNS requests from the management center to Cisco Umbrella:

1. Configure the Cisco Umbrella connection settings.
2. Create and configure an Umbrella DNS policy.
3. Associate the Umbrella DNS policy with an access control policy.
4. Deploy the changes.

For detailed information about how to set up the Umbrella DNS Connector in the management center, see Configuring the Umbrella DNS Connector for Cisco Secure Firewall Management Center.

DNS policy components

DNS policy components are configuration elements that

- enable blocking of connections based on domain name using a Block list
- exempt connections from blocking using a Do Not Block list, and
- provide granular network traffic handling through configurable rules and settings.

DNS policy configuration options

These configurations can be changed after creating a DNS policy:

- **Name and Description**: Each DNS policy must have a unique name. A description is optional.
- **Rules**: Rules provide a granular method of handling network traffic based on the domain name. Rules in a DNS policy are numbered, starting at 1. The system matches traffic to DNS rules in top-down order by ascending rule number.

When you create a DNS policy, the system populates it with a default Global Do-Not-Block List for DNS rule and a default Global Block List for DNS rule. Both rules are fixed to the first position in their respective categories. You cannot modify these rules, but you can disable them.

Note If multitenancy is enabled for your Cloud-Delivered Firewall Management Center, the system is organized into a hierarchy of domains, including ancestor and descendant domains. These domains are distinct and separate from the domain names used in DNS management.

A descendant list contains the domains on the Block or Do Not Block lists of system subdomain users. From an ancestor domain, you cannot view the contents of descendant lists. If you do not want subdomain users to add domains to a Block or Do Not Block list:

- disable the descendant list rules, and
- enforce Security Intelligence using the access control policy inheritance settings

The system evaluates rules in this order:

1. Global Do-Not-Block List for DNS rule (if enabled)
2. Descendant DNS Do-Not-Block Lists rule (if enabled)
3. Rules with a Do Not Block action
4. Global Block List for DNS rule (if enabled)
5. Descendant DNS Block Lists rule (if enabled)
6. Rules with an action other than Do Not Block

Usually, the system handles DN-based network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic. If no DNS rules match the traffic, the system continues evaluating the traffic based on the associated access control policy's rules. DNS rule conditions can be simple or complex.

License requirements for DNS policies

User roles

- Admin
- Access Admin
- Network Admin

Important You must apply the Network Discovery policy on the device for a successful DNS validation on the traffic.

Managing DNS and Umbrella DNS Policies

Use the DNS Policy page to create, edit, delete, copy, and compare custom DNS and Umbrella DNS policies for comprehensive network security management.

Use the DNS Policy page (**Policies** > **Access Control heading** > **DNS**) to manage custom DNS and Umbrella DNS policies.

In addition to custom policies that you create, the system provides the Default DNS Policy and Default Umbrella DNS Policy. The default DNS policy uses the default Block list and Do Not Block list. You can edit and use this system-provided custom policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Manage your DNS policy:

- Compare—To compare DNS policies, click **Compare Policies** and proceed as described in Compare policies, on page 219.
- Copy—To copy a DNS policy, click **Copy** ( ) and proceed as described in Edit DNS policies, on page 2562.
- Create—To create a new Umbrella DNS policy, click **New Policy** > **Umbrella DNS Policy** and proceed as described in Create an umbrella DNS policy, on page 2579.
- Delete—To delete a DNS or Umbrella DNS policy, click **Delete** ( ), then confirm you want to delete the policy.
- Edit—To modify an existing DNS policy, click **Edit** ( )) and proceed as described in Edit DNS policies, on page 2562. To modify an existing Umbrella DNS policy, click **Edit** ( )) and proceed as described in Edit Umbrella DNS policies and rules, on page 2579.

You have successfully managed your DNS policies. The policies are now available for deployment to your network devices for DNS-based security filtering.

Create basic DNS policies

Creating a basic DNS policy establishes a foundation for DNS traffic filtering and management that you can customize to meet your organization's security requirements.

When you create a new DNS policy, it contains default settings. You must then edit it to customize the behavior.

Follow these steps to create a basic DNS policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Click **Add DNS Policy** > **DNS Policy**.

Step 3 Give the policy a unique **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

The DNS policy is created with default settings and appears in the DNS policies list.

What to do next

Configure the policy. See Edit DNS policies, on page 2562.

Edit DNS policies

Edit DNS policies to update policy configurations, modify rule settings, and maintain network security requirements.

Only one person should edit a DNS policy at a time, using a single browser window. If multiple users attempt to save the same policy, only the first set of saved changes are retained.

To protect the privacy of your session, after thirty minutes of inactivity on the policy editor, a warning appears. After sixty minutes, the system discards your changes.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Click **Edit** ( ) next to the DNS policy you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Edit your DNS policy:

- Name and Description—To change the name or description, click the field and type the new information.
- Rules—To add, categorize, enable, disable, or otherwise manage DNS rules, click **Rules** and proceed as described in Create and edit DNS rules, on page 2563.

Step 4 Click **Save**.

The DNS policy is updated with your changes and ready for deployment.

What to do next

- Optionally, further configure the new policy as described in *Logging Connections with Security Intelligence* in the *Cisco Secure Firewall Management Center Administration Guide*.
- Deploy configuration changes; see Deploy configuration changes, on page 202.

DNS rules

A DNS rule is a Security Intelligence component that

- handles traffic based on the domain name requested by a host,
- operates after any traffic decryption and before access control evaluation, and
- matches traffic in the order specified, with the system handling network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic.

DNS rule components

In addition to its unique name, each DNS rule has these basic components:

- **State**: By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.
- **Position**: Rules in a DNS policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.
- **Conditions**: Conditions specify the specific traffic the rule handles. A DNS rule must contain a DNS feed or list condition, and can also match traffic by security zone, network, dynamic attributes, or VLAN.
- **Action**: A rule's action determines how the system handles matching traffic.

A rule's action determines how the system handles matching traffic:

- Traffic with a **Do Not Block** action is allowed, subject to further access control inspection.
- Monitored traffic is subject to further evaluation by remaining rules on the DNS Block list. If the traffic does not match a DNS Block list rule, it is inspected with access control rules. The system logs a Security Intelligence event for the traffic.
- Traffic on a Block list is dropped without further inspection. You can also return a Domain Not Found response, or redirect the DNS query to a sinkhole server.

Related Topics

Security intelligence, on page 2027

Create and edit DNS rules

Create and edit DNS rules to define how the system handles DNS queries by specifying actions and conditions for domain name resolution.

In a DNS policy, you can add up to a total of 32767 DNS lists to the Block list and Do Not Block list rules; that is, the number of lists in the DNS policy cannot exceed 32767.

Follow these steps to create and edit DNS rules:

Procedure

Step 1 In the DNS policy editor, you have the following options:

- To add a new rule, click **Add DNS Rule**.
- To edit an existing rule, click **Edit** ( ).

Step 2 Enter a **Name**.

Step 3 Configure the rule components, or accept the defaults:

- Action—Choose a rule **Action**; see DNS rule actions, on page 2565.
- Conditions—Configure the rule's conditions; see DNS rule conditions, on page 2566.
- Enabled—Specify whether the rule is **Enabled**.

Step 4 Click **Save**.

The DNS rule is created or updated with the specified configuration and is ready for deployment.

What to do next

- Deploy configuration changes; see Deploy configuration changes, on page 202.

DNS rule management

DNS rule management is a policy administration feature that enables you to add, edit, move, enable, disable, delete, and otherwise manage DNS rules within your policy.

DNS rule management interface

The **Rules** tab of the DNS policy editor provides the interface for DNS rule management operations.

For each rule, the policy editor displays this information:

- Rule name
- Summary of rule conditions
- Rule action

Additional icons represent **Warning** ( ), **Error** ( ), and other important **Information** ( ). Disabled rules are dimmed and marked `(disabled)` beneath the rule name.

Enable and disable DNS rules

Enable or disable DNS rules to control whether the system uses them to evaluate network traffic and generate warnings and errors.

When you create a DNS rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules in a DNS policy, disabled rules are dimmed, although you can still modify them. Note that you can also enable or disable a DNS rule using the DNS rule editor.

Follow these steps to enable or disable DNS rules:

Procedure

Step 1 In the DNS policy editor, right-click the rule and choose a rule state.

Step 2 Click **Save**.

The DNS rule state is updated. Disabled rules appear dimmed in the policy rule list but can still be modified.

What to do next

- Deploy configuration changes.

DNS rule order evaluation

DNS rule order evaluation is a traffic processing mechanism that

- matches traffic to DNS rules in top-down order by ascending rule number,
- handles network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic, and
- applies different continuation behavior based on rule type.

Rule evaluation behavior

Rules in a DNS policy are numbered, starting at 1. The system behavior differs based on rule type:

- For Monitor rules, the system logs the traffic, then continues evaluating traffic against lower-priority DNS Block list rules.
- For non-Monitor rules, the system does **not** continue to evaluate traffic against additional, lower-priority DNS rules after that traffic matches a rule.

Rule order precedence follows this hierarchy:

- The Global Do-Not-Block List for DNS is always first, and takes precedence over all other rules.
- The Do-Not-Block List section precedes the Block List section; Do-Not-Block List rules always take precedence over other rules.
- The Global Block List for DNS is always first in the Block List section, and takes precedence over all other Monitor and Block list rules.
- The Block List section contains Monitor and Block list rules.
- When you first create a DNS rule, the system positions it last in the Do-Not-Block List section if you assign a **Do Not Block** action, or last in the Block List section if you assign any other action.

You can drag and drop rules to reorder them.

DNS rule actions

A DNS rule action is a configuration setting that

- determines handling for matching traffic, governing whether the system will block, not block, or monitor traffic based on rule conditions,
- controls logging behavior, determining when and how details about matching traffic are recorded, and
- impacts action prioritization when configured with TID.

DNS rule action types

DNS rules support these action types:

- **Do Not Block**: Allows traffic to pass to the next phase of inspection, which is access control rules. The system does not log *Do Not Block list* matches. Logging of these connections depends on their eventual disposition.
- **Monitor**: Forces connection logging; matching traffic is neither immediately allowed nor blocked. Traffic is matched against additional rules to determine whether to permit or deny it. The first non-Monitor DNS rule matched determines whether the system blocks the traffic. If there are no additional matching rules, the traffic is subject to access control evaluation. For connections monitored by a DNS policy, the system logs end-of-connection Security Intelligence and connection events to the Cloud-Delivered Firewall Management Center database.
- **Drop**: Drops the traffic without further inspection.
- **Domain Not Found**: Returns a non-existent internet domain response to the DNS query, which prevents the client from resolving the DNS request.
- **Sinkhole**: Returns a sinkhole object's IPv4 or IPv6 address in response to the DNS query (A and AAAA records only). The sinkhole server can log, or log and block, follow-on connections to the IP address. If you configure a **Sinkhole** action, you must also configure a sinkhole object.

Logging behavior varies based on the action type:

- For a connection blocked based on the **Drop** or **Domain Not Found** actions, the system logs beginning-of-connection Security Intelligence and connection events. Because blocked traffic is immediately denied without further inspection, there is no unique end of connection to log.
- For a connection blocked based on the **Sinkhole** action, logging depends on the sinkhole object configuration. If you configure your sinkhole object to only log sinkhole connections, the system logs end-of-connection connection events for the follow-on connection. If you configure your sinkhole object to log and block sinkhole connections, the system logs beginning-of-connection connection events for the follow-on connection, then blocks that connection.

DNS rule conditions

A DNS rule condition is a traffic identification criterion that

- identifies the type of traffic that rule handles,
- can be simple or complex, and
- must include a DNS feed or list condition within a DNS rule.

DNS rule condition requirements

You can also optionally control traffic by security zone, network, dynamic attributes, or VLAN.

When adding conditions to a DNS rule:

- If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion.

- You can configure multiple conditions per rule. Traffic must match **all** the conditions in the rule for the rule to apply to traffic. For example, a rule with a DNS feed or list condition and network condition but no VLAN tag condition evaluates traffic based on the domain name and source or destination, regardless of any VLAN tagging in the session.
- For each condition in a rule, you can add up to 50 criteria. Traffic that matches **any** of a condition's criteria satisfies the condition. For example, you can use a single rule to block traffic based on up to 50 DNS lists and feeds.

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

DNS policy rule conditions

A DNS policy rule condition is a DNS rule component that

- allows you to control traffic if a DNS list, feed, or category contains the domain name requested by the client,
- must be defined in a DNS rule, and
- applies the configured rule action to traffic regardless of whether you add a global or custom Block or Do Not Block list.

DNS condition behavior

The system applies the configured rule action to the traffic regardless of the list type. For example, if you add the Global Do Not Block List to a rule, and configure a **Drop** action, the system blocks all traffic that should have been allowed to pass to the next phase of inspection.

Dynamic attributes rule conditions

A dynamic attributes rule condition is a DNS rule matching mechanism that

- uses dynamic objects containing IP addresses or endpoint device type objects for source or destination matching,
- uses Security Group Tag (SGT) objects containing manually defined tags or ISE-defined tags for source-only matching, and
- applies logical operations where objects of the same type are ORed together and objects of different types are ANDed together.

Dynamic attributes configuration and behavior

You can use these types of dynamic attributes to match connections in DNS rules:

- (Source or destination.) Dynamic objects, which contain IP addresses. Endpoint device type objects are source only. For more information, see Dynamic objects, on page 2966 and the chapter on Dynamic Attributes Connector.
- (Source only.) Security Group Tag (SGT) objects, which contain tags either manually defined or defined through ISE. For more information, see Source and destination security group tag (SGT) matching, on page 2374 and Security group tags, on page 2972.

When you configure dynamic attributes for a DNS rule, objects of the same type in the same source or destination list are ORed together and objects of different types are ANDed together. For example, if you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originates from (or is destined to) one of those IP addresses.

Initially, all **Dynamic Objects** and **Security Group Tags** are listed when you open the **Dynamic Attributes** tab. You can deselect an option to remove those objects from the list. You can also start typing in the search box to find the object you want.

DNS rules

A DNS rule is a network security mechanism that controls and filters DNS queries and responses within network traffic

Control traffic based on DNS and security zone

Control traffic flow by implementing DNS rules with security zone conditions to manage network access and security policies.

Zone conditions in DNS rules allow you to control traffic by its source security zone. A *security zone* is a grouping of one or more interfaces, which may be located across multiple devices.

Procedure

Step 1 In the DNS rule editor, click **Zones**.

Step 2 Find and select the zones you want to add from the **Available Zones**. To search for zones to add, click the **Search by name** prompt above the **Available Zones** list, then type a zone name. The list updates as you type to display matching zones.

Step 3 Click to select a zone, or right-click and then select **Select All**.

Step 4 Click **Add to Source**, or drag and drop.

Step 5 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2572.

Step 6 Save or continue editing the rule.

The DNS rule is configured with security zone conditions to control traffic based on source security zones and DNS names.

What to do next

- Deploy configuration changes.

Control traffic based on DNS and network

Control traffic by explicitly specifying the source IP addresses for the traffic you want to manage through DNS rules.

Network conditions in DNS rules allow you to control traffic by its source IP address. You can explicitly specify the source IP addresses for the traffic you want to control.

Procedure

Step 1 In the DNS rule editor, click **Networks**.

Step 2 Find and select the networks you want to add from the **Available Networks**, as follows:

- To add a network object on the fly, which you can then add to the condition, click **Add** (+) above the **Available Networks** list and proceed as described in Create a network object, on page 2985.
- To search for network objects to add, click the **Search by name or value** prompt above the **Available Networks** list, then type an object name or the value of one of the object's components. The list updates as you type to display matching objects.

Step 3 Click **Add to Source**, or drag and drop.

Step 4 Add any source IP addresses or address blocks that you want to specify manually. Click the **Enter an IP address** prompt below the **Source Networks** list; then type an IP address or address block and click **Add**.

Step 5 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2572.

Step 6 Save or continue editing the rule.

The DNS rule is configured with network conditions to control traffic based on the specified source IP addresses and DNS names.

What to do next

- Deploy configuration changes.

Control traffic based on DNS and VLAN

This task allows you to control VLAN-tagged traffic by configuring VLAN conditions in DNS rules, enabling precise traffic management based on DNS names and VLAN identifiers.

VLAN conditions in DNS rules allow you to control VLAN-tagged traffic. The system uses the innermost VLAN tag to identify a packet by VLAN.

When you build a VLAN-based DNS rule condition, you can manually specify VLAN tags. Alternately, you can configure VLAN conditions with VLAN tag *objects*, which are reusable and associate a name with one or more VLAN tags.

Procedure

Step 1 In the DNS rule editor, select **VLAN Tags**.

Step 2 Find and select the VLANs you want to add from the **Available VLAN Tags**, as follows:

- To add a VLAN tag object on the fly, which you can then add to the condition, click **Add** (+) above the Available VLAN Tags list and proceed as described in Create a VLAN tag object, on page 3057.
- To search for VLAN tag objects and groups to add, click the **Search by name or value** prompt above the **Available VLAN Tags** list, then type either the name of the object, or the value of a VLAN tag in the object. The list updates as you type to display matching objects.

Step 3 Click **Add to Rule**, or drag and drop.

Step 4 Add any VLAN tags that you want to specify manually. Click the **Enter a VLAN Tag** prompt below the **Selected VLAN Tags** list; then type a VLAN tag or range and click **Add**. You can specify any VLAN tag from 1 to 4094; use a hyphen to specify a range of VLAN tags.

Step 5 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2572.

Step 6 Save or continue editing the rule.

The DNS rule is configured with VLAN conditions, allowing the system to control traffic based on both DNS names and VLAN tags.

What to do next

- Deploy configuration changes.

Control traffic based on DNS list or feed

Control network traffic by applying DNS-based filtering rules using predefined or custom DNS lists and threat intelligence feeds.

Use DNS lists and feeds in security policies to block or allow traffic based on domain reputation and threat intelligence data.

Procedure

Step 1 In the DNS rule editor, click **DNS**.

Step 2 Find and select the DNS lists and feeds you want to add from the **DNS Lists and Feeds**, as follows:

- To add a DNS list or feed on the fly, which you can then add to the condition, click **Add** (+) above the **DNS Lists and Feeds** list and proceed as described in Create custom security intelligence feeds, on page 3030.
- To search for DNS lists, feeds, or categories to add, click the **Search by name or value** prompt above the **DNS Lists and Feeds** list, then type an object name or the value of one of the object's components. The list updates as you type to display matching objects.
- For descriptions of the system-provided threat categories, see Security intelligence categories, on page 2034.

Step 3 Click **Add to Rule**, or drag and drop.

Step 4 Save or continue editing the rule.

The DNS lists and feeds are now configured in your rule and will filter traffic based on the selected criteria.

What to do next

- Deploy configuration changes.

Controlling traffic based on security group tag or dynamic attributes

This task allows you to control traffic using dynamic attributes conditions in DNS rules based on security group tags or other dynamic attributes.

Dynamic Attributes conditions in DNS rules allow you to control traffic based on security group tag or other dynamic attributes. To use these attributes, you must apply security group tags to traffic in your network, or create the dynamic attribute objects you need using the API or the Cisco Secure Dynamic Attributes Connector. For more information about enabling dynamic attributes, see Dynamic attributes rule conditions, on page 2569.

When you configure dynamic attributes for a DNS rule, objects of the same type in the same source or destination list are ORed together and objects of different types are ANDed together. For example, if you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originates from (or is destined to) one of those IP addresses.

Procedure

Step 1 In the DNS rule editor, click **Dynamic Attributes**.

Step 2 Select the objects you want to use, and click either **Add Sources** or **Add Destinations**.

Initially, all **Dynamic Objects** and **Security Group Tags** are listed when you open the **Dynamic Attributes** tab. You can deselect an option to remove those objects from the list. You can also start typing in the search box to find the object you want.

You can use these objects to identify the source of the connection, the destination, or both.

Note
You can use SGT and endpoint device type objects as source criteria only.

Step 3 Click the **DNS** tab and add the lists or feeds that include the DNS names you are controlling. For more information, see Control traffic based on DNS list or feed, on page 2572.

Step 4 Save or continue editing the rule.

You have successfully configured dynamic attributes for DNS rules to control traffic based on security group tags or other dynamic attributes.

What to do next

- Deploy configuration changes.

Use a DNS sinkhole to enforce content restriction

This task configures a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Typically, a DNS sinkhole directs traffic away from a particular target. This procedure describes how to configure a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Because Google SafeSearch uses a single IPv4 address for the VIP, hosts must use IPv4 addressing.

Caution If your network includes proxy servers, this content restriction method is not effective unless you position your Firewall Threat Defense devices between the proxy servers and the Internet.

This procedure enforces content restriction for Google searches only. It does not apply to any other search engine.

Before you begin

This procedure applies to Firewall Threat Defense only, and requires the IPS license.

Follow these steps to use a DNS sinkhole to enforce content restriction:

Procedure

Step 1 Obtain a list of supported Google domains via the following URL: https://www.google.com/supported_domains.

Step 2 Create a custom DNS list on your local computer, and add the following entries:

- To enforce Google SafeSearch, add an entry for each supported Google domain.
- To enforce YouTube Restricted Mode, add a "youtube.com" entry.

The custom DNS list must be in text file (.txt) format. Each line of the text file must specify an individual domain name, stripped of any leading periods. For example, the supported domain ".google.com" must appear as "google.com".

Step 3 Upload the custom DNS list to the Cloud-Delivered Firewall Management Center; see Upload new custom security intelligence lists to the Cloud-Delivered Firewall Management Center, on page 3032.

Step 4 Determine the IPv4 address for the Google SafeSearch VIP. For example, run **nslookup** on forcesafesearch.google.com.

Step 5 Create a sinkhole object for the SafeSearch VIP; see Create a sinkhole object, on page 3033.

Use the following values for this object:

- IPv4 Address—Enter the SafeSearch VIP address.
- IPv6 Address—Enter the IPv6 loopback address (**::1**).
- Log Connections to Sinkhole—Click Log Connections.
- Type—Choose **None**.

Step 6 Create a basic DNS policy; see Create basic DNS policies, on page 2561.

Step 7 Add a DNS rule for the sinkhole; see Create and edit DNS rules, on page 2563.

For this rule:

- Check the **Enabled** check box.
- Choose **Sinkhole** from the **Action** drop-down list.
- Choose the sinkhole object you created from the **Sinkhole** drop-down list.
- Add the custom DNS list you created to the **Selected Items** list on **DNS**.
- (Optional) Choose a network in **Networks** to limit content restriction to specific users. For example, if you want to limit content restriction to student users, assign students to a different subnet than faculty, and specify that subnet in this rule.

Step 8 Associate the DNS policy with an access control policy; see Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Step 9 Deploy configuration changes.

The DNS sinkhole is configured to enforce content restriction by redirecting traffic to the Google SafeSearch VIP, which filters Google and YouTube search results.

Requirement: deploy DNS policy configuration changes

After you finish updating your DNS policy configuration, you must deploy it as part of access control configuration.

- Associate your DNS policy with an access control policy, as described in Configure security intelligence, on page 2030.
- Deploy configuration changes.

Cisco umbrella DNS policies

A Cisco Umbrella DNS policy is a security mechanism that

- redirects DNS queries to Cisco Umbrella for domain validation and policy enforcement,
- allows or blocks requests based on domain names and applies DNS-based security policies, and
- provides two lines of protection through local DNS inspection and cloud-based Cisco Umbrella policies.

DNS query redirection process

Cisco Umbrella DNS Connection in the management center helps to redirect DNS queries to Cisco Umbrella. This allows Cisco Umbrella to validate requests, allow or block them based on the domain names, and apply DNS-based security policy on the request. If you use Cisco Umbrella, you must configure the Cisco Umbrella Connection (**Integration** > **Other Integrations** > **Cloud Services** and choose the **Cisco Umbrella Connection**) to redirect DNS queries to Cisco Umbrella.

The Umbrella Connector is part of the system's DNS inspection. If your existing DNS inspection policy map decides to block or drop a request based on your DNS inspection settings, the request is not forwarded to Cisco Umbrella. Thus, you have two lines of protection:

- Your local DNS inspection policy
- Your Cisco Umbrella cloud-based policy

When redirecting DNS lookup requests to Cisco Umbrella, the Umbrella Connector adds an EDNS (Extension mechanisms for DNS) record. An EDNS record includes the device identifier information, organization ID, and client IP address. Your cloud-based policy can use those criteria to control access in addition to the reputation of the FQDN. You can also elect to encrypt the DNS request using DNSCrypt to ensure the privacy of usernames and internal IP addresses.

To redirect DNS requests from the management center to Cisco Umbrella:

1. Configure the Cisco Umbrella connection settings.
2. Create and configure an Umbrella DNS policy.
3. Associate the Umbrella DNS policy with an access control policy.
4. Deploy the changes.

For detailed information about how to set up the Umbrella DNS Connector in the management center, see Configuring the Umbrella DNS Connector for Cisco Secure Firewall Management Center.

Redirect DNS requests to Cisco umbrella

Redirect DNS requests from the device to Cisco Umbrella for enhanced security and DNS filtering capabilities.

Use this procedure when you need to configure DNS redirection to Cisco Umbrella using the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Ensure that you meet the prerequisites.

Prerequisites for configure the umbrella DNS connector, on page 2576

Step 2 Configure the Cisco Umbrella connection settings.

Configure Cisco umbrella connection settings, on page 2578

Step 3 Create an Umbrella DNS policy.

Create an umbrella DNS policy, on page 2579

Step 4 Configure the Umbrella DNS policy.

Edit Umbrella DNS policies and rules, on page 2579

Step 5 Associate the Umbrella DNS policy with an access control policy.

Associate the umbrella DNS policy with an access control policy, on page 2580

DNS requests from the device are now redirected to Cisco Umbrella for processing and security filtering.

Prerequisites for configure the umbrella DNS connector

This reference provides the prerequisites that must be met before configuring the Umbrella DNS Connector, including minimum platform requirements, account setup, certificate management, and network connectivity requirements.

Table 137: Minimum supported platforms

Product	Version
Secure Firewall Threat Defense	6.6 and above
Cloud-Delivered Firewall Management Center	7.2 and above

- Establish an account with Cisco Umbrella at https://umbrella.cisco.com, and log into Umbrella at http://login.umbrella.com.

- Import the CA certificate from the Cisco Umbrella server to the Cloud-Delivered Firewall Management Center. In Cisco Umbrella, choose **Deployments** > **Configuration** > **Root Certificate** and download the certificate.

  You must import the root certificate to establish the HTTPS connection with the Cisco Umbrella registration server. The certificate needs to be trusted for SSL server validation, which is a non-default option in the Cloud-Delivered Firewall Management Center. Copy and paste this certificate for the device in the Cloud-Delivered Firewall Management Center(**Devices** > **Certificates**).

  ```

  When you add the certificate in the management center, ensure that you check the **CA Only** check box.

- Install the certificate on the device.
- Obtain this data from Umbrella:
  - Organization ID
  - Network Device Key
  - Network Device Secret
  - Legacy Network Device Token
- Ensure that the Cloud-Delivered Firewall Management Center is connected to the internet.
- Ensure that the base license with the export-controlled feature option is enabled in the Cloud-Delivered Firewall Management Center.
- Ensure that the DNS server is configured to resolve api.opendns.com.
- Ensure that the Cloud-Delivered Firewall Management Center can resolve management.api.umbrella.com for policy configuration.
- Configure the Firewall Threat Defense route to api.opendns.com.

Configure Cisco umbrella connection settings

Configure the token and settings required to register the device with Cisco Umbrella and enable DNS security services.

The Cisco Umbrella Connection settings define the token that is needed to register the device with Cisco Umbrella.

Before you begin

Establish an account with Cisco Umbrella https://umbrella.cisco.com, and then log into Umbrella at https://dashboard.umbrella.com and obtain the required information to establish connection to Cisco Umbrella.

Follow these steps to configure Cisco Umbrella connection settings:

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services** and choose the **Cisco Umbrella Connection**.

Step 2 Obtain the following details and add them to the **General** settings:

- **Organization ID**—A unique number that identifies your organization on Cisco Umbrella. Every Umbrella organization is a separate instance of Umbrella and has its own dashboard. Organizations are identified by their name and their organization ID (Org ID).
- **Network Device Key**—The key to fetch umbrella policy from Cisco Umbrella.
- **Network Device Secret**—The secret to fetch umbrella policy from Cisco Umbrella.
- **Legacy Network Device Token**—An Umbrella Legacy Network Devices API token is issued through the Cisco Umbrella dashboard. Umbrella requires the API token to register a network device.

Step 3 Under **Advanced**, configure the following optional settings:

- **DNSCrypt Public Key**—DNSCrypt authenticates and encrypts the DNS queries between the endpoint and the DNS server. To enable DNScrypt, you can configure the DNScrypt public key for certificate verification. The key is a 32-byte hexadecimal value and is preconfigured to B735:1140:206F:225d:3E2B:d822:D7FD:691e:A1C3:3cc8:D666:8d0c:BE04:bfab:CA43:FB79, which is the public key of the Umbrella Anycast servers.
- **Management Key**—A key to fetch datacenter details from Umbrella cloud for VPN policy.
- **Management Secret**—A secret used to fetch datacenters from Umbrella cloud for VPN.

Step 4 Click **Test Connection**—Test if the Cisco Umbrella Cloud is reachable from the Cloud-Delivered Firewall Management Center. When you provide the required organization ID and network device details, the umbrella connection is created.

Step 5 Click **Save**.

The Cisco Umbrella connection is configured and the device is ready to register with Cisco Umbrella using the specified credentials and settings.

Create an umbrella DNS policy

Create an Umbrella DNS policy to implement DNS-based security controls and filtering for network protection.

Umbrella DNS policies provide DNS security by blocking malicious domains and controlling access to web content through DNS filtering.

Before you begin

Follow these steps to create an Umbrella DNS policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 Click **Add DNS Policy** > **Umbrella DNS Policy**.

Step 3 Give the policy a unique **Name** and, optionally, a **Description**.

Step 4 Click **Save**.

The Umbrella DNS policy is created and ready for configuration with DNS security rules.

What to do next

Configure the policy. See Edit Umbrella DNS policies and rules, on page 2579.

Edit Umbrella DNS policies and rules

Edit Umbrella DNS policies and rules to modify protection policies, configure bypass domains, enable DNSCrypt encryption, and adjust connection timeout settings to meet your organization's specific DNS security requirements.

Use this procedure when you need to modify existing Umbrella DNS policies and their associated rules. You can update protection policy settings, configure local domain bypasses, enable encryption options, and adjust timeout parameters to optimize DNS security for your network environment.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **DNS**.

Step 2 In the DNS Policy page, select the Umbrella DNS policy that you want to edit and click **Edit** ( ).

Refresh the Umbrella Protection Policy

If you want to get the latest Umbrella Protection Policy from Cisco Umbrella, click the **Refresh** icon next to **Umbrella Protection Policy Last Updated**.

To configure or modify Umbrella Connection settings for the Management Center, go to **Integration** > **Other Integrations** > **Cloud Services** Choose the **Cisco Umbrella Connection**.

Step 3 In the Umbrella DNS policy editor, select the Umbrella DNS rule and click **Edit** ( ).

Step 4 Configure the rule components, or accept the defaults:

- **Umbrella Protection Policy**—Specify the name of the Cisco Umbrella policy to apply to the device.
- **Bypass Domain**—Specify the name of the local domains for which DNS requests should bypass Cisco Umbrella and instead go directly to the configured DNS servers.

  For example, you can have your internal DNS server resolve all names for the organization's domain name on the assumption that all internal connections are allowed.
- **DNSCrypt**— Enable DNSCrypt to encrypt connections between the device and Cisco Umbrella.

  Enabling DNScrypt starts the key-exchange thread with the Umbrella resolver. The key-exchange thread performs the handshake with the resolver every hour and updates the device with a new secret key. As DNScrypt uses UDP/443, you must ensure that the class map used for DNS inspection includes that port. Note that the default inspection class already includes UDP/443 for DNS inspection.
- **Idle Timeout**—Configure the idle timeout after which a connection from a client to the Umbrella server will be removed if there is no response from the server.

Step 5 Click **Save**.

Your Umbrella DNS policy and rule modifications are saved and ready to be deployed. The updated settings will take effect when the policy is applied to devices.

What to do next

Associate the Umbrella DNS policy with an access control policy. For more information, see Associate the umbrella DNS policy with an access control policy, on page 2580.

Associate the umbrella DNS policy with an access control policy

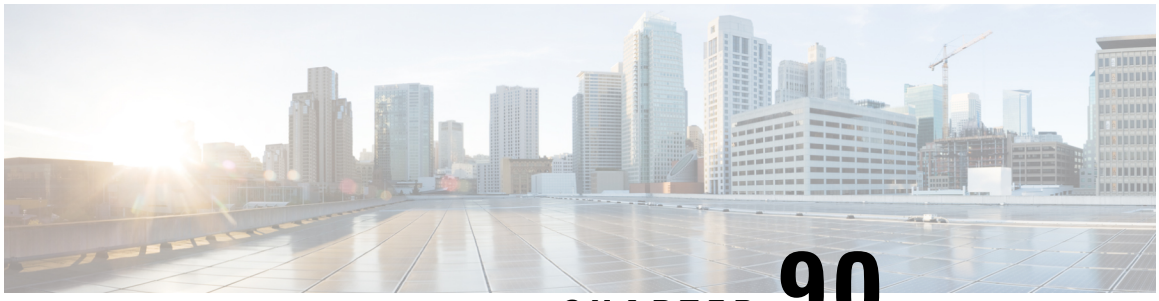
This task associates an Umbrella DNS policy with an access control policy to enable DNS-based security intelligence filtering before deploying the policy on the device.

Before you deploy the Umbrella DNS policy on the device, you must associate it with an access control policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control** and select the access policy to edit.

Step 2 Select **Security Intelligence**.



Step 3 From the **Umbrella DNS Policy** drop-down list, select the Umbrella DNS policy.

Step 4 Click **Save**.

The Umbrella DNS policy is now associated with the access control policy and will provide DNS-based security intelligence filtering when deployed.

What to do next

Deploy configuration changes; see Deploy configuration changes, on page 202.

CHAPTER 90

File Policies for Network Malware Protection

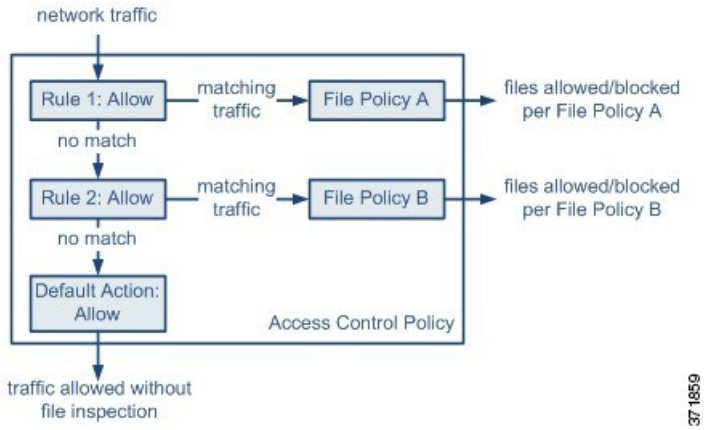
The following topics provide an overview of file control, file policies, file rules, Advanced Malware Protection (AMP), cloud connections, and dynamic analysis connections.

- Network malware protection and file policies, on page 2583
- Prerequisites for file policies, on page 2584
- License requirements for file and malware policies, on page 2585
- Best practices for file policies and malware detection, on page 2585
- Configure malware protection, on page 2589
- Cloud connections for malware protection, on page 2594
- File policies and file rules, on page 2597
- Retrospective disposition changes, on page 2613
- File and malware inspection performance and storage options, on page 2613
- Tune file and malware inspection performance and storage, on page 2615
- (Optional) Malware protection with Secure Endpoint, on page 2615

Network malware protection and file policies

Advanced Malware Protection (AMP) for Firepower can detect, capture, track, analyze, log, and optionally block the transmission of malware in network traffic. In the Cloud-Delivered Firewall Management Center web interface, this feature is called malware defense, formerly called AMP for Firepower. Advanced Malware Protection identifies malware using managed devices deployed inline and threat data from the Cisco cloud.

You associate file policies with access control rules that handle network traffic as part of your overall access control configuration.



When the system detects malware on your network, it generates file and malware events. To analyze file and malware event data, see the *File/Malware Events and Network File Trajectory* chapter in the *Cisco Secure Firewall Management Center Administration Guide* .

File policies

A file policy is a set of configurations that the system uses to perform malware protection and file control, as part of your overall access control configuration. This association ensures that before the system passes a file in traffic that matches an access control rule's conditions, it first inspects the file. Consider the following diagram of a simple access control policy in an inline deployment.

File policy traffic flow

Consider this diagram of a simple access control policy in an inline deployment.

The policy has two access control rules, both of which use the Allow action and are associated with file policies. The policy's default action is also to allow traffic, but without file policy inspection. In this scenario, traffic is handled as follows:

- Traffic that matches `Rule 1` is inspected by `File Policy A`.
- Traffic that does not match `Rule 1` is evaluated against `Rule 2`. Traffic that matches `Rule 2` is inspected by `File Policy B`.
- Traffic that does not match either rule is allowed; you cannot associate a file policy with the default action.

By associating different file policies with different access control rules, you have granular control over how you identify and block files transmitted on your network.

Prerequisites for file policies

This reference lists the prerequisites necessary for implementing file policies in your network security deployment.

Model support

Any

Secure Firewall 200 supports Malware Analysis through AMP Cloud Lookup only. It does not support the storing of files or the submission of files for analysis. This includes Spero, Local Malware Analysis, File Capture, and Clam AV. Any unsupported feature configured in a policy is automatically turned off when deployed to the device.

Supported domains

Any

User roles

- Admin
- Access Admin

License requirements for file and malware policies

This reference provides the specific license requirements needed to implement various file rule actions and malware detection capabilities in file and malware policies.

To Do This	License Required	File Rule Action
Block or allow all files of a particular type (for example, block all .exe files)	IPS (for Firewall Threat Defense devices) Protection (for Classic devices)	Allow, Block, Block with Reset
Selectively allow or block files based on a judgment that it contains or is likely to contain malware	IPS (for Firewall Threat Defense devices) Protection (for Classic devices) Malware Defense	Malware Cloud Lookup, Block Malware
Store files	IPS (for Firewall Threat Defense devices) Protection (for Classic devices) Malware Defense	Any file rule action with **Store Files** selected

For details about Malware Defense licenses, refer to:

- *Malware Defense Licenses* in the *Cisco Secure Firewall Management Center Administration Guide*

Best practices for file policies and malware detection

In addition to the items described below, follow the steps in Configure malware protection, on page 2589 and referenced topics.

File rule best practices

Consider these guidelines and limitations when configuring file rules:

Prerequisites

- You cannot perform malware analysis on all file types detected by the system. After you select values from the **Application Protocol**, **Direction of Transfer**, and **Action** drop-down lists, the system constrains the list of file types.
- If a file rule is configured with a **Malware Cloud Lookup** or **Block Malware** action and the Cloud-Delivered Firewall Management Center cannot establish connectivity with the AMP cloud, the system cannot perform any configured rule action options until connectivity is restored.

General file rule best practices

- A rule configured to block files in a passive deployment does not block matching files. Because the connection continues to transmit the file, if you configure the rule to log the beginning of the connection, you may see multiple events logged for this connection.
- A policy can include multiple rules. When you create the rules, ensure that no rule is "shadowed" by a previous rule.
- Cisco recommends that you enable **Reset Connection** for the **Block Files** and **Block Malware** actions to prevent blocked application sessions from remaining open until the TCP connection resets. If you do not reset connections, the client session will remain open until the TCP connection resets itself.

Dynamic Analysis

- The file types supported for dynamic analysis are a subset of the file types supported for other types of analysis. To view the file types supported for each type of analysis, navigate to the file rule configuration page, select the **Block Malware** action, and select the checkboxes of interest.

  To ensure that the system examines all file types, create separate rules (within the same policy) for dynamic analysis and for other types of analysis.
- If you are monitoring high volumes of traffic, do **not** store all captured files, or submit all captured files for dynamic analysis. Doing so can negatively impact system performance.

File detection best practices

Consider these notes and limitations when implementing file detection:

Prerequisite

If adaptive profiling is not enabled, access control rules cannot perform file control, including AMP.

General file detection best practices

- If a file matches a rule with an application protocol condition, file event generation occurs after the system successfully identifies a file's application protocol. Unidentified files do not generate file events.
- To detect ISO files, set the "Limit the number of bytes inspected when doing file type detection" option to a value greater than 36870, as described in File and malware inspection performance and storage options, on page 2613.
- .Exe files inside some .rar archives cannot be detected, including possibly rar5.

- If the file disposition is Neutral, it is an unknown disposition.

FTP-Specific considerations

- FTP transfers commands and data over different channels. In a passive or inline tap mode deployment, the traffic from an FTP data session and its control session may not be load-balanced to the same internal resource.

Email protocols considerations

- If the total number of bytes for all file names for files in a POP3, POP, SMTP, or IMAP session exceeds 1024, file events from the session may not reflect the correct file names for files that were detected after the file name buffer filled.
- When transmitting text-based files over SMTP, some mail clients convert newlines to the CRLF newline character standard. Since Mac-based hosts use the carriage return (CR) character and Unix/Linux-based hosts use the line feed (LF) character, newline conversion by the mail client can modify the size of the file. Note that some mail clients default to newline conversion when processing an unrecognizable file type.

File blocking best practices

Consider these notes and limitations for file blocking:

HTTP transfers

- File rules with **Block Files** and **Block Malware** actions block automatic resumption of file download via HTTP by blocking new sessions with the same file, URL, server, and client application detected for 24 hours after the initial file transfer attempt occurs.
- In rare cases, if traffic from an HTTP upload session is out of order, the system cannot reassemble the traffic correctly and therefore will not block it or generate a file event.

End-of-File detection

- If an end-of-file marker is not detected for a file, regardless of transfer protocol, the file will not be blocked by a **Block Malware** rule or the custom detection list. The system waits to block the file until the entire file has been received, as indicated by the end-of-file marker, and blocks the file after the marker is detected.
- If the end-of-file marker for an FTP file transfer is transmitted separately from the final data segment, the marker will be blocked and the FTP client will indicate that the file transfer failed, but the file will actually completely transfer to disk.

SMB or NetBIOS-ssn transfers

- If you transfer a file over NetBIOS-ssn (such as an SMB file transfer) that is blocked with a **Block Files** rule, you may see a file on the destination host. However, the file is unusable because it is blocked after the download starts, resulting in an incomplete file transfer.

- If you create file rules to detect or block files transferred over NetBIOS-ssn (such as an SMB file transfer), the system does not inspect the ongoing file transfers. However, the system inspects the new files that are transferred after you deploy an access control policy invoking the file policy.
- SMB has a functionality called multi-channel which creates multiple parallel sessions with the same IP address and different ports. For a given transaction over multi-channel, the file download is multiplexed across these sessions which is not inspected by the system as a single file.
- Files transferred concurrently in a single TCP or SMB session are not inspected.
- In a cluster environment, if an existing SMB session is moved to a new device due to a cluster role change or a device failure, then the files in any ongoing file transfers may not be inspected.
- Some SMB file transfers between Microsoft Windows systems use very high TCP window size for quick file transfers. To detect or block such file transfers, it is recommended that you increase the value of **Maximum Queued Bytes** and **Maximum Queued Segments** under **Network Analysis Policy** > **TCP Stream Configuration** > **Troubleshooting Options**.

High availability

If you configure Firewall Threat Defense high availability, and failover occurs while the original active device is identifying the file, the file type is not synced. Even if your file policy blocks that file type, the new active device downloads the file.

File policy best practices

Follow these best practices for file policy configuration to ensure proper functionality and optimal performance.

Prerequisites

- For file blocking to work, the NAP policy you apply to the access control policy must be operating in Protection mode, also known as Inline mode.
- You can associate a single file policy with an access control rule whose action is **Allow**, **Interactive Block**, or **Interactive Block with reset**.
- You **cannot** use a file policy to inspect traffic handled by the access control default action.

Encrypted traffic

By default, file inspection of encrypted payloads is disabled. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has file inspection configured.

Attention The File Inpsect preprocessor with the following generator IDs (GIDs) are enabled by default for file/malware policy: GID: 146 and GID: 147.

General file policy best practices

- For a new policy, the web interface indicates that the policy is not in use. If you are editing an in-use file policy, the web interface tells you how many access control policies use the file policy. In either case, you can click the text to jump to the Access Control Policies page.

- Based on your configuration, you can either inspect a file the first time the system detects it, and wait for a cloud lookup result, or pass the file on this first detection without waiting for the cloud lookup result.
- If you enable an access control policy with a file policy that uses either a Malware action or a Store Files option, the computing power and system performance of the device is reduced.
- NEW_OFFICE file type in file policy configuration identifies Microsoft files: DOCX, XLSX, and PPTX. When you apply a policy action to NEW_OFFICE, the action applies uniformly to all three file types—DOCX, XLSX, and PPTX.

  If your security requirements need differentiated handling of Office file formats, such as blocking DOCX documents while permitting XLSX spreadsheets, do not use the NEW_OFFICE aggregate file type. Instead, perform these steps:

  1. Select individual file types (DOCX, XLSX, PPTX) separately in your file policy rule.
  2. Create separate rules with distinct actions for each format you need to control granularly.
  3. Test your policy to ensure each Office format is handled according to your security intent.

  This approach ensures that your file policy aligns with your organization's security posture and prevents unintended blocking of legitimate business traffic.

Configure malware protection

You need to set up your system to protect your network from malicious software by following a series of configuration steps.

Procedure

Step 1 Plan and prepare for malware protection, on page 2590

Step 2 Configure file policies, on page 2591

Step 3 Add file policies to your access control configuration, on page 2591

Step 4 Configure network discovery policies to associate file and malware events with hosts on your network.

(Do not simply turn on network discovery; you must configure it to discover hosts on your network to build a network map of your organization.)

See Network Discovery Policies and subtopics.

Step 5 Deploy policies to managed devices.

See Deploy configuration changes, on page 202.

Step 6 Test your system to be sure it is processing malicious files as you expect it to.

Step 7 Verify and monitor malware protection, on page 2593

What to do next

- (Optional) To further enhance detection of malware in your network, deploy and integrate Cisco's Secure Endpoint product. Refer to (Optional) Malware protection with Secure Endpoint, on page 2615 and subtopics.

Plan and prepare for malware protection

This procedure is the first set of steps in the complete process for configuring your system to provide malware protection.

Procedure

Step 1 Purchase and install licenses.

Refer to License requirements for file and malware policies, on page 2585 and *Licenses* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 2 Understand how file policies and malware protection fit into your access control plan.

Refer to the chapter Access Control Policies, on page 1997.

Step 3 Understand the file analysis and malware protection tools.

Refer to File rule actions, on page 2604 and subtopics.

Consider also Advanced and archive file inspection options, on page 2598.

Step 4 Determine whether you will use public clouds or private (on-premises) clouds for malware protection (file analysis and dynamic analysis.)

Refer to Cloud connections for malware protection, on page 2594 and subtopics.

Step 5 If you will use private (on-premises) clouds for malware protection: Purchase, deploy, and test those products.

For information, contact your Cisco sales representative or authorized reseller.

Step 6 Configure your firewall to allow communications with your chosen clouds.

Refer to *Security, Internet Access, and Communication Ports* in the *Cisco Secure Firewall Management Center Administration Guide*.

Step 7 Configure connections between Firepower and the malware protection clouds (public or private, as applicable).

What to do next

Continue with the next step in the malware protection workflow:

Refer to Configure malware protection, on page 2589.

Configure file policies

File policies are a critical component of the malware protection workflow that allow you to define specific rules and advanced options for file inspection and handling.

Before you begin

Complete the tasks up to this point in the malware protection workflow:

Refer to Configure malware protection, on page 2589.

Procedure

Step 1 Review file policy and file rule restrictions.

Refer to Best practices for file policies and malware detection, on page 2585 and subtopics.

Step 2 Create a file policy.

Refer to Create or edit a file policy, on page 2597.

Step 3 Create rules within your file policy.

Refer to File rules, on page 2602 and subtopics.

Step 4 Configure advanced options.

Refer to Advanced and archive file inspection options, on page 2598.

What to do next

Continue with the next step in the malware protection workflow:

Refer to Configure malware protection, on page 2589.

Add file policies to your access control configuration

An access control policy can have multiple access control rules associated with file policies. You can configure file inspection for any Allow or Interactive Block access control rule, which permits you to match different file and malware inspection profiles against different types of traffic on your network before it reaches its final destination.

Before you begin

Complete the tasks up to this point in the malware protection workflow:

See Configure malware protection, on page 2589.

Procedure

Step 1 Review guidelines for file policies in access control policies. (These are different from the file rule and file policy guidelines.)

Review File and intrusion inspection order, on page 2050.

Step 2 Associate the file policy with an access control policy.

Refer to Configure an access control rule to perform malware protection, on page 2592

Step 3 Assign the access control policy to managed devices.

See Assign access control policy to devices, on page 2014.

What to do next

Continue with the next step in the malware protection workflow:

Refer to Configure malware protection, on page 2589.

Configure an access control rule to perform malware protection

Access control rules with file policies provide comprehensive malware protection by inspecting traffic flows and applying security analysis to files traversing your network.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Note Inline normalization is enabled automatically when a file policy is included in an access control rule. For more information, refer to The Inline Normalization Preprocessor.

Before you begin

- Adaptive profiling **must** be enabled (its default state) for access control rules to perform file control, including AMP.
- You must be an Admin, Access Admin, or Network Admin user to perform this task.

Procedure

Step 1 In the access control rule editor (from **Policies > Access Control)**, choose an **Action** of **Allow**, **Interactive Block**, or **Interactive Block with reset**.

Step 2 Choose a **File Policy** to inspect traffic that matches the access control rule, or choose **None** to disable file inspection for matching traffic.

Step 3 (Optional) Disable logging of file or malware events for matching connections by clicking **Logging** and unchecking **Log Files**.

Note
Cisco recommends that you leave file and malware event logging enabled.

Step 4 Save the rule.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Verify and monitor malware protection

Ongoing maintenance is essential for protecting your network.

Before you begin

Configure your system to protect your network from malware.

Refer to Configure malware protection, on page 2589 and referenced procedures.

Procedure

Step 1 Ensure that your system always has the most current and effective protection.

Refer to Maintain your system: file types eligible for dynamic analysis, on page 2596.

Step 2 Configure alerts for malware-related events and health monitoring.

See the *Cisco Secure Firewall Management Center Administration Guide* for information on *Configuring malware defense Alerting* and for information about the following modules:

- Local Malware Analysis
- Security Intelligence
- Threat Data Updates on Devices
- Intrusion and File Event Rate
- AMP for Firepower Status

- Secure Endpoint Status

What to do next

Review "What to do next items" in the malware protection workflow:

Refer to Configure malware protection, on page 2589.

Cloud connections for malware protection

Connections to public or private clouds are required in order to protect your network from malware.

AMP clouds

The Advanced Malware Protection (AMP) cloud is a Cisco-hosted server that uses big data analytics and continuous analysis to provide intelligence that the system uses to detect and block malware on your network.

The AMP cloud provides dispositions FOR possible malware detected IN network traffic by managed devices, as well as data updates FOR local malware analysis and file pre-classification.

If your organization has deployed Secure Endpoint and configured Firepower to import its data, the system imports this data from the AMP cloud, including scan records, malware detections, quarantines, and indications of compromise (IOC).

Cisco offers these options for obtaining data from the Cisco cloud about known malware threats:

- **AMP public cloud**: Your Cloud-Delivered Firewall Management Center communicates directly with the public Cisco cloud. There are three public AMP clouds, in the United States, Europe, and Asia.

Dynamic analysis cloud

Dynamic analysis cloud options include:

- Secure Malware Analytics Cloud: Public cloud that processes eligible files that you send for dynamic analysis, and provides threat scores and dynamic analysis reports. Firepower supports 200 samples/day FOR Secure Malware Analytics analysis.

AMP cloud connection configurations

Change AMP options

Use this procedure to modify AMP (Advanced Malware Protection) for Networks configuration settings that control automatic signature updates and data sharing with the Cisco cloud.

Procedure

Step 1 Choose **Integration** > **Other Integrations** > **Cloud Services**.

Step 2 Configure these parameters:

Table 138: AMP for networks options

Option	Description
Enable Automatic Local Malware Detection Updates	The local malware detection engine statically analyzes and preclassifies files using signatures provided by Cisco. If you enable this option, the Cloud-Delivered Firewall Management Center checks for signature updates once every 30 minutes.
Share URI from Malware Events with Cisco	The system can send information about the files detected in network traffic to the AMP cloud. This information includes URI information associated with detected files and their SHA-256 hash values. Although sharing is opt-in, transmitting this information to Cisco helps future efforts to identify and track malware.

Step 3 Click **Save**.

Dynamic analysis connections

Dynamic analysis connections are network connections that enable real-time security analysis and threat detection capabilities.

Prerequisites for dynamic analysis

This topic lists the prerequisites to use dynamic analysis.

- You must be an Admin, Access Admin, or Network Admin user, and be in the global domain, to use dynamic analysis.
- With the appropriate license, the system automatically has access to the Secure Malware Analytics Cloud.
- Dynamic analysis requires that managed devices have direct or proxied access to the Secure Malware Analytics Cloud or an on-premises Secure Malware Analytics Appliance on port 443.
- See also Files eligible for dynamic analysis, on page 2609.
-

View the default dynamic analysis connection

By default, the Cloud-Delivered Firewall Management Center can connect to the public Secure Malware Analytics Cloud for file submission and report retrieval. You can neither configure nor delete this connection.

Procedure

Step 1 Choose **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 You can view the cloud in use on the default dynamic analysis connection. To associate the device, click **Associate** ( ). For more information, refer to Enable access to dynamic analysis results in the public cloud, on page 2596.

Enable access to dynamic analysis results in the public cloud

Secure Malware Analytics offers more detailed reporting on analyzed files than is available in the Cloud-Delivered Firewall Management Center. If your organization has a Secure Malware Analytics Cloud account, you can access the Secure Malware Analytics portal directly to view additional details about files sent for analysis from your managed devices. However, for privacy reasons, file analysis details are available only to the organization that submitted the files. Therefore, before you can view this information, you must associate your Cloud-Delivered Firewall Management Center with the files submitted by its managed devices.

Before you begin

You must have a Secure Malware Analytics Cloud account, and have your account credentials ready.

Procedure

Step 1 Select **Integration** > **AMP** > **Dynamic Analysis ConnectionsAMP** > **Dynamic Analysis Connections**.

Step 2 Click **Associate** ( ) in the table row corresponding to the Secure Malware Analytics Cloud.

A Secure Malware Analytics portal window opens.

Step 3 Sign in to the Secure Malware Analytics Cloud.

Step 4 Click **Submit Query**.

Note
Do not change the default value in the **Devices** field.

If you have difficulties with this process, contact your Secure Malware Analytics representative at Cisco TAC.

It may take up to 24 hours for this change to take effect.

What to do next

After the association is activated, refer to *Viewing Dynamic Analysis Results in the Cisco Cloud* in the *Cisco Secure Firewall Management Center Administration Guide*.

Maintain your system: file types eligible for dynamic analysis

The list of file types eligible for Dynamic Analysis is determined by the vulnerability database (VDB), which is updated periodically (but no more than once per day.) If you are an Admin user, you can update file types eligible for dynamic analysis.

The supported file types for automatic submission can vary in every release. The currently supported files for automatic submission are:

- PE Executable (32-bit Only)

- EXE
- DLL
- PDF
- MSOLE2 (Microsoft Object Linking and Embedding Compound File)
- DOCX, PPTX, XLSX

Note GZ and ZIP file types are not supported for automatic submission.

Procedure

Step 1 Do one of the following:

- (Recommended) Refer to *Vulnerability Database Update Automation* as discussed in the *Cisco Secure Firewall Management Center Administration Guide*
- Regularly check for new VDB updates, and *Manually Update the VDB* as discussed in the *Cisco Secure Firewall Management Center Administration Guide* when needed.

  If you choose this option, we recommend that you schedule regular reminders to do this.

Step 2 If your file policies specify individual file types instead of the **Dynamic Analysis Capable** file type category, update your file policies to use the newly supported file types.

Step 3 If the list of eligible file types changes, deploy to managed devices.

File policies and file rules

File policies and file rules work together to control file handling and inspection in network traffic.

Create or edit a file policy

File policies allow you to control file transfers and provide malware protection by defining rules that specify which files can be transferred, blocked, or inspected for threats.

Before you begin

If you are configuring policies for malware protection, refer to all required procedures in Configure file policies, on page 2591.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Create a new policy, or edit an existing policy.

If you are editing an existing policy: If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Tip

To make a copy of an existing file policy, click **Copy** ( ), then type a unique name for the new policy in the dialog box that appears. You can then modify the copy.

Step 3 Add one or more rules to the file policy as described in Create file rules, on page 2611.

Step 4 Optionally, select Advanced and configure advanced options as described in Advanced and archive file inspection options, on page 2598.

Step 5 Save the file policy.

What to do next

- If you are configuring policies for malware protection, see other required procedures in Configure file policies, on page 2591.
- Otherwise:
  - Add the file policy to an access control rule as described in Add file policies to your access control configuration, on page 2591.
  - Deploy configuration changes.

Advanced and archive file inspection options

The Advanced Settings in the file policy editor provides general options for file analysis and archive file inspection to enhance security policy configuration.

The Advanced Settings in the file policy editor has these general options:

- **First Time File Analysis**—Select this option to analyze first-seen files while AMP cloud disposition is pending. The file must match a rule configured to perform a malware cloud lookup and Spero, local malware, or dynamic analysis. If you deselect this option, files detected for the first time are marked with an Unknown disposition
- **Enable Custom Detection List**—Block files on the custom detection list.
- **Enable Clean List**—If enabled, this policy will allow files that are on the clean list.
- **If AMP Cloud disposition is Unknown, override disposition based upon threat score**—Select an option:
  - If you select **Disabled,** the system will not override the disposition provided by the AMP Cloud.

- If you set a threshold threat score, files with an AMP cloud verdict of Unknown are considered malware if their Dynamic Analysis score is equal to or worse than the threshold.
- If you select a lower threshold value, you increase the number of files treated as malware. Depending on the action selected in your file policy, this can result in an increase of blocked files.

The Advanced Settings in the file policy editor has these archive file inspection options:

- **Inspect Archives**—Enables inspection of the contents of archive files, for archive files as large as the **Maximum file size to store** advanced access control setting.
- **Block Encrypted Archives**—Blocks password-protected archives.
- **Block Uninspectable Archives**—Blocks archive files with contents that the system is unable to inspect for reasons other than encryption. This usually applies to corrupted files, or those that exceed your specified maximum archive depth.
- **Max Archive Depth**—Blocks nested archive files that exceed the specified depth. The top-level archive file is not considered in this count; depth begins at 1 with the first nested file.

Archive files

Archive files are files that contain other files, such as `.zip` or `.rar` files.

If any individual file in an archive matches a file rule with a block action, the system blocks the entire archive, not just the individual file.

Archive file inspection capabilities

The system provides various options for inspecting archive files.

- **File types**: A complete list of inspectable archive file types appears in the Cloud-Delivered Firewall Management Center web interface on the file rule configuration page. To view that page, see Create file rules, on page 2611. Contained files that can be inspected appears in the same page.
- **File size**: You can inspect archive files as large as the **Maximum file size to store** file policy advanced access control setting.
- **Nested archives**: Archive files can contain other archive files, which can in turn contain archive files. The level at which a file is nested is its *archive file depth*. Note that the top-level archive file is not included in the depth count; depth begins at 1 with the first nested file. The system can inspect up to three levels of nested files beneath the outermost archive file (level 0). You can configure your file policy to block archive files that exceed that depth (or a lower maximum depth that you specify). If you choose not to block files that exceed the maximum archive file depth of 3, when archive files that contain some extractable contents and some contents nested at a depth of 3 or greater appear in monitored traffic, the system examines and reports data only for the files it was able to inspect. All features applicable to uncompressed files (such as dynamic analysis and file storage) are available for nested files inside archive files.
- **Encrypted files**: You can configure the system to block archives whose contents are encrypted or otherwise cannot be inspected.
- **Archives that are not inspected**: If traffic that contains an archive file is on a Security Intelligence Block list or Do Not Block list, or if the top-level archive file's SHA-256 value is on the custom detection list, the system does not inspect the contents of the archive file. If a nested file is blocked, the entire archive is blocked; however, if a nested file is allowed, the archive is not automatically passed (depending

on any other nested files and characteristics). .Exe files inside some .rar archives cannot be detected, including possibly rar5.

For details about options for archive file inspection, see Advanced and archive file inspection options, on page 2598.

Archive file dispositions

Archive file dispositions are based on the dispositions assigned to the files inside the archive. All archives that contain identified malware files receive a disposition of `Malware`. Archives without identified malware files receive a disposition of `Unknown` if they contain any unknown files, and a disposition of `Clean` if they contain only clean files.

Table 139: Archive file disposition by contents

Archive File Disposition	Number of Unknown Files	Number of Clean Files	Number of Malware Files
`Unknown`	1 or more	Any	0
`Clean`	0	1 or more	0
`Malware`	Any	Any	1 or more

Archive files, like other files, may have dispositions of `Custom Detection` or `Unavailable` if the conditions for those dispositions apply.

Archive contents and details

If your file policy is configured to inspect archive file contents, you can use the context menu in a table on pages under the Analysis > Files menu, and the network file trajectory viewer to view information about the files inside an archive when the archive file appears in a file event, malware event, or as a captured file.

All file contents of the archive are listed in table form, with a short summary of their relevant information: name, SHA-256 hash value, type, category, and archive depth. A network file trajectory icon appears by each file, which you can click to view further information about that specific file.

Override file disposition using custom lists

Override file disposition using custom lists is a security mechanism that

- allows administrators to correct incorrect file dispositions from the AMP cloud by adding SHA-256 values to specific file lists
- enables treating files as clean or malware regardless of the original cloud disposition, and
- provides per-file policy control without reevaluating the file's disposition on subsequent detection.

File list types and usage

If a file has a disposition in the AMP cloud that you know to be incorrect, you can add the file's SHA-256 value to a file list that overrides the disposition from the cloud:

- To treat a file as if the AMP cloud assigned a clean disposition, add the file to the *clean list*.

- To treat a file as if the AMP cloud assigned a malware disposition, add the file to the *custom detection list*.

On subsequent detection, the device either allows or blocks the file without reevaluating the file's disposition. You can use the clean list or custom detection list per file policy.

Note To calculate a file's SHA-256 value, you must configure a rule in the file policy to either perform a malware cloud lookup or block malware on matching files.

For complete information about using file lists in Firepower, refer to File lists, on page 2973.

Alternatively, if applicable, use Centralized file lists from Secure Endpoint, on page 2601.

Centralized file lists from Secure Endpoint

If your organization has deployed Secure Endpoint, Firepower can use Block and Allow lists created in Secure Endpoint when it queries the AMP cloud for file dispositions.

Requirements for centralized file lists

Your deployment must meet these requirements:

- Your organization must be using the AMP public cloud.
- Your organization has deployed Secure Endpoint.
- You have registered your system to Secure Endpoint using the procedure in Integrate Firepower and Secure Endpoint, on page 2618.

To create and deploy these lists, refer to the documentation or online help for Secure Endpoint.

Note File lists created in Firepower override file lists created in Secure Endpoint.

Manage file policies

The **File Policies** page displays a list of existing file policies along with their last-modified dates. You can use this page to manage your file policies.

Note The system checks for updates to the list of file types eligible for dynamic analysis (no more than once a day). If the list of eligible file types changes, this constitutes a change in the file policy; any access control policy using the file policy is marked out-of-date if deployed to any devices. You must deploy policies before the updated file policy can take effect on the device. See Maintain your system: file types eligible for dynamic analysis, on page 2596.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Manage your file policies:

- Compare—Click **Compare Policies**; see Comparing policies.
- **Create**— To create a file policy, click **New File Policy** and proceed as described in Create or edit a file policy, on page 2597.
- **Copy**— To copy a file policy, click **Copy** ( ).

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- **Delete**— If you want to delete a file policy, click **Delete** ( ), then click **Yes** and **OK** as prompted.

  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Deploy—Choose **Deploy** > **Deploy**; see Deploy configuration changes, on page 202.
- **Edit**— If you want to modify an existing file policy, click **Edit** ( ).
- **Report**—Click **Report**( ); Refer to Generate current policy reports, on page 220.

File rules

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

File rule actions

When a file matches a rule, the rule can:

- allow or block files based on simple file type matching
- block files based on disposition (whether or not evaluation indicates that it is malicious)
- store files to the device (For information, see Captured files and file storage, on page 2609)
- submit stored (captured) files for local malware, Spero, or dynamic analysis

In addition, the file policy can:

- automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list
- treat a file as if it is malware if the file's threat score exceeds a configurable threshold

- inspect the contents of archive files (such as `.zip` or `.rar`)
- block archive files whose contents are encrypted, nested beyond a specified maximum archive depth, or otherwise uninspectable

File rule components

File rules consist of several components that determine how the system detects and handles files transmitted over various application protocols. Understanding these components helps configure effective file detection and inspection policies.

Table 140: File rule components

File Rule Component	Description
application protocol	The system can detect and inspect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB). **Any**, the default, detects files in HTTP, SMTP, IMAP, POP3, FTP, and NetBIOS-ssn (SMB) traffic. To improve performance, you can restrict file detection to only one of those application protocols on a per-file rule basis.
direction of transfer	You can inspect incoming FTP, HTTP, IMAP, POP3, and NetBIOS-ssn (SMB) traffic for downloaded files; you can inspect outgoing FTP, HTTP, SMTP, and NetBIOS-ssn (SMB) traffic for uploaded files. **Tip** Use **Any** to detect files over multiple application protocols, regardless of whether users are sending or receiving.
file categories and types	The system can detect various types of files. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. You can configure file rules that detect individual file types, or on entire categories of file types. For example, you could block all multimedia files, or just ShockWave Flash (swf) files. Or, you could configure the system to alert you when a user downloads a BitTorrent (torrent) file. Note that executables include file types that can run macros and scripts, since these can contain malware. For a list of file types the system can inspect, select **Policies** > **Access Control heading** > **Malware & File** , create a temporary new file policy, then click **Add Rule**. Select a file type category and the file types that the system can inspect appear in the **File Types** list. **Note** Frequently triggered file rules can affect system performance. For example, detecting multimedia files in HTTP traffic (YouTube, for example, transmits significant Flash content) could generate an overwhelming number of events.

File Rule Component	Description
file rule action	A file rule's action determines how the system handles traffic that matches the conditions of the rule. Depending on the selected action, you can configure whether the system stores the file or performs Spero, local malware, or dynamic analysis on a file. If you select a Block action, you can also configure whether the system also resets the blocked connection. For descriptions of these actions and options, see File rule actions, on page 2604. File rules are evaluated in rule-action, not numerical, order. For details, see File rule actions: evaluation order, on page 2611.

File rule actions

File rules give you granular control over which file types you want to log, block, or scan for malware. Each file rule has an associated action that determines how the system handles traffic that matches the conditions of the rule. To be effective, a file policy must contain one or more rules. You can use separate rules within a file policy to take different actions for different file types, application protocols, or directions of transfer.

File rule actions include these types:

- *Detect Files* rules allow you to log the detection of specific file types to the database, while still allowing their transmission.
- *Block Files* rules allow you to block specific file types. You can configure options to reset the connection when a file transfer is blocked, and store captured files to the managed device.
- *Malware Cloud Lookup* rules allow you to obtain and log the disposition of files traversing your network, while still allowing their transmission.
- *Block Malware* rules allow you to calculate the SHA-256 hash value of specific file types, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.

File rule action options

Depending on the action you select, you have different options:

File Rule Action Option	Block Files capable?	Block Malware capable?	Detect Files capable?	Malware Cloud Lookup capable?
Spero Analysis* for MSEXE	no	yes, you can submit executable files	no	yes, you can submit executable files
Dynamic Analysis*	no	yes, you can submit executable files with Unknown file dispositions	no	yes, you can submit executable files with Unknown file dispositions
Capacity Handling	no	yes	no	yes

File Rule Action Option	Block Files capable?	Block Malware capable?	Detect Files capable?	Malware Cloud Lookup capable?
Local Malware Analysis*	no	yes	no	yes
Reset Connection	yes (recommended)	yes (recommended)	no	no
Store files	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select

* For complete information about these options, refer to Malware protection options, on page 2605 and its subtopics.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Malware protection options

The system applies several methods of file inspection and analysis to determine whether a file contains malware.

File inspection sequence

Depending on the options you enable in a file rule, the system inspects files using these tools, in order:

1. Spero analysis, on page 2607 and AMP cloud lookup, on page 2607
2. Local malware analysis, on page 2608
3. Dynamic analysis, on page 2608

For a comparison of these tools, see Comparison of malware protection options, on page 2605.

(You can also, if you choose, block all files based on their file type. For more information, see Block all files by type, on page 2611.)

Refer to information about Cisco's Secure Endpoint product at (Optional) Malware protection with Secure Endpoint, on page 2615 and subtopics.

Comparison of malware protection options

This table details the benefits and drawbacks of each type of file analysis, as well as the way each malware protection method determines a file's disposition.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis	Structural analysis of executable files, submits Spero signature to the AMP Cloud for analysis	Less thorough than local malware analysis or dynamic analysis, only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.
Local malware analysis	Consumes fewer resources than dynamic analysis, and returns results more quickly, especially if the detected malware is common	Less thorough results than dynamic analysis	Disposition changes from Unknown to Malware only on positive identification of malware.
Dynamic analysis	Thorough analysis of unknown files using Secure Malware Analytics	Eligible files are uploaded to the public cloud or an on-premises appliance. It takes some time to complete analysis	Threat score determines maliciousness of a file. Disposition can be based on the threat score threshold configured in the file policy.
Spero analysis and local malware analysis	Consumes fewer resources than configuring local malware analysis and dynamic analysis, while still using AMP cloud resources to identify malware	Less thorough than dynamic analysis, Spero analysis only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.
Spero analysis and dynamic analysis	Uses full capabilities of AMP cloud in submitting files and Spero signatures	Results obtained less quickly than if using local malware analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes based on configured threat score threshold in the file policy, and from Unknown to Malware if the Spero analysis identifies malware.
Local malware analysis and dynamic analysis	Thorough results in using both types of file analysis	Consumes more resources than either alone	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if local malware analysis identifies malware, or based on configured threat score threshold in the file policy.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis, local malware analysis and dynamic analysis	Most thorough results	Consumes most resources in running all three types of file analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if Spero analysis or local malware analysis identifies malware, or based on configured threat score threshold in the file policy.
(Block transmission of all files of a specified file type)	Does not require a Malware Defense license (This option is not technically a malware protection option.)	Legitimate files will also be blocked	(No analysis is performed.)

Note Preclassification does not itself determine a file's disposition; it is merely one of the factors that determine whether a file is eligible for Dynamic Analysis.

Spero analysis

Spero analysis examines structural characteristics such as metadata and header information in executable files. After generating a Spero signature based on this information, if the file is an eligible executable file, the device submits it to the Spero heuristic engine in the AMP cloud. Based on the Spero signature, the Spero engine determines whether the file is malware. You can also configure rules to submit files for Spero analysis without also submitting them to the AMP cloud.

Note You cannot manually submit files for Spero analysis.

AMP cloud lookup

For files that are eligible for assessment using Advanced Malware Protection, the Cloud-Delivered Firewall Management Center performs a malware cloud lookup, querying the AMP cloud for the file's disposition based on its SHA-256 hash value.

Performance optimization

To improve performance, the system caches dispositions returned by the cloud and uses the cached disposition for known files rather than querying the AMP cloud. For more information about this cache, see Cached disposition longevity, on page 2608.

Local malware analysis

Local malware analysis allows a managed device to locally inspect executables, PDFs, office documents, and other types of files for the most common types of malware, using a detection rule set provided by the Talos Intelligence Group. Because local analysis does not query the AMP cloud, and does not run the file, local malware analysis saves time and system resources.

Local malware analysis behavior

When the system identifies malware through local malware analysis, it updates the existing file disposition from Unknown to Malware and generates a new malware event. If the system does not identify malware, it does not update the file disposition from Unknown to Clean.

After the system runs local malware analysis, it caches file information such as SHA-256 hash value, timestamp, and disposition, so that if detected again within a certain period of time, the system can identify malware without additional analysis. For more information about the cache, see Cached disposition longevity, on page 2608.

Local malware analysis does not require establishing communications with the Secure Malware Analytics Cloud. However, you must configure communications with the cloud to submit files for dynamic analysis, and to download updates to the local malware analysis ruleset.

Cached disposition longevity

Dispositions returned from an AMP cloud query, associated threat scores, and dispositions assigned by local malware analysis, have a time-to-live (TTL) value. After a disposition has been held for the duration specified in the TTL value without update, the system purges the cached information. Dispositions and associated threat scores have the following TTL values:

TTL values for dispositions and threat scores

Dispositions and associated threat scores have these TTL values:

- Clean — 4 hours
- Unknown — 1 hour
- Malware — 1 hour

If a query against the cache identifies a cached disposition that timed out, the system re-queries the local malware analysis database and the AMP cloud for a new disposition.

Dynamic analysis

Dynamic analysis is a security analysis method that

- automatically submits files for behavioral analysis using Secure Malware Analytics (formerly Threat Grid), Cisco's file analysis and threat intelligence platform,
- runs files in a sandbox environment to analyze behavior and determine maliciousness, and
- returns a threat score indicating the likelihood that a file contains malware.

Dynamic analysis process and capabilities

You can configure your file policy to automatically submit files for dynamic analysis using Secure Malware Analytics (formerly Threat Grid), Cisco's file analysis and threat intelligence platform.

Devices submit eligible files to Secure Malware Analytics (either the public cloud or to an on-premises appliance, whichever you have specified) regardless of whether the device stores the file.

Secure Malware Analytics runs the file in a sandbox environment, analyzes the file's behavior to determine whether the file is malicious, and returns a threat score that indicates the likelihood that a file contains malware. From the threat score, you can view a dynamic analysis summary report with the reasons for the assigned threat score. You can also look in Secure Malware Analytics to view detailed reports for files that your organization submitted, as well as scrubbed reports with limited data for files that your organization did not submit.

For more information about Cisco Secure Malware Analytics, refer to https://www.cisco.com/c/en/us/products/security/threat-grid/index.html

To configure your system to perform dynamic analysis, see the topics under Dynamic analysis connections, on page 2595.

Files eligible for dynamic analysis

A file's eligibility for dynamic analysis depends on the file type, the file size, and the file rule's action.

Additional requirements:

- The system submits only files that match the file rules you configure.
- The file must have a malware cloud lookup disposition of Unknown or Unavailable at the time the file is sent for analysis.
- The system must preclassify the file as potential malware.

Dynamic analysis and capacity handling

Capacity handling is a system feature that temporarily stores files that are otherwise eligible for dynamic analysis if the system is temporarily unable to submit files to the cloud, either because the device cannot communicate with the cloud or because the maximum number of submissions has been reached. The system submits the stored files when the hindering condition has passed.

Storage options

Some devices can store files on the device hard drive or in a malware storage pack. Refer Malware storage packs, on page 2610.

Captured files and file storage

The file storage feature allows you to capture selected files detected in traffic, and automatically store a copy of the file temporarily to a device’s hard drive, or, if installed, to the malware storage pack.

File capture and storage capabilities

After your device captures files, you can:

- Store captured files on the device's hard drive for later analysis.
- Download the stored file to a local computer for further manual analysis or archival purposes.
- Manually submit eligible captured files for AMP cloud lookup or dynamic analysis.

Note that once a device stores a file, it will not re-capture it if the file is detected in the future and the device still has that file stored.

Note When a file is detected for the first time on your network, you can generate a file event that represents the file's detection. However, if your file rule performs a malware cloud lookup, the system requires additional time to query the AMP cloud and return a disposition. Due to this delay, the system cannot store this file until the second time it is seen on your network, and the system can immediately determine the file's disposition.

Whether the system captures or stores a file, you can:

- Review information about the captured file from **Analysis** > **Unified Events**, including whether the file was stored or submitted for dynamic analysis, file disposition, and threat score, allowing you to quickly review possible malware threats detected on your network.
- View the file's trajectory to determine how it traversed your network and which hosts have a copy.
- Add the file to the clean list or custom detection list to always treat the file as if it had a clean or malware disposition on future detection.

You configure file rules in a file policy to capture and store files of a specific type, or with a particular file disposition, if available. After you associate the file policy with an access control policy and deploy it to your devices, matching files in traffic are captured and stored. You can also limit the minimum and maximum file sizes to store.

Stored files are not included in system backups.

Malware storage packs

A malware storage pack

- provides additional storage capacity for file data when installed in security devices
- allows the primary hard drive to store events and configuration files by dedicating the entire storage pack to captured files, and
- automatically receives stored files from the primary hard drive when installed on devices that already contain file data.

Storage allocation and file management

Based on your file policy configuration, your device may store a substantial amount of file data to the hard drive. You can install a malware storage pack in the device; the system stores files to the malware storage pack, allowing more room on the primary hard drive to store events and configuration files. The system periodically deletes older files. If the device's primary hard drive does not have enough available space, and does not have an installed malware storage pack, you cannot store files.

Caution Do not attempt to install a hard drive that was not supplied by Cisco in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase **only** from Cisco. Contact Support if you require assistance with the malware storage pack.

Without a malware storage pack installed, when you configure a device to store files, it allocates a set portion of the primary hard drive's space to captured file storage. If you configure capacity handling to temporarily

store files for dynamic analysis, the system uses the same hard drive allocation to store these files until it can resubmit them to the cloud.

When you install a malware storage pack in a device and configure file storage or capacity handling, the device allocates the entire malware storage pack for storing these files. The device cannot store any other information on the malware storage pack.

When the allocated space for captured file storage fills to capacity, the system deletes the oldest stored files until the allocated space reaches a system-defined threshold. Based on the number of files stored, you may see a substantial drop in disk usage after the system deletes files.

If a device has already stored files when you install a malware storage pack, the next time you restart the device, any captured files or capacity handling files stored on the primary hard drive are moved to the malware storage pack. Any future files the device stores are stored to the malware storage pack.

For more information on using MSP on the Firepower devices, see the Firepower Hardware Installation Guide for your device.

Block all files by type

If your organization wants to block not only the transmission of malware files, but all files of a specific type, regardless of whether the files contain malware, you can do so.

File type categories and licensing

File control is supported for all file types where the system can detect malware, plus many additional file types. These file types are grouped into basic categories, such as multimedia (swf, mp3), executables (exe, torrent), and PDFs.

Blocking all files based on their type is not technically a malware protection feature; it does not require a Malware Defense license and does not query the AMP cloud.

File rule actions: evaluation order

A file policy will likely contain multiple rules with different actions for different situations. If more than one rule can apply to a particular situation, the evaluation order described in this topic applies. In general, simple blocking takes precedence over malware inspection and blocking, which takes precedence over simple detection and logging.

The order of precedence of file-rule actions is:

- *Block Files*
- *Block Malware*
- *Malware Cloud Lookup*
- *Detect Files*

Create file rules

Use this procedure when you need to add file rules to an existing file policy to control file handling and security actions.

Caution Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Before you begin

If you are configuring rules for malware protection, refer to Configure file policies, on page 2591.

Procedure

Step 1 Select **Policies** > **Access Control heading** > **Malware & File** .

Step 2 Click the edit icon to modify an existing file policy.

Step 3 In the file policy editor, click **Add Rule**.

Step 4 Select an **Application Protocol** and **Direction of Transfer** as described in File rule components, on page 2603.

Step 5 Select one or more **File Types**.

The file types you see depend on the selected application protocol, direction of transfer, and action.

You can filter the list of file types in these ways:

- Select one or more **File Type Categories**, then click **All types in selected Categories.**
- Search for a file type by its name or description. For example, type `Windows` in the **Search name and description** field to display a list of Microsoft Windows-specific files.

Tip
Hover your pointer over a file type to view its description.

Step 6 Select a file rule **Action** as described in File rule actions, on page 2604, with consideration for File rule actions: evaluation order, on page 2611.

The actions available to you depend on the licenses you have installed. Refer to License requirements for file and malware policies, on page 2585.

Step 7 Depending on the action you selected, configure options:

- reset the connection after blocking the file
- store files that match the rule
- enable Spero analysis*
- enable local malware analysis*
- enable dynamic analysis* and capacity handling

* For information about these options, refer to File rule actions, on page 2604 and Malware protection options, on page 2605 and its subtopics.

Step 8 Click **Add.**

Step 9 Click **Save** to save the policy.

What to do next

- If you are configuring policies for malware protection, return to Configure file policies, on page 2591.
- Deploy configuration changes.

Access control rule logging for malware protection

When the system detects a prohibited file (including malware) according to the settings in the file policy, it automatically logs an event to the Cloud-Delivered Firewall Management Center database. If you do not want to log file or malware events, you can disable this logging on a per-access-control-rule basis.

The system also logs the end of the associated connection to the Cloud-Delivered Firewall Management Center database, regardless of the logging configuration of the invoking access control rule.

Retrospective disposition changes

File dispositions can change. For example, as new information is discovered, the AMP cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a malware-identified file is actually clean. When the disposition changes for a file you queried in the past week, the AMP cloud notifies the system so it can automatically take action the next time it detects that file being transmitted. A changed disposition is called a retrospective disposition.

File and malware inspection performance and storage options

Increasing the file sizes can affect the performance of the system.

Table 141: Advanced access control file and malware defense options

Field	Description	Guidelines and Restrictions
Limit the number of bytes inspected when doing file type detection	Specifies the number of bytes inspected when performing file type detection.	0 - 4294967295 (4GB) 0 removes the restriction. The default value is the maximum segment size of a TCP packet (1460 bytes). In most cases, the system can identify common file types using the first packet. To detect ISO files, enter a value greater than 36870.

Field	Description	Guidelines and Restrictions
Allow file if cloud lookup for Block Malware takes longer than (seconds)	Specifies how long the system will hold the last byte of a file that matches a **Block Malware** rule and that does not have a cached disposition, while malware cloud lookup occurs. If the time elapses without the system obtaining a disposition, the file passes. Dispositions of Unavailable are not cached.	0 - 30 seconds Do *not* set this option to 0 without contacting Support. Cisco recommends that you use the default value to avoid blocking traffic because of connection failures.
Do not calculate SHA-256 hash values for files larger than (in bytes)	Prevents the system from storing files larger than a certain size, performing a malware cloud lookup on the files, or blocking the files if added to the custom detection list.	0 - 4294967295 (4GB) 0 removes the restriction. This value must be greater than or equal to **Maximum file size to store (bytes)** and **Maximum file size for dynamic analysis testing (bytes)**.

Maximum file size for advanced file inspection and storage (bytes)	These settings specify:
	• The file size that the system can inspect using these detectors:
	  • Spero analysis
	  • Sandboxing and preclassification
	  • Local malware analysis/ClamAV
	  • Archive inspection
	• The file size that the system can store using a file rule.
		0 - 10485760 (10MB)
		0 disables file storage.
		Must be less than or equal to **Maximum file size to store (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**.

Minimum file size for advanced file inspection and storage (bytes)		0 - 10485760 (10MB) 0 disables file storage. Must be greater than or equal to **Minimum file size to store (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**.
Maximum file size for dynamic analysis testing (bytes)	Specifies the minimum file size the system can submit to the AMP cloud for dynamic analysis.	0 -10485760 (10MB) Must be less than or equal to **Maximum file size for dynamic analysis testing (bytes)** and **Do not calculate SHA-256 hash values for files larger than (in bytes)**. The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis. The system checks the AMP cloud for updates to the minimum file size you can submit (no more than once a day). If the new minimum size is larger than your current value, your current value is updated to the new minimum, and your policy is marked out-of-date.

Field	Description	Guidelines and Restrictions
Minimum file size for dynamic analysis testing (bytes)	Specifies the maximum file size the system can submit to the AMP cloud for dynamic analysis.	0 -10485760 (10MB) Must be greater than or equal to **Minimum file size for dynamic analysis testing (bytes)**, and less than or equal to **Do not calculate SHA-256 hash values for files larger than (in bytes)**. The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis. The system checks the AMP cloud for updates to the maximum file size you can submit (no more than once a day). If the new maximum size is smaller than your current value, your current value is updated to the new maximum, and your policy is marked out-of-date.

Tune file and malware inspection performance and storage

File and malware inspection can impact system performance and storage utilization. Tuning these settings helps ensure optimal security posture while maintaining acceptable system performance.

Before you begin

You must be an Admin, Access Admin, or Network Admin user to perform this task.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings**.

Step 2 Click **Edit** ( ) next to **Files and Malware Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Set any of the options described in File and malware inspection performance and storage options, on page 2613.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

(Optional) Malware protection with Secure Endpoint

Cisco's Secure Endpoint is a separate malware-protection product that can supplement malware protection provided by the system and be integrated with your Firepower deployment.

Secure Endpoint is Cisco's enterprise-class Advanced Malware Protection solution that runs as a lightweight connector on individual users' endpoints (computers and mobile devices) to discover, understand, and block advanced malware outbreaks, advanced persistent threats, and targeted attacks.

Benefits of Secure Endpoint

- Configure custom malware detection policies and profiles for your entire organization, as well as perform flash and full scans on all your users' files
- Perform malware analysis, including view heat maps, detailed file information, network file trajectory, and threat root causes
- Configure multiple aspects of outbreak control, including automatic quarantines, application blocking to stop non-quarantined executables from running, and exclusion lists
- Create custom protections, block execution of certain applications based on group policy, and create custom Allowed Applications lists
- Use the Secure Endpoint management console to help you mitigate the effect of malware. The management console provides a robust, flexible web interface where you control all aspects of your Secure Endpoint deployment and manage all phases of an outbreak.

For detailed information about Secure Endpoint, refer to:

- https://www.cisco.com/c/en/us/products/security/amp-for-endpoints/index.html.
- Online help in the Secure Endpoint management console.
- Secure Endpoint documentation available from: http://docs.amp.cisco.com.

Comparison of malware protection: Firepower vs. Secure Endpoint

This table compares the advanced malware protection differences between Firepower malware protection and Secure Endpoint across various features including detection methods, network traffic inspection, malware analysis, mitigation capabilities, and licensing requirements.

Table 142: Advanced malware protection differences by detecting product

Feature	Firepower Malware Protection (malware defense)	Secure Endpoint
File type detection and blocking method (file control)	In network traffic, using access control and file policies	Not supported
Malware detection and blocking method	In network traffic, using access control and file policies	On individual endpoints (end-user computers and mobile devices), using a connector that communicates with the AMP cloud
Network traffic inspected	Traffic passing through a managed device	None; connectors installed on endpoints directly inspect files
Malware intelligence data source	AMP cloud (public or private)	AMP cloud (public or private)
Malware detection robustness	Limited file types	All file types

Feature	Firepower Malware Protection (malware defense)	Secure Endpoint
Malware analysis choices	Cloud-Delivered Firewall Management Center-based, plus analysis in the AMP cloud	Cloud-Delivered Firewall Management Center-based, plus additional options on the Secure Endpoint management console
Malware mitigation	Malware blocking in network traffic, Cloud-Delivered Firewall Management Center-initiated remediations	Secure Endpoint-based quarantine and outbreak control options, Cloud-Delivered Firewall Management Center-initiated remediations
Events generated	File events, captured files, malware events, and retrospective malware events	Malware events
Information in malware events	Basic malware event information, plus connection data (IP address, port, and application protocol)	In-depth malware event information; no connection data
Network file trajectory	Cloud-Delivered Firewall Management Center-based	Cloud-Delivered Firewall Management Center and the Secure Endpoint management console each have a network file trajectory. Both are useful.
Required licenses or subscriptions	Licenses required to perform file control and malware defense	Secure Endpoint subscription. No license is required to bring Secure Endpoint data into Cloud-Delivered Firewall Management Center.

Integrate Secure Firewall with Secure Endpoint

If your organization has deployed Secure Endpoint, you can optionally integrate that product with your Secure Firewall deployment.

Integration with Secure Endpoint does not require a dedicated Secure Firewall license.

Benefits of integrating Firepower and Secure Endpoint

Integrating your Secure Endpoint deployment with your system offers these benefits:

- Centralized Blocked Applications and Allowed Applications lists configured in Secure Endpoint can determine verdicts for file SHAs sent from Firepower to the AMP cloud for disposition.

  Refer to Centralized file lists from Secure Endpoint, on page 2601.

- The system can import malware events detected by Secure Endpoint into Cloud-Delivered Firewall Management Center so you can manage these events along with malware events generated by the system. Imported data for these events includes scans, malware detections, quarantines, blocked executions, and cloud recalls, as well as indications of compromise (IOCs) that Cloud-Delivered Firewall Management Center displays for hosts that it monitors.

- You can view file trajectory and other details in the Secure Endpoint console.

Important If you use a Cisco AMP Private Cloud, refer to limitations at Secure Endpoint and AMP private cloud, on page 2618.

Secure Endpoint and AMP private cloud

If you configure a Cisco AMP private cloud to collect Secure Endpoint data on your network, all Secure Endpoint connectors send data to the private cloud, which forwards that data to the Cloud-Delivered Firewall Management Center. The private cloud does not share any of your endpoint data over an external connection.

Private cloud functionality and limitations

The private cloud acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes importing Secure Endpoint data. The private cloud does not share any of your endpoint data over an external connection.

The integration features that are not available with an AMP private cloud are:

- Use of Blocked Applications and Allowed Applications lists configured in Secure Endpoint. (These lists are used to block or allow files.)
- Visibility in Secure Endpoint of malware events generated from Firepower.

You can configure multiple private clouds to support the capacity you require.

Integrate Firepower and Secure Endpoint

If your organization has deployed Cisco's Secure Endpoint product, you can integrate that application with Firepower to achieve the benefits described in Benefits of integrating Firepower and Secure Endpoint, on page 2617.

When you integrate with Secure Endpoint, you must configure the Secure Endpoint connection even if you already have malware defense (AMP for Firepower) connections configured. You can configure multiple Secure Endpoint cloud connections.

Note Secure Endpoint connections that have not registered successfully do not affect malware defense.

Before you begin

- You must be an Admin user to perform this task.
- Secure Endpoint must be set up and working properly on your network.
- If you are connecting to the AMP cloud after either reimaging or restoring your Cloud-Delivered Firewall Management Center from backup, use the Secure Endpoint management console to remove the previous connection.
- You will need your Secure Endpoint credentials to log in to the Secure Endpoint console during this procedure.

Procedure

Step 1 Choose **Integration** > **AMP** > **AMP Management**.

Step 2 Click **Add AMP Cloud Connection**.

Step 3 From the **Cloud Name** drop-down list, choose the cloud you want to use.

Step 4 If you want to use this cloud for both malware defense and Secure Endpoint, select the **Use for AMP for Firepower** check box.

If you configured a different cloud to handle malware defense (AMP for Firepower) communications, you can clear this check box; if this is your only AMP cloud connection, you cannot.

Step 5 Click **Register**.

A **Spinning state** () icon indicates that a connection is pending, for example, after you configure a connection on the Cloud-Delivered Firewall Management Center, but before you authorize it using the Secure Endpoint management console. A **Denied** () icon indicates that the cloud denied the connection or the connection failed for another reason.

Step 6 Confirm that you want to continue to the Secure Endpoint management console, then log into the management console.

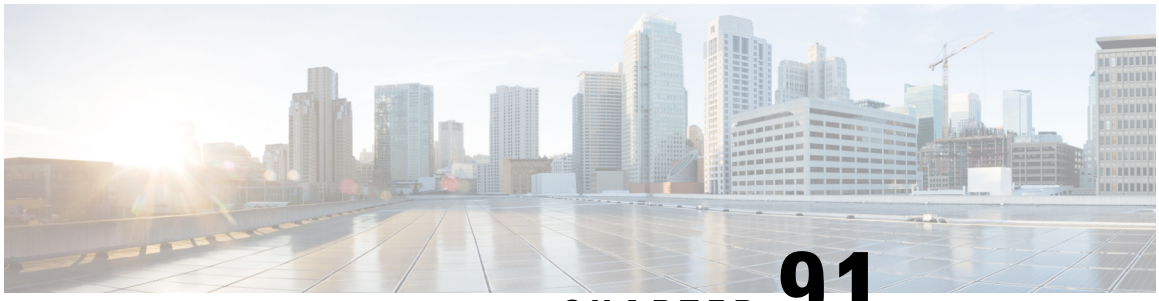
Step 7 Using the management console, authorize the AMP cloud to send Secure Endpoint data to Cloud-Delivered Firewall Management Center.

Step 8 If you want to restrict the data that the Cloud-Delivered Firewall Management Center receives, select specific groups within your organization for which you want to receive information.

By default, the AMP cloud sends data for all groups. To manage groups, choose **Management** > **Groups** on the Secure Endpoint management console. For detailed information, see the management console online help.

Step 9 Click **Allow** to enable the connection and start the transfer of data.

Clicking **Deny** returns you to the Cloud-Delivered Firewall Management Center, where the connection is marked as denied. If you navigate away from the Applications page on the Secure Endpoint management console, and neither deny nor allow the connection, the connection is marked as pending on the Cloud-Delivered Firewall Management Center's web interface. The health monitor does **not** alert you of a failed connection in either of these situations. If you want to connect to the AMP cloud later, delete the failed or pending connection, then recreate it.



Incomplete registration of the Secure Endpoint connection does not disable the malware defense connection.

What to do next

- In the Secure Endpoint console window, configure settings as needed. For example, define group membership for your management center and assign policies. For information, see the Secure Endpoint online help or other documentation.
- The default health policy warns you if the Cloud-Delivered Firewall Management Center cannot connect to the Secure Endpoint portal after an initial successful connection, or if the connection is deregistered using the AMP portal.

  Verify that the Secure Endpoint Status monitor is enabled under **System** () > **Health** > **Policy**.
- To verify that the connection is correctly configured:
  1. On the **Integration** > **AMP** > **AMP Management** page, click the Cloud Name that includes Secure Endpoint in the **Cisco AMP Solution Type** column.
  2. In the Secure Endpoint console window that displays, choose **Accounts > Applications**.

3. Verify that your Cloud-Delivered Firewall Management Center is on the list.
4. In the Secure Endpoint console window, choose **Manage > Computers**.
5. Verify that your Cloud-Delivered Firewall Management Center is on the list.

CHAPTER 91

Dynamic Attributes Connector

The following topics discuss how to configure and use the Dynamic Attributes Connector.

- About the Dynamic Attributes Connector , on page 2621
- Enable the dynamic attributes connector, on page 2624
- Dashboard, on page 2624
- Connectors, on page 2631
- Create an adapter, on page 2659
- Create dynamic attributes filters, on page 2661
- Disable the dynamic attributes connector, on page 2664
- Dynamic firewall, on page 2664
- Use Dynamic Objects in Access Control Policies, on page 2679
- Troubleshoot the Dynamic Attributes Connector, on page 2683

About the Dynamic Attributes Connector

The dynamic attributes connector enables your access control and DNS policy to adapt in real time to the changes in public and private cloud workloads and business-critical software-as-a-service (SaaS) applications. It simplifies policy management by keeping rules up to date without tedious manual updates and policy deployment. Customers require policy rules to be defined based on non-network constructs such as VM name or security group, so that firewall policy is persistent even when the IP address or VLAN changes.

Supported connectors

We currently support:

Table 143: List of supported connectors by dynamic attributes connector version and platform

CSDAC version	AWS	AWS security groups	AWS service tags	Azure	Azure Service Tags	Cisco Cyber Vision	Cisco Multicl. Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	vCenter	Tenable	Webex	Zoom
Version 1.1 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	No	Yes	Yes	No	No	No
Version 2.0 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	Yes	Yes	Yes	No	No	No
Version 2.2 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	Yes	Yes	Yes	Yes	No	No	No

CSDAC version	AWS	AWS security groups	AWS service tags	Azure	Azure Service Tags	Cisco Cyber Vision	Cisco Multicl. Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	vCenter	Tenable	Webex	Zoom
Version 2.3 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	Yes	Yes	Yes	Yes	No	Yes	Yes
Version 3.0 (on-premises)	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes
Cloud-delivered (Security Cloud Control)	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes

More information about connectors:

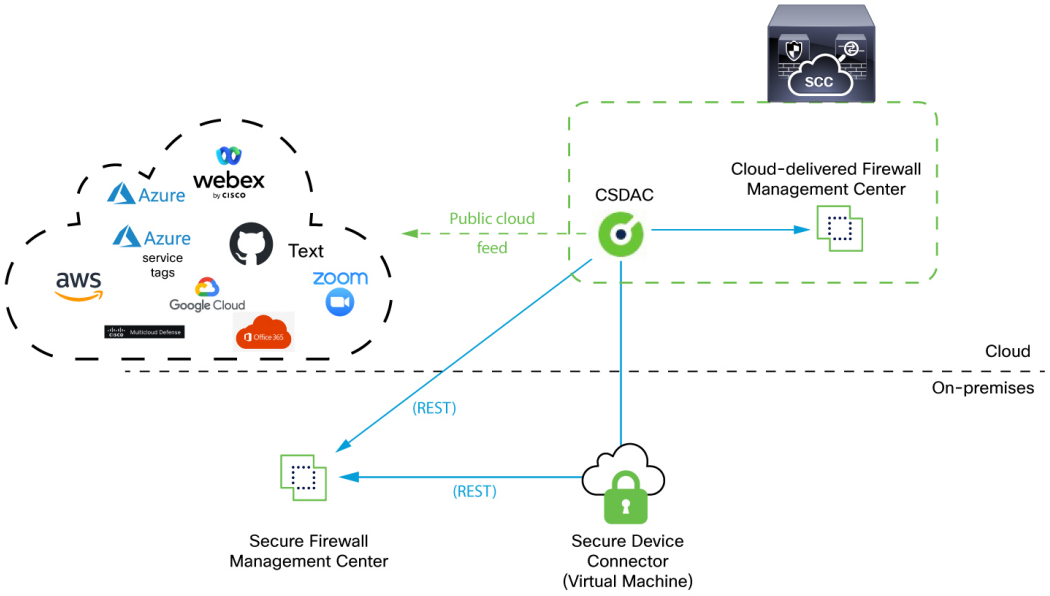
  For more information, see Create a Webex connector, on page 2657.



- Zoom IP addresses

  For more information, see Create a Zoom connector, on page 2658.

How It Works

This topic discusses the architecture of the dynamic attributes connector.

The following figure shows how the system functions at a high level.

- The system supports certain public cloud providers.

  This topic discusses supported *connectors* (which are the connections to those providers).

- The dynamic attributes connector is provided with Security Cloud Control; it includes a Cloud-Delivered Firewall Management Center adapter and you can connect to an On-Prem Firewall Management Center using the Secure Device Connector.

  For more information about the Secure Device Connector, see Secure Device Connector (SDC).

- The *adapter* defined by the dynamic attributes connector receives those dynamic attributes filters as *dynamic objects* and enables you to use them in access control rules.

  You can create the following types of adapters:

  - *On-Prem Firewall Management Center* for an on-premises device.

    This type of device might be managed by Security Cloud Control or it might be a standalone.

  - *Cloud-Delivered Firewall Management Center* for devices managed by Security Cloud Control.

Enable the dynamic attributes connector

Enable the dynamic attributes connector to allow objects from cloud networking products to be used in Cloud-Delivered Firewall Management Center access control and DNS rules.

This task discusses how to enable the dynamic attributes connector in the Cloud-Delivered Firewall Management Center. The dynamic attributes connector is an integration that enables objects from cloud networking products to be used in Cloud-Delivered Firewall Management Center access control and DNS rules.

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center if you have not done so already.

Step 2 Click **Administration** > **Dynamic Attributes Connector**.

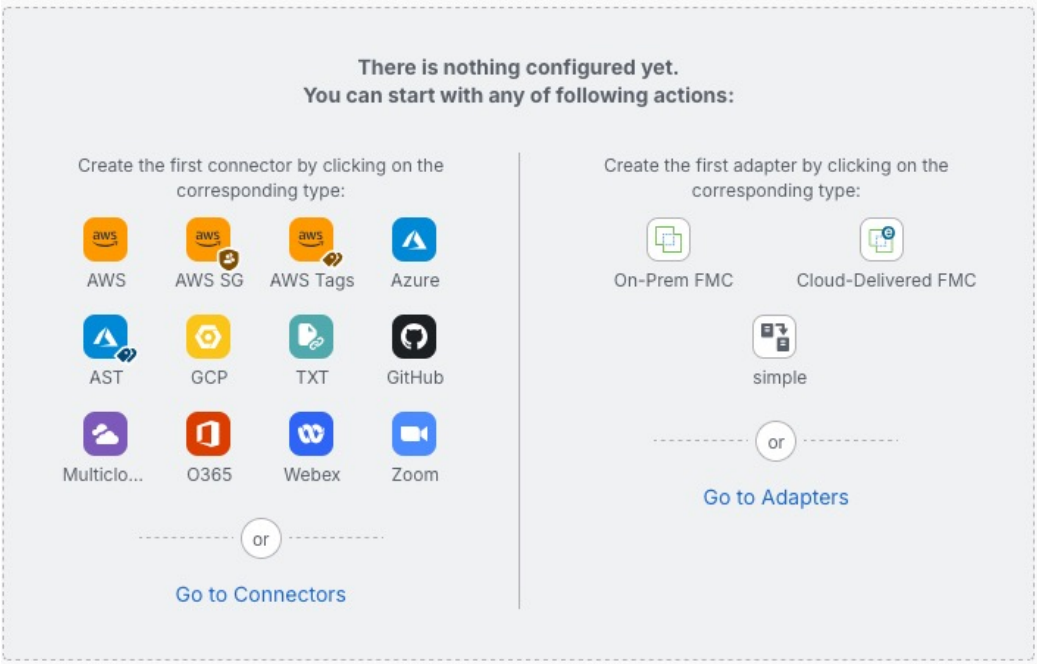
Step 3 Slide to **Enabled**.

Step 4 The system displays messages when the dynamic attributes connector is enabled.

In the event of errors, try again. If errors persist, contact Cisco TAC.

See Connectors, on page 2631.

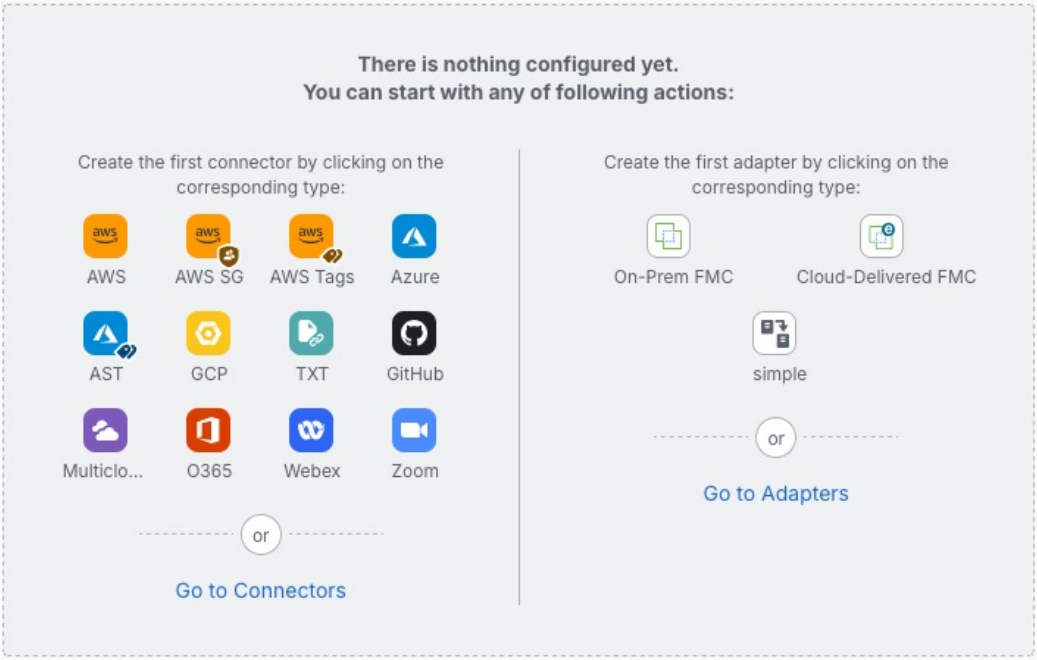
Dashboard



Dashboard capabilities include:

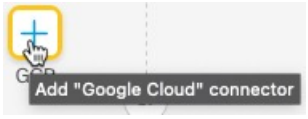
- Add, edit, and delete connectors and dynamic attributes filters.
- See how connectors and dynamic attributes filters are related to each other.
- View warnings and errors.

Dashboard access and functionality



To access the dynamic attributes connector dashboard, log in to Security Cloud Control and click **Administration** > **Dynamic Attributes Connector** at the top of the page.

The dynamic attributes connector Dashboard page displays an example of an unconfigured system:



Dashboard of an unconfigured system

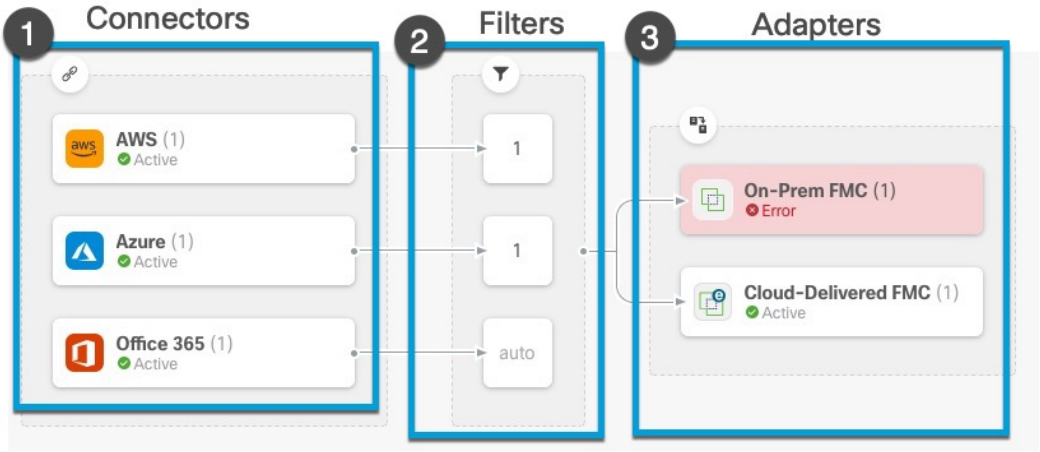
This sample dynamic attributes connector Dashboard page shows how an unconfigured system appears initially.

The Dashboard initially displays all the types of connectors you can configure for your system. You can do any interaction:

- Hover the mouse pointer over a connector and click 

to create a new one.
- Click **Go to Connectors** to add, edit, or delete connectors (good for creating, editing, or deleting multiple connectors at the same time).

  For more information, see Connectors, on page 2631.



Related Topics:

- Dashboard of a configured system, on page 2626
- Add, edit, or delete connectors, on page 2627
- Add, edit, or delete dynamic attributes filters, on page 2629

Dashboard of a configured system

Sample dynamic attributes connector Dashboard page of a configured system displays at-a-glance information about configured connectors, filters, and adapters.

Click an area in the figure to learn more about it or click one of the links that follow the figure.

1 Connectors, on page 2631
2 Create dynamic attributes filters, on page 2455
3 Create an adapter, on page 2659

The Dashboard shows the following (from left to right):

Connectors column	Filters column	Adapters column
List of connectors with a number indicating how many of each type are configured. Connectors collect dynamic attributes that could be sent to the configured adapter. Dynamic attributes filters specify what data is sent. Click to view more information about all configured connectors. You can also click the name of a connector to add, edit, or delete connectors; or to view detailed information about them. For more information, see Add, edit, or delete connectors, on page 2627.	List of dynamic attributes filters associated with each connector with a number indicating how many of each filter are associated with a connector. Click to view more information about all configured filters. You can also click the name of a filter to add, edit, or delete filters; or to view detailed information about them. For more information, see Add, edit, or delete dynamic attributes filters, on page 2629.	List of adapters. Adapters receive dynamic objects from configured connectors using configured dynamic attributes filters; these dynamic objects can be used in access control policies without the need to deploy them. Click to view more information about all configured adapters. You can also click the name of an adapter to add, edit, or delete adapters; or to view detailed information about them. For more information, see Create an adapter, on page 2659.

Note Some connectors, such as Outlook 365 and Azure Service tags, automatically pull available dynamic objects without the need for a dynamic attributes filters. Those connectors display **Auto** in the column.

The Dashboard indicates whether or not an object is available. The Dashboard page is refreshed every 15 seconds but you can click **Refresh** ( ) at the top of the page at any time to refresh immediately. If issues persist, check your network connection.

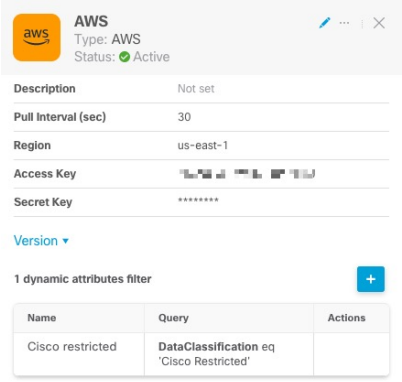
Add, edit, or delete connectors

The Dashboard enables you to manage connectors by viewing, adding, editing, or deleting them. You can also view error information for connectors and troubleshoot issues.

Use the dynamic attributes connector dashboard when you need to manage connectors for your network security infrastructure. The dashboard provides comprehensive options for connector management and troubleshooting.

Procedure

Step 1 Access the connector dashboard and select your desired action.



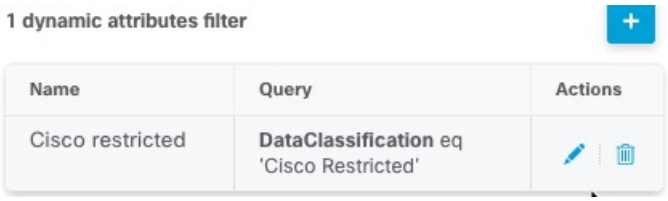
The Dashboard enables you to view or edit connectors. You can click the name of a connector to view all instances of that connector or you can click for the following additional options:

- **Go to Connectors** to view all connectors at the same time; you can add, edit, and delete connectors from there.

- **Add Connector** > ***type*** to add a connector of the indicated type.

Step 2 Click any connector in the connectors column ( ) to display more information about it.

An example follows:

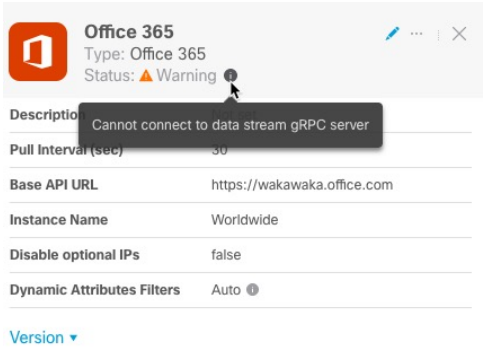


Step 3 Choose from the following management options.

- Click the Edit icon ( ) to edit this connector.
- Click the More icon ( ) for additional options.
- Click to close the panel.
- Click **Version** to display the version of the . You can optionally copy the version to the clipboard if necessary for Cisco TAC.

Step 4 Use the table at the bottom of the panel to add dynamic attributes filters or to edit or delete connectors.

A sample follows:



Click the Add icon ( ) to add a dynamic attributes filter for this connector. For more information, see Create dynamic attributes filters, on page 2455.

Hover the mouse pointer over the Actions column to either edit or delete the indicated connector.

Step 5 To view error information for a connector, click the name of the connector that is displaying the error.

Step 6 In the right pane, click **Information** ( ).

An example follows.

Step 7 To resolve this issue, edit the connector settings as discussed in Create an office 365 connector, on page 2653.

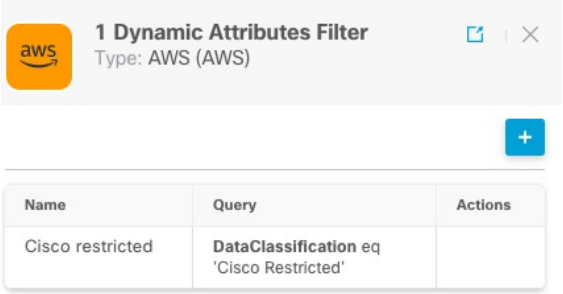
Step 8 If you cannot resolve the issue, click **Version** and copy the version to a text file.

Step 9 Get your Security Cloud Control tenant ID as discussed in Get your tenant ID, on page 2684.

What to do next

Provide all of this information to Cisco TAC.

Add, edit, or delete dynamic attributes filters



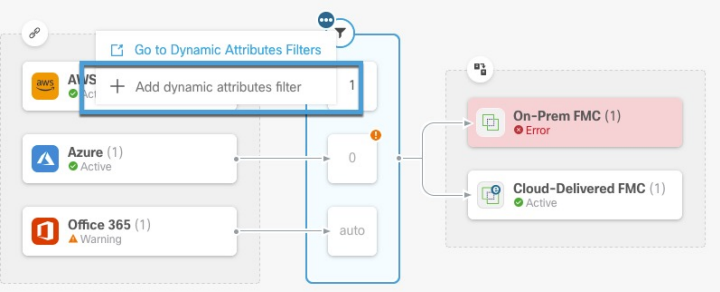
The dashboard enables you to add, edit, or delete dynamic attributes filters. You can click the name of a filter to view all instances of that filter or you can click  for additional options.

You can click the name of a filter to view all instances of that filter or you can click  for the following additional options:

- **Go to Dynamic Attributes Filters** to view all configured dynamic attributes filters. You can add, edit, or delete dynamic attributes filters from there.
- **Add Dynamic Attributes Filters** to add a filter.

For more information about adding dynamic attributes filters, see Create dynamic attributes filters, on page 2455.

An example follows:



Note Some connectors, such as Outlook 365 and Azure Service tags, automatically pull available dynamic objects without the need for a dynamic attributes filters. Those connectors display **Auto** in the column.

You have these options:

- Click a filter instance to view summary information about dynamic attributes filters associated with a connector.
- Click the Add icon ( ) to add a new dynamic attributes filter.

  For more information, see Create dynamic attributes filters, on page 2455.
- Click in the filters column ( ) indicates the indicated connector has no associated dynamic attributes filters. Without associated filters, the connector can send nothing to Cloud-Delivered Firewall Management Center.

  One way to resolve the issue is to click in the filters column and click **Add Dynamic Attributes Filter**. A sample follows.

- Click to add, edit, or delete filters.
- Click to close the panel.

Connectors

A connector is an interface with a cloud service. It retrieves network information from the cloud service to enable the network information to be used in policies on the Security Cloud Control. It supports both air gap mode and network download mode configurations.

Supported connectors

We support these connectors:

Table 144: List of supported connectors by dynamic attributes connector version and platform

CSDAC version	AWS	AWS security groups	AWS service tags	Azure	Azure Service Tags	Cisco Cyber Vision	Cisco Multicl. Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	vCenter	Tenable	Webex	Zoom

Cloud-delivered (Security Cloud Control)	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes

Amazon Web Services connector user permissions and imported data

The dynamic attributes connector imports dynamic attributes from Amazon Web Services (AWS) to Security Cloud Control for use in policies.

Dynamic attributes imported

The connector imports these dynamic attributes from AWS:

- *Tags*, user-defined key-value pairs you can use to organize your AWS EC2 resources.

  For more information, see Tag your EC2 Resources in the AWS documentation

- *IP addresses* of virtual machines in AWS.

Minimum permissions required

The dynamic attributes connector requires a user at minimum with a policy that permits `ec2:DescribeTags`, `ec2:DescribeVpcs`, and `ec2:DescribeInstances` to be able to import dynamic attributes.

Create an AWS user with minimal permissions for the dynamic attributes connector

This task creates a service account with minimum permissions to send dynamic attributes to Security Cloud Control.

For a list of the dynamic attributes that can be sent, refer to Amazon Web Services connector user permissions and imported data, on page 2631.

Before you begin

You must already have set up your Amazon Web Services (AWS) account. For more information about doing that, see this article in the AWS documentation.

Follow these steps to create an AWS user with minimal permissions for the dynamic attributes connector:

Procedure

Step 1 Log in to the AWS console as a user with the admin role.

Step 2 From the Dashboard, click **Security, Identity & Compliance** > **IAM**.

Step 3 Click **Access Management** > **Users**.

Step 4 Click **Add Users**.

a) In the **User Name** field, enter a name to identify the user.

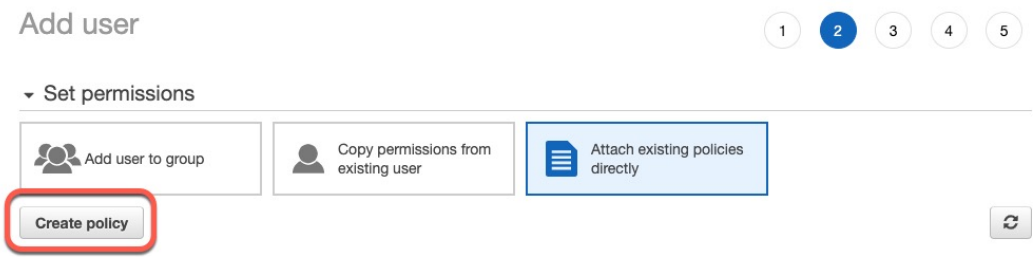
b) Click **Access Key - Programmatic Access**.

c) At the Set permissions page, click **Next** without granting the user access to anything. You can grant user access later.

d) Add tags to the user if desired.

e) Click **Create User**.

f) Click **Download .csv** to download the user's key to your computer.



Note
This is the only opportunity you have to retrieve the user's key.

g) Click **Close**.

Step 5 At the Identity and Access Management (IAM) page in the left column, click **Access Management** > **Policies**.

Step 6 Click **Create Policy**.

a) On the Create Policy page, click **JSON**.

b) Enter the following policy in the field:

```
{
 "Version": "2012-10-17",
 "Statement": [
```

```
    {
     "Effect": "Allow",
     "Action": [
      "ec2:DescribeTags",
      "ec2:DescribeInstances",
      "ec2:DescribeVpcs"
     ],
     "Resource": "*"
    }
   ]
}
```

c) Click **Next**.

Step 7 Click **Review**.

On the Review Policy page, enter the requested information and click **Create Policy**.

Step 8 Attach your policy

a) On the Policies page, enter all or part of the policy name in the search field and press Enter.
b) Click the policy you just created.
c) Click **Actions** > **Attach**.
d) If necessary, enter all or part of the user name in the search field and press Enter.
e) Click **Attach Policy**.

What to do next

Create an AWS connector, on page 2633.

Create an AWS connector

Create a connector to send dynamic objects from AWS to the firewall for use in security policies.

This task discusses how to configure a connector that sends data from AWS to the Security Cloud Control for use in policies.

Before you begin

Create a user with at least the privileges discussed in Create an AWS user with minimal permissions for the dynamic attributes connector, on page 2632.

Follow these steps to create an AWS connector:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of these actions:

- Add a new connector: click Add icon (), then click the name of the connector.

- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the required information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS.
Region	(Required.) Enter your AWS region code.
Access Key	(Required.) Enter your access key.
Secret Key	(Required.) Enter your secret key.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.

The Status column displays **Ok**.

Amazon Web Services security groups connector—About user permissions

The dynamic attributes connector imports dynamic attributes from AWS to Security Cloud Control for use in policies.

Minimum permissions required

The dynamic attributes connector requires a user at minimum with a policy that permits `ec2:DescribeTags`, `ec2:DescribeVpcs`, and `ec2:DescribeInstances` to be able to import dynamic attributes.

Create an AWS security groups connector

This task creates a connector that sends AWS security groups data to the Security Cloud Control for use in policies.

This task discusses how to configure a connector that sends AWS security groups data to the Security Cloud Control for use in policies.

Before you begin

Complete these steps:

- Create AWS security groups as discussed in Work with security groups on the AWS documentation site.
- Create a user with at least the privileges discussed in Create an AWS user with minimal permissions for the dynamic attributes connector, on page 2632.

Follow these steps to create an AWS Security Groups connector:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Region	(Required.) Enter your AWS region code.
AWS Access Key	(Required.) Enter your access key.
AWS Secret Key	(Required.) Enter your secret key.

a) Click **Test** and make sure the test succeeds before you save the connector.

b) Click **Save**.

The Status column displays **Ok**.

Create an AWS service tags connector

Create a connector for Amazon Web Services (AWS) service tags to the Security Cloud Control for use in policies.

For more information, see resources like the following on the AWS documentation site:

- What are tags?
- AWS IP address ranges
- Tagging your AWS resources
- Guidance for Tagging on AWS
- AWS service points

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit a connector: click Edit icon ().
- Delete a connector: click Delete icon ().

Step 5 Enter the necessary information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
URL	(Required.) Do not change the URL unless advised to do so.

a) Click **Test** and make sure **Test connection succeeded** is displayed before you save the connector.

b) Click **Save**.

The Status column displays **Ok**.

Azure connector—About user permissions and imported data

The dynamic attributes connector imports dynamic attributes from Azure to Security Cloud Control for use in policies.

Dynamic attributes imported

We import these dynamic attributes from Azure:

- *Tags*, key-value pairs associated with resources, resource groups, and subscriptions.

For more information, see this page in the Microsoft documentation.

- *IP addresses* of virtual machines in Azure.

Minimum permissions required

The dynamic attributes connector requires a user at minimum with the **Reader** permission to be able to import dynamic attributes.

Create an Azure user with minimal permissions for the dynamic attributes connector

Create an Azure service account with minimal permissions to send dynamic attributes to Security Cloud Control.

This task discusses how to set up a service account with minimum permissions to send dynamic attributes to Security Cloud Control. For a list of these attributes, see Azure connector—About user permissions and imported data, on page 2636.

Before you begin

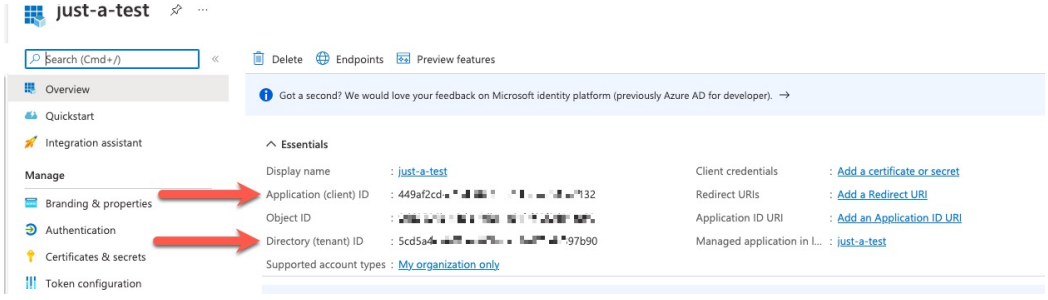
You must already have a Microsoft Azure account. To set one up, see this page on the Azure documentation site.

Follow these steps to create an Azure user with minimal permissions for the dynamic attributes connector:

Procedure

Step 1 Log in to the Azure Portal as the owner of the subscription.

Step 2 Click **Azure Active Directory**.



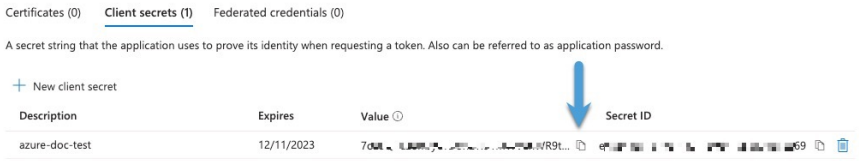
Find the instance of Azure Active Directory for the application you want to set up.

Step 3 Click **Add** > **App registration**.

a) In the **Name** field, enter a name to identify this application.
b) Enter other information on this page as required by your organization.
c) Click **Register**.

Step 4 On the next page, write down or copy the Client ID (also referred to as *application ID*) and the tenant ID (also referred to as the *directory ID*).

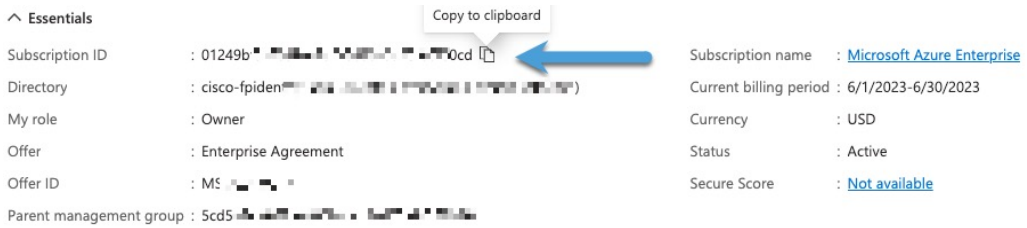
Here is a sample:



Step 5 Next to Client Credentials, click **Add a certificate or secret**.

Step 6 Click **New Client Secret**.

a) Enter the requested information and click **Add**.

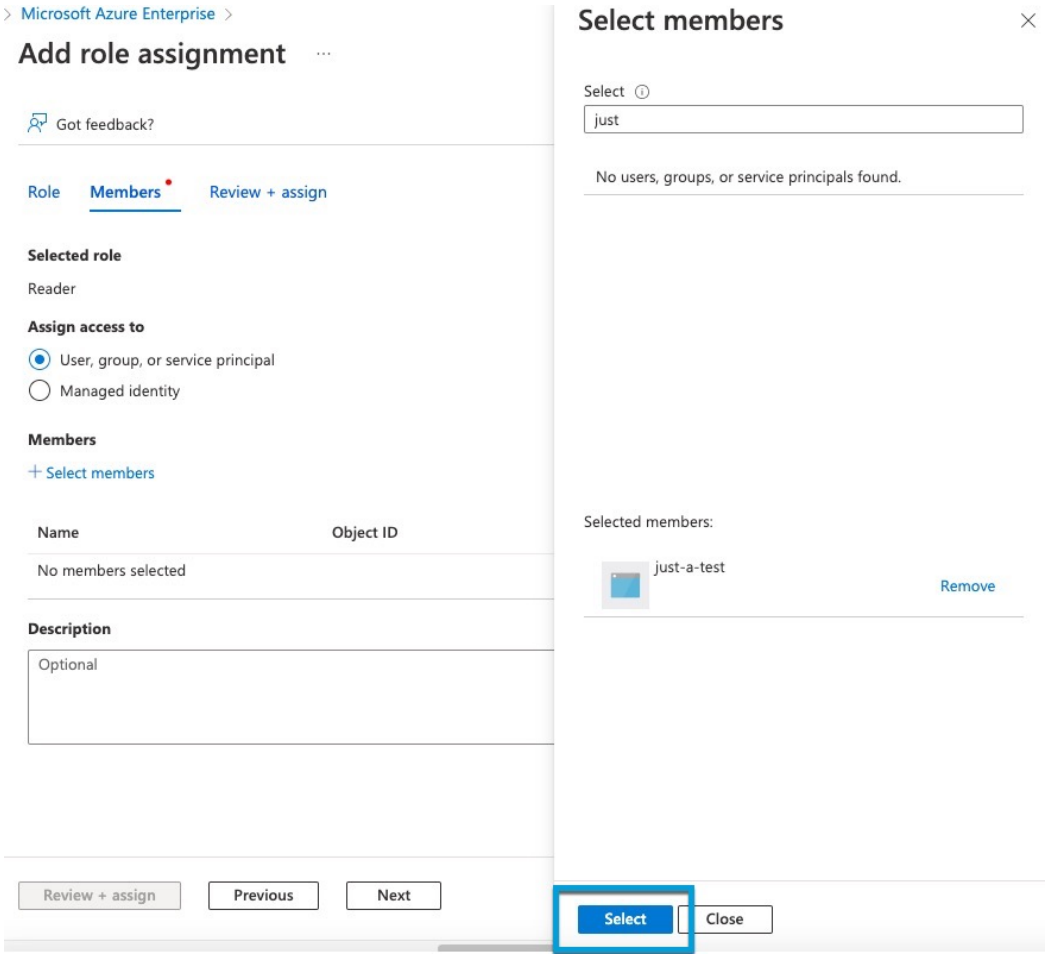


b) Copy the value of the **Value** field to the clipboard. This value, *and not the* ***Secret ID***, is the client secret.

Step 7 Go back to the main Azure Portal page and click **Subscriptions**.

a) Click the name of your subscription.

b) Copy the subscription ID to the clipboard.



Step 8 Click **Access Control (IAM)**.

a) Click **Add** > **Add role assignment**.

b) Click **Reader** and click **Next**.

c) Click **Select Members**.

d) On the right side of the page, click the name of the app you registered and click **Select**.

e) Click **Review + Assign** and follow the prompts to complete the action.

Also see Create an Azure connector, on page 2639.

Create an Azure connector

Create a connector to send data from Azure to Security Cloud Control for use in policies.

This connector enables integration between Azure and your security management platform to retrieve dynamic object information for policy implementation.

Before you begin

Create an Azure user with at least the privileges discussed in Create an Azure user with minimal permissions for the dynamic attributes connector, on page 2637.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Subscription ID	(Required.) Enter your Azure subscription ID.
Tenant ID	(Required.) Enter your tenant ID.
Client ID	(Required.) Enter your client ID.
Client Secret	(Required.) Enter your client secret.

a) Click **Test** and make sure **Test connection succeeded** is displayed before you save the connector.

b) Click **Save**.

The Status column displays **Ok**.

Create an Azure service tags connector

Create a connector for Azure service tags to enable use in policies with automatically updated IP addresses from Microsoft.

This topic discusses how to create a connector for Azure service tags to the Security Cloud Control for use in policies. The IP addresses associated with these tags are updated every week by Microsoft.

For more information, see Virtual network service tags on Microsoft TechNet.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

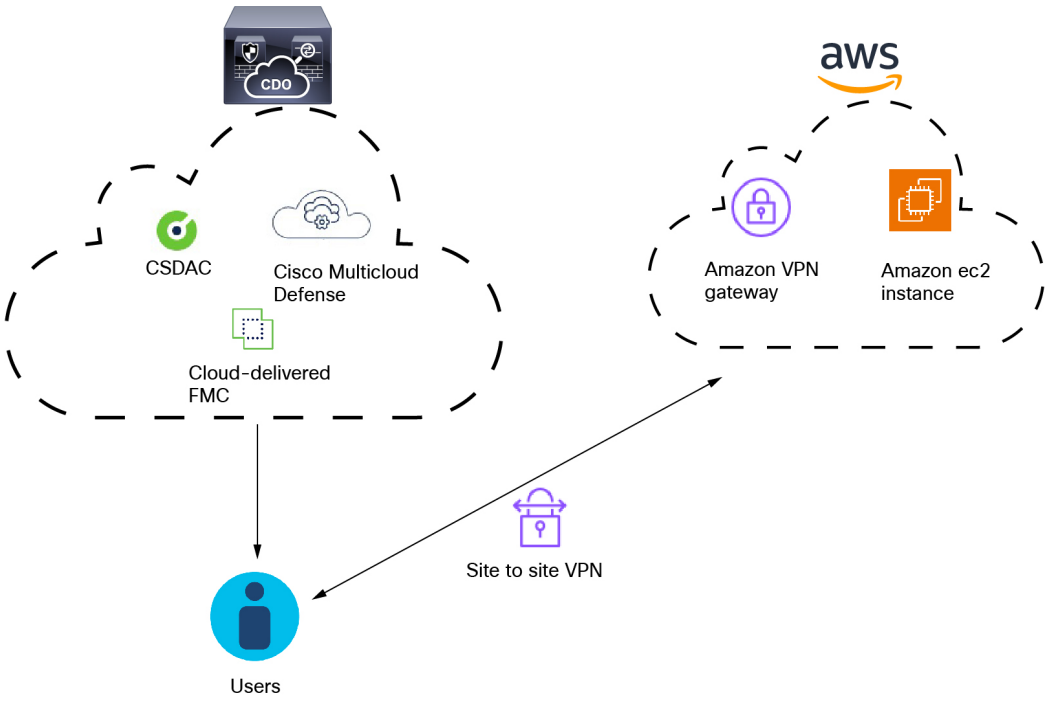
- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the required information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Subscription ID	(Required.) Enter your Azure subscription ID.
Tenant ID	(Required.) Enter your tenant ID.
Client ID	(Required.) Enter your client ID.
Client Secret	(Required.) Enter your client secret.

a) Click **Test** and make sure **Test connection succeeded** is displayed before you save the connector.

b) Click **Save**.



The Status column displays **Ok**.

Create a Multicloud Defense connector

This topic discusses how to create a connector for Cisco Multicloud Defense. The connector sends dynamic application address objects to the configured Cloud-Delivered Firewall Management Center.

For more information, see the Address Objects chapter in the *Cisco Multicloud Defense User Guide* and address object API documentation.

The following figure shows how the Cisco Multicloud Defense connector works.

As the figure shows:

- Users logging in and out of AWS create activity monitored by Multicloud Defense.
- The dynamic attributes connector and Multicloud Defense, both included in Security Cloud Control, send IP addresses from that activity to the Cloud-Delivered Firewall Management Center.
- These IP addresses can then be used in access control rules by the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter a **Name** and optional **Description** to identify the connector.

Step 6 Enter a **Pull Interval**. (Default 30 seconds.) Interval at which objects are retrieved from the Multicloud Defense Connector.

Step 7 Click **Test** and make sure the test succeeds before you save the connector.

Step 8 Click **Save**.

Step 9 Make sure **Ok** is displayed in the Status column.

You must create a Cloud-Delivered Firewall Management Center adapter as discussed in Create an adapter, on page 2659.

Create a Cisco cyber vision connector

This task creates a connector to send data from Cisco Cyber Vision to the firewall, enabling dynamic attribute integration between these systems.

This task discusses how to send data from Cisco Cyber Vision to the Security Cloud Control.

Before you begin

Cisco Cyber Vision must be reachable from the machine on which the dynamic attributes connector is running. You must know its IP address, port, and API key.

To find the API key in the Cyber Vision management console, click **Admin** > **API** > **Token**, then click **Show** to display the token and  to copy the token to the clipboard.

Follow these steps to create a Cisco Cyber Vision connector:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon (), then click the name of the connector.
- Edit a connector: click Edit icon ().
- Delete a connector: click Delete icon ().

Step 5 Enter the required information.

Value	Description
Name	(Required) Enter a name to uniquely identify this connector.
Description	Optional description.

Value	Description
Cyber Vision Prefix	Enter an alphanumeric string to identify dynamic objects from this Cyber Vision's IP address when objects are sent to Security Cloud Control. If you have one Cyber Vision IP address, you can enter any value such as **1**.
Pull Interval	(Default 60 seconds) Interval at which data mappings are retrieved from Cyber Vision. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Host	(Required) Enter the Cyber Vision fully qualified host name or IP address.
Port	(Required) Enter the Cyber Vision listen port.
Version 4	(Required) Toggle this button to enable or disable Version 4. When you enable Version 4, the connector fetches hosts and vulnerabilities from the Cyber Vision platform. The Network Map API on the uses this data. When you disable Version 4, the connector fetches groups from the Cyber Vision platform and adds them as dynamic objects.
Token	(Required) Enter the API token.
Score Type	Choices are CVSS and CSRS. **CVSS**: Common vulnerability scoring system (CVSS) is an industry-standard system that retrieves values from the national vulnerability database to describe risk associated with vulnerabilities. CVSS scores power a vulnerability's severity and risk value. **CSRS**: The Cisco Security Risk Score (CSRS) CSRS evaluates vulnerabilities beyond technical severity, focusing on how attackers might exploit them. Scores range from 0 to 100 and are based on factors such as existing vulnerabilities, threat intelligence, and the effectiveness of security controls. This score helps prioritize critical vulnerabilities and allocate resources effectively.
Severity	Click the minimum vulnerability severity level for the dynamic attributes connector to send IP addresses to the Secure Firewall Management Center. (For example, if you click high, IP addresses of hosts with either high or severe vulnerabilities are sent.) Choices: • Critical • High • Medium • Low
Dynamic Object Name	Enter a name to identify the dynamic object created by this connector.

Value	Description
Certificate	You have these options: • Paste the certificate authority (CA) chain as discussed in Manually get a certificate authority (CA) chain, on page 2646. • Click **Get Certificate** > **Fetch** to automatically fetch the certificate. Ensure that you have specified a valid host and IP address that exactly matches the server certificate. • Click **Get Certificate** > **Browse from file** to upload a certificate chain you downloaded previously. Ensure that the host or IP address of the certificate you upload exactly matches the Common Name of the CA certificate you enter in host or IP address field.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.

Status column displays **Ok**.

Create an adapter, on page 2659

Create a generic text connector

Use this task to create a connector that retrieves IP addresses from text files and sends them to the firewall for use in access control rules.

This task discusses how to create an ad hoc list of IP addresses you maintain manually and retrieve at an interval you select (30 seconds by default). You can update the list of addresses anytime you want.

For example, you might have a list of IP addresses for an "allow list" in access control rules and another list of IP addresses for a "block list" in access control rules.

Before you begin

Create text files with IP addresses and put it on a web server that is accessible from the Security Cloud Control. IP addresses can include CIDR notation. The text file must have only one IP address per line.

You can specify up to 10,000 IP addresses per text file.

Follow these steps to create a generic text connector:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

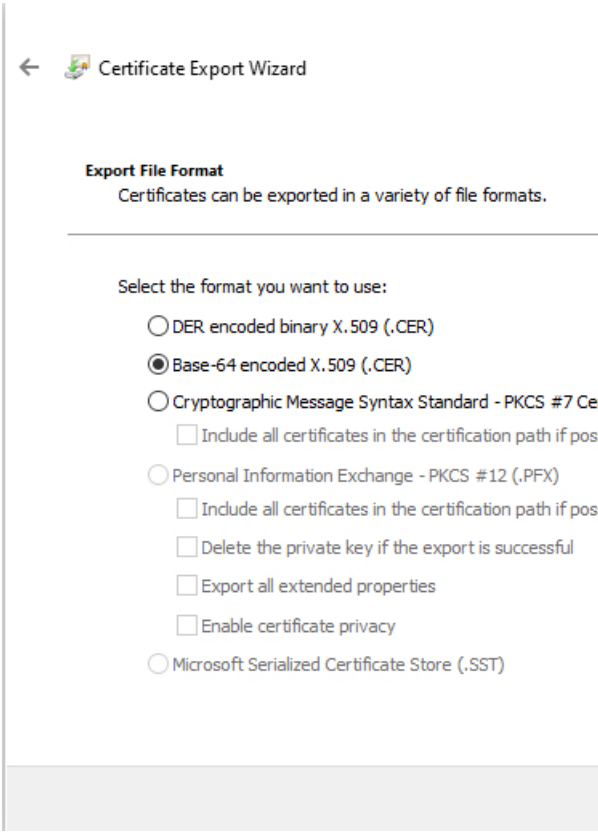
Step 5 Enter the following information:

Item	Description
Name	Enter a name to identify the connector.
Description	(Optional.) Enter a description
Pull Interval	Change the frequency, in seconds, at which the dynamic attributes connector retrieves IP addresses from the text file. The default is 30 seconds. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
URLs	Enter a URL from which to retrieve IP addresses.
Add another URL	(Optional.) Click the link to add more URLs to an existing list.
Certificate	(Optional.) If a certificate chain is required for a secure connection to the web server, you have these options: • Click **Get Certificate** > **Fetch** to automatically fetch the certificate or, if that is not possible, get the certificate manually as discussed in Manually get a certificate authority (CA) chain, on page 2646. • Click **Get Certificate** > **Browse from file** to upload a certificate chain you downloaded previously.

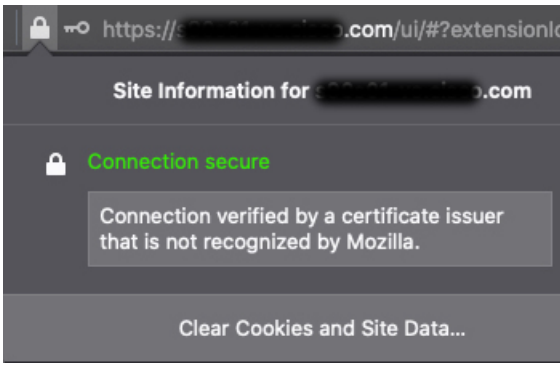
a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.
c) Status column displays **Ok**

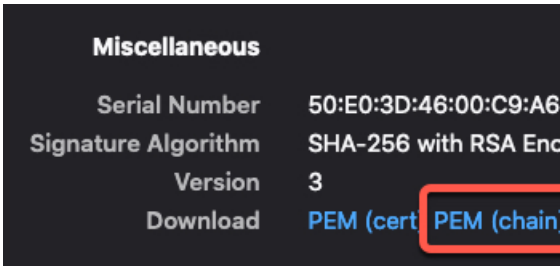
Manually get a certificate authority (CA) chain

If the certificate authority chain is not fetched automatically, use one of these browser-specific procedures to get a certificate chain to securely connect to vCenter or Cloud-Delivered Firewall Management Center .



The *certificate chain* is the root certificate and all subordinate certificates.





Procedure

	Command or Action	Purpose

Step 1	Get a Certificate Chain—Mac (Chrome and Firefox)	**a.** Open a Terminal window.
		b. Enter this command:
		`security verify-cert -P` *`url[:port]`*
		where *url* is the URL (including scheme) to vCenter or Cloud-Delivered Firewall Management Center . For example:
		`security verify-cert -P https://myvcenter.example.com`
		If you access vCenter or Cloud-Delivered Firewall Management Center using NAT or PAT, you can add a port as follows:
		`security verify-cert -P https://myvcenter.example.com:12345`
		c. Save the entire certificate chain to a plaintext file.
		• *Include* all `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` delimiters.
		• *Exclude* any extraneous text (for example, the name of the certificate and any text contained in angle brackets (< and >) as well as the angle brackets themselves.
		d. Repeat these tasks for vCenter Cloud-Delivered Firewall Management Center .

Step 2	Get a Certificate Chain—Windows Chrome	**a.** Log in to vCenter or Cloud-Delivered Firewall Management Center using Chrome. **b.** In the browser address bar, click the lock to the left of the host name. **c.** Click **Certificate**. **d.** Click the **Certification Path** tab. **e.** Click the top (that is, first) certificate in the chain. **f.** Click **View Certificate**.

	Command or Action	Purpose
		g. Click the **Details** tab. **h.** Click **Copy to File**. **i.** Follow the prompts to create a CER-formatted certificate file that includes the entire certificate chain. When you're prompted to choose an export file format, click **Base 64-Encoded X.509 (.CER)**.  Follow the prompts to complete the export. Open the certificate in a text editor. Repeat the process for all certificates in the chain. You must paste each certificate in the text editor in order, first to last. Repeat these tasks for vCenter or Cloud-Delivered Firewall Management Center .

	Command or Action	Purpose
Step 3	Get a Certificate Chain—Windows Firefox	**a.** Log in to vCenter or Cloud-Delivered Firewall Management Center using Firefox. **b.** Click the lock to the left of the host name. **c.** Click the right arrow (**Show connection details**).  **d.** Click **More Information**. **e.** Click **View Certificate**. **f.** If the resulting dialog box has tab pages, click the tab page corresponding to the top-level CA. **g.** Scroll to the Miscellaneous section. **h.** Click **PEM (chain)** in the Download row.  **i.** Save the file. Repeat these tasks for vCenter or Cloud-Delivered Firewall Management Center .

Create a GitHub connector

Create a GitHub connector that sends data to the Security Cloud Control for use in policies. The IP addresses associated with these tags are maintained by GitHub.

For more information, see About GitHub's IP addresses.

Note Do not change the URL because doing so will fail to retrieve any IP addresses.

Before you begin

You do not have to create a dynamic attributes filters.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter a **Name** and an optional description.

a) (Optional) In the **Pull Interval** field, change the frequency, in seconds, at which the dynamic attributes connector retrieves IP addresses from GitHub. The default is 21,600 seconds (6 hours).

b) Click **Test** and make sure the test succeeds before you save the connector.

c) Click **Save**.

The Status column displays **Ok**.

Google cloud connector user permissions and imported data

A Google Cloud connector imports dynamic attributes from Google Cloud to Security Cloud Control for use in policies.

Dynamic attributes imported

The connector imports these dynamic attributes from Google Cloud:

- *Labels*: Key-value pairs you can use to organize your Google Cloud resources. For more information, see Creating and Managing Labels in the Google Cloud documentation.
- *Network tags*: Key-value pairs associated with an organization, folder, or project. For more information, see Creating and Managing Tags in the Google Cloud documentation.
- *IP addresses*: Virtual machine addresses in Google Cloud.

The dynamic attributes connector requires a user at minimum with the **Basic** > **Viewer** permission to be able to import dynamic attributes.

Create a Google Cloud user with minimal permissions for the dynamic attributes connector

Create a service account with minimum permissions to send dynamic attributes to Security Cloud Control.

This task sets up a service account that provides the minimum permissions necessary for the dynamic attributes connector. For a list of these attributes, see Google cloud connector user permissions and imported data, on page 2650.

Before you begin

You must already have set up your Google Cloud account. For more information about doing that, see Setting Up Your Environment in the Google Cloud documentation.

Procedure

Step 1 Log in to your Google Cloud account as a user with the owner role.

Step 2 Click **IAM & Admin** > **Service Accounts** > **Create Service Account**.

Step 3 Enter the following information:

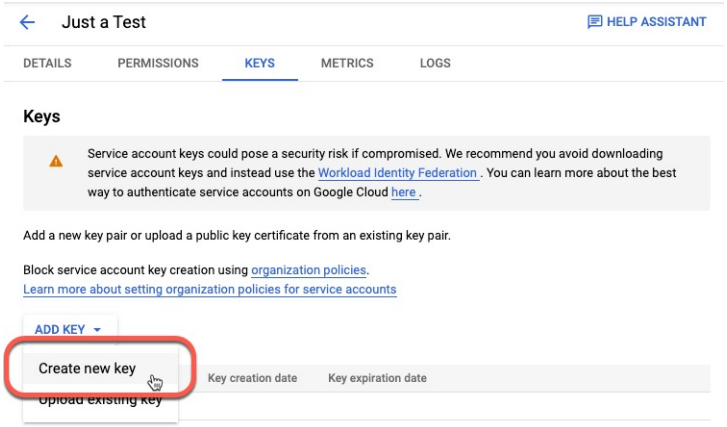
- **Service account name**: A name to identify this account; for example, **CSDAC**.
- **Service account ID**: Should be populated with a unique value after you enter the service account name.
- **Service account description**: Enter an optional description.

For more information about service accounts, see Understanding Service Accounts in the Google Cloud documentation.

Click **Create and Continue**.

Step 4 Follow the prompts on your screen until the Grant users access to this service account section is displayed.

Grant the user the **Basic** > **Viewer** role.



Click **Done**.

A list of service accounts is displayed.

Step 5 Click **More** (⋮) at the end of the row of the service account you created.

Step 6 Click **Manage Keys**.

Step 7 Click **Add Key** > **Create New Key**.

Step 8 Click **JSON**.

Step 9 Click **Create**.

The JSON key is downloaded to your computer.

Keep the key handy when you configure the GCP connector.

See Create a google cloud connector, on page 2652.

Create a google cloud connector

Create a Google Cloud connector to enable data transmission from your Google Cloud environment to the firewall for dynamic security attribute monitoring and management.

The Google Cloud connector allows the firewall to receive real-time data from your Google Cloud infrastructure, enabling dynamic security policies based on cloud resource attributes.

Before you begin

Have your Google Cloud JSON-formatted service account data ready; it's required to set up the connector.

Follow these steps to create a Google Cloud connector:

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
GCP region	(Required.) Enter the GCP region in which your Google Cloud is located. For more information, see Regions and Zones in the Google Cloud documentation.
Service account	Paste the JSON code for your Google Cloud service account.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.

The Status column displays **Ok**.

Create an office 365 connector

Create a connector for Office 365 tags to send data to the Security Cloud Control for use in policies.

The IP addresses associated with these tags are updated every week by Microsoft. You do not have to create a dynamic attributes filter to use the data.

For more information, refer to Office 365 URLs and IP address ranges on docs.microsoft.com.

Procedure

Step 1 Log in to Security Cloud Control.

Click **Firewall**.

Step 2 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 3 Do any of the following:

- Add a new connector: click Add icon (+), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 4 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Base API URL	(Required.) Enter the URL from which to retrieve Office 365 information, if it's different from the default. For more information, see Office 365 IP Address and URL web service on the Microsoft documentation site.
Instance name	(Required.) From the list, click an instance name. For more information, see Office 365 IP Address and URL web service on the Microsoft documentation site.
Disable optional IPs	(Required.) Enter **true** or **false**.

Click **Test** and make sure the test succeeds before you save the connector.

Step 5 Click **Save**.

The Status column displays **Ok**.

Create an adapter, on page 2659

Tenable connector

These topics provide information about creating and using the Tenable connector for vulnerability management.

About the Tenable connector

Tenable Vulnerability Management is a platform that helps organizations understand, report, and manage known vulnerabilities. When used with the Cloud-Delivered Firewall Management Center, the Tenable connector:

- Creates a dynamic object with a list of IP addresses known to have Common Vulnerability Exposures (CVEs).
- Populates those IP addresses and associated vulnerabilities to the Cloud-Delivered Firewall Management Center network map as host entries.

  Network map entries provide the basis for intrusion policy recommendations.

The dynamic object created by this connector can be used in access control rules, or anywhere dynamic objects are supported. For example, you can use the dynamic object to block vulnerable devices from accessing highly sensitive resources.

Supported products

We support Tenable Vulnerability Management only. We *do not* support Tenable Security Center.

Get the Tenable API key and secret

To configure the Tenable connector, you must create an API key and secret as described in this topic.

Note API keys inherit the permissions of the user account that generates them. Create the API key and secret using an account with full visibility to all hosts and vulnerabilities. For more information, see Permissions.

Procedure

Step 1 Log in to Tenable as an administrator.

Step 2 Click your profile image in the top right of the page.

Step 3 Click **My Profile** > **API Keys**.

Step 4 Click **Generate**.
You are required to confirm the action.

Step 5 Under Custom API keys, click (Copy to clipboard) to copy both the access key and secret key to the clipboard.

Step 6 Save these values for later use.

What to do next

See Create a Tenable connector, on page 2655.

Create a Tenable connector

This task explains how to configure the Tenable connector in Cisco Security Cloud. After you configure the connector, you must also configure an adapter to receive the dynamic object.

Before you begin

- Configure Tenable Vulnerability Management : Consult Tenable documentation.
- Get required information: Get the Tenable API key and secret, on page 2655.

We support Tenable Vulnerability Management only. We *do not* support Tenable Security Center.

Required User Role:

- Super Admin

Procedure

Step 1 Log in to Cisco Security Cloud.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 21600 seconds or six hours.) Interval at which IP mappings are retrieved from Tenable. We recommend a minimum value of 3600 seconds (one hour) to avoid issues with Tenable rate limiting.
Integration Key	Enter the API key you got in Get the Tenable API key and secret, on page 2655.
Secret Key	Enter the secret key obtained in Get the Tenable API key and secret, on page 2655.
Dynamic Object Name	Enter a name to identify the dynamic object created by this connector.
Severity Score	Click the minimum vulnerability severity level for the dynamic attributes connector to send IP addresses to the Cloud-Delivered Firewall Management Center. (For example, if you click **high**, IP addresses of hosts with either high or severe vulnerabilities are sent.) Choices: • **Critical** • **High** • **Medium** • **Low**

Value	Description
Severity System	Choices: • **VPR**: (Vulnerability priority rating.) Proprietary Tenable vulnerability rating that dynamically scores threats. VPR values range from 0.1-10.0, with a higher value representing a higher likelihood of exploit: • VPR **critical** is 9.0 and greater • VPR **high** is 7.0 and greater • VPR **medium** is 4.0 and greater • VPR **low** is 0.1 and greater • **CVSSv3**: (Common vulnerability scoring system version 3.) Industry-standard system that retrieves values from the national vulnerability database to describe risk associated with vulnerabilities. CVSS scores power a vulnerability's severity and risk value. For more information, see CVSS vs. VPR.

Step 6 Click **Test**. Save the connector only after the test succeeds.

Step 7 Click **Save**.

Step 8 Make sure **Ok** is displayed in the Status column.

See Create an adapter, on page 2659.

About Tenable dynamic objects in IDS, IPS, and access control policies

You can use IPS, IDS, and access control policies and rules to monitor or block traffic to and from servers with vulnerabilities identified by the Tenable connector:

1. To monitor traffic and inform you about vulnerabilities *without* blocking the traffic, create an intrusion detection system (IDS) policy with recommendations.
2. To monitor traffic, inform you about vulnerabilities, and block matching traffic, create an intrusion prevention system (IPS) policy with recommendations.
3. Create a new access control policy or add rules to an existing policy. Associate your IDS or IPS policy with an access control rule.

For information about intrusion policies for access control, refer to the Snort 3 configuration guide.

Create a Webex connector

This task creates a Webex connector that sends IP addresses to the management system for use in policies. The IP addresses associated with these tags are maintained by Webex.

This section discusses how to create a Webex connector that sends data to the Security Cloud Control for use in policies. The IP addresses associated with these tags are maintained by Webex. You do not have to create a dynamic attributes filters.

For more information, see Port Reference for Webex Calling.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Webex. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Provider Reserved IPs	(Required.) (Required.) Slide to enabled to retrieve any reserved IP addresses.

a) Click **Test** and make sure the test succeeds before you save the connector.
b) Click **Save**.
c) The Status column displays **Ok**.

Create a Zoom connector

Create a Zoom connector that sends data to the Security Cloud Control for use in policies.

The IP addresses associated with these tags are maintained by Zoom. You do not have to create a dynamic attributes filters.

For more information, see Zoom network firewall or proxy server settings.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new connector: click Add icon ( ), then click the name of the connector.
- Edit a connector: click Edit icon (Edit).
- Delete a connector: click Delete icon (Delete).

Step 5 Enter this information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.
Description	Optional description.
Pull Interval	(Default 30 seconds.) Interval at which IP mappings are retrieved from Zoom. The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
Provider Reserved IPs	(Required.) Slide to enabled to retrieve any reserved IP addresses.

a) Click **Test** and make sure the test succeeds before you save the connector.

b) Click **Save**.

The Status column displays **Ok**.

Create an adapter

An *adapter* is a secure connection to Cloud-Delivered Firewall Management Center or an On-Prem Firewall Management Center to which you push network information from cloud objects for use in access control policies.

You can create the following adapters:

- *On-Prem Firewall Management Center* for an on-premises Cloud-Delivered Firewall Management Center.

- *Cloud-Delivered Firewall Management Center* for devices managed by Cisco Security Cloud.

Note You must have a **Super Admin** user role to create the first adapter. To view or modify existing adapters, you must have an Admin or Super Admin user role.

How to create an On-Premises Firewall Management Center adapter

This topic discusses how to create an adapter to push dynamic objects from the dynamic attributes connector to Cisco Security Cloud.

Before you begin

Onboard the firewall manager to Cisco Security Cloud as discussed in *Onboard a Management Center* in the *Managing Security and Network Devices with Security Cloud Control* online help.

Note Currently, you can use the Tenable connector with the On-Premises Firewall Management Center only to create the dynamic object. The On-Premises Firewall Management Center does *not* receive network map entries from the Tenable connector, so you cannot use it with intrusion policy recommendations.

Required User Role: Super Admin

Procedure

Step 1 Log in to Cisco Security Cloud as a user with the Super Admin role.

Step 2 Click **Administration** > **Dynamic Attributes Connector** > **Adapters**.

Step 3 To add an adapter, click Add icon ( ) > On-Premises Firewall Management Center.

Step 4 To edit or delete an adapter, click Edit icon (Edit), or Delete icon (Delete).

Step 5 Add or edit this information.

Value	Description
Name	(Required.) Enter a unique name to identify this adapter.
Description	(Optional) Enter a description of the adapter.
Primary Device	Click the IP address of a management center associated with your tenant.
Secondary Device	(Optional) If you have a secondary On-Premises Firewall Management Center, click its name.

Step 6 Click **OK**.

How to create a Cloud-Delivered Firewall Management Center adapter

This topic discusses how to create an adapter to push dynamic objects from the dynamic attributes connector to Cisco Security Cloud.

Before you begin

Required User Role:

- Super Admin

Procedure

Step 1 Log in to Cisco Security Cloud as a user with the Super Admin role.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Adapters**.

Step 4 To add an adapter, click Add icon ( ) > Cloud-Delivered Firewall Management Center.

Step 5 To edit or delete an adapter, click Edit icon (Edit), or Delete icon (Delete).

Step 6 Edit the following information.

Value	Description
Name	(Required.) Enter a unique name to identify this adapter.
Description	Optional description of the adapter.
Cloud FMC URL	From the list, click the URL for your Cloud-Delivered Firewall Management Center.

Step 7 Click **Test** and make sure the test succeeds before you save the adapter.

Step 8 Click **Save**.

Create dynamic attributes filters

Create dynamic attributes filters to expose them as dynamic objects in Security Cloud Control for use in access control policies.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Security Cloud Control as dynamic objects that can be used in access control policies. For example, restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules or DNS rules using dynamic attributes filters, on page 2456.

Before you begin

Connectors, on page 2631

Procedure

Step 1 Log in to Security Cloud Control.

a) Click **Firewall**.

b) Click **Administration** > **Dynamic Attributes Connector** > **Dynamic Attributes Filters**.

Step 2 Do any of the following:

- Add a new filter: click **Add** ( ).
- Edit or delete a filter: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 3 Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in a policy and in the Security Cloud Control Object Manager (**External Attributes** > **Dynamic Object**).
Connector	From the list, click the name of a connector to use.
Query	Click Add .

Step 4 To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: • **Equals** to exactly match the key to the value. • **Contains** to match the key to the value if any part of the value matches.

Item	Description
Values	Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 5 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

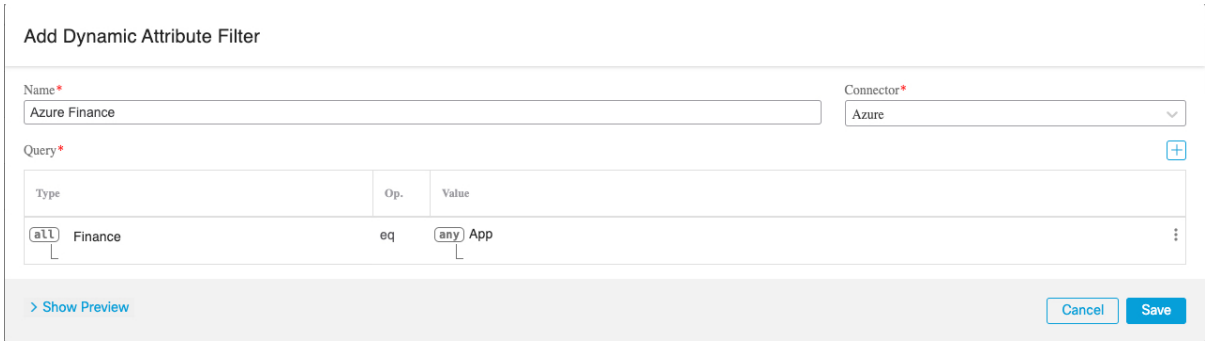
Step 6 When you're finished, click **Save**.

Step 7 (Optional.) Verify the dynamic object in the Security Cloud Control.

a) Log in to the Security Cloud Control.

b) Click **Policies** > **Firewall Threat Defense**.

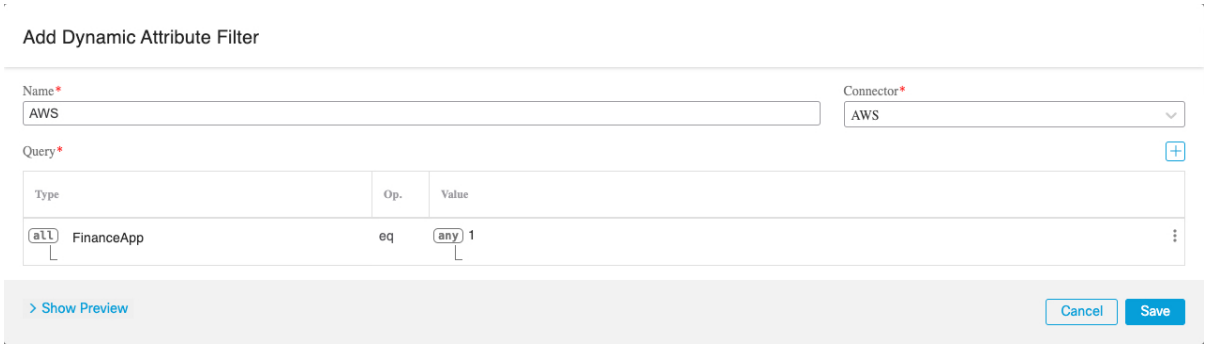
c) Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.



The dynamic attribute query you created should be displayed as a dynamic object.

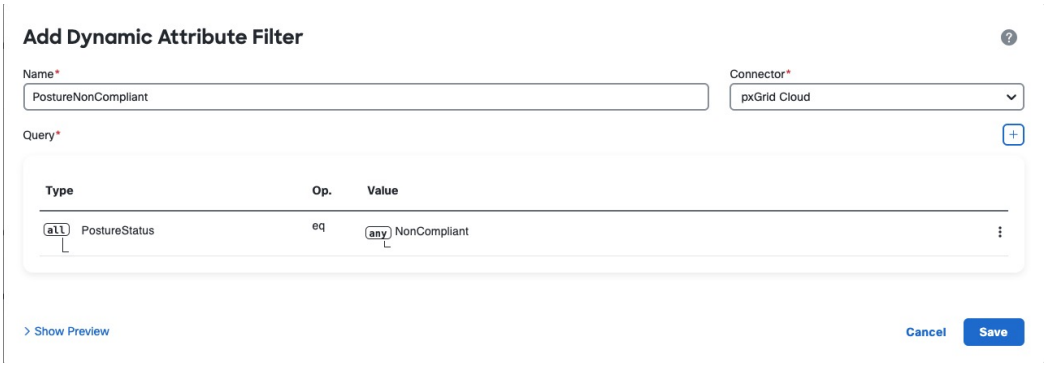
Dynamic attribute filter examples

This topic provides some examples of setting up dynamic attribute filters.



Example: azure

This example shows one criterion: a server tagged as a Finance app.



Example: AWS

This example shows one criterion: a FinanceApp with a value of 1.

Example: pxGrid cloud

This example shows one criterion: PostureStatus is NonCompliant.

Disable the dynamic attributes connector

Disable the Dynamic Attributes Connector when you no longer wish to collect dynamic objects from cloud sources.

If you no longer wish to collect dynamic objects from cloud sources, you can disable the Dynamic Attributes Connector in the Cloud-Delivered Firewall Management Center.

Procedure

Step 1 Log in to the Cloud-Delivered Firewall Management Center if you have not done so already.

Step 2 Click **Administration** > **Dynamic Attributes Connector**.

Step 3 Slide to **Disabled**.

Dynamic firewall

A dynamic firewall integrates user identity data with user trust data provided by Identity Intelligence to enhance your ability to detect identity-based exploits in your network.

Identity data integration

The dynamic firewall integrates user identity data from Microsoft AD and ISE with user trust data.

Dynamic Firewall

A dynamic firewall integrates identity sources with Identity Intelligence to provide user and device trust information.

Enhanced identity information

Previously, the Security Cloud Control collected information about users exclusively from the configured identity sources, such as Microsoft Active Directory, the passive identity agent, Cisco Identity Services Engine (Cisco ISE), and so on. This information generally included user name, group, and IP address.

The dynamic firewall enables you to pair user identity with intelligence and use that information in reporting and access control policies.

To use the dynamic firewall, you must:

- Have an Identity Intelligence tenant

  See Duo Identity Security with Cisco Identity Intelligence.

- Set up an identity source:
  - Cisco Identity Services Engine (Cisco ISE)
  - pxGrid Cloud

    pxGrid Cloud combines identity and posture in the same feed

    More information: What is pxGrid?

  In addition to providing authentication information, Cisco ISE and pxGrid Cloud can provide the following:

  - SGT Exchange Protocol (SXP) over TCP binding and directory session information if desired. For more information, see the *Cisco Identity Services Engine Administrator Guide*
  - Posture and mobile device management compliance. For more information, see Compliance.

- Set up an identity realm:
  - Create an LDAP realm or an Active Directory realm and realm directory, on page 2325
  - Create a Microsoft Azure AD (SAML) realm for passive authentication, on page 2298

The *identity source* provides authentication information (login, logout) as well as posture. The identity source can also provide SXP binding and session directory information if desired.

The *identity realm* provides user, group, and IP address information.

How to configure the dynamic firewall

This topic helps you understand the concepts and options to configure the dynamic firewall discussed in Dynamic Firewall, on page 2664.

Summary

The dynamic firewall integrates an identity source (such as Cisco ISE) with Cisco Identity Intelligence, which provides user trust information to the Cloud-Delivered Firewall Management Center.

1. Configure Cisco Identity Intelligence to collect user trust information.
2. Configure a supported Cloud-Delivered Firewall Management Center identity source.
3. Configure a supported identity realm.

4. Enable the dynamic attributes connector.
5. Configure the dynamic firewall.

Workflow

The following procedure provides a high-level overview of how to configure the dynamic firewall.

1. As a Duo user with the Owner role, provision a Cisco Identity Intelligence tenant.

   You can provision a tenant from Duo Advantage as discussed in *Provision Your Cisco Identity Intelligence Tenant*.

2. In Cisco Identity Intelligence, create an API integration and use the information to set up the dynamic firewall.

   We use Cisco Identity Intelligence to find user and device risk information in your network.

   For more information about Cisco Identity Intelligence, see How-to Guides.

   For more information about this task, see Get required information for Identity Intelligence, on page 2667.

3. (Microsoft Azure AD realm only.) In Identity Intelligence, create a Microsoft Entra ID integration.

   For more information, see Microsoft Entra ID (Azure AD) Data Integration.

4. Create an identity source. (If you already have an identity source, continue with the next step.)

   You can do this in any of the following ways:

   - The Configure Dynamic Firewall dialog box displays **Configure** links to start setting up your identity source.
   - Click **Integration** > **Other Integrations** > **Identity Sources**.

   For more information about creating identity sources, see:

   - Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390
   - Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier), on page 2436
   - Configuring a pxGrid Cloud identity source, on page 2468

5. Create an identity realm.

   We support the following realms:

   - Create an LDAP realm or an Active Directory realm and realm directory, on page 2325

     Only Microsoft AD is supported; LDAP realms are not supported.

   - Create a Microsoft Azure AD (SAML) realm for passive authentication, on page 2298

6. Create the dynamic firewall instance. (If you already have a dynamic firewall instance, continue with the next step.)

   Click **Administration** > **Dynamic Attributes Connector** and click **Configure Dynamic Firewall**.

   See Create a dynamic firewall instance, on page 2669.

7. Associate your identity source with Cisco Identity Intelligence.

See Associate an identity source with Identity Intelligence, on page 2670.

8. View system-defined filters.

   We create dynamic attributes filters for the following:

   - Untrusted device
   - Trusted device
   - Untrusted user
   - Questionable user

   You can edit or replace these dynamic attributes filters as discussed in Create dynamic attributes filters, on page 2677.

9. View system-defined access control rules.

   We create an access control policy named Dynamic Firewall Policy (or similar) with the following rules:

   - Block an untrusted user from any source network to any destination network.
   - Monitor a questionable user from any source network to any destination network.
   - Block an untrusted device from any source network to any destination network.

   You can edit or delete the access control policy and rules as discussed in View and edit the system-created access control policy, on page 2676.

Get required information for Identity Intelligence

Get the necessary credentials and configuration values from Identity Intelligence to enable integration with the dynamic firewall.

This task discusses how to create an API client, which provides all the get required information to set up Identity Intelligence in the dynamic firewall.

If you already have an API client and you know the values of all these parameters, you can skip this procedure and continue with Create a dynamic firewall instance, on page 2669:

- **Client ID**
- **API URL**
- **Token URL**
- **Client Secret**

Before you begin

Integrating with the dynamic firewall requires you to create an *API client integration* in Identity Intelligence.

Among the values you must know about your API client integration is the client secret, which is displayed when you create the API client only. For that reason you might need to create the API integration first.

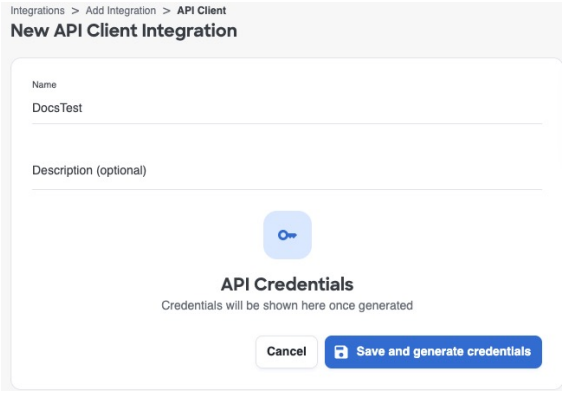
For more information about creating an API cilent integration, see Public API.

Follow these steps to get required information for Identity Intelligence:

Procedure

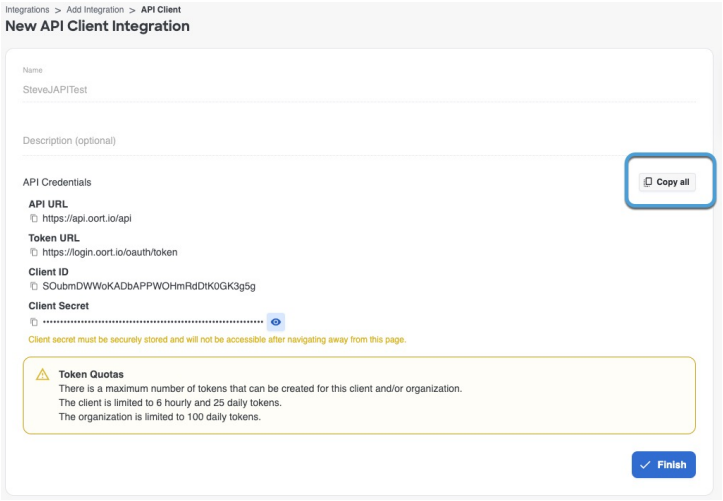
Step 1 Log in to your Identity Intelligence tenant.

Step 2 Click (**Integrations**).



Step 3 Click **Add Integration**.

Step 4 On the next page, under API Clients, click **Add API Client**.



Step 5 Enter a **Name** and an optional **Description**.

Step 6 Click **Save and Generate Credentials**.

This figure shows an example.

Step 7 On the next page, click **Copy all** as this figure shows.

Step 8 Save the credentials for later use.

Step 9 Click **Finish**.

What to do next

See Create a dynamic firewall instance, on page 2669.

Create an identity source and realm for the dynamic firewall

Before you configure the dynamic firewall, you must configure a supported identity realm and identity source.

Configure an identity realm

These identity realms are supported:

- Create an LDAP realm or an Active Directory realm and realm directory, on page 2325

  Only Microsoft AD is supported; LDAP realms are not supported.

- Create a Microsoft Azure AD (SAML) realm for passive authentication, on page 2298

Configure an identity source

These identity sources are supported:

- On-premises Cisco ISE: Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390
- Single or multiple Cisco ISE clusters:
  - Configuring a pxGrid Cloud identity source, on page 2468
  - Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier), on page 2436

Create a dynamic firewall instance

Create a new instance of the dynamic firewall to establish an association between an identity source and Identity Intelligence.

This task discusses how to create a new instance of the dynamic firewall, which is an association between an identity source and Identity Intelligence.

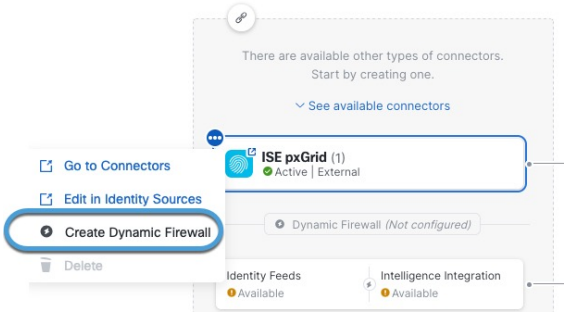
Before you begin

Complete all these steps:

- Create an identity source:
  - Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390.
  - Create a pxGrid Cloud identity source, on page 2443.

Follow these steps to create a dynamic firewall instance:

Procedure



Step 1 If you haven't already done so, log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector**.

Step 4 Click next to the name of the identity source with which to add the dynamic firewall.

The following figure shows an example.

Note
If you do not see an identity source, create one before continuing:

- Ways to configure the Cisco Identity Services Engine (Cisco ISE) identity source, on page 2390
- Configuring a pxGrid Cloud identity source (Cisco ISE 3.3 or earlier), on page 2436
- Configuring a pxGrid Cloud identity source, on page 2468

Step 5 Click **Create Dynamic Firewall**.

Step 6 Continue with Associate an identity source with Identity Intelligence, on page 2670.

Associate an identity source with Identity Intelligence

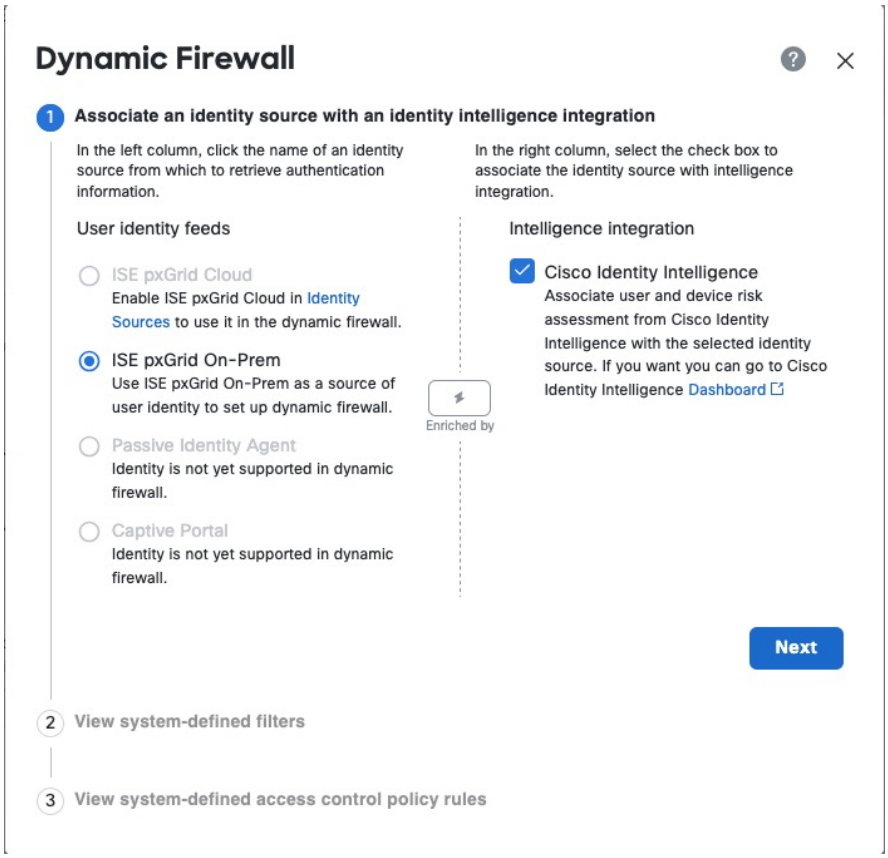
Associate a supported identity source with Identity Intelligence to enable user and device trust ratings for dynamic firewall configuration.

This task discusses how you associate an identity source with Identity Intelligence, which provides user and device trust ratings to the Security Cloud Control.

For more information, see User Trust Level.

Before you begin

Before you begin, make sure you:



- Understand how the identity realm, identity source, and Identity Intelligence work together as discussed in Dynamic Firewall, on page 2664.
- Completed the tasks discussed in Create a dynamic firewall instance, on page 2669.

Procedure

Step 1 Start with Create a dynamic firewall instance, on page 2669.

Step 2 On the next page, from the left column, click your identity source. Then, in the right column, select the **Cisco Identity Intelligence** check box to add user intelligence, including user and device risk.

The following figure shows an example.

Step 3 Click **Next**.

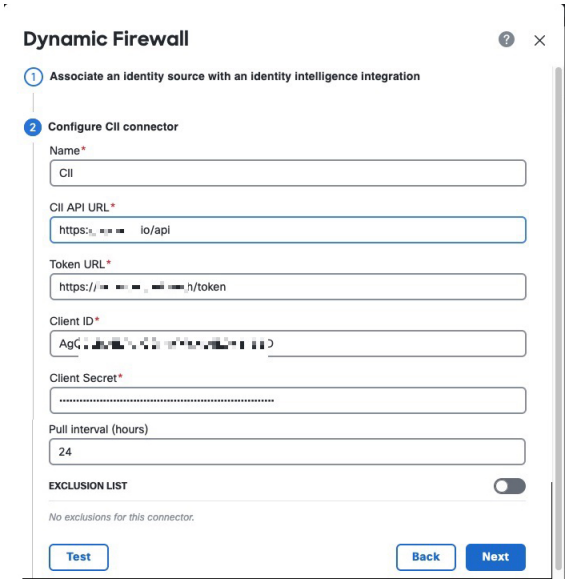
Step 4 Continue with Configure Identity Intelligence, on page 2671.

Configure Identity Intelligence

This task enables integration between the dynamic firewall and Identity Intelligence.

This task discusses how you associate an identity source with Identity Intelligence, which provides user and device risk ratings to the Security Cloud Control.

Before you begin



Complete the tasks discussed in Associate an identity source with Identity Intelligence, on page 2670.

Procedure

Step 1 Complete the tasks discussed in Associate an identity source with Identity Intelligence, on page 2670.

Step 2 If you selected the **Cisco Identity Intelligence** check box, enter the information you found for Identity Intelligence as described in Get required information for Identity Intelligence, on page 2667.

The following figure shows an example.

Step 3 (Optional.) For Identity Intelligence to consider a specific set of users as trusted, slide **Exclusion List** to **Slider enabled** ( ).

Enter one user name per line in **username@domain.com** format. Users in this list are considered trusted by Identity Intelligence.

Step 4 Click **Test**.

Only if the test succeeds, continue with the next step.

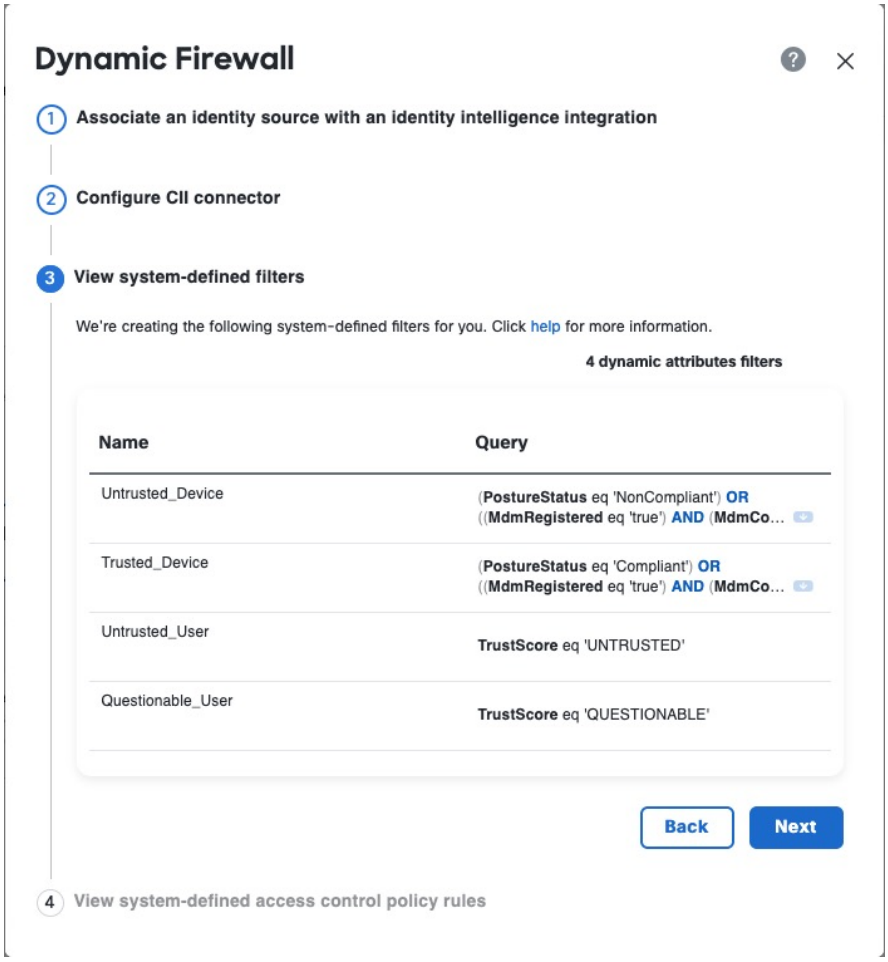
If any errors are displayed, check all of your Identity Intelligence values and try again.

Step 5 Click **Next**.

Step 6 Continue with View system-defined filters, on page 2672.

View system-defined filters

This task allows you to examine and understand the system-defined dynamic attributes filters that are automatically created during the configuration process.



This task discusses how you associate an identity source with Cisco Identity Intelligence, which provides user and device risk ratings to the Security Cloud Control.

Before you begin

See Configure Identity Intelligence, on page 2671.

Procedure

Step 1 The system displays a set of system-defined dynamic attributes filters, as shown in the following figure.

Step 2 View the system-created filters. Click on any row to expand the filter so you can view the filter and see its details.

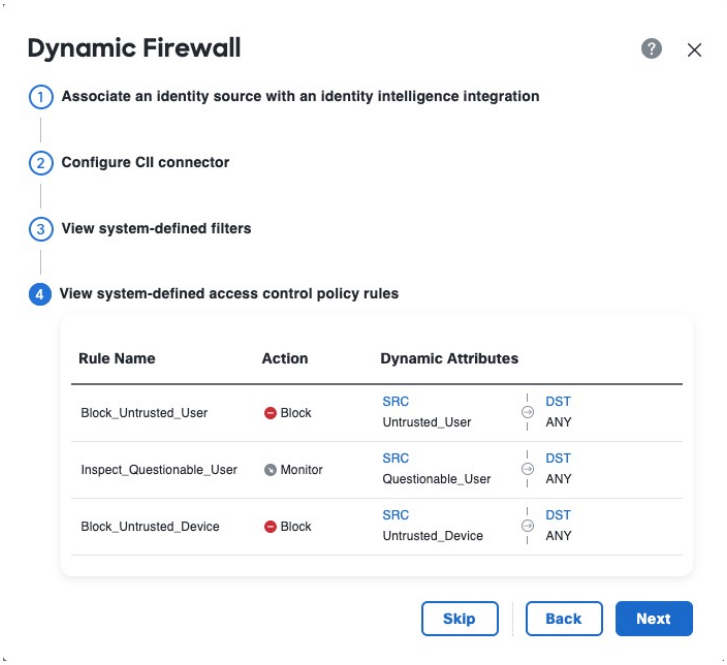
Step 3 Click **Next**.

Step 4 Continue with View system-defined access control rules, on page 2673.

View system-defined access control rules

This task allows you to review and decide whether to create system-defined access control rules for your dynamic firewall instance.

This task discusses access control rules created by the dynamic firewall.

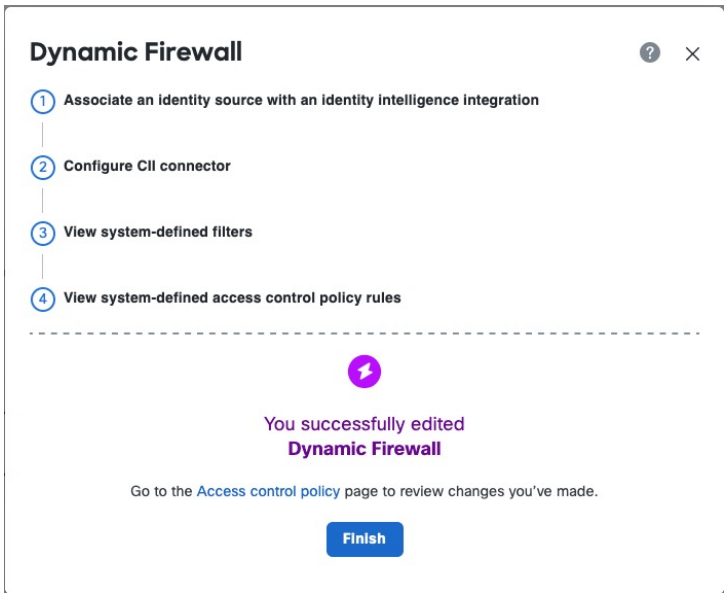


Before you begin

See View system-defined filters, on page 2672.

Procedure

Step 1 View the system-created access control rules.



The following figure shows an example.

Step 2 Choose one of these options:

- Click **Skip** to skip creating these access control rules. You can create your own anytime.
- Click **Next** to create an access control policy named Dynamic Firewall Policy with the rules shown in the preceding figure.
- Click **Back** to return to system-created filters.

Step 3 After you click **Next**, if you created access control rules successfully, the following page is displayed:

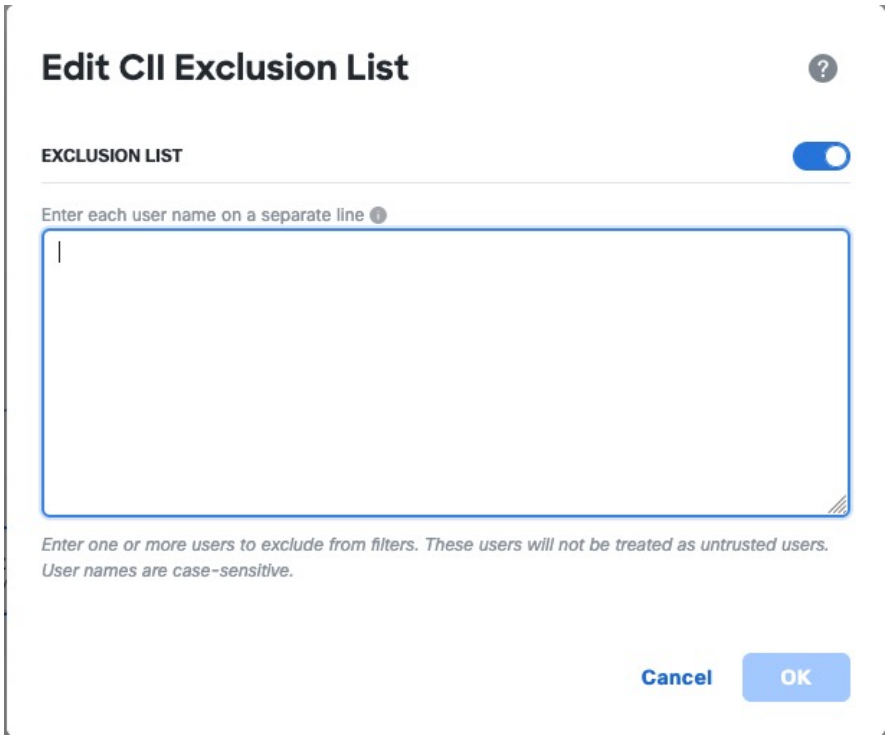
Edit the user exclusion list

Specify users provided by Identity Intelligence as always being trusted.

You can instruct Identity Intelligence to treat specific users as trusted.

Before you begin

Configure the dynamic firewall as discussed in Create a dynamic firewall instance, on page 2669.



Procedure

Step 1 Click **Administration** > **Dynamic Attributes Connector**.

Step 2 Click next to the name of the identity source.

Step 3 Click **Edit CII Exclusion List**.

The following dialog box is displayed.

Step 4 In the provided field, enter one user name in `username@domain.com` format on a line, press Enter, and enter another user name.

Each user name is considered as trusted by Identity Intelligence.

View and edit the system-created access control policy

Customize the system-created access control policy by adding devices, changing rules, reordering rules, or deleting rules to meet your specific network security requirements.

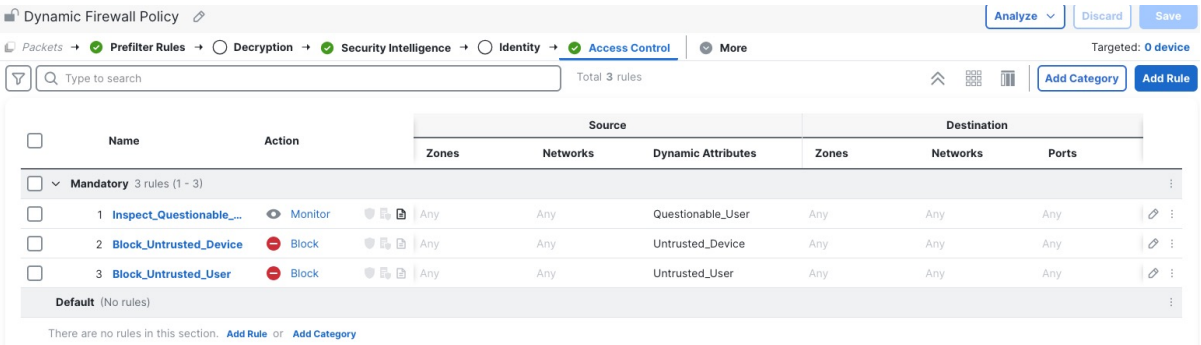
This topic discusses how you can edit the system-created access control rules and policy. Initially, the policy isn't associated with any devices but if you want to use it you can add devices, change rules, reorder rules, or delete rules.

Before you begin

Complete the tasks described in View system-defined access control rules, on page 2673.

Follow these steps to view and edit the system-created access control policy:

Procedure



Step 1 If you haven't already done so, log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Policies** > **Firewall Threat Defense** > **Access Control heading** > **Access Control**.

Step 4 Click **Edit** ( ) next to the policy named Dynamic Firewall Policy (or similar).

The following figure shows a sample access control policy.

Note that in this access control policy, only the rule set to monitor questionable users logs anything. To adjust the logging settings, see Logging settings for access control policies, on page 2014.

Step 5 Do any of the following:

- Target the access control policy at devices: Assign access control policy to devices, on page 2014.
- Edit the policy, including adding logging: Manage access control policies, on page 2002.
- Edit access control rules: Access control rule management, on page 2062.
- Set advanced policy options: Configure advanced settings for the access control policy, on page 2688.
- Associate other policies with this access control policy: Associate prefilter, decryption, and identity policies with an access control, on page 2016.

Create dynamic attributes filters

Create dynamic attributes filters that can be used as dynamic objects in access control policies to restrict access based on specific criteria such as group membership.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Security Cloud Control as dynamic objects that can be used in access control policies. For example, you could restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules or DNS rules using dynamic attributes filters, on page 2456.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 Click **Firewall**.

Step 3 Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.

Step 4 Do any of the following:

- Add a new filter: click **Add** ( ).
- Edit or delete a filter: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 5 Enter the following information.

- **Name**: Unique name to identify the dynamic filter (as a dynamic object) in access control policy and in the Security Cloud Control Object Manager (**External Attributes** > **Dynamic Object**).
- **Connector**: From the list, click the name of a connector to use.

Step 6 To add a query, enter the following information.

- **Key**: Click a key from the list. Keys are fetched from the connector.
- **Operation**: Click one of the following:
  - **Equals** to exactly match the key to the value.
  - **Contains** to match the key to the value if any part of the value matches.
- **Values**: Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 7 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

When you're finished, click **Save**.

What to do next

Verify the dynamic object in the Security Cloud Control.

1. Log in to the Security Cloud Control.
2. Click **Policies** > **Firewall Threat Defense**.
3. Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.

The dynamic attribute query you created should be displayed as a dynamic object.

Use Dynamic Objects in Access Control Policies

The dynamic attributes connector enables you to configure dynamic attributes filters, seen in the Security Cloud Controlas dynamic objects, in access control rules.

Dynamic objects in access control rules

A *dynamic object* is automatically pushed from the dynamic attributes connector to the Secure Firewall Manager after you create connectors and save a dynamic attributes filter on the connector.

You can use these dynamic objects on the access control rule's **Dynamic Attributes** tab page. You can add dynamic objects as source or destination attributes.

Dynamic object usage examples

In an access control block rule, you can add a Finance dynamic object as a destination attribute to block access to Finance servers by whatever objects match the other criteria in the rule.

Dynamic attributes filter limitations

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

Create dynamic attributes filters

Create dynamic attributes filters to expose them as dynamic objects in Security Cloud Control for use in access control policies.

Dynamic attributes filters that you define using the Dynamic Attributes Connector are exposed in the Security Cloud Control as dynamic objects that can be used in access control policies. For example, restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

For more information about access control rules, see Create access control rules or DNS rules using dynamic attributes filters, on page 2456.

Before you begin

Connectors, on page 2631

Procedure

Step 1 Log in to Security Cloud Control.

a) Click **Firewall**.

b) Click **Administration** > **Dynamic Attributes Connector** > **Dynamic Attributes Filters**.

Step 2 Do any of the following:

- Add a new filter: click **Add** ( ).
- Edit or delete a filter: Click **More** ( ), then click **Edit** or **Delete** at the end of the row.

Step 3 Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in a policy and in the Security Cloud Control Object Manager (**External Attributes** > **Dynamic Object**).
Connector	From the list, click the name of a connector to use.
Query	Click Add .

Step 4 To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: • **Equals** to exactly match the key to the value. • **Contains** to match the key to the value if any part of the value matches.
Values	Click either **Any** or **All** and click one or more values from the list. Click **Add another value** to add values to your query.

Step 5 Click **Show Preview** to display a list of networks or IP addresses returned by your query.

Step 6 When you're finished, click **Save**.

Step 7 (Optional.) Verify the dynamic object in the Security Cloud Control.

a) Log in to the Security Cloud Control.

b) Click **Policies** > **Firewall Threat Defense**.

c) Click **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.

The dynamic attribute query you created should be displayed as a dynamic object.

Dynamic attributes rule conditions

Dynamic attributes rule conditions allow you to specify access control rules based on real-time properties such as network objects, device types, locations, and security tags. These conditions determine how access control rules match traffic based on various attributes, optimizing policy flexibility and accuracy.

Types of dynamic attributes

Dynamic attributes include:

- (source or destination) Dynamic objects (such as from the dynamic attributes connector)

  The dynamic attributes connector enables you to collect data (such as networks and IP addresses) from cloud providers and send it to the Cloud-Delivered Firewall Management Center so they can be used in access control rules.

  For more information about the dynamic attributes connector, see About the Dynamic Attributes Connector , on page 2621.

- (source only) SGT objects contain tags either manually defined or defined in ISE. For more information, see Source and destination security group tag (SGT) matching, on page 2374 and Security group tags, on page 2972.

- (source only) Location IP objects, defined by Cisco ISE

- (source only) Device type objects, defined by Cisco ISE (also referred to as endpoint profile objects)

Combining objects in rules

Dynamic attributes can be used as source criteria and destination criteria in access control rules. Use these guidelines:

- Objects of different types are ANDd together

- Objects of a similar type are ORd together

For example, if you choose source destination criteria SGT 1, SGT 2, and device type 1, the rule matches if device type 1 is detected on either SGT 1 or SGT 2.

If you select both a security group tag, and a dynamic object that lists IP addresses, the rule matches if traffic with the tag originating from, or destined to, one of those IP addresses.

Create access control rules or DNS rules using dynamic attributes filters

Create access control rules using dynamic objects that are based on dynamic attributes filters you have previously configured.

This topic discusses how to create access control rules using dynamic objects (these dynamic objects are named after the dynamic attributes filters you created previously).

To add dynamic attributes filters to DNS policies, see Create basic DNS policies, on page 2561.

To add dynamic attributes filters to DNS policies, see Creating Basic DNS Policies.

Before you begin

Create dynamic attributes filters as discussed in Create dynamic attributes filters, on page 2455.

Note You cannot create dynamic attributes filters for Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Outlook 365, Tenable, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

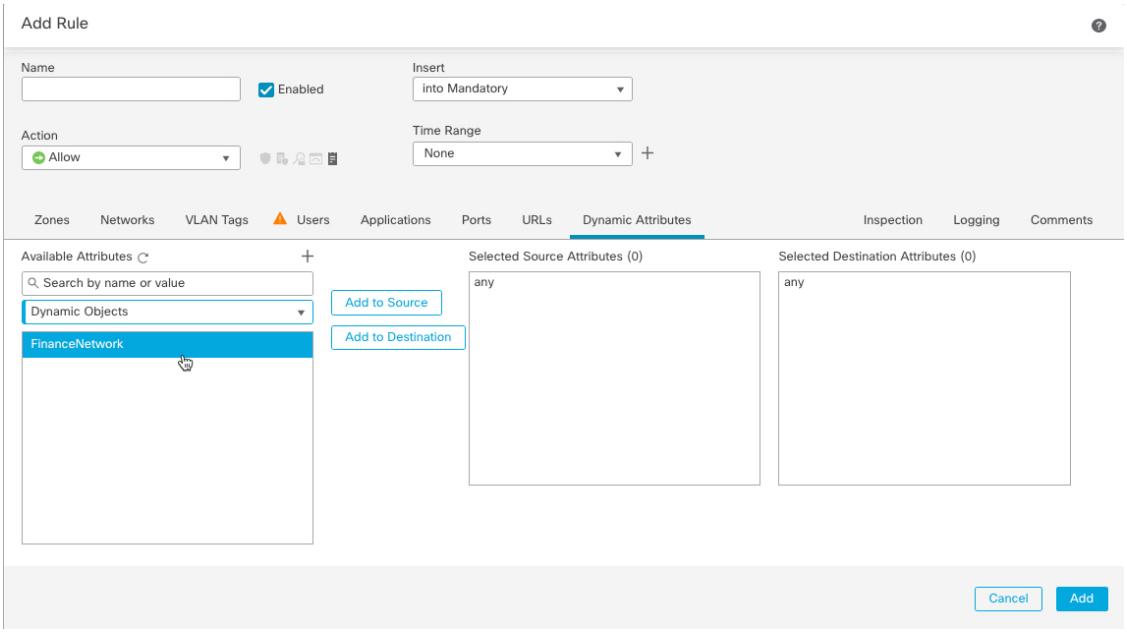
Follow these steps to create access control rules or DNS rules using dynamic attributes filters:

Procedure

Step 1 Log in to Security Cloud Control as a user with the Super Admin role.

Click **Policies** > **Firewall Threat Defense** > **Access Control heading** > **Access Control**.

Step 2 Click **Firewall**.



Step 3 Click **Edit** ( ) next to an access control policy.

Step 4 Click **Add Rule**.

Step 5 Click the **Dynamic Attributes** tab.

Step 6 In the Available Attributes section, from the list, click **Dynamic Objects**.

The following figure shows an example.

This example shows a dynamic object named `APIC Dynamic Attribute` that corresponds to the dynamic attribute filter created in the dynamic attributes connector.

Step 7 Add the desired object to source or destination attributes.

Step 8 Add other conditions to the rule if desired.

See Dynamic attributes rule conditions, on page 2681.

Use dynamic objects in DNS policies

Use dynamic objects in DNS rules to enable dynamic filtering capabilities based on attributes from the dynamic attributes connector.

The dynamic attributes connector enables you to configure dynamic filters seen in the Cloud-Delivered Firewall Management Center as dynamic objects, in DNS rules. For information about DNS policies, see DNS Policies for Security Intelligence, on page 2557.

A dynamic object is automatically pushed from the dynamic attributes connector to the Cloud-Delivered Firewall Management Center after you create connectors and save a dynamic attributes filter on the connector.

You can use these dynamic objects on the DNS rule's Dynamic Attributes tab page, similarly to the way you use Security Group Tags (SGTs). You can add dynamic objects as source or destination attributes, except for endpoint device type objects, which are source only.

Procedure

Step 1 Click **Policies** > **Access Control heading** > **DNS** and create or edit a DNS policy.

Step 2 Add or edit a rule.

Step 3 Click the **Dynamic Attributes** tab.

Step 4 In the **Dynamic Attributes** list, select the objects you want to use, then add them to the source or destination lists as appropriate.

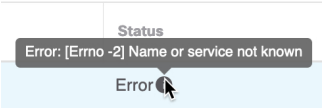
Initially, all security group and dynamic objects are listed, by you can uncheck the Security Group option to see dynamic objects only.

Step 5 On the **DNS** tab, select the appropriate list or feed to match the DNS requests you are targeting.

Step 6 Add other conditions to the rule if desired and set the action.

Step 7 Click **Save**.

Troubleshoot the Dynamic Attributes Connector



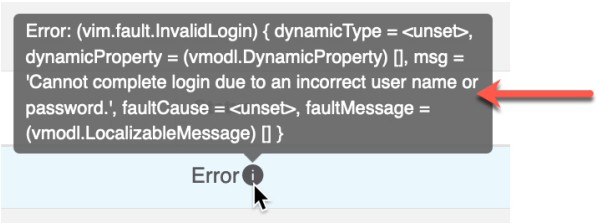
How to troubleshoot issues with the dynamic attributes connector, including using provided tools.

Troubleshoot error messages

This reference provides error messages and troubleshooting solutions for dynamic attributes connectors and adapters in the dynamic attributes connector.

Problem: name or service not known error

This error is displayed as a tooltip when you hover the mouse over an error condition on a connector. An example follows; yours might look different.



Solution: Edit the connector and check for:

- A trailing slash on a host name
- Verify the password is correct

Problem: incorrect username or password

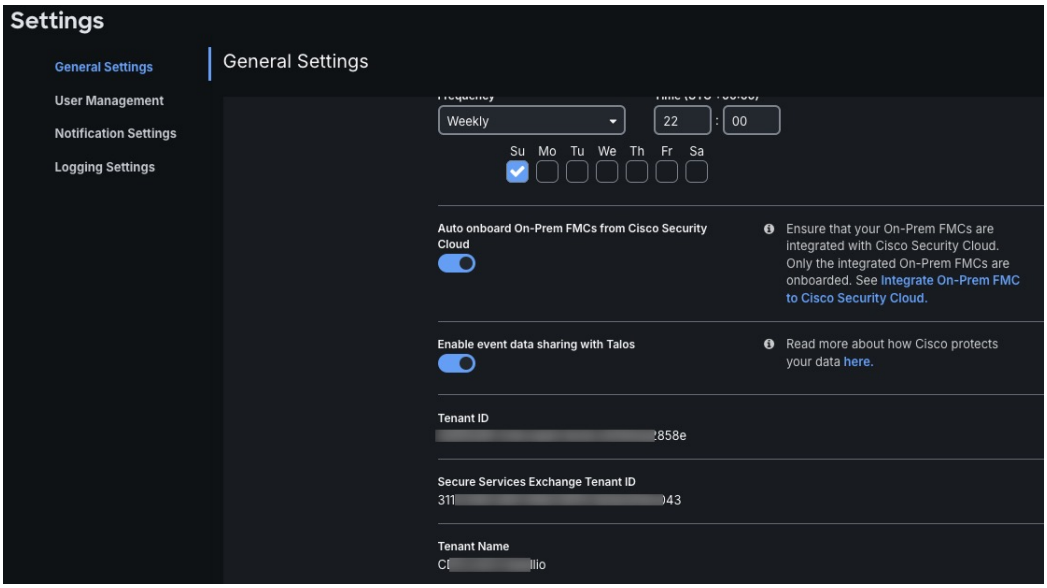
This error is displayed as a tooltip when you hover the mouse over an error condition on a connector.

Solution: Edit the connector and change the user name or password.

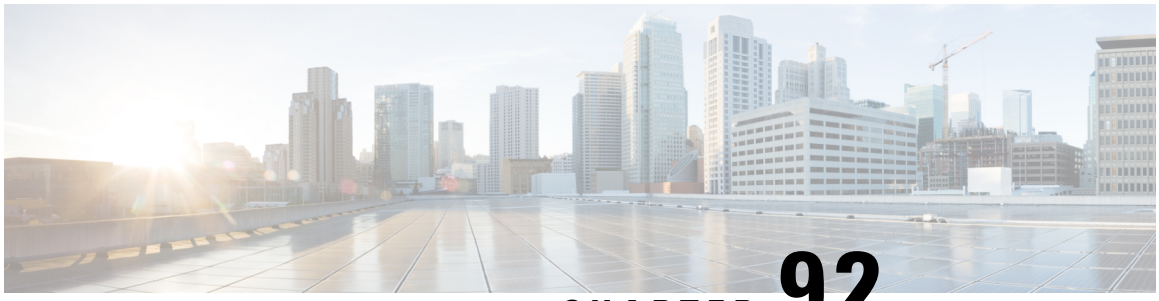
Get your tenant ID

This task provides your tenant ID to Cisco TAC for troubleshooting assistance with the dynamic attributes connector.

If you require assistance with the dynamic attributes connector, you must provide your tenant ID to Cisco TAC so we can look at your logs.



Procedure



Step 1 Log in to Security Cloud Control.

Step 2 Click **Administration** > **General Settings**.

Step 3 Copy your tenant ID to the clipboard to provide to Cisco TAC.

A sample follows.

CHAPTER 92

Advanced Settings for Access Control

Advanced access control policy settings typically require little or no modification. The default settings are appropriate for most deployments.

- Requirements and prerequisites for advanced settings, on page 2687
- Configure advanced settings for the access control policy, on page 2688

Requirements and prerequisites for advanced settings

This reference provides the requirements and prerequisites needed to configure advanced settings for access control policy, including model support, domain compatibility, and user role permissions.

Model support

Any

Supported domains

Any

User roles

- Admin
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies** > **Access Control heading** > **Access Control** and choose the **Access Control Policy** > **Modify Access Control Policy** > **Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for network analysis and intrusion policies, the configuration of the Security Intelligence policy for the access

control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.

- **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

Configure advanced settings for the access control policy

Configure advanced settings to customize access control policy behavior for specific security requirements and performance optimization.

Advanced access control policy settings typically require little or no modification. The default settings are appropriate for most deployments. Note that many of the advanced preprocessing and performance options in access control policies may be modified by rule updates as described in *Update Intrusion Rules* in the *Cisco Secure Firewall Management Center Administration Guide* .

Caution See Configurations that restart the snort process when deployed or activated, on page 198 for a list of advanced setting modifications that restart the Snort process, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. Refer to Snort restart traffic behavior, on page 196.

Before you begin

Inheriting settings from a parent policy:

- If the access control policy has a base policy, you can elect to inherit settings from the base policy. Select **Inherit from (*base policy*)** for each setting group where you want to use the parent policy's settings. If you are allowed to configure unique settings for the policy, you must deselect the option to make your edits.
- If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. In this case, inheritance has been configured so that these settings are locked. The settings are read-only.

Follow these steps to configure advanced settings for the access control policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Create or edit an access control policy.

Step 3 Select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 For each settings group, click **Edit** ( ) and configure the settings as needed.

For each feature group, a separate dialog box is opened where you can make your changes. Click **OK** to save any changes.

- **General Settings**—These settings apply broadly to the policy, including URL filtering options. For more information, see General settings, on page 2691.
- **Identity Policy Settings**—Select the policy to be used to implement user identity discovery. You must implement an identity policy to get user or user group information in connection events, or to write access control rules based on users or groups. For more information, see Identity policies, on page 2505.
- **Decryption Policy Settings**—Select the policy to be used when decrypting connections. You must decrypt traffic to apply inspection to encrypted connections.
- **TLS Server Identity Discovery**—Whether to allow the firewall to extract certificate details such as Common Name (CN), Organization, or Subject Alternative Names (SANs) even when TLS 1.3 encryption would normally hide them. This improves policy accuracy without requiring a decryption rule; the original client connection remains encrypted. For more information, see TLS server identity discovery, on page 2692.
- **Prefilter Policy Settings**—Select the policy to be used for statically offloading large flows, implementing early connection blocks, or rezoning plain-text tunnel traffic.
- **Network Analysis and Intrusion Policies**—Advanced network analysis and intrusion policy settings allow you to:
  - Specify the intrusion policy and associated variable set that are used to inspect packets that must pass before the system can determine exactly how to inspect that traffic.
  - Change the access control policy's default network analysis policy, which governs many preprocessing options.
  - Use custom network analysis rules and network analysis policies to tailor preprocessing options to specific security zones, networks, and VLANs.
- **Threat Defense Service Policy**—Use the service policy to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. The service policy rules are applied after the access control rules. For more information, see Service Policies, on page 2707.
- **Files and Malware Settings**—Tune file and malware inspection performance and storage, on page 2615 provides information on performance options for file control and malware defense.
- **Threat Detection**—Configure the portscan detector to detect and prevent portscan activity in all types of traffic to protect networks from eventual attacks. Portscan traffic can be detected efficiently in both allowed and denied traffic..
- **Elephant Flow Settings**—Elephant flows are large, long duration, and fast flows that can cause duress for Snort cores. There are two actions that you can apply on elephant flows to reduce system stress, CPU hogging, packet drops, and so on. These actions are:
  - Bypass any or all applications—This action bypasses flow from Snort inspection.
  - Throttle—This action applies dynamic rate limit policy (10% reduction) on elephant flows.

  For more information, see Configure elephant flow detection, on page 2736.
- **Intelligent Application Bypass Settings**—(Use **Elephant Flow Settings** instead of this option.) Intelligent application bypass (IAB) is an expert-level configuration that specifies applications to bypass or test for bypass if traffic exceeds a combination of inspection performance and flow thresholds.

IAB settings are applicable for Snort2 devices or pre 7.2.0 Snort3 devices. For more information, see Intelligent application bypass, on page 2693.

- **Transport/Network Layer Preprocessor Settings**—Advanced transport and network preprocessor settings apply globally to all networks, zones, and VLANs where you deploy your access control policy. For more information, see Transport/network layer preprocessor settings, on page 2699.
- **Detection Enhancement Settings**—Detection enhancement settings determine whether adaptive profiles are used for application detection and intrusion rules in the access control policy. Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party. For more information, see Detection enhancement settings, on page 2700.
- **Performance Settings**—Settings for improving the performance of your system as it analyzes traffic for attempted intrusions. These settings are very advanced and should be left as defaults by most users. See Performance settings, on page 2702.
- **Latency-Based Performance Settings**—Settings specific to latency-based performance. These settings are very advanced and should be left as defaults by most users. See Latency-based performance settings, on page 2704.
- **Shadow Traffic**—The Shadow traffic dashboard enhances the visibility of traffic originating from unsanctioned privacy technologies. This type of traffic is specifically designed to evade traditional network monitoring and analysis by advanced firewalls. There is also a shadow traffic type attribute added to connection and unified events. You can disable this option if you do not need visibility on traffic that might contain unsanctioned content. For more information, see *The Shadow Traffic Widget* in the *Cisco Secure Firewall Management Center Administration Guide*
- **Advanced Logging**—Enable this feature to enrich connection logs with application data and forward the generated logs to the syslog destinations. Application logging leverages existing deep packet inspection capabilities to extract application data and enables you to enhance network monitoring and gain deeper insights into network traffic. This feature applies to Snort 3 Firewall Threat Defense devices.

  For more information about the application logging, see *.Application-Aware Event Logging* in the *Cisco Secure Firewall Management Center Administration Guide*

  Note
  Application logging can cause performance drop within network if used without filters configured in the access control rule. Filter specific traffic types using the access control rules to reduce the volume of logged traffic.

Step 5 Click **Save** to save the changes to the access control policy.

- To get back to the rules list, click **Access Control** in the packet flow line.
- You must deploy the configuration to apply changes to the managed devices.

The advanced settings for the access control policy are configured and saved. The changes will take effect after deployment to the managed devices.

General settings

General settings are advanced configuration options that

- control URL logging and character limits for connection events,
- manage user bypass timeouts for interactive blocking,
- determine URL cache lookup behavior and traffic inspection settings, and
- enable threat intelligence and DNS reputation enforcement features.

General advanced settings configuration options

These are the general advanced settings that you can configure for an access control policy:

- **Maximum URL characters to store in connection events**—Sets the maximum character length of each URL requested by users in end-of-connection events. Disabling or limiting the number of stored URL characters might improve system performance. The default is 1024. The range is 0 to 4096.

  Set the length to 0 to disable URL logging. Storing zero characters does not affect URL filtering. The system filters traffic based on requested URLs even though the system does not record them.

- **Allow an Interactive Block to bypass blocking for (seconds)**—Sets the time allowed for browsing after the user bypasses a URL filtering block. After the timeout expires, the user must bypass the block again. The default is 600 seconds (10 minutes). The range is 0 to 31536000 (8760 hours).

  Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.

- **Retry URL cache miss lookup**—This setting determines what the system does when it needs to look up a URL's category and reputation in the cloud.

  The first time the system encounters a URL that does not have a locally stored category and reputation, it looks up that URL in the cloud and adds the result to the local data store. This allows faster processing of that URL in the future.

  By default, this setting is enabled. The system momentarily delays the traffic while it checks the cloud for the URL's reputation and category, and uses the cloud verdict to handle the traffic.

  If you disable this setting, when the system encounters a URL that is not in its local cache, the traffic is immediately passed and handled according to the rules configured for uncategorized and reputationless traffic.

  In passive deployments, the system does not retry the lookup, as it cannot hold packets.

- **Enable reputation enforcement on DNS traffic**—Whether to have the system evaluate domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address. Enable this option to improve URL filtering performance and efficacy. The default is enabled. For details and additional instructions, see DNS filtering, on page 2099 and subtopics.

- **Inspect traffic during policy apply**—Whether to inspect traffic when you deploy configuration changes unless specific configurations require restarting the Snort process. The default is enabled.

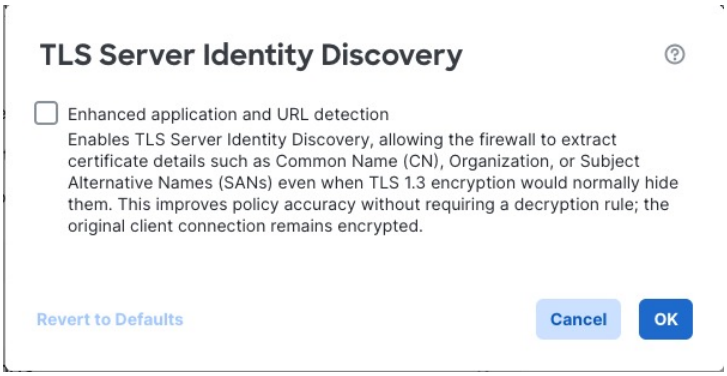
  When this option is enabled, resource demands could result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. The assigned device determines whether traffic drops during this interruption or passes without further inspection. See Snort restart scenarios, on page 194 for more information.

TLS server identity discovery

TLS server identity discovery is an access control policy advanced setting that enables early application detection and URL categorization for encrypted traffic.

TLS server identity discovery configuration

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by RFC 8446, is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.



You can enable this feature, referred to as *TLS server identity discovery*, when you configure advanced settings for an access control policy. Certain features are not supported, such as STARTTLS traffic, the HTTP CONNECT method, and in a network where another device is already decrypting traffic.

If you enable this option, we recommend you also enable the decryption policy's advanced TLS adaptive server identity probe option as well. Together, these options enable more efficient decryption of TLS 1.3 traffic. For more information, see TLS 1.3 decryption best practices, on page 2184.

When a new connection starts that will be affected by TLS server identity discovery, the Firewall Threat Defense holds the original ClientHello packet to determine the identity of the server to which it connects before continuing. The Firewall Threat Defense device sends a specialized connection from the Firewall Threat Defense to the server. The server's response includes the server certificate, the specialized connection is terminated, and the original connection is evaluated as required by the access control policy.

TLS server identity discovery prioritizes the certificate's Common Name (CN) over the Server Name Indication (SNI).

To enable TLS server identity discovery, click the **Advanced** tab, click **Edit** (✎) for the setting, and select **Early application detection and URL categorization**.

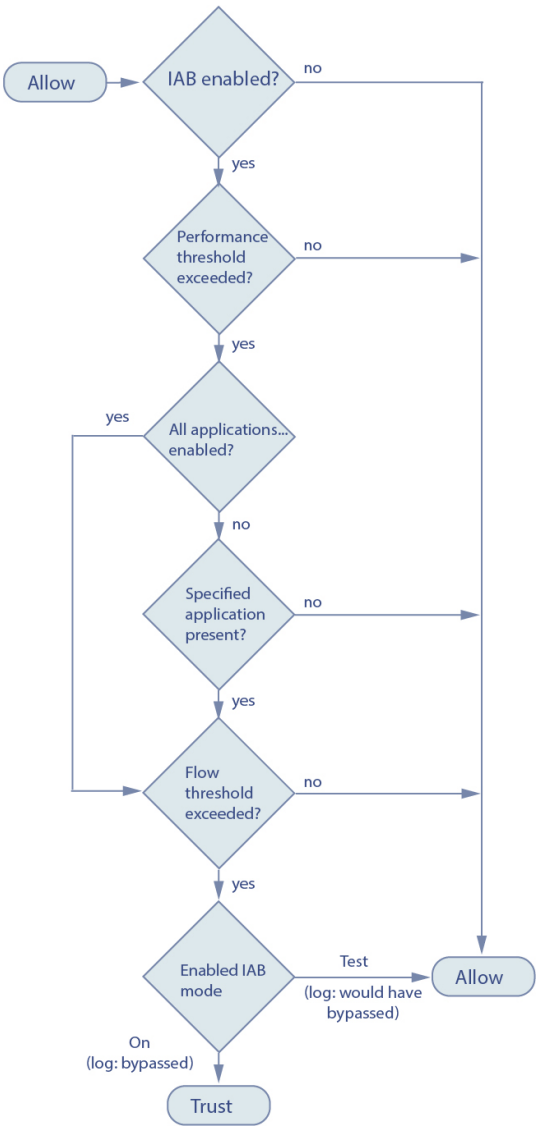
We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. An decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

Note

- TLS server identity discovery *cannot* be used with any of the following:
  - STARTTLS traffic
  - The HTTP CONNECT method
  - Traffic that is already being decrypted by another device on the network
- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is supported on any Secure Firewall Threat Defense Virtual version deployed in AWS. TLS server identity is incompatible with certain deployment scenarios that involve Gateway Load Balancer (GWLB). Whether the device initiates a server certificate probe depends on its deployment method with GWLB and the traffic direction.
  - Geneve single-arm flow: The probe *is not initiated* for either east–west or north–south traffic. A connection event **PROBE_FLOW_DROP_BYPASS_PROXY** increments every time the device attempts to extract the server certificate.
  - Geneve dual-arm flow: The probe *is initiated only* for north–south traffic.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

Intelligent application bypass

Intelligent application bypass (IAB) is a security feature that



- identifies applications that you trust to traverse your network without further inspection if performance and flow thresholds are exceeded
- implements on traffic allowed by access control rules or the access control policy's default action, before the traffic is subject to deep inspection, and
- can be configured so that when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

Additional information

For example, if a nightly backup significantly impacts system performance, you can configure thresholds that, if exceeded, trust traffic generated by your backup application.

A test mode allows you to determine whether thresholds are exceeded and, if so, to identify the application flows that would have been bypassed if you had actually enabled IAB (called *bypass mode*).

This graphic illustrates the IAB decision-making process:

Configure intelligent application bypass

This task enables intelligent application bypass (IAB) to improve system performance by bypassing inspection of specified traffic when performance thresholds are exceeded.

Not all deployments require IAB, and those that do might use it in a limited fashion. Do not enable IAB unless you have expert knowledge of your network traffic, especially application traffic, and system performance, including the causes of predictable performance issues. Before you run IAB in bypass mode, make sure that trusting the specified traffic does not expose you to risk.

Before you begin

IAB settings are applicable for Snort2 devices or pre 7.2.0 Snort3 devices. For Snort 3 devices, use elephant flow detection instead.

Follow these steps to configure intelligent application bypass:

Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** (✎) next to **Intelligent Application Bypass Settings**.

Step 2 Set the enabled **State** for IAB.

Turn IAB **Off** or **On**, or enable IAB in **Test** mode.

In test mode, connection events and dashboards tell you what the system would have done if IAB had been on, but traffic is not impacted. Use test mode to check your configuration.

Step 3 Set the **Performance Sample Interval**.

The **Performance Sample Interval** specifies the time in seconds between IAB performance sampling scans, during which the system collects system performance metrics for comparison to IAB performance thresholds. The default is 5 seconds. The range is 1 to 1000 seconds.

Step 4 Select the **Bypassable Applications and Filters**.

Choose from:

- ***X* Applications/Filters**—Click the link and select the applications or application filters whose traffic you want to bypass. You can select by general attributes, specific applications, or both. For example, you could limit bypassable traffic to very low risk applications only.
- **All applications including unidentified applications**—Do not restrict bypass. When an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type. This is the default.

Step 5 Configure the performance and flow thresholds.

You must configure at least one **Inspection Performance Thresholds** and one **Flow Bypass Thresholds**. However, all have defaults and you do not need to change the settings if the defaults are appropriate for your network.

When a performance threshold is exceeded, the system examines flow thresholds and, if one threshold is exceeded, trusts the specified traffic. If you enable more than one of either, only one of each must be exceeded.

a) Click **Configure** under **Inspection Performance Thresholds** and configure the options.

Inspection performance thresholds provide intrusion inspection performance limits that, if exceeded, trigger the inspection of flow thresholds. Inspection performance thresholds set to 0 are ignored.

You can configure one or more of these thresholds:

- **Drop Percentage**—The average packets dropped as a percentage of total packets, when packets are dropped because of performance overloads caused by expensive intrusion rules, file policies, decompression, and so on. This does not refer to packets dropped by normal configurations such as intrusion rules.

  Note that specifying an integer greater than 1 activates IAB when the specified percentage of packets is dropped. When you specify 1, any percentage from 0 through 1 activates IAB. This allows a small number of packets to activate IAB.

  The default is 5%. The range is 0 to 100.

- **Processor Utilization Percentage**—Average percentage of processor resources used. The default is 95. The range is 0 to 100.
- **Packet Latency**—The average packet latency in microseconds. The default is 1000. The range is 0 to 1000000.
- **Flow Rate**—The rate at which the system processes flows, measured as the number of flows per second. Note that this option configures IAB to measure flow *rate*, not flow *count*. The default is 0. The range is 0 to 1000000.

b) Click **Configure** under **Flow Bypass Thresholds** and configure the options.

Flow bypass thresholds provide flow limits that, if exceeded, trigger IAB to trust bypassable application traffic in bypass mode or allow application traffic subject to further inspection in test mode. Flow bypass thresholds set to 0 are ignored.

You can configure one or more of these flow bypass thresholds:

- **Bytes per Flow**—The maximum number of kilobytes a flow can include. The default is 500000. The range is 0 to 2147483647.
- **Packets per Flow**—The maximum number of packets a flow can include. The default is 0. The range is 0 to 2147483647.
- **Flow Duration**—The maximum number of seconds a flow can remain open. The default is 0. The range is 0 to 2147483647.
- **Flow Velocity**—The maximum transfer rate in kilobytes per second. The default is 250000. The range is 0 to 2147483647.

Step 6 Click **OK** to save IAB settings.

Step 7 Click **Save** to save the policy.

Intelligent application bypass is configured for the access control policy with the specified performance and flow thresholds.

What to do next

- Deploy configuration changes.

IAB logging and analysis

IAB logging and analysis is a monitoring system that

- forces an end-of-connection event. This event logs both bypassed flows and flows that would have been bypassed, regardless of whether you have enabled connection logging
- provides connection events. These events indicate when flows are bypassed in bypass mode or would have been bypassed in test mode, and
- enables custom dashboard widgets and reports based on connection events. These widgets and reports display long-term statistics for bypassed and would-have-bypassed flows.

IAB connection events

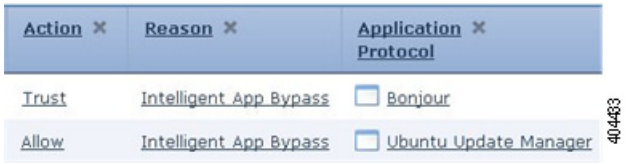
IAB connection events provide specific information about bypassed and would-have-bypassed flows through these key fields:

- Action: When **Reason** includes `Intelligent App Bypass`:
  - **Allow**—indicates that the applied IAB configuration was in test mode and traffic for the application specified by **Application Protocol** remains available for inspection.
  - **Trust**—indicates that the applied IAB configuration was in bypass mode and traffic for the application specified by **Application Protocol** has been trusted to traverse the network without further inspection.
- Reason: `Intelligent App Bypass` indicates that IAB triggered the event in bypass or test mode.
- Application Protocol: This field displays the application protocol that triggered the event.

You can create custom analysis dashboard widgets to display long-term IAB statistics based on connection events. Specify these settings when creating the widget:

- **Preset**: None
- **Table**: Application Statistics
- **Field**: any
- **Aggregate**: either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections
- **Filter**: any

You can create custom reports to display long-term IAB statistics based on connection events. Specify these settings when creating the report:



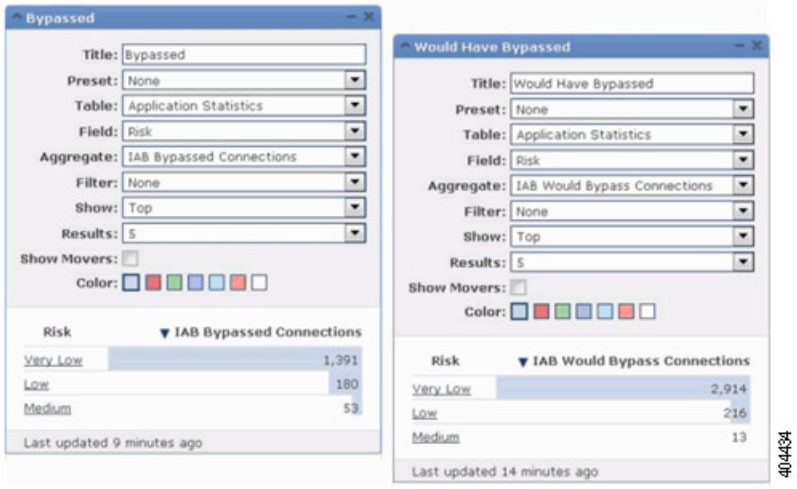
- **Table**: Application Statistics
- **Preset**: None
- **Filter**: any
- **X-Axis**: any
- **Y-Axis**: either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections

Connection event examples

In the truncated graphic, some fields are omitted. The graphic shows the **Action**, **Reason**, and **Application Protocol** fields for two connection events resulting from different IAB settings in two separate access control policies.

For the first event, the `Trust` action indicates that IAB was enabled in bypass mode and Bonjour protocol traffic was trusted to pass without further inspection.

For the second event, the `Allow` action indicates that IAB was enabled in test mode, so Ubuntu Update Manager traffic was subject to further inspection but would have been bypassed if IAB had been in bypass mode.



In the truncated graphic, some fields are omitted. The flow in the second event was both bypassed (**Action**: `Trust`; **Reason**: `Intelligent App Bypass`) and inspected by an intrusion rule (**Reason**: `Intrusion Monitor`). The `Intrusion Monitor` reason indicates that an intrusion rule set to **Generate Events** detected but did not block an exploit during the connection. In the example, this happened before the application was detected. After the application was detected, IAB recognized the application as bypassable and trusted the flow.

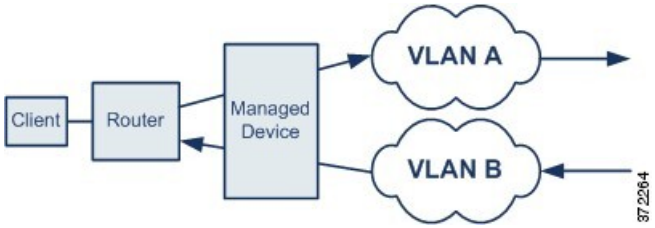
In the custom analysis dashboard widget examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

The graphic shows two abbreviated report examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

Transport/network layer preprocessor settings



Transport/network layer preprocessor settings are access control policy configurations that

- apply globally to all networks, zones, and VLANs where you deploy your access control policy
- control how the system handles VLAN headers, active responses, and connection tracking, and
- affect traffic reassembly and rule processing for transport and network layer communications.

Configuration options

These settings control various aspects of transport and network layer processing:

- **Ignore the VLAN header when tracking connections**—Whether to ignore or include VLAN headers when identifying traffic. Different VLAN tags in traffic traveling in different directions for the same connection can affect traffic reassembly and rule processing. For example, traffic for the same connection could be transmitted over VLAN A and be received over VLAN B. Select this option if the device might see different VLANs for the same connection. This option is off by default.

- **Maximum Active Responses**—For a TCP connection that triggers a preprocessor/intrusion drop rule that is configured to provide an active response, the maximum number of active responses per TCP connection. When additional traffic occurs on a connection where an active response has been initiated, and the traffic occurs more than **Minimum Response Seconds** after a previous active response, the system sends another active response unless the specified maximum has been reached. A setting of 0 disables additional active responses triggered active response rules. The default is no limit. The range is 0 to 25.

Note You have to specifically configure drop rules to provide active responses. For TCP connections, the active response is a RESET packet. For UDP connections, the system sends an ICMP unreachable packet to the source of the connection.

- **Minimum Response Seconds**—Until **Maximum Active Responses** occur, specifies the number of seconds to wait before any additional traffic on a connection where the system has initiated an active response results in a subsequent active response. The default is no limit. The range is 1 to 300.
- **Session Termination Logging Threshold**—Do not modify this option unless instructed to do so by Cisco Technical Support.

  Support might ask you during a troubleshooting call to configure your system to log a message when an individual connection exceeds the specified threshold. Changing the setting for this option will affect performance and should be done only with Support guidance. This option specifies the number of bytes that result in a logged message when the session terminates and the specified number was exceeded. The upper limit is 1GB.

Detection enhancement settings

Detection enhancement settings are adaptive profile configurations that

- determine whether adaptive profiles are used for application detection and intrusion rules in the access control policy
- enable the system to adapt processing behavior using host information either detected by network discovery or imported from a third party, and
- provide control over profile update frequency and network scope for performance optimization.

Detection enhancement setting options

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates enabled, the system adapts processing behavior using host information detected by network discovery or imported from a third party.

Note To enable adaptive profiles in Snort 3, you must select both the **Enable** and **Enable Profile Updates** options.

The detection enhancement settings include these options:

- **Enable**—You must enable adaptive profiling (its default state) for access control rules to perform application and file control, including malware protection (AMP), and for intrusion rules to use service metadata.
- **Enable Profile Updates**—Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host. Profile updates also compare metadata in an intrusion rule to host information to determine whether a rule should apply for a particular host. For more information, see:

- Adaptive profile updates, on page 2701
- Adaptive profile updates and recommended rules, on page 2702

- **Adaptive Profiles – Attribute Update Interval**—When profile updates are enabled, you can control how frequently in minutes network map data is synced from the management center to its managed devices. The system uses the data to determine what profiles should be used when processing traffic. Increasing the value for this option can improve performance in a large network.
- **Adaptive Profiles – Networks**—Optionally, when profile updates are enabled, you can improve performance by constraining profile updates to a comma-separated list of IP addresses, address blocks, and network variables. If you use a network variable, the system uses the variable's value in the variable set linked to the default intrusion policy for your access control policy. For example, you could enter 192.168.1.101, 192.168.4.0/24, or $HOME_NET. IPv4 and IPv6 are supported.

  The default value (0.0.0.0/0) applies adaptive profile updates to all networks.

Adaptive profile updates

An adaptive profile update is a network analysis feature that

- adapts processing behavior using host information either detected by network discovery or imported from a third party
- switches to the appropriate operating system profile based on the operating system in the host profile for the target host, and
- helps to defragment IP packets and reassemble streams in the same way as the operating system on the target host.

Adaptive profile operation

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party.

Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host.

Manually configured target-based profiles apply either the default operating system profile you select, or profiles you bind to specific hosts. Profile updates, however, switch to the appropriate operating system profile based on the operating system in the host profile for the target host.

Adaptive profile update scenario

Consider a scenario where you configure profile updates for the 10.6.0.0/16 subnet and set the default IP Defragmentation target-based policy to Linux. The Cloud-Delivered Firewall Management Center where you configure the settings has a network map that includes the 10.6.0.0/16 subnet.

- When the system detects traffic from Host A, which is not in the 10.6.0.0/16 subnet, it uses the Linux target-based policy to reassemble IP fragments.

- When the system detects traffic from Host B, which is in the 10.6.0.0/16 subnet, it retrieves Host B's operating system data from the network map. The system uses a profile based on that operating system to defragment the traffic destined for Host B.

Adaptive profile updates and recommended rules

Adaptive profile updates and recommended rules are security features that

- compare metadata in a rule to host information to determine whether a rule should apply for a particular host
- provide different approaches to rule optimization, with adaptive profiles applying rules dynamically on a packet-by-packet basis while recommended rules provide suggestions for rule state changes, and
- can be used in combination to ensure appropriate rule enablement and efficient rule application for specific traffic.

Feature characteristics and differences

The adaptive profile updates feature is an advanced setting in an access control policy that applies globally to all intrusion policies invoked by that access control policy. The Cisco recommended rules feature applies to the individual intrusion policy where you configure it.

Like recommended rules, profile updates compare metadata in a rule to host information to determine whether a rule should apply for a particular host. However, while recommended rules provide recommendations for enabling or disabling rules using that information, profile updates use the information to apply specific rules to specific traffic.

This table compares the key differences between adaptive profile updates and recommended rules:

Recommended rules require your interaction to implement suggested changes to rule states. Profile updates, on the other hand, do not modify intrusion policies. Treatment of rules based on profile updates happens on a packet-by-packet basis.

Additionally, recommended rules can result in enabling disabled rules. Profile updates, in contrast, only affect the application of rules that are already enabled in intrusion policies. Profile updates never change the rule state.

You can use profile updates and recommended rules in combination. Profile updates use the rule state for a rule when your intrusion policy is deployed to determine whether to include it as a candidate for applying, and your choices to accept or decline recommendations are reflected in that rule state. You can use both features to ensure that you have enabled or disabled the most appropriate rules for each network you monitor, and then to apply enabled rules most efficiently for specific traffic.

Performance settings

Performance settings are access control policy advanced settings that

- tune the performance of your system as it analyzes traffic for attempted intrusions
- apply to Snort and are relevant only if you apply intrusion policies in rules or as the default action, and
- should be changed only if you are a Snort intrusion rule expert, or at the direction of Cisco Technical Support.

Performance setting categories

These settings are organized into separate tabs for each group of settings:

- **Pattern Matching Limits**: The maximum number of events to queue and TCP payload detection options
- **Performance Statistics**: Time range and packet count settings for performance sampling
- **Regular Expression Limits**: PCRE matching and recursion limits
- **Intrusion Event Logging Limits**: Event queue and logging configuration

Pattern Matching Limits include these options:

- **Maximum Pattern States to Analyze Per Packet**: The maximum number of events to queue. The default is 5.
- **Disable Content Checks on Traffic Subject to Future Reassembly**: Whether to detect TCP payload before reassembly. It includes inspection of packets before and after stream reassembly. This process requires more processing overhead and may decrease performance. If the option is not selected, the TCP payload is detected after reassembly. The default is off.

Performance Statistics settings control when the system updates performance statistics. When the number of seconds specified elapses between performance statistics updates, the system verifies it has analyzed the specified number of packets. If it has, the system updates performance statistics. Otherwise, the system waits until it analyzes the specified number of packets.

- **Sample time (seconds)**: The time range for taking a performance sample. The default is 300 seconds.

  Configuring a very low value (for example, 1 second) for the sample time can cause a huge impact on the device; the performance statistics logged on the device can cause disk space issues and affect the operation of the device. Hence, we recommend you do not configure a very low value.

- **Minimum number of packets**: How many packets to consider the minimum for a valid performance statistic. The default is 0.
- **Troubleshooting Options**:
  - **Log Session/Protocol Distribution**: Support might ask you during a troubleshooting call to enable this option to configure the system to calculate the performance statistics only when the Snort process is shut down or restarted.
  - **Summary**: Enable this option only if instructed by Cisco Technical Support.

Regular Expression Limits ensure a minimum level of performance. The default Perl compatible regular expression (PCRE) limits ensure a minimum level of performance. Overriding these limits could increase security but could also significantly impact performance by permitting packet evaluation against inefficient regular expressions.

- **Match Limit State**: The limit for matching regular expressions. You can select **Default Value**, which is 3500, **Unlimited**, or **Custom**. If you select custom, specify the number of times to attempt to match a pattern defined in a PCRE regular expression in **Match Limit**. Specify 0 to completely disable PCRE match evaluations.
- **Match Recursion Limit State**: The limit for matching regular expression recursions. You can select **Default Value**, which is 3500, **Unlimited**, or **Custom**. If you select custom, specify the number of

recursions when evaluating a PCRE regular expression against the packet payload in **Match Recursion Limit**. Specify 0 to completely disable PCRE recursions.

Note For a custom match recursion limit to be meaningful, it must be smaller than the match limit.

Intrusion Event Logging Limits control event queuing and reporting. When the intrusion rules engine evaluates traffic against rules, it places the events generated for a given packet or packet stream in an event queue, then reports the top events in the queue to the user interface. When configuring the intrusion event logging limits, you can specify how many events can be placed in the queue and how many are logged, and select the criteria for determining event order within the queue.

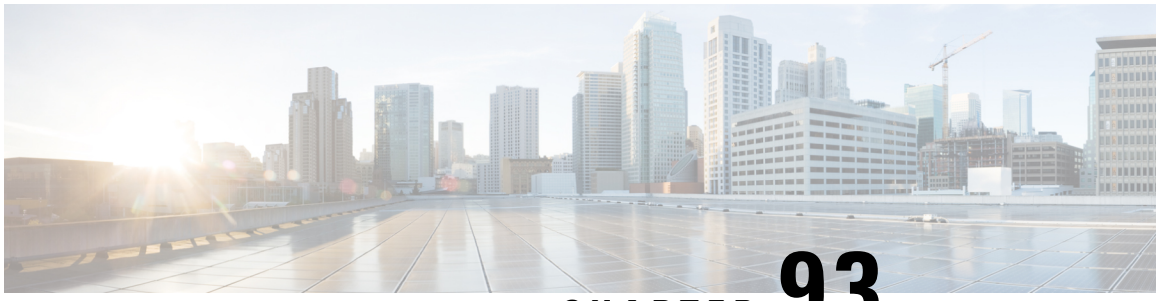
- **Maximum Events Stored Per Packet**: The maximum number of events that can be stored for a given packet or packet stream. The default is 8.
- **Maximum Events Logged Per Packet**: The number of events logged for a given packet or packet stream. This cannot exceed the **Maximum Events Stored Per Packet** value. The default is 5.
- **Prioritize Events Logging By**: The value used to determine event ordering within the event queue. The highest ordered event is reported through the user interface. You can select:
  - **Content Length** (the default), which orders events by the longest identified content match. When events are ordered by content length, rule events always take precedence over decoder and preprocessor events.
  - **Priority**, which orders events in the queue by the event priority.

Latency-based performance settings

Latency-based performance settings are policy configurations that

- use thresholding to manage packet and rule processing performance,
- apply to Snort and are relevant only if you apply intrusion policies in rules or as the default action, and
- are automatically populated by the latest deployed intrusion rule update by default.

Performance setting behavior



By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default. Change these settings only if you are a Snort intrusion rule expert, or at the direction of Cisco Technical Support.

The latency settings that are applied depend on the security level of the network analysis policy (NAP) associated with the access control policy. Generally, this is the default NAP policy. However, if custom network analysis rules are configured, and if any of these specify a NAP policy that is more secure than the default NAP policy, then latency settings are based on the most secure NAP policy among the custom rules. If the default NAP policy or any custom rules invoke a custom NAP policy, then the security level used in the evaluation is the system-provided base policy on which each custom NAP policy is based.

The above is true regardless of whether the effective threshold and/or network analysis configurations are inherited or configured directly in the policy.

Use these settings to tune the latency-based performance of your system:

- **Apply Settings From**: Whether to apply latency-based performance settings from an **Installed Rule Update**, the default, or from your **Custom** settings.
- **Packet Handling**: Packet latency thresholding measures the total elapsed time taken to process a packet by applicable decoders, preprocessors, and rules, and ceases inspection of the packet if the processing time exceeds a configurable threshold. By default, the latency-based performance setting for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting. Select **Enabled** to turn it on. If you selected **Custom**, also enter the **Threshold** time in microseconds for when inspection of a packet should cease. The default is 256.
- **Rule Handling**: Rule latency thresholding measures the elapsed time each rule takes to process an individual packet, suspends the violating rule along with a group of related rules for a specified time if the processing time exceeds the rule latency threshold a configurable consecutive number of times, and restores the rules when the suspension expires. You can configure these options only if you select **Custom**.
  - **Enabled**: This option is selected automatically if you select custom. If you do not want use this feature, deselect the option. All other settings on this tab require the feature to be enabled.
  - **Threshold (microseconds)**: Specifies the time in microseconds that rules should not exceed when examining a packet. The default is 512.
  - **Consecutive Threshold Violations Before Suspending Rule**: Specifies the consecutive number of times rules can take longer than the time set for threshold to inspect packets before rules are suspended. The default is 3.
  - **Suspension Time**: How long a suspended rule should be suspended. The default is 10.

CHAPTER 93

Service Policies

You can use Threat Defense Service Policies to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions or rules applied to an interface or applied globally.

- Threat defense service policies, on page 2707
- Requirements and prerequisites for service policies, on page 2709
- Guidelines and limitations for service policies, on page 2709
- Configure threat defense service policies, on page 2710
- Monitor service policies, on page 2719
- Examples for service policy rules, on page 2720

Threat defense service policies

Use Threat Defense service policies to apply services to specific traffic classes. Service policies let you apply different services to different connections entering the device or interface.

Traffic class types

A traffic class is a combination of the interface and an extended access control list (ACL). The ACL "allow" rules determine which connections are part of the class. Any "denied" traffic in the ACL simply does not have the service applied to it: these connections are not actually dropped. You can use IP addresses and TCP/UCP ports to identify matching connections as precisely as you require.

There are two types of traffic class:

- **Interface-based rules**—If you specify a security zone or interface group in a service policy rule, the rule applies to the ACL "allowed" traffic that goes through any interface that is part of the interface objects.

  Interface-based rules that are applied to the ingress interface always take precedence over global rules for any feature. If an ingress interface-based rule applies to a connection, the system ignores any matching global rule. If no ingress interface or global rule applies, then an interface service rule on the egress interface is applied.

- **Global rules**—These rules apply to all interfaces. If an interface-based rule does not apply to a connection, the global rules are checked and applied to any connections that the ACL "allows." If none apply, then the connections proceed without any services applied.

A given connection can match only one traffic class, either interface-based or global, for a given feature. There should be at most one rule for a given interface object/traffic flow combination.

Service policy rules are applied after access control rules. These services are configured only for connections you are allowing.

Service policy relationships with FlexConfig and other features

Connection-related service policy features are managed separately from other service-rule features, so overlapping traffic classes generally aren't an issue, but they should still be configured carefully.

Service policy feature interactions

Because connection-related service policy features are treated as a separate feature group from other service-rule implemented features, you should not run into problems with overlapping traffic classes. However, please be mindful when configuring these features:

- QoS policy rules: QoS policy rules are implemented using the service policy CLI. These rules are applied before connection-based service policy rules. However, both QoS and connection settings can be applied to the same or overlapping traffic classes.
- FlexConfig policies: You can use FlexConfig policies to implement custom application inspections and NetFlow. Use the **show running-config** command to examine the CLI that already configures service rules, including the **policy-map**, **class-map**, and **service-policy** commands. Netflow and application inspection are compatible with QoS and connection settings, but you need to understand the existing configuration before implementing FlexConfig. Connection settings are applied before application inspections and Netflow.

Note Traffic classes that are created from the Threat Defense service policy are named **class_map_***ACLname*, where *ACLname* is the name of the extended ACL object used in the service policy rule.

Connection settings

Connection settings refer to a variety of features that manage connections through a device.

Connection setting types

Connection settings include these types:

- **Global timeouts for various protocols**—All global timeouts have default values. Change them only if you experience premature connection loss. You configure global timeouts in the Threat Defense platform policy. Select **Devices** > **Platform Settings**.
- **Connection timeouts per traffic class**—You can override the global timeouts for specific types of traffic using service policies. All traffic class timeouts have default values, so you do not have to set them.
- **Connection limits and TCP Intercept**—By default, there are no limits on how many connections can go through (or to) the Firewall Threat Defense. Use service policy rules to set limits on particular traffic classes. This protects servers from denial of service attacks Particularly, you can set limits on embryonic connections (those that have not finished the TCP handshake), which protects against SYN flooding

attacks. When embryonic limits are exceeded, the TCP Intercept component activates to proxy connections and throttle attacks.

- **Dead connection detection (DCD)**—Enable dead connection detection if you have persistent connections that are valid but often idle. These connections may get closed when they exceed idle timeout settings. Dead connection detection identifies idle but valid connections and keeps them alive by resetting their idle timers. Whenever idle times are exceeded, DCD probes both sides of the connection to see if both sides agree that the connection is valid.. The **show service-policy** command output includes counters to show the amount of activity from DCD. You can use the **show conn detail** command to get information about the initiator and responder and how often each has sent probes.
- **TCP sequence randomization**—Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. By default, the Firewall Threat Defense randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions. Randomization prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. However, TCP sequence randomization effectively breaks TCP SACK (Selective Acknowledgement), as the sequence numbers the client sees are different from what the server sees. You can disable randomization per traffic class if desired.
- **TCP normalization**—The TCP Normalizer protects against abnormal packets. You can configure how some types of packet abnormalities are handled by traffic class. You can configure TCP Normalization using the FlexConfig policy.
- **TCP state bypass**—You can bypass TCP state checking if you use asymmetrical routing in your network.

Requirements and prerequisites for service policies

This topic outlines the model support, domain compatibility, and user role requirements for configuring service policies.

Guidelines and limitations for service policies

Service policies apply to routed or switch interfaces only, in either routed or transparent mode. They do not apply to inline set or passive interfaces.

You can have at most 25 traffic classes for a given interface or the global policy. Specifically, this means that you cannot have more than 25 service policy rules for the global policy for a given security zone or interface group. However, for interfaces, because the same interface can appear in both a security zone and interface group, be aware that the actual limitation is based on the interfaces, and not the zone/group. Thus, you might be prevented from having 25 rules per zone/group based on the membership of your zones/groups.

You can have at most one rule for a given interface object/traffic flow combination.

When you make service policy changes to the configuration, all new connections use the new service policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. If you want all connections to immediately use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. Use an SSH or Console CLI session to enter the **clear conn** or **clear local-host** commands.

QoS rules and service policy rules (in the access control policy) are translated to commands on the firewall. This includes creating policy maps. There can be only one policy map per interface. The system automatically combines QoS and service policy configurations in a single policy map per interface.

However, you can also create policy maps manually using FlexConfig. For lower-end firewalls, such as the Secure Firewall 3100, you can create up to 64 policy maps in the configuration. For more powerful firewalls, such as the Firepower 4100, you can create up to 128. Be careful not to exceed this limit, or deployment will fail. You can view the device configuration from the CLI or use the deployment transcript to see how rules are translated to commands.

Configure threat defense service policies

You can use Threat Defense service policies to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications.

A service policy consists of multiple actions or rules applied to an interface or applied globally. Use Threat Defense service policies to apply services to specific traffic classes.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** (✎) for the access control policy whose Threat Defense service policy you want to edit.

Step 2 Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 3 Click **Edit** (✎) in the **Threat Defense Service Policy** group.

A dialog box opens that shows the existing policy. The policy consists of an ordered list of rules, separated between global rules (which apply to all interfaces) and interface-based rules. The table shows the interface object and extended access control list name (which combined defines the traffic class for the rule), and the services applied.

Step 4 Do any of the following:

- Click **Add Rule** to create a new rule. See Configure a service policy rule, on page 2711.
- Click **Edit** (✎) to edit an existing rule. See Configure a service policy rule, on page 2711.

- Click **Delete** ( ) to delete a rule.
- Click a rule and drag it to a new location to move it. You cannot drag rules between the interface and global lists. Instead you must edit the rule to change the interface/global setting. The first rule in the list that matches a connection is applied to the connection.

Step 5 Click **OK** when you are finished editing the policy.

Step 6 Click **Save** on the **Advanced** window. The changes are not saved until you click **Save**.

Configure a service policy rule

Use this procedure to apply specific services and connection settings to defined traffic classes, enabling you to control and customize how network traffic is handled.

Service policy rules allow you to control and customize how network traffic is handled by applying specific services and connection settings to defined traffic classes.

Before you begin

Go to **Objects** > **Object Management** > **Access List** > **Extended** and create an extended access list that defines the traffic to which the rule applies. The rule is applied to any connections that match Allow rules in the extended access list. Define the ACL rules precisely, so that your service policy rule applies to only the traffic that requires the service.

If you are creating an interface-based rule, you must also have configured the interfaces on the assigned devices and added them to security zones or interface groups.

Follow these steps to configure a service policy rule:

Procedure

Step 1 If you are not already in the Threat Defense service policy dialog box, choose **Policies** > **Access Control heading** > **Access Control**, edit the access control policy, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, then edit the **Threat Defense Service Policy**.

Step 2 Do any of the following:

- Click **Add Rule** to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The service policy rule wizard opens to step you through the process of configuring the rule.

Step 3 In the **Interface Object** step, select the option that defines the interfaces that will use the policy.

- **Apply Globally**—Select this option to create a global rule, which applies to all interfaces.
- **Select Interface Objects**—Select this option to create an interface-based rule. Then, select the security zones or interface objects that contain the desired interfaces, and click **Add** to move them to the selected list. The service policy rule will be configured on each interface contained in the selected objects; it is not configured on the zone/group itself.

Click **Next** when the interface criterion is complete.

Step 4 In the **Traffic Flow** step, select the extended ACL object that defines the connections to which the rule applies, then click **Next**.

Step 5 In the **Connection Setting** step, configure the services to apply to this traffic class.

- **Enable TCP State Bypass** (TCP connections only)—Implement TCP state bypass. Connections subject to TCP state bypass are not inspected by any inspection engines, and they bypass all TCP state checking and TCP normalization. For detailed information, see Bypass TCP state checks for asymmetrical routing (TCP state bypass), on page 2714.

  Note
  Use TCP state bypass for troubleshooting purposes or when asymmetric routing cannot be resolved. This feature disables multiple security features, which can cause a high number of connections if you do not implement it properly with a narrowly-defined traffic class.

- **Randomize TCP Sequence Number** (TCP connections only)—Whether to enable or disable TCP sequence number randomization. Randomization is enabled by default. For more information, see Disable TCP sequence randomization, on page 2718.

- **Enable Decrement TTL** (TCP connections only)—Decrement the time-to-live (TTL) on packets that match the class. If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as Open Shortest Path First (OSPF) hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences.

  Note
  If you want the Firewall Threat Defense device to appear on traceroutes, you must configure the decrement TTL option and also set the Internet Control Message Protocol (ICMP) unreachable rate limit in the platform settings policy. See Configure the Firewall Threat Defense device to appear on traceroutes, on page 2723.

- **Connections**—Limits for the number of connections allowed for the entire class. You can configure these options:

  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections that are allowed, between 0 and 2000000, for the entire class. For TCP, this count applies to established connections only. The default is 0, which allows unlimited connections. Because the limit is applied to a class, one attacking host can consume all the connections and leave none for the rest of the hosts that are matched to the class. Set the per-client limit to ameliorate this problem.

  - **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections (those that have not finished the TCP handshake) allowed, between 0 and 2000000. The default is 0, which allows unlimited connections. By setting a non-zero limit, you enable TCP intercept, which protects inside systems from a denial of service (DoS) attack perpetrated by flooding an interface with TCP SYN packets. Also set the per-client options to protect against SYN flooding. For more information, see Protect servers from a SYN flood DoS attack (TCP intercept), on page 2720.

- **Connections Per Client**—Limits for the number of connections allowed for a given client (source IP address). You can configure these options:

- **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections allowed per client, between 0 and 2000000. For TCP, this includes established, half-open (embryonic), and half-closed connections. The default is 0, which allows unlimited connections. This option restricts the maximum number of simultaneous connections that are allowed for each host that is matched to the class.
- **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections allowed per client, between 0 and 2000000. The default is 0, which allows unlimited connections. For more information, see Protect servers from a SYN flood DoS attack (TCP intercept), on page 2720.

- **Connections SYN Cookie MSS**—The server maximum segment size (MSS) for SYN-cookie generation for embryonic connections upon reaching the embryonic connections limit, from 48 to 65535 . The default is 1380. This setting is meaningful only if you configure **Maximum Embryonic** for connections or per-client, or both.
- **Connections Timeout**—The timeout settings to apply to the traffic class. These timeouts override the global timeouts defined in the platform settings policy. You can configure these options:
  - **Embryonic** (TCP connections only)—The timeout period until a TCP embryonic (half-open) connection is closed, between 0:0:5 and 1193:00:00. The default is 0:0:30.
  - **Half Closed** (TCP connections only)—The idle timeout period until a half-closed connection is closed, between 0:0:30 and 1193:0:0. The default is 0:10:0. Half-closed connections are not affected by dead connection detection (DCD). Also, the system does not send a reset when taking down half-closed connections.
  - **Idle** (TCP, UDP, ICMP, IP connections)—The idle timeout period after which an established connection of any protocol closes, between 0:0:1 and 1193:0:0. The default is 1:0:0, unless you select the TCP state bypass option, where the default is 0:2:0.
  - **Reset Connection Upon Timeout** (TCP connections only)—Whether to send a TCP RST packet to both end systems after idle connections are removed.
- **Detect Dead Connections** (TCP connections only)—Whether to enable dead connection detection (DCD). Before expiring an idle connection, the system probes the end hosts to determine if the connection is valid. If both hosts respond, the connection is preserved, otherwise the connection is freed. When operating in transparent firewall mode, you must configure static routes for the endpoints. You cannot configure DCD on connections that are also offloaded, so do not configure DCD on connections you are fast-pathing in the prefilter policy. Use the **show conn detail** command in the Firewall Threat Defense CLI to track how many DCD probes have been sent by the initiator and responder.

  Configure these options:
  - **Detection Timeout**—The time duration in hh:mm:ss format to wait after each unresponsive DCD probe before sending another probe, between 0:0:1 and 24:0:0. The default is 0:0:15.

    For systems that are operating in a cluster or high-availability configuration, we recommend that you do not set the interval to less than one minute (0:1:0). If the connection needs to be moved between systems, the changes required take longer than 30 seconds, and the connection might be deleted before the change is accomplished.
  - **Detection Retries**—The number of consecutive failed retries for DCD before declaring the connection dead, from 1 to 255. The default is 5.

Step 6 Click **Finish** to save your changes.

The rule is added to the bottom of the appropriate list, either Interfaces or Global. Global rules are matched in top-down order. Rules in the Interfaces list are matched in top down order for each interface object. Place rules for narrowly-defined traffic classes above broader rules, to ensure the right services get applied. You can move rules within each list by using drag and drop. You cannot move rules between lists.

Bypass TCP state checks for asymmetrical routing (TCP state bypass)

TCP state bypass allows traffic to bypass stateful inspection checks on Firewall Threat Defense devices.

Implementation considerations

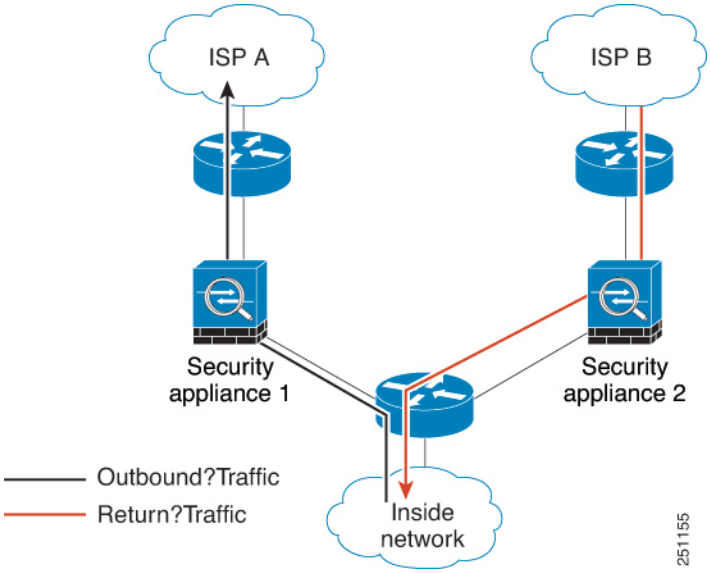
If you have an asymmetrical routing environment in your network, where the outbound and inbound flow for a given connection can go through two different Firewall Threat Defense devices, you need to implement TCP state bypass on the affected traffic.

However, TCP state bypass weakens the security of your network, so you should apply bypass on very specific, limited traffic classes.

The asymmetrical routing problem

The asymmetrical routing problem occurs when return traffic for a connection goes through a different firewall than the outbound traffic. This causes packets to be dropped because they do not match existing connection entries in the fast path table.

Traffic inspection and fast path operation



By default, the Firewall Threat Defense inspects all traffic using the Adaptive Security Algorithm. The Firewall Threat Defense allows or drops traffic based on the security policy. The Firewall Threat Defense maximizes the firewall performance by checking the state of each packet (new connection or established connection). It assigns new connection SYN packets to the session management path. It assigns established connections to the fast path. It assigns packets requiring advanced inspection to the control plane path.

The Firewall Threat Defense allows TCP packets that match existing connections to pass through via the fast path without rechecking every aspect of the security policy. This feature improves performance. However, the fast path establishment method can interfere with asymmetric routing solutions. The method uses SYN packets and performs checks such as TCP sequence number validation. Both outbound and inbound flows of a connection must pass through the same Firewall Threat Defense device.

Asymmetric routing scenario

For example, a new connection goes to Security Appliance 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through Security Appliance 1, then the packets match the entry in the fast path, and are passed through. But if subsequent packets go to Security Appliance 2, where no SYN packet went through the session management path, then no entry exists in the fast path for the connection, and Security Appliance 2 drops the packets. The following figure shows an asymmetric routing example where the outbound traffic goes through a different Firewall Threat Defense than the inbound traffic:

Figure 392: Asymmetric routing

If you have asymmetric routing configured on upstream routers and traffic alternates between two Firewall Threat Defense devices, then you can configure TCP state bypass for specific traffic. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. This feature treats TCP traffic similarly to a UDP connection: when a non-SYN packet matching the specified networks enters the Firewall Threat Defense device, and there is not a fast path entry, then the packet goes through the session management path to establish the connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

Guidelines and limitations for TCP state bypass

TCP state bypass unsupported features

The system does not support these features when you use TCP state bypass:

- Application inspection—Inspection requires both inbound and outbound traffic to go through the same Firewall Threat Defense, so inspection is not applied to TCP state bypass traffic.
- Snort inspection—Inspection requires both inbound and outbound traffic to go through the same device. However, Snort inspection is not automatically bypassed for TCP state bypass traffic. You must also configure a prefilter fastpath rule for the same traffic class for which you configure TCP state bypass. Otherwise, packets might be dropped unexpectedly because the TCP Normalizer is also not engaged.
- TCP Intercept, maximum embryonic connection limit, TCP sequence number randomization—The Firewall Threat Defense does not keep track of the state of the connection, so these features are not applied.
- TCP normalization—The TCP normalizer is disabled.
- TLS server identity discovery cannot be used with TCP state bypass on an inline or inline tap interface.

TCP state bypass NAT guidelines

Because the translation session is established separately for each device, be sure to configure static NAT on both devices for TCP state bypass traffic. If you use dynamic NAT, the address chosen for the session on Device 1 will differ from the address chosen for the session on Device 2.

Configure TCP state bypass

Configure TCP state bypass to handle asymmetrical routing environments where standard TCP state checking would interfere with traffic flow.

To bypass TCP state checking in asymetrical routing environments, carefully define a traffic class that applies only to the affected hosts or networks. Then, enable TCP state bypass on the traffic class using a service policy. You must also configure a corresponding prefilter fastpath policy for the same traffic to ensure that the traffic bypasses inspection.

Because bypass reduces the security of the network, limit its application as much as possible.

Before you begin

Follow these steps to configure TCP state bypass:

Procedure

Step 1 Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from 10.1.1.1 to 10.2.2.2, do the following:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, bypass.
d) Click **Add** to add a rule.
e) Keep **Allow** for the action.
f) Enter 10.1.1.1 beneath the **Source** list and click **Add**. Then, enter 10.2.2.2 beneath the **Destination** list, and click **Add**.
g) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, then click **Add**. Do not enter a port number. Add TCP as the protocol. This will cover all ports.
h) In the Extended Access List Entry dialog box, click **Add** to add the rule to the ACL.
i) In the Extended Access List Object dialog box, click **Save** to save the ACL object.

Step 2 Configure the TCP state bypass service policy rule.

For example, to configure TCP state bypass for this traffic class globally, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Select **Enable TCP State Bypass**.
g) (Optional.) Adjust the **Idle** timeout for bypassed connections. The default is 2 minutes.

h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

Click **Save** on **Advanced** to save the changes to the access control policy.

Step 3 Configure a prefilter fastpath rule for the traffic class.

You cannot use the ACL object in the prefilter rule, so you need to recreate the traffic class either directly in the prefilter rule, or by first creating network objects that define the class.

This procedure assumes that you already have a prefilter policy attached to the access control policy. If you have not created a prefilter policy yet, go to **Policies** > **Prefilter** and first create the policy. You can then follow this procedure to attach it to the access control policy and create the rule.

Keeping with our example, this procedure creates a fastpath rule for TCP traffic from 10.1.1.1 to 10.2.2.2.

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy that has the TCP bypass service policy rule.
b) Click the link for the **Prefilter Policy**, which is to the left immediately under the policy description.
c) In the Prefilter Policy dialog box, select the policy to assign to the device if the correct one is not already selected. Do not click OK.

Because you cannot add rules to the default prefilter policy, you must choose a custom policy.

d) In the Prefilter Policy dialog box, click **Edit** ( ). This action opens a new browser window where you can edit the policy.
e) Click **Add Prefilter Rule** and configure a rule with these properties.

- **Name**—Any name that you find meaningful will do, such as TCPBypass.
- **Action**—Select **Fastpath**.
- **Interface Objects**—If you configured TCP state bypass as a global rule, leave the default, any, for both source and destination. If you created an interface-based rule, select the same interface objects you used for rule in the **Source Interface Objects** list, and keep any as the destination.
- **Networks**—Add 10.1.1.1 to the **Source Networks** list, and 10.2.2.2 to the **Destination Networks** list. You can either use network objects or manually add the addresses.
- **Ports**—Under **Selected Source Ports**, select TCP(6), **do not enter a port**, and click **Add**. This applies the rule to all TCP traffic, regardless of TCP port number.

f) Click **Add** to add the rule to the prefilter policy.
g) Click **Save** to save your changes to the prefilter policy.

You can now close the prefilter edit window and return to the access control policy edit window.

h) In the access control policy edit window, the Prefilter Policy dialog box should still be open. Click **OK** to save your changes to the prefilter policy assignment.
i) Click **Save** on the access control policy to save the changed prefilter policy assignment, if you changed it.

You can now deploy the changes to the affected devices.

Disable TCP sequence randomization

Disable TCP initial sequence number randomization to prevent issues with data scrambling and to support specific network configurations that require non-randomized sequence numbers.

Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. The Firewall Threat Defense device randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. However, TCP sequence randomization effectively breaks TCP SACK (Selective Acknowledgement), as the sequence numbers the client sees are different from what the server sees.

You can disable TCP initial sequence number randomization if data is getting scrambled or if there is another necessity. This is useful in these situations:

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the device, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- If you use a WAAS device that requires the device not to randomize the sequence numbers of connections.
- If you enable hardware bypass for the ISA 3000, and TCP connections are dropped when the ISA 3000 is no longer part of the data path.

Procedure

Step 1 Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from any host to 10.2.2.2, do the following:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, preserve-sq-no.
d) Click **Add** to add a rule.
e) Keep **Allow** for the action.
f) Leave the **Source** list empty, enter 10.2.2.2 beneath the **Destination** list, and click **Add**.
g) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, and click **Add**. Do not enter a port number, simply add TCP as the protocol, which will cover all ports.
h) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.
i) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

Step 2 Configure the service policy rule that disables TCP sequence number randomization.

For example, to disable randomization for this traffic class globally, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.

c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Deselect **Randomize TCP Sequence Number**.
g) (Optional.) Adjust the other connection options as needed.
h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

Click **Save** on **Advanced** to save the changes to the access control policy.

You can now deploy the changes to the affected devices.

Monitor service policies

You can monitor service-policy related information using the device CLI. Use these commands to get the information you need.

Commands for monitoring service policies.

- **show conn** [**detail**]

  Shows connection information. Detailed information uses flags to indicate special connection characteristics. For example, the "b" flag indicates traffic subject to TCP state bypass.

  When you use the **detail** keyword, you can see information about dead connection detection (DCD) probing, which shows how often the connection was probed by the initiator and responder. For example, the connection details for a DCD-enabled connection would look like this:

```
TCP dmz: 10.5.4.11/5555 inside: 10.5.4.10/40299,
    flags UO , idle 1s, uptime 32m10s, timeout 1m0s, bytes 11828,
cluster sent/rcvd bytes 0/0, owners (0,255)
  Traffic received at interface dmz
        Locally received: 0 (0 byte/s)
  Traffic received at interface inside
        Locally received: 11828 (6 byte/s)
  Initiator: 10.5.4.10, Responder: 10.5.4.11
  DCD probes sent: Initiator 5, Responder 5
```

- **show service-policy**

  Shows service policy statistics, including dead connection detection (DCD) statistics.

- **show threat-detection statistics top TCP-intercept** [**all** | **detail**]

  View the top 10 protected servers under attack. The **all** keyword shows the history data of all the traced servers. The **detail** keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

Examples for service policy rules

Provides examples of service policy rules to help users understand how to configure and implement service policies effectively.

Protect servers from a SYN flood DoS attack (TCP intercept)

This task configures TCP intercept to protect servers from SYN flood denial of service attacks by limiting embryonic connections and enabling monitoring statistics.

A SYN-flooding denial of service (DoS) attack occurs when an attacker sends a series of SYN packets to a host. These packets usually originate from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests from legitimate users.

You can limit the number of embryonic connections to help prevent SYN flooding attacks. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination.

When the embryonic connection threshold of a connection is crossed, the Firewall Threat Defense acts as a proxy for the server. It generates a SYN-ACK response to the client SYN request using the SYN cookie method. This approach prevents the connection from being added to the SYN queue of the targeted host. The SYN cookie is the initial sequence number returned in the SYN-ACK that is constructed from MSS, time stamp, and a mathematical hash of other items to essentially create a secret. If the Firewall Threat Defense receives an ACK from the client with the correct sequence number, and within the valid time window, it authenticates the client and allows the connection to the server. The component that performs the proxy is called TCP intercept.

Setting connection limits can protect a server from a SYN flood attack. You can optionally enable TCP intercept statistics and monitor the results of your policy. The following procedure explains the end-to-end process.

Before you begin

- Ensure that you set the embryonic connection limit lower than the TCP SYN backlog queue on the server that you want to protect. Otherwise, valid clients can no longer access the server during a SYN attack. To determine reasonable values for embryonic limits, carefully analyze the capacity of the server, the network, and server usage.
- Depending on the number of CPU cores on your Secure Firewall Threat Defense device model, the maximum concurrent and embryonic connections can exceed the configured numbers due to the way each core manages connections. In the worst case scenario, the device allows up to n-1 extra connections and embryonic connections, where n is the number of cores. For example, if your model has 4 cores, if you configure 6 concurrent connections and 4 embryonic connections, you could have an additional 3 of each type. To determine the number of cores for your model, enter the **show CPU core** command in the device CLI.

Follow these steps to protect servers from a SYN flood DoS attack using TCP intercept:

Procedure

Step 1 Create the extended ACL that defines the traffic class, which is the list of servers you want to protect.

For example, to define a traffic class to protect the web servers with the IP addresses 10.1.1.5 and 10.1.1.6:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, protected-servers.
d) Click **Add** to add a rule.
e) Keep **Allow** for the action.
f) Leave the **Source** list empty, enter 10.1.1.5 beneath the **Destination** list, and click **Add**.
g) Also enter 10.1.1.6 beneath the **Destination** list and click **Add**.
h) Click **Port**, select **HTTP** in the available ports list, and click **Add to Destination**. If your server also support HTTPS connections, also add that port.
i) Click **Add** to add the rule to the ACL.

Click **Save** to save the ACL object.

Step 2 Configure the service policy rule that sets embryonic connection limits.

For example, to set the total concurrent embryonic limit to 1000 connections, and the per-client limit to 50 connections, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** ( ) for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Enter 1000 for **Connections** > **Maximum Embryonic**.
g) Enter 50 for **Connections Per Client** > **Maximum Embryonic**.

(Optional.) Adjust the other connection options as needed.

h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

Click **OK** to save the changes to the service policy.

Click **Save** on **Advanced** to save the changes to the access control policy.

Step 3 (Optional.) Configure the rates for TCP intercept statistics.

TCP intercept uses these options to determine the rate for collecting statistics. All options have default values, so if these rates suit your needs, you can skip this step.

- Rate Interval—The size of the history monitoring window, between 1 and 1440 minutes. The default is 30 minutes. During this interval, the system samples the number of attacks 30 times.
- Burst Rate—The threshold for syslog message generation, between 25 and 2147483647. The default is 400 per second. When the burst rate is exceeded, the device generates syslog message 733104.
- Average Rate—The average rate threshold for syslog message generation, between 25 and 2147483647. The default is 200 per second. When the average rate is exceeded, the device generates syslog message 733105.

If you want to adjust these options, do this:

a) Choose **Objects** > **Object Management** > **FlexConfig** > **Text Object**.
b) Click **Edit** ( ) for the **threat_defense_statistics** system-defined object.
c) Although you can directly change the values, the recommended approach is to open the **Override** section and click **Add** to create a device override.
d) Select the devices to which you will assign the service policy (through the access control policy assignment) and click **Add** to move them to the selected list.
e) Click **Override**.
f) The object must have 3 entries, so click **Count** as needed until you get 3.
g) Enter the values you need, in order from 1-3, as rate interval, burst rate, and average rate. Consult the object description to verify you enter the values in the right order.
h) Click **Add** in the Object Override dialog box.
i) Click **Save** in the Edit Text Object dialog box.

Step 4 Enable TCP intercept statistics.

You must configure a FlexConfig policy to enable TCP intercept statistics.

a) Choose **Devices** > **FlexConfig**.
b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new policy and assign it to the affected devices.
c) Select the **Threat_Detection_Configure** object in the **Available FlexConfig** list and click >>. The object is added to the **Selected Append FlexConfigs** list.
d) Click **Save**.
e) (Optional.) You can verify that you have the right settings by clicking **Preview Config** and selecting one of the devices.

The system generates the CLI commands that will be written to the device during the next deployment. These commands will include those needed for the service policy as well as those needed for threat detection statistics. Scroll to the bottom of the preview to see the appended CLI. The TCP intercept statistics command should look something like this, if you use the default values (line break added for clarity):

```
###Flex-config Appended CLI ###

threat-detection statistics tcp-intercept rate-interval 30
       burst-rate 400 average-rate 200
```

Step 5 You can now deploy the changes to the affected devices.

Step 6 Monitor the TCP intercept statistics from the device CLI using these commands:

- **show threat-detection statistics top TCP-intercept** [**all** | **detail**]—View the top 10 protected servers under attack. The **all** keyword shows the history data of all the traced servers. The **detail** keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

  Note
  You can use the **shun** command to block attacking host IP addresses. To remove the block, use the **no shun** command.

- **clear threat-detection statistics TCP-intercept**—Erases TCP intercept statistics.

Example:

```
hostname(config)# show threat-detection statistics top tcp-intercept
Top 10 protected servers under attack (sorted by average rate)
Monitoring window size: 30 mins    Sampling interval: 30 secs
<Rank> <Server IP:Port> <Interface> <Ave Rate> <Cur Rate> <Total> <Source IP (Last Attack
Time)>
--------------------------------------------------------------------------------
1    10.1.1.5:80 inside 1249 9503 2249245 <various> Last: 10.0.0.3 (0 secs ago)
2    10.1.1.6:80 inside 10 10 6080 10.0.0.200 (0 secs ago)
```

Configure the Firewall Threat Defense device to appear on traceroutes

Make the Firewall Threat Defense device appear as a hop in traceroute results by decrementing the time-to-live on packets and adjusting ICMP rate limits.

By default, the Firewall Threat Defense device does not appear on traceroutes as a hop. To make it appear, you need to decrement the time-to-live on packets that pass through the device, and increase the rate limit on ICMP unreachable messages. To accomplish this, you must configure a service policy rule and adjust the ICMP platform settings policy.

Note If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences. Keep these considerations in mind when defining your traffic class.

Procedure

Step 1 Create the extended ACL that defines the traffic class for which to enable traceroute reporting.

For example, to define a traffic class for all addresses, but excluding OSPF traffic, do the following:

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List**.
c) Enter a **Name** for the object, for example, traceroute-enabled.
d) Click **Add** to add a rule to exclude OSPF.
e) Change the action to **Block**, click **Port**, select **OSPFIGP (89)** as the protocol beneath the **Destination Ports** list, and click **Add** to add the protocol to the selected list.
f) Click **Add** on the Extended Access List Entry dialog box to add the OSPF rule to the ACL.
g) Click **Add** to add a rule to include all other connections.
h) Keep **Allow** for the action, and leave both the Source and Destination lists empty.
i) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.

Ensure that the OSPF deny rule is above the Allow Any rule. Drag and drop to move the rules if necessary.

Click **Save** on the Extended Access List Object dialog box to save the ACL object.

Step 2 Configure the service policy rule that decrements the time-to-live value.

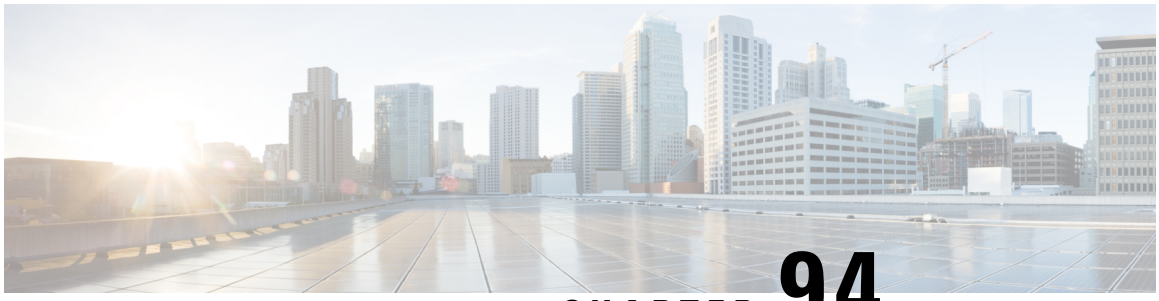
For example, to decrement time-to-live globally, do the following:

a) Choose **Policies** > **Access Control heading** > **Access Control**, and edit the policy assigned to the devices that require this service.
b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.
c) Click **Add Rule**.
d) Select **Global** and click **Next**.
e) Select the extended ACL object you created for this rule and click **Next**.
f) Select **Enable Decrement TTL**.
g) (Optional.) Adjust the other connection options as needed.
h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.

   Click **OK** to save the changes to the service policy.

   Click **Save** on **Advanced** to save the changes to the access control policy.

You can now deploy the changes to the affected devices.



Step 3 Increase the rate limit on ICMP unreachable messages.

a) Choose **Devices** > **Platform Settings**.
b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new Threat Defense platform settings policy and assign it to the affected devices.
c) Select **ICMP** from the table of contents.
d) Increase the **Rate Limit**, for example, to 50. You might also want to increase the **Burst Size**, for example, to 10, to ensure enough responses are generated within the rate limit.

   You can leave the ICMP rules table empty, it is not related to this task.

e) Click **Save**.

Step 4 You can now deploy the changes to the affected devices.

CHAPTER 94

Threat Detection

Threat detection's portscan detector is a mechanism designed to help you detect and prevent portscan activity in all types of traffic to protect networks from eventual attacks. Portscan traffic can be detected efficiently in both allowed and denied traffic.

Portscan is a form of network reconnaissance that is often used by attackers as a prelude to an attack. In a portscan, an attacker determines the types of network protocols or services a host supports and sends specially crafted packets to a targeted host. By examining the packets that the host responds with, the attacker can often determine which ports are open on the host and, either directly or by inference, which application protocols are running on these ports.

- Portscan detection and prevention, on page 2725
- Requirements and prerequisites for threat detection, on page 2727
- Limitations for threat detection configuration, on page 2728
- Best practices for portscan prevention, on page 2729
- Configure portscan detection and prevention, on page 2729
- Monitoring threat detection, on page 2731

Portscan detection and prevention

Portscan detection and prevention is a threat detection system that:

- identifies port scan activity and issues events when they are found,
- optionally prevents port scans by automatically blocking scanners, and
- sends you events and also blocks the attacker for a duration that you set.

Pre-defined sensitivity levels for portscan detection

When configuring detection settings, you select from these pre-defined sensitivity levels. Except for custom, each level has pre-set values for each protocol for the number of ports (TCP, UDP), protocols (IP), or hosts (TCP, UDP, IP, ICMP) that must be scanned within a set time interval (expressed in seconds). Also, all types of scans and sweeps are enabled.

Note When counting ports or protocols, threat detection increments the number if the port or protocol in the current packet differs from the previous packet. For example, if you have an application that opens connections in 10 set ports randomly, the total number of ports scanned could mount so quickly that your port number will be exceeded within the interval. The system does not count only unique ports.

Exceeding the number within the interval can indicate a scanning attack. Portscan events are generated only when the port/protocol/host numbers are exceeded for the moving time interval window.

These sensitivity levels determine portscan detection behavior:

- **Low**—This level uses the shortest time window for portscan detection, coupled with high counts for ports, protocols, and hosts. Thus, you should see portscan events for the most aggressive scanners only. Select this sensitivity level to suppress false positives, but remember that some types of port scans, such as slow or filtered scans, might be missed. For more detail on how low sensitivity detection works, see Detection in the low sensitivity level, on page 2727.
- **Medium**—This level uses moderate values for both the interval and port/protocol/host counts. However, very active hosts such as network address translators and proxies might generate false positives. Add such hosts to the ignore scanner list. This is the default sensitivity level and a good place to start.
- **High**—This level uses a much longer time window for portscan detection, coupled with lower counts for ports, protocols, and hosts. With this level, you are most likely to see events for even the least aggressive port scans or sweeps, so you are more likely to notice all attackers. However, this level would likely result in the most portscan events issued, and potentially the highest number of false positives.
- **Custom**—If you want to configure any setting differently than one of the predefined sensitivity levels, or disable a particular type of scan or sweep, the level automatically switches to custom. If you want to adjust the options, first select the level that most closely matches what you want, then edit the values as appropriate.

Table 145: Sensitivity level settings

Setting	Low	Medium	High
Interval (TCP/UDP/IP/ICMP)	60 seconds	90 seconds	600 seconds (10 minutes)
TCP/UDP portscan - Number of Ports	120 seconds	90 seconds	60 seconds
TCP/UDP portsweep - Number of Hosts	180 seconds	150 seconds	100 seconds
IP protocol scan - Number of Protocols	30 seconds	15 seconds	10 seconds
IP protocol sweep - Number of Hosts	25 seconds	20 seconds	10 seconds
ICMP host sweep - Number of Hosts	50 seconds	30 seconds	20 seconds

Detection in the low sensitivity level

When you select the low sensitivity level, the system tracks negative responses for TCP, UDP, and ICMP initial packets. An alert is triggered only when the number of unsuccessful connections exceeds the rejection threshold (10% for low sensitivity) and the port or IP protocol count exceeds the configured threshold. This mitigates false positives.

Low sensitivity level detection behavior

Rejection threshold applies to low sensitivity (or equivalent custom settings) only; it does not apply to other sensitivity levels or their custom equivalents.

When there is a mix of allowed and blocked traffic, the number of rejected ports or hosts is calculated based on the difference between allowed and blocked traffic. In the case of only blocked traffic, the rejection threshold is not considered.

These criteria are not used for UDP/ICMP connections on interfaces configured in inline sets.

Low sensitivity level detection scenarios

In low sensitivity mode, the port count threshold is 120. Thus, the rejection count threshold is 10% of 120, which is 12. Here are examples that show how the system issues portscan events with this configuration:

- An attacker initiates connections with 131 ports of the target and the target positively acknowledges all the initiations. Port count = 131, which is greater than the threshold, but a portscan alert is not triggered because there are no negative acknowledgements.
- An attacker initiates connections with 131 ports of the target and the target positively acknowledges 121 initiations and negatively acknowledges 10 initiations. Port count = 131, which is greater than the threshold, but reject port count = 10, which is lesser than the rejection threshold. Therefore, a portscan alert is not triggered.
- An attacker initiates connections with 134 ports of the target and the target positively acknowledges 121 initiations and negatively acknowledges 13 initiations. Port count = 134, which is greater than the threshold, and reject port count = 13 is also higher than the rejection threshold. Therefore a portscan alert is triggered.

Requirements and prerequisites for threat detection

Model support

Firewall Threat Defense running version 7.2+ and Snort 3.

Supported domains

Access Admin

Network Admin

Limitations for threat detection configuration

Threat detection requires Snort 3 and has specific version requirements and configuration interactions that vary by management platform.

- Threat detection requires Snort 3. The Network Analysis Policy (NAP) port scan configuration is always ignored for devices running Snort 3; you must configure port scan using threat detection. For Snort 2, you can configure port scan through the NAP policy only. If there are Snort 2 devices assigned to the access control policy, the threat detection settings will not be deployed to those unsupported devices.
- Threat detection requires Snort 3. The managed device must be running version 7.2 or higher. For Snort 2, or devices running versions lower than 7.2, you can configure port scan through the NAP policy. Note that the threat detection feature is not the same as the port scan feature in the NAP policy. If there are non-Snort 3 devices running version 7.2 or higher that are assigned to the access control policy, the threat detection settings are not deployed to those unsupported devices.
- If you configure port scan in the NAP policy on a device running 7.1 or lower, that configuration is not translated to the threat detection feature on upgrade to 7.2. You must manually configure threat detection. Although the NAP and threat detection port scan options are similar, they do not match one-to-one.
- If you configure threat detection, any port scan configuration in the NAP policy is ignored and not configured on the devices that support threat detection.
- The NAP port scan feature for Snort 3 is always ignored for devices running version 7.2 or higher. To configure port scanning, you must use the threat defense settings.
- Threat detection works on traffic that passes through the device only. It does not work on traffic directed to the device.
- In a high availability setup, port scanning statistics are not synchronized to the standby unit. However, blocked hosts are synchronized and continue to be blocked until the duration period expires in case of a failover.
- (Devices running Threat Defense versions 7.2 through 7.7). For nodes in a cluster, detection and prevention happen on the individual cluster node. That is, if node B detects and blocks traffic from a host, node A will not be aware of that action because port scan statistics are not synchronized across cluster nodes.
- (Devices running Threat Defense version 10.0+). For nodes in a cluster, detection and prevention happen at the cluster level. Port scans can be detected when they happen across nodes or in an individual node. Shunned hosts are shunned on all devices in the cluster. Shuns are released at the same time on all nodes. Statistics are available at the cluster level.
- For inline sets, or for interfaces that are configured to be part of an equal-cost multipath (ECMP) traffic zone, detection and prevention are done at the zone level. Port scan statistics for a host are accumulated across all interfaces of a zone. Similarly, when a host crosses configured thresholds, it is blocked across all interfaces of the corresponding zone.
- Although the port scan events generated by the threat detection feature are the same as the ones Snort issues for port scan, you do not need to enable port scanning intrusion rules to get the events. Threat detection works regardless of your intrusion policy implementation.

Best practices for portscan prevention

Portscan prevention mode can result in unintended traffic outage. In prevention mode, hosts are blocked from further scanning of networks on all protocols for the configured duration. Review the detection and prevention parameters carefully to ensure legitimate traffic is not blocked.

Before configuring portscan in prevention mode:

- Start using portscan in detection mode.
- Observe the generated portscan events.
- Tune the sensitivity level, monitored networks, ignore scanner list, and ignore target list. If a pre-defined sensitivity level does not work well for your situation, configure custom settings as needed.
- Repeat the process until false positives are eliminated and the event rate represents an accurate picture of port scanning in your network. Ensure that you are comfortable with blocking the remaining identified scanners.

Configure portscan detection and prevention

This task enables threat detection to watch for port scanning activity and optionally automatically block scanners for a period of time.

Portscan is a form of network reconnaissance that is often used by attackers as a prelude to an attack. In a portscan, an attacker determines the types of network protocols or services a host supports and sends specially crafted packets to a targeted host. By examining the packets that the host responds with, the attacker can often determine which ports are open on the host and, either directly or by inference, which application protocols are running on these ports.

You can enable threat detection to watch for port scanning activity and optionally, automatically block scanners for a period of time.

Before you begin

Fully Qualified Domain Name (FQDN), wildcard mask, any, any-ipv4, and any-ipv6 network objects are not supported for portscan configuration. These objects are not shown in the **Monitor**, **Ignore Scanner**, **Ignore Target**, and **Exclude** fields.

Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** (✎) next to **Threat Detection**.

Step 2 In the **Threat Detection** window, select the **Portscan mode**:

- **Disable**—Turn off threat detection. This is the default mode. You can click **Revert to Defaults** to return to this unconfigured state.

- **Detection**—Perform portscan detection, but alert on problems only. Do not take action against potential attackers. We suggest you use this mode initially until you fine-tune the threat detection settings to avoid excessive false positives.
- **Prevention**—Perform portscan detection and actively block identified scanners, that is, hosts that are performing the port scan.

Step 3 Configure the **Traffic Selection** options.

The traffic selection options determine which networks are monitored, the type of connections monitored, and whether any scanners or target hosts should be exempted from the monitored networks. By default, the system monitors permitted connections on all networks.

- **Detection On Traffic**—Select the types of connection that will be monitored for portscan activity: **Permitted**, **Denied**, or **All** traffic. The default is **Permitted**.
- **Monitor**—Select the network objects that define the networks to monitor for portscan or sweep activity. The default is any network, IPv4 or IPv6. Use this option to limit scanning to untrusted networks.
- **Ignore Scanner**—Select the network objects that define the hosts or networks, from within the range of the monitored networks, that should be ignored. For example, if you have set up your own scanner to test your network, you can exempt the address of your scanner to avoid unnecessary reporting on the address. Do not include addresses that are outside the monitored networks, as these addresses are already ignored.
- **Ignore Target**—Select the network objects that define the hosts or networks that should be ignored as targets, that is, victims of a portscan or sweep.

Step 4 Click the **Configuration** tab and select the scanning sensitivity level.

The predefined sensitivity levels, **Low**, **Medium**, and **High**, set the port scanning options to values that are increasingly aggressive. For example, if you select low, you would expect to see fewer port scanning events, and you could potentially miss attackers more easily than if you selected medium or high. On the other hand, if you select high, you might see more events and also, potentially, more false positives. The default level is medium. For more information on these levels, see Pre-defined sensitivity levels for portscan detection, on page 2725.

As you select the levels, you can see the related values within the protocol sections: **TCP**, **UDP**, **IP**, and **ICMP**. If you change any of the preset values, or disable a type of scan, the sensitivity mode automatically changes to **Custom**.

Within each protocol section, the options are:

- **Interval**—The time range, in seconds, within which the configured values for portscan or portsweep are exceeded. For example, if you select 90 seconds, and 60 as the number of TCP portscan ports, a scanner would need to try 60 ports on a host within 90 seconds for it to be considered a portscan. The system generates events only if the number of ports, protocols, or hosts (for a portsweep) are exceeded within the specified interval.

  You can specify a range between 30 to 600 seconds. The longer the period, the more likely a host might be identified as a scanner.
- **Portscan** (TCP/UDP)—Select whether to monitor for port scanning against single hosts, and specify the number of ports that must be scanned within the interval to count as a portscan attack. The allowed range is 1-256.

- **Portsweep** (TCP/UDP)—Select whether to monitor for port sweeping against multiple hosts, and specify the number of hosts that must be scanned for a given port within the interval to count as a portsweep attack. The allowed range is 1-256.
- **Protocol Scan** (IP)—Select whether to monitor for protocol scanning against single hosts, and specify the number of protocols that must be scanned within the interval to count as a protocol scan attack. The allowed range is 1-255.
- **Protocol Sweep** (IP)—Select whether to monitor for protocol sweeping against multiple hosts, and specify the number of hosts that must be scanned for a given protocol within the interval to count as a protocol sweep attack. The allowed range is 1-256.
- **Hostsweep** (ICMP)—Select whether to monitor for ICMP host sweeping against multiple hosts, and specify the number of hosts that must be scanned within the interval to count as a hostsweep attack. The allowed range is 1-256.

Step 5 If you selected prevention mode, click the **Prevention** tab and configure the options.

In prevention mode, hosts are automatically blocked from further scanning of networks on all protocols for the configured duration. Review the detection and prevention parameters carefully to ensure legitimate traffic is not blocked.

- **Exclude**—Select the network objects that define the hosts or networks, from within the range of the monitored networks, that should be excluded from automatic blocking. Even if these hosts violate your scanning detection parameters, the system will not block them.
- **Duration**—How long, in seconds, automatically blocked scanner hosts should be prevented from sending traffic of any kind through the device. After the duration period ends, the hosts are automatically cleared and can again send traffic through the device. The allowed range is 600 to 2592000 seconds. The default is 3600 seconds (1 hour).

  If you need to manually unblock a host, SSH to the firewall that is blocking the host and use the **clear threat-detection portscan attacker** command.

Step 6 Click **OK** to save the threat detection settings.

Step 7 Click **Save** to save the access control policy.

What to do next

Deploy configuration changes.

Monitoring threat detection

The following topics explain how to monitor portscan activity.

View portscan alerts

Portscan activity is alerted through the existing portscan-specific intrusion events. Intrusion events with generator ID (GID) 122 and Snort ID from SIDs 1 through 27 are generated. For these events, the *(port_scan)*

string is prepended in the event messages. The events include packet information along with packet data containing the statistics that triggered the alert.

To viewportscan events, go to **Analysis** > **Unified Events**.

Portscan issues these events regardless of your intrusion policy or NAP configuration. Events are issued only when scanners exceed the number of configured ports, protocols, or hosts for the various types of scan or sweep within the configured time interval for the associated protocol. A port scan from one host generates one event per set interval as soon as the threshold is met. If the same host initiates a new port scan during the same interval, no event is reported.

Table 146: Portscan events

Portscan type	Intrusion event
TCP Regular, Decoy, Distributed Scan	122:1 (port_scan) TCP portscan
TCP Portsweep	122:3 (port_scan) TCP portsweep
TCP Distributed Scan	122:4 (port_scan) TCP distributed portscan
IP Regular, Decoy, Distributed Protocol Scan n	122:9 (port_scan) IP protocol scan
IP Protocol Sweep	122:11 (port_scan) IP protocol sweep
IP Distributed Scan	122:12 (port_scan) IP distributed protocol scan
UDP Regular, Decoy, Distributed Scan	122:17 (port_scan) UDP portscan
UDP Portsweep	122:19 (port_scan) UDP portsweep
UDP Distributed Scan	122:20 (port_scan) UDP distributed portscan
ICMP Sweep	122:25 (port_scan) ICMP sweep
Portscan Block	122:100 (port_scan) host blocked due to portscan activity

Monitor portscan on the firewall

To monitor portscan, log in to the device Command-Line Interface (CLI) and use these commands.

- **show threat-detection portscan** [**attacker** | **target** | **shun**]

  Shows the IP addresses of scanners, those that have been shunned (blocked), and hosts that have been targeted by scans or sweeps.

- **show threat-detection portscan statistics** [**host** [*ipv4_address* | *ipv6_address*]] [**protocol** {**tcp** | **udp** | **IP** | **icmp**}]

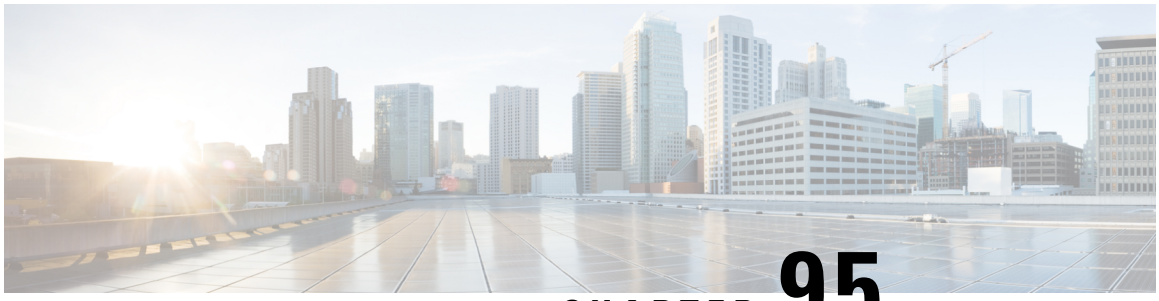
  Shows statistics related to the port scan system. You can specify host, protocol, or host and protocol to filter the output to the desired information.

- **clear threat-detection portscan** [**attacker** | **target** | **shun**] [*ipv4_address mask* | *ipv6_address/prefix*]

Manually unblocks scanners (attackers) or identified targets. Enter the command without parameters to clear all attackers, targets, or shunned hosts.

- **clear threat-detection portscan statistics** [**host** [*ipv4_address* | *ipv6_address*]] [**protocol** {**tcp** | **udp** | **IP** | **icmp**}]

  Erases statistics related to portscan, so that you can more clearly see the current state of scanning through this device. Enter the command without parameters to clear all statistics. Alternatively, specify a host, protocol, or host and protocol, to limit the reset to the specified items.



Unblocking a host

If you configure threat detection in prevention mode and the system blocks a host that you know is not an attacker, you can manually unblock the host before the host is automatically unblocked when the duration period expires.

To manually unblock the host, log in to the device CLI where the host is blocked and enter the clear threat-detection portscan attacker command. For example:

```
> clear threat-detection portscan attacker 10.2.0.100 255.255.255.255
1 tracker object deleted and 1 shun entry removed
```

Consider adding the host IP address to the exclude list in the prevention configuration.

CHAPTER 95

Elephant Flow Detection

Elephant flows are extremely large (in total bytes), continuous flows set up by a TCP (or other protocols) flow measured over a network link. By default, elephant flows are those larger than 1 GB/10 seconds. They can cause performance duress in Snort cores. Elephant flows are not numerous, but they can occupy a disproportionate share of the total bandwidth over a period of time. They can lead to problems, such as high CPU utilization, packet drops, and other issues.

From Cloud-Delivered Firewall Management Center 7.2.0 onwards (Snort 3 devices only), you can use the elephant flow feature to detect and remediate elephant flows, which helps to reduce system stress and resolve the mentioned issues.

- Elephant flow detection and remediation, on page 2735
- Elephant flow upgrade from Intelligent Application Bypass, on page 2736
- Configure elephant flow detection, on page 2736
- Use case - Configure Elephant Flow Detection Outcomes, on page 2739

Elephant flow detection and remediation

Elephant flow detection and remediation is a feature that

- detects elephant flows in network traffic,
- applies remediation actions to manage these flows, and
- requires Snort 3 as the detection engine to function.

Remediation actions

These remediation actions can be applied:

- **Bypass elephant flow**—You can configure elephant flow to bypass Snort inspection. If this is configured, Snort does not receive any packet from that flow.
- **Throttle elephant flow**—You can apply rate-limit to the flow and continue to inspect flows. The flow rate is calculated dynamically, and the system reduces the flow rate by 10 percent. Snort sends the verdict (with QoS flow reduced by 10 percent) to the firewall engine. If you choose to bypass all applications, including unidentified applications, you cannot configure the throttle action (rate-limit) for any flow.

Elephant flow upgrade from Intelligent Application Bypass

For devices running 7.2.0 or later, you must configure elephant flow settings under the **Elephant Flow Settings** section in the access control policy (Advanced settings tab) because Intelligent Application Bypass (IAB) is deprecated from version 7.2.0 onwards for Snort 3 devices.

Post-upgrade to 7.2.0 (or later), if you are using a Snort 3 device, the elephant flow configuration settings will be picked and deployed from the **Elephant Flow Settings** section and not from the **Intelligent Application Bypass Settings** section, so if you have not migrated to Elephant Flow configuration settings, your device will lose the elephant flow configuration upon the next deployment.

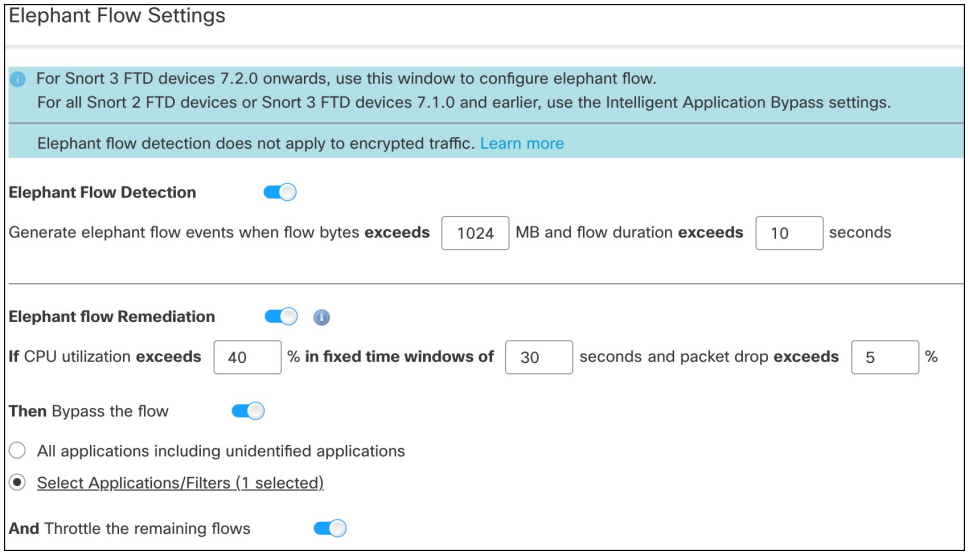
This table shows the IAB or elephant flow configurations that can be applied to version 7.2.0 or later and to version 7.1.0 or earlier that are running Snort 3 or Snort 2 engines.

Cloud-Delivered Firewall Management Center	Firewall Threat Defense	Elephant Flow or IAB Configuration
Cloud-Delivered Firewall Management Center 7.0 or 7.1	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device	Configuration from IAB is applicable.
Cloud-Delivered Firewall Management Center 7.2.0	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device (7.1.0 and earlier)	Configuration from IAB is applicable.
	Snort 3 device (7.2.0 and later)	Configuration from Elephant Flow is applicable.

Configure elephant flow detection

Configure elephant flow detection to take actions on elephant flows. This helps resolve issues such as system duress, high CPU utilization, packet drops and related performance problems.

Attention Elephant flow detection is not applicable for prefiltered, trusted, or fast-forwarded flows, which do not process through Snort. As elephant flows are detected by Snort, elephant flow detection is not applicable for encrypted traffic.



Procedure

Step 1 In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** ( ) next to **Elephant Flow Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Figure 393: Configure elephant flow detection

Figure 394: Configure elephant flow detection

Step 2 Configure the values for flow bytes and flow duration for the **Elephant Flow Detection** toggle button that is enabled by default.

When they exceed your configured values, elephant flow events are generated.

Step 3 To remediate elephant flows, enable the **Elephant Flow Remediation** toggle button.

Step 4 To set the criteria for remediation of the elephant flow, configure the values for CPU utilization percentage, duration of fixed time windows, and packet drop %.

CPU utilization is calculated per elephant flow and is derived from the flow latency. If the CPU utilization crosses the configured threshold and other configurations, such as fixed time windows and packet drops, are also matched, the elephant flow remediation actions are applied. Similarly, packet drop calculation is based on the packets dropped per CPU. After the packet drop percentage exceeds the configured value on a specific CPU, the remediation actions are applied. For example, consider that configurations are set to the default, that is, CPU utilization of 40%, fixed time window of 30 seconds, and packet drop of 5%. On a specific CPU, if more than 5% of packet drops are detected and the CPU utilization per flow exceeds 40% in the fixed time frame of 30 seconds, then the flows are either bypassed or throttled.

Step 5 Configure the actions for elephant flow remediation when it meets the configured criteria.

a. **Bypass the flow**—Enable this button to bypass Snort inspection for selected applications or filters. Choose from:

   - **All applications including unidentified applications**—Select this option to bypass all the application traffic. If you configure this option, you cannot configure the throttle action (rate-limit) for any flow.
   - **Select Applications/Filters**—Select this option to select the applications or filters whose traffic you want to bypass; see the topic *Configuring Application Conditions and Filters* in the *Access Control Rules* chapter in the Cisco Secure Firewall Management Center Device Configuration Guide.

b. **Throttle the flow**—Enable this button to apply rate-limit to the flow and continue to inspect flows. Note that you can select the applications or filters to bypass Snort inspection and throttle the remaining flows.

Note
Automatic removal of throttle from a throttled elephant flow occurs when the system is out of duress, that is, the percentage of Snort packet drops is less than your configured threshold. Consequently, rate limiting is also removed.

You can also manually remove throttling from a throttled elephant flow, using these threat defense commands:

- **clear efd-throttle <5-tuple/all> bypass**—This command removes throttling from the throttled elephant flow and bypasses Snort inspection.
- **clear efd-throttle <5-tuple/all>**—This command removes throttling from the throttled elephant flow and Snort inspection continues. Elephant flow remediation is skipped after using this command.

  For more information about these commands, refer to the Cisco Secure Firewall Threat Defense Command Reference.

Step 6 In the **Remediation Exemption Rule** section, click **Add Rule** to configure L4 access control list (ACL) rules for flows that must be exempted from remediation.

a) In the **Add Rule** window, use the **Networks** tab to add the network details, that is the source network and the destination network. Use the **Ports** tab to add the source port and the destination port.

   If an elephant flow is detected and it matches the rules that are defined, an event is generated with the reason as **Elephant Flow Exempted** in the **Reason** column header of **Connection Events**.

b) In the **Remediation Exemption Rule** section, you can view the flows that are exempt from the remediation action.

c) Click **OK** to save the elephant flow settings.

Step 7 Click **Save** to save the policy.

What to do next

Deploy configuration changes.

After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can view this in the **Reason** field of your connection event. The three reasons for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted

Attention Enabling elephant flow detection alone does not cause generation of connection events for elephant flows. If a connection event is already logged for another reason and the flow is also an elephant flow, then the **Reason** field contains this information. However, to ensure that you are logging all elephant flows, you must enable connection logging in the applicable access control rules.

Refer to Cisco Secure Firewall Elephant Flow Detection for more information.

Use case - Configure Elephant Flow Detection Outcomes

This use case provides a sample scenario for configuring outcomes and system responses that detect elephant flows in network traffic to optimize performance and resource usage.

Elephant flows

An elephant flow is an extremely large network connection that

- consists of long-running connections set up by TCP or other protocols measured over a network link,
- measures larger than 1 GB per 10 seconds by default, and
- can cause performance duress or issues in Snort cores by consuming excessive CPU resources.

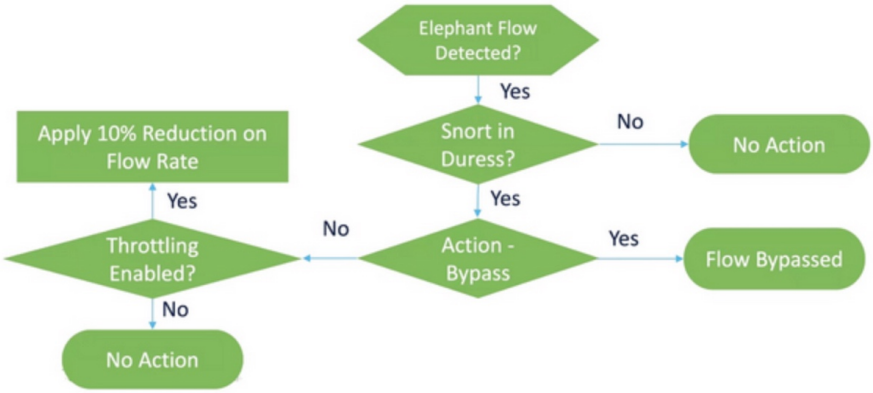
Impact on system performance

Elephant flows can potentially consume an excessive amount of CPU resources and impact other competing flows for detection resources and cause issues, such as increased latency or packet drops.

Benefits of elephant flow detection and remediation

- Elephant flow configuration allows customization and the option to bypass or even throttle elephant flows.
- You can choose to bypass or throttle flows that are based on your chosen applications to provide Snort inspection of suspect traffic, while bypassing more trusted traffic.
- Elephant flow remediation helps prioritize and free up more bandwidth for your internal applications, depending on your specific requirements.

How elephant flows work



Summary

The key components involved in the elephant flow process are:

- System detection: Monitors for Snort duress conditions based on configured parameters.
- Flow identification: Determines when a flow qualifies as an elephant flow.
- CPU monitoring: Tracks CPU utilization against configured thresholds.
- Bypass action: Allows traffic for trusted applications to pass without Snort inspection.
- Throttle action: Reduces the flow throughput in 10 percent increments until CPU utilization drops below the threshold.

Workflow

Figure 395: Elephant flow workflow

These stages describe how elephant flows are processed:

1. The system continuously monitors traffic flows and applies intrusion policy processing to all flows, including potential elephant flows, ensuring that attacks are detected early in connections.
2. When an elephant flow is detected based on configured parameters, the system evaluates whether a Snort duress condition exists by checking CPU utilization and time window parameters.

   No action is taken unless the system detects a Snort duress condition (performance issue). The system does not throttle or bypass a flow just because it is large.
3. If duress conditions are met, the system determines whether to bypass or throttle the elephant flow based on configuration settings.

   The actions of throttle and bypass are mutually exclusive. This means that you can either bypass or throttle a flow, but not both.
4. For bypass actions, if configured for specific applications only, the system allows trusted application flows to pass without Snort inspection while throttling remaining flows causing duress.

   This ensures that other non-trusted application flows still receive full Snort inspection, although their bandwidth is reduced.
5. For throttle actions, the system reduces flow throughput in 10 percent increments until CPU utilization reduces to below the configured threshold.

Sample business scenarios

In a data center, several activities are happening, such as replication of data between clusters, virtual machine integration, and database backup. Users in an organization could be watching videos on an OTT service or downloading them. Bandwidth utilization for such activities might result in elephant flows that slow down the network and impact the performance of important tasks. As a network administrator (and depending on your specific requirements), you want visibility into such large flows that are causing bandwidth issues and remediate them.

As an example, let's see how you can configure elephant flow parameters to bypass Snort inspection for WebEx traffic (which your organization uses for real-time video conferencing) and throttle the remaining applications or connections, including videos, movies, and so on.

Prerequisites

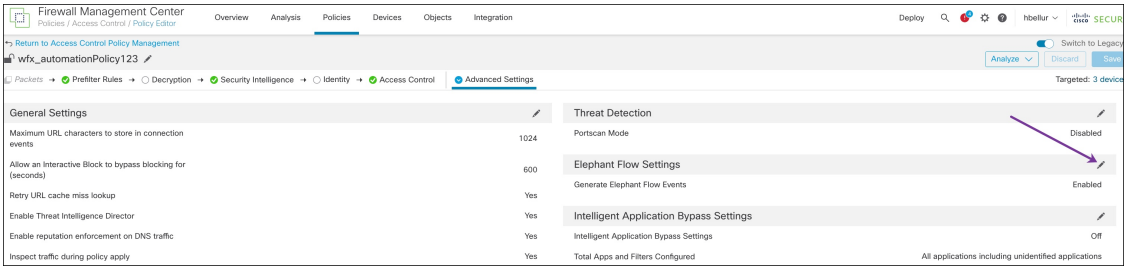
Ensure that you are running management center 7.2.0 or later and that the managed threat defense is also 7.2.0 or later.

When you enable only elephant flow detection, no additional connection events are generated. The system adds the Elephant Flow notation to matching connections that are already logged to the management center. **To log these events, you must enable connection logging in your access control policy.** You can do that for specific rules or add a Monitor rule that logs all connections, including elephant flows.

Configure elephant flow parameters

Configure elephant flow detection and remediation settings to identify high-bandwidth connections, and manage them through bypassing or throttling to maintain optimal system performance during high CPU utilization.

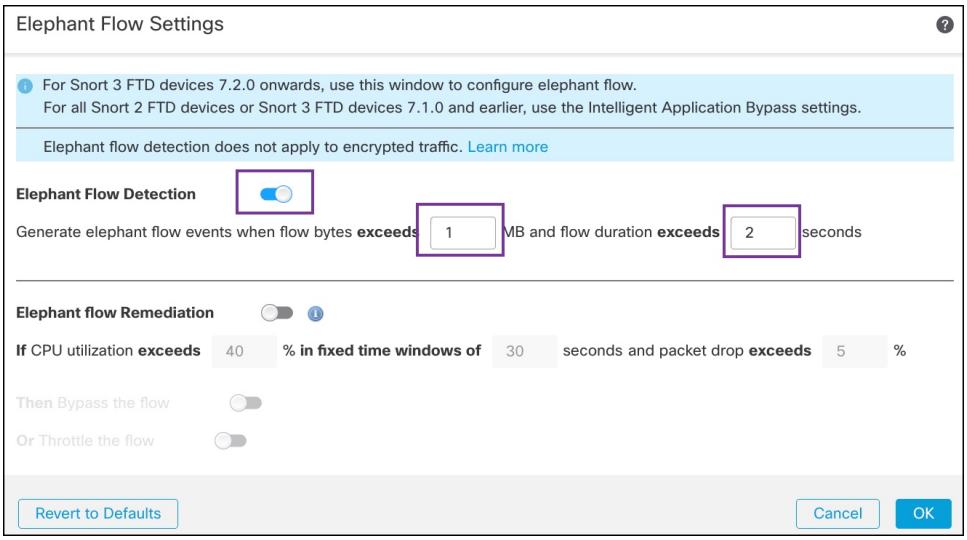
Elephant flows are high-bandwidth, long-duration connections that can impact system performance. By configuring elephant flow parameters, you can detect these flows and apply appropriate remediation actions such as bypassing trusted applications from inspection or throttling flows that cause system duress.



Procedure

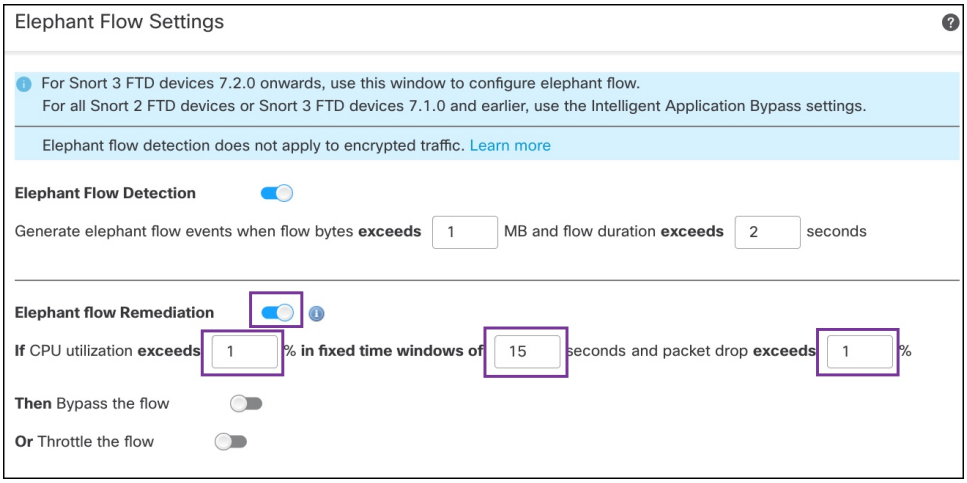
Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

Step 2 Click **Edit** (✎) next to the access control policy that you want to edit.



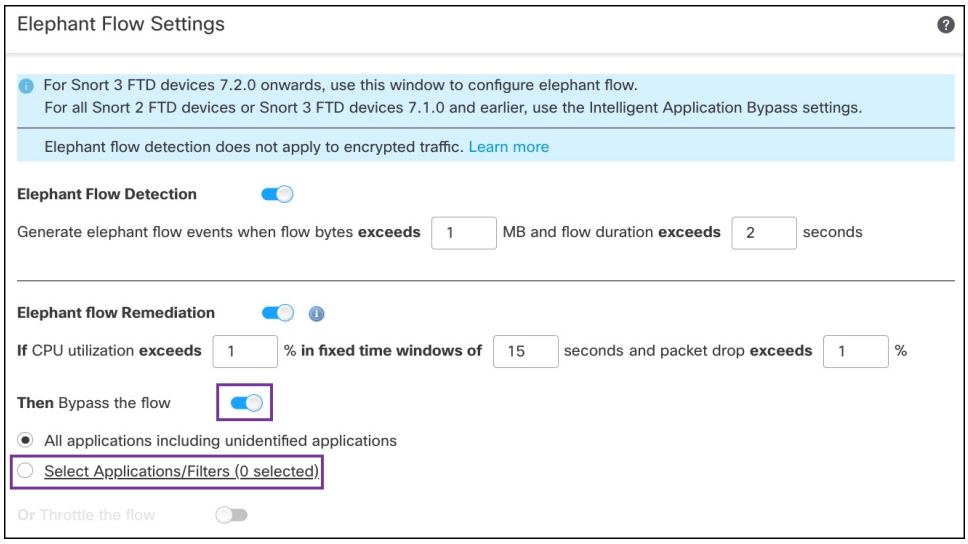
Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** (✎) next to **Elephant Flow Settings**.

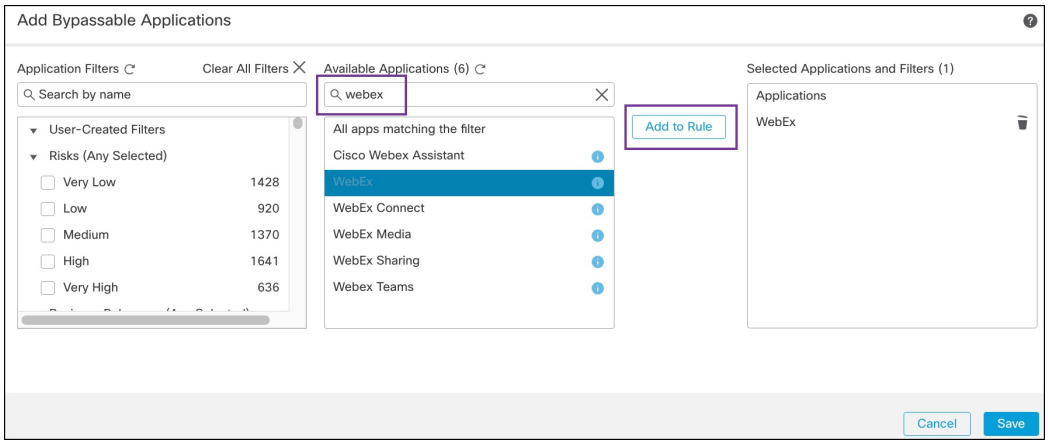


Step 5 The **Elephant Flow Detection** toggle button is enabled by default. The default setting enables detection only and no default action is configured. The detection settings allow you to adjust the flow bytes and duration so that you can identify the elephant flows in your system.

As a test setting, configure the flow bytes and duration parameters, as shown in the following figure.



Step 6 Enable the **Elephant Flow Remediation** toggle button. When an elephant flow is detected, you can choose to bypass or throttle the flow. Bypassing a flow means that the traffic is allowed to pass without Snort inspection. Throttling indicates that the flow throughput is reduced. This rate reduction is done in 10 percent increments until the CPU utilization decreases to less than the configured threshold.



As a test setting, configure the elephant flow remediation parameters as shown in the following figure.

Step 7 Enable the **Bypass the flow** toggle button and click the **Select Applications/Filters** radio button.

Step 8 Under **Application Filters**, search for and select the **WebEx** application, add it to the rule, and click **Save**. This means that WebEx connections are trusted and prioritized. These connections will skip Snort inspection if detected as elephant flows based on the configured parameters.

Step 9 Enable the **Throttle** toggle button to throttle the remaining flows (causing duress). This ensures that all the other flows are slowed down in 10 percent increments until the Snort duress condition is met.

Click **OK** and then **Save**.

What to do next

Deploy configuration changes.

View events for elephant flows

This task enables you to monitor elephant flow connection events to track flow detection, bypass, and throttling activities through the Reason field in connection events.

After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can see this information in the **Reason** field of your connection events. The three types for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted

Procedure

Step 1 Choose **Analysis** > **Unified Events**.

Step 2 On the **Events** tab, in the search field, type "Reason" and then "Elephant Flow" to search for elephant flow events.

Tip
To see **Elephant Flow Trusted** or **Elephant Flow Throttled** events, type "Reason" and then "Elephant Flow Trusted" or "Elephant Flow Throttled", depending on what you want to search.

Step 3 View the elephant flow that was detected mid-flow and the **Reason** field shows **Elephant Flow**. At the end of the flow, it was bypassed and the **Reason** field shows **Elephant Flow Trusted**.

Configure elephant flow remediation exemption

This task allows you to create exemption rules for specific flows that should not be subject to remediation actions even when detected as elephant flows.

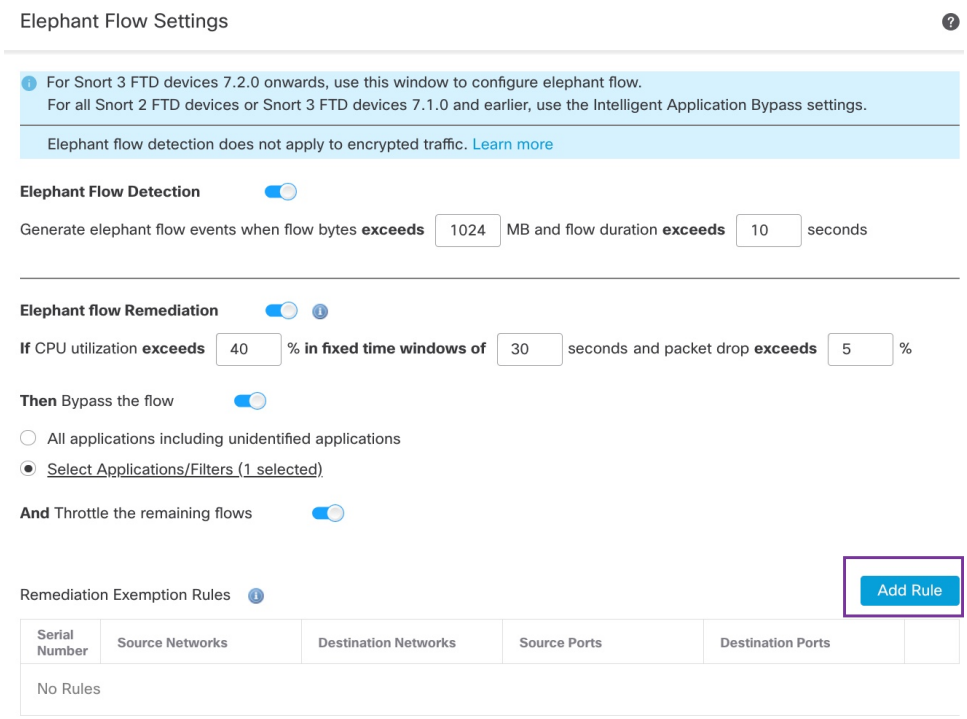
You can configure L4 access control list (ACL) rules for flows that must be exempted from remediation. If a flow is detected as an elephant flow and it matches the rules that are defined, that flow is exempted from remediation.

Before you begin

You must be running management center version 7.4.0 or later and the managed threat defense must also be on version 7.4.0 or later.

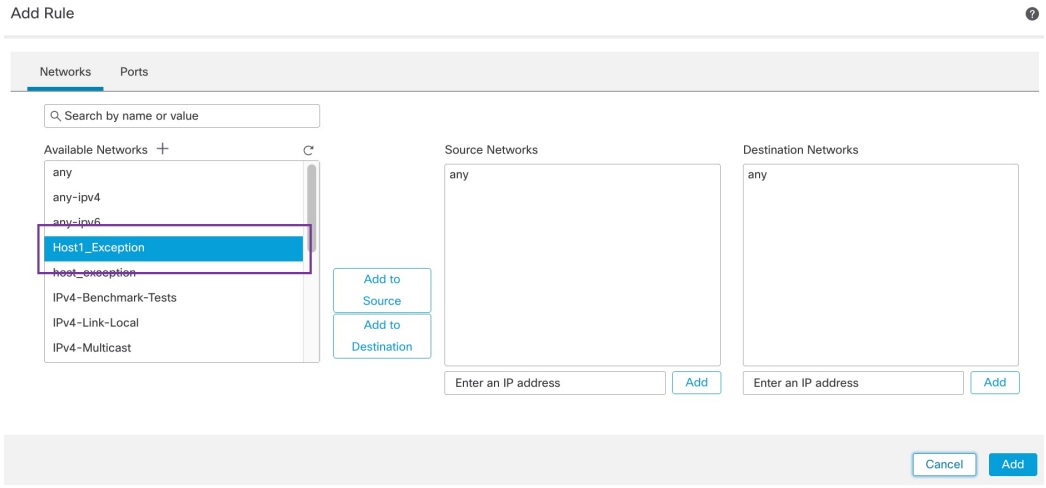
Follow these steps to configure elephant flow remediation exemption.

Procedure



Step 1 Choose **Policies** > **Access Control heading** > **Access Control**.

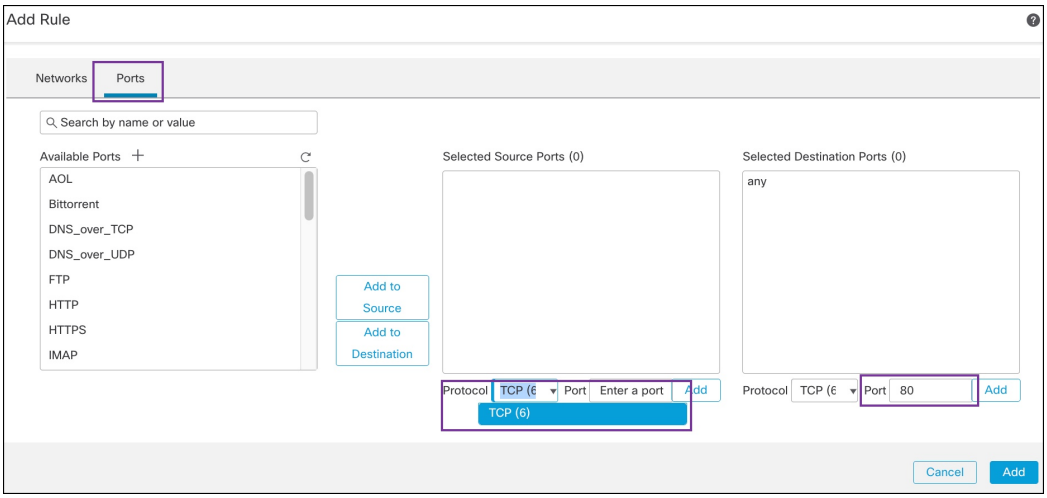
Step 2 Click **Edit** ( ) next to the access control policy you want to edit.



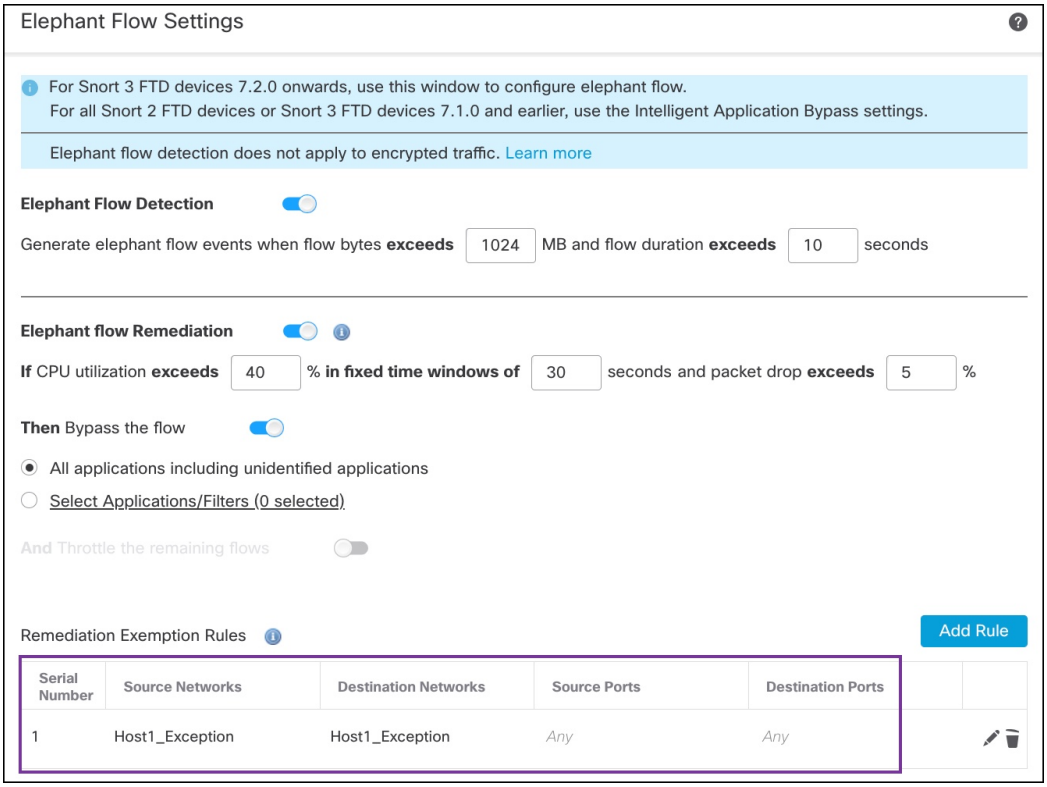
Step 3 Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Step 4 Click **Edit** ( ) next to **Elephant Flow Settings**. Ensure that you have configured the elephant flow detection and remediation parameters. See Configure elephant flow parameters, on page 2741.

Step 5 Click the **Add Rule** button next to **Remediation Exemption Rules**.



Step 6 From the list of **Available Networks**, choose the configured host to exempt from elephant flow remediation. For the purposes of this example, we have created a host called "Host1_Exception."



Step 7 Click **Add to Source** or **Add to Destination** as needed to add this host to the source or destination.

Step 8 Click the **Ports** tab.

a) For the source port, choose **Protocol** as TCP, enter **80** as the destination port, then click **Add**.

b) Click **OK**.

Step 9 Click **Save**.

What to do next

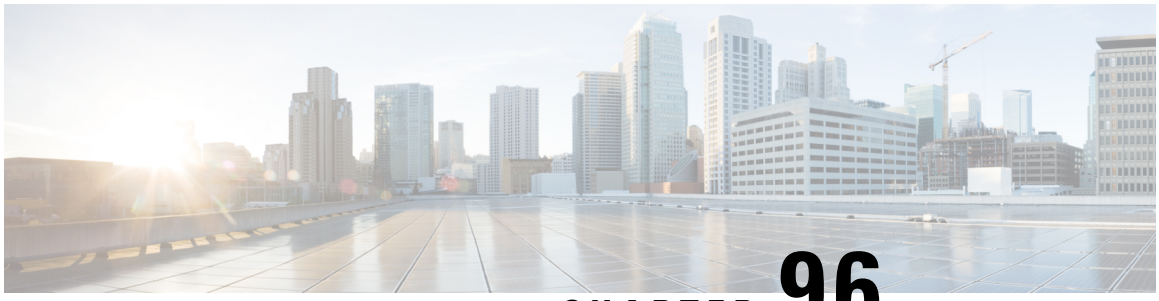
Deploy configuration changes.

View events for elephant flow remediation exemption

This task allows you to monitor and review elephant flows that have been exempted from remediation to understand network traffic patterns and exemption reasons.

Elephant flows are high-volume network connections that may require special handling. When these flows are exempted from remediation, you can view the exemption events to track and analyze the decision.

Procedure



Step 1 Choose **Analysis** > **Unified Events**.

Step 2 View the elephant flows that were exempted from remediation. The **Reason** field shows **Elephant Flow Exempted**.

- Elephant Flow Detection

CHAPTER 96

Policy Analyzer and Optimizer

Security Cloud Control provides the Policy Analyzer and Optimizer, which is an intelligent cloud service that can analyze security policies, detect anomalies, and provide recommendations on remediations that can be performed to optimize the policies.

- About Policy Analyzer and Optimizer, on page 2749
- Common Policy Analyzer and Optimizer concepts, on page 2750

- Troubleshooting Policy Analyzer and Optimizer, on page 2770
- Frequently Asked Questions About Policy Analyzer and Optimizer, on page 2771

About Policy Analyzer and Optimizer

AgenticOps for firewalls provides operational insights and tools that help improve firewall management, policy hygiene, and deployment readiness. One such capability is Policy Analyzer and Optimizer, which uses an algorithmic approach to evaluate firewall policy rules and identify anomalies such as duplicate, shadowed, redundant, or otherwise optimizable rules. For more information, refer to AgenticOpsInsights to know more about the various other functionalities that AgenticOps provides.

Secure Firewall Threat Defense devices with extensive policies may have numerous duplicate or shadowed rules. Such large policies with unoptimized rulesets can lead to excessive consumption of device memory, delayed loading of rules, and long search duration, resulting in inefficient security policy enforcement, reduced network speeds, and extended deployment durations.

Policy Analyzer and Optimizer is an intelligent Security Cloud Control Firewall Management service that analyzes firewall policies, detects rule anomalies, and helps you understand where a policy can be optimized. Policy Analyzer and Optimizer supports access control policies policies for Cloud-Delivered Firewall Management Center and supported Security Cloud Control-managed On-Premises Firewall Management Center data sources.

In addition, Policy Analyzer and Optimizer can do the following:

- View policy health and optimization opportunities for the selected management center data source.
- Analyze policies on demand or rely on scheduled analysis that runs every 24 hours.
- Download analysis reports as PDFs after analysis completes.
- Use Access Control Policy Analyzer and Optimizer remediation workflows where supported.
- Stage and apply remediation for an entire anomaly category, selected observations, or individual rules within supported observations.
- Use Network Address Translation Policy Analyzer and Optimizer findings and AgenticOps insights to investigate NAT policies that contain optimizable rules.

Supported policy types

Security Cloud Control Firewall Management performs anomaly analysis on the following policy types:

Table 147: Supported policy types for Policy Analyzer and Optimizer

Policy type	Use this section when	Current scope
Access control policy	You want to analyze access control policies, review access control findings, and apply supported remediations.	Analysis, remediation, reporting, remediation history, and policy insights.
Network address translation policy	You want to analyze NAT policies for shadowed and redundant NAT rules.	Analysis and reporting for fully shadowed and fully redundant NAT rules. NAT remediation is not available in this release.

Common Policy Analyzer and Optimizer concepts

Policy Analyzer and Optimizer uses these shared concepts across access control policy analysis and NAT policy analysis.

Table 148: Common Policy Analyzer and Optimizer concepts

Concept	Common behavior	Policy-type difference
Data source	A Cloud-Delivered Firewall Management Center or an On-Premises Firewall Management Center selected in Policy Analyzer and Optimizer.	The Access Control tab can be used for supported On-Premises Firewall Management Center data sources. The Network Address Translation tab is available only when Network Address Translation Policy Analyzer and Optimizer is enabled through AgenticOps for the selected data source.

Concept	Common behavior	Policy-type difference
Sync	Fetches current policy inventory and metadata, including newly created, deleted, or modified policies.	Sync does not, by itself, create a new analysis summary. If the policy changed after the last analysis, run analysis again or wait for scheduled analysis.
Analysis	Evaluates selected policies and produces policy health information, observations, and report data.	Access control Policy Analyzer and Optimizer evaluates access control rule and object findings. Network Address Translation Policy Analyzer and Optimizer evaluates NAT rule shadowing and redundancy.
Reporting	Provides a downloadable analysis report after analysis completes.	Access control Policy Analyzer and Optimizer also provides remediation reports after supported remediation is applied.
Remediation	A workflow that stages selected changes and applies them only when you select Apply Remediation.	Available for access control policies. Network Address Translation Policy Analyzer and Optimizer does not provide an Apply Remediation workflow. You can stage remediation for an entire anomaly category, selected observations within a category, or individual rules within an expanded observation. You can also select individual rules within an expanded observation. Using the suggested remediations, you can disable or delete selected Duplicate Rules and Expired Rules, remove selected fully overlapped objects from rules, and merge selected Mergeable Rules.

Prerequisites to use Policy Analyzer and Optimizer

Before you use Policy Analyzer and Optimizer, verify the prerequisites that apply to your policy type and data source.

- The On-Premises Firewall Management Center must be integrated with Security Cloud Control.

Note In the On-Premises Firewall Management Center, navigate to **Integration** > **Cisco Security Cloud** and check the **Enable Policy Analysis & Optimization** checkbox after integrating with the Cisco Security Cloud.

- The Cloud-Delivered Firewall Management Center must be provisioned in Security Cloud Control Firewall Management.

Prerequisites to use Policy Analyzer and Optimizer for access control policy

- Access control policy analysis is supported on the On-Premises Firewall Management Center operating on Version 7.2 or later. The Cisco-recommended Version is 7.6 or later, because these versions support cross-launch to Policy Analyzer and Optimizer directly from On-Premises Firewall Management Center.
- Access control policy to be analyzed must be associated with a Firewall Threat Defense device that is managed by an On-Premises Firewall Management Center integrated with Security Cloud Control.

Prerequisites to use Policy Analyzer and Optimizer for Network Address Translation

- NAT policy analysis is supported on the On-Premises Firewall Management Center operating on Version 7.6 or later.
- Network Address Translation Policy Analyzer and Optimizer availability also depends on AgenticOps being enabled for the selected tenant and data source. For more information, refer to Enable AgenticOps Insights.
- Enable AgenticOps for the Cloud-Delivered Firewall Management Center or On-Premises Firewall Management Center data source that you want to analyze. Choose **Insights & Reports** > **Settings** > **Policy Analyzer and Optimizer** > **Data Sources** and enable AgenticOps for the management center you want.

Note If an On-Premises Firewall Management Center is running a version earlier than 7.6, access control Policy Analyzer and Optimizer may still be available for analyzing access control policy, but Network Address Translation Policy Analyzer and Optimizer is not available for that data source.

Enable Policy Analyzer and Optimizer for Security Cloud Control-managed On-Premises Firewall Management Center

Onboard your On-Premises Firewall Management Center to Security Cloud Control, navigate to **Administration** > **Integrations** > **Firewall Management Center**, select the On-Premises Firewall Management Center, and choose **Policy Analyzer and Optimizer** under **System** in the right pane. See Onboard an On-Premises Firewall Management Center for more information.

If you have an On-Premises Firewall Management Center Version 7.6 and want to use Policy Analyzer and Optimizer, follow the steps below:

Procedure

Step 1 In your On-Premises Firewall Management Center, navigate **Integration** > **Security Cloud Control**.

Step 2 If you have not integrated your On-Premises Firewall Management Center with Cisco Security Cloud, click **Enable Security Cloud Control** and follow the steps. To authorize the cloud integration, you must choose an existing Security Cloud Control tenant or provision a new one, to which your on-premises Firewall Management Center will get onboarded, after the cloud integration is successful.

Step 3 After integrating your On-Premises Firewall Management Center with Security Cloud Control, check the **Enable Policy Analyzer and Optimizer** checkbox and click **Save**.

Policy Analyzer and Optimizer licensing requirements

Policy Analyzer and Optimizer requires no additional licensing. It comes as part of the Security Cloud Control Firewall Management base subscription.

Open Policy Analyzer and select a data source

You can open Policy Analyzer and Optimizer from Security Cloud Control Firewall Management or cross-launch from supported On-Premises Firewall Management Center policy pages.

Follow these steps to open Policy Analyzer and Optimizer and select a data source:

Procedure

Step 1 In the Security Cloud Control Firewall Management left pane, choose **Administration** > **Integrations** > **Firewall Management Center**.

Step 2 Select **Cloud-Delivered FMC** or an On-Premises Firewall Management Center.

Step 3 Click Policy Analyzer and Optimizer under **System**.

Note
Alternatively, choose **Insights & Reports** > **Policy Analyzer and Optimizer**.

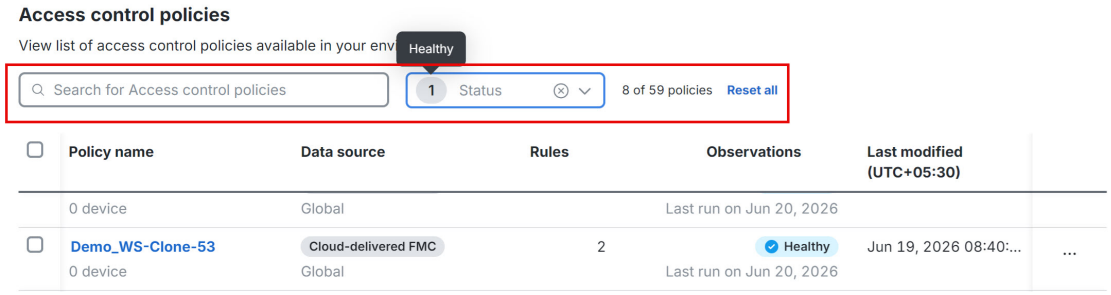
Step 4 Use the data source selector at the top of the Policy Analyzer and Optimizer page to choose the Cloud-Delivered Firewall Management Center or On-Premises Firewall Management Center whose policies you want to review.

Step 5 Choose the **Access Control** tab depending on the policy type that you want to analyze.

Note
If the selected data source is not enabled for AgenticOps, the **Network address translation** tab shows a message indicating that the NAT Policy Analyzer and Optimizer require AgenticOps for the selected data

source. However, you can still utilize the access control Policy Analyzer and Optimizer if the access control prerequisites are met.

Sync and analysis behavior



Policy Analyzer and Optimizer displays policy metadata, including analysis status, last modified time, and last analyzed time. Last modified reflects changes made to the policy in the management center that manages it. Last analyzed reflects the analysis run that produced the current Policy Analyzer and Optimizer summary.

Use **Sync with FMC** to fetch the latest access control and NAT policy inventories and modified timestamps from the management center. Each Policy Analyzer and Optimizer tab shows the sync success or failure status for the policy type on that tab. If a policy was modified after the last analysis, the displayed analysis can be out of date until you run analysis again or a scheduled analysis runs.

Search and filter policies in Policy Analyzer and Optimizer

Use the **Search for access control policies** field and the **Status** field to narrow the access control policy list.

Search helps you find a policy by name. Status filtering helps you find policies by analysis state, such a **Healthy**, **Error**, **In progress**, **Analysis pending**, **Optimizable**, or **Analysis out of date**.

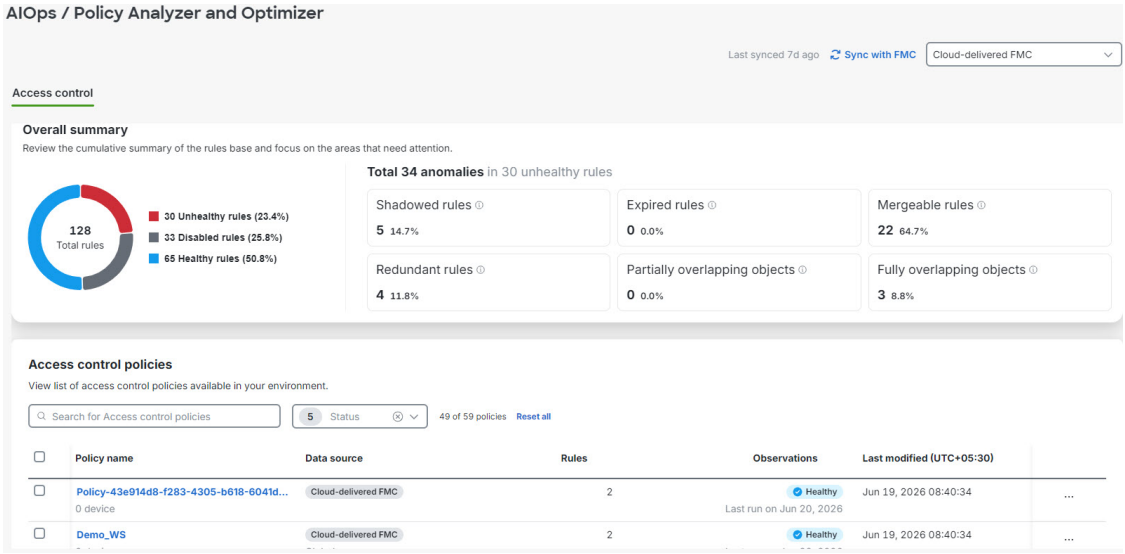
- **Search for access control policies**: Finds access control policies that match the policy name you enter.
- **Status**: Filters access control policies by their current analysis state.

Access control policy analysis and optimization

Use the **Access Control** tab when you want to analyze access control policies, review access control policy findings, and apply the remediations that Policy Analyzer and Optimizer supports for access control rules and objects.

After provisioning a Cloud-Delivered Firewall Management Center or onboarding an On-Premises Firewall Management Center to your Security Cloud Control Firewall Management tenant and creating policies, you can start analyzing them using the Policy Analyzer and Optimizer.

For more information, refer to Onboard an On-Premises Firewall Management Center and Enable Cloud-Delivered Firewall Management Center on Your Security Cloud Control.



Analyze access control policies

Use this procedure to assess an access control policy before making changes, review policy health, or re-run analysis after policy updates. If a policy has not been analyzed, you can start a new analysis. If the analysis is out of date, you can re-analyze the policy to refresh the results.

Note When you create a new policy, it might take a while for the Policy Analyzer and Optimizer to fetch the policy details and show up on the **Policy Analyzer and Optimizer**. Click the refresh ( ) button on the top-right corner to manually refresh the page to see new policies.

Procedure

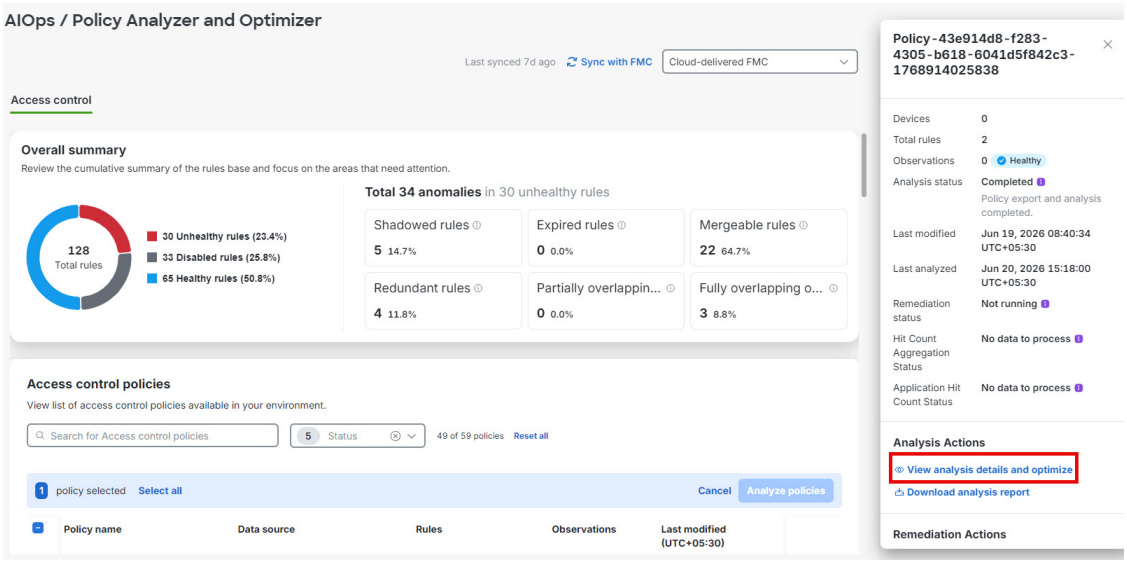
Step 1 Choose **Insights & Reports** > **Policy Analyzer and Optimizer**.

Step 2 In the right pane, select **Cloud-delivered FMC** or an On-Premises Firewall Management Center from the drop-down list as the data source whose policies you wish to analyze.

Step 3 In the **Access Control** area, select the policy you want to analyze or review.

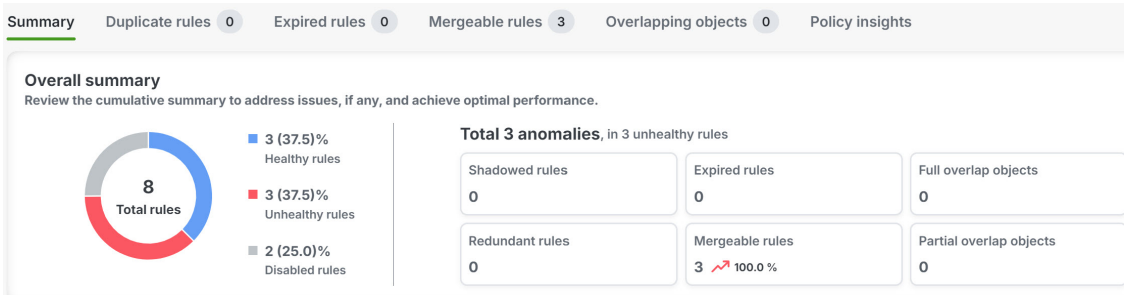
Note

- For an unanalyzed policy, click on **Analyze Policies**.
- If the policy status indicates **Analysis out of date**, click on **Re-analyze Policy** under **Analysis Actions** on the right.



The **Overall summary** section displays the total number of rules categorized by their health status: healthy, disabled, or unhealthy, for the selected management center (Cloud-Delivered Firewall Management Center or On-Premises Firewall Management Center).

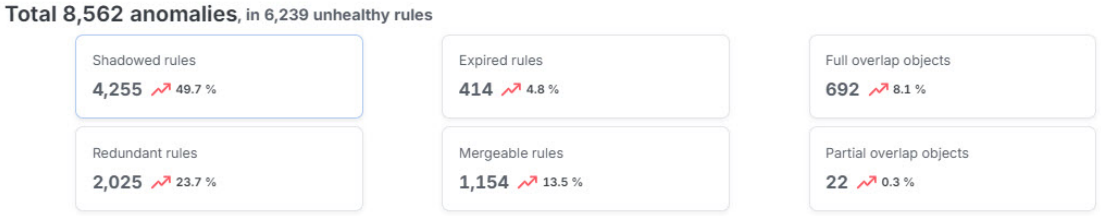
The dashboard also highlights specific anomalies within your unhealthy rules. You can review the count and percentage for the categories: Shadowed rules, Expired rules, Mergeable rules, Redundant rules, Partially overlapping rules, Fully overlapping objects.



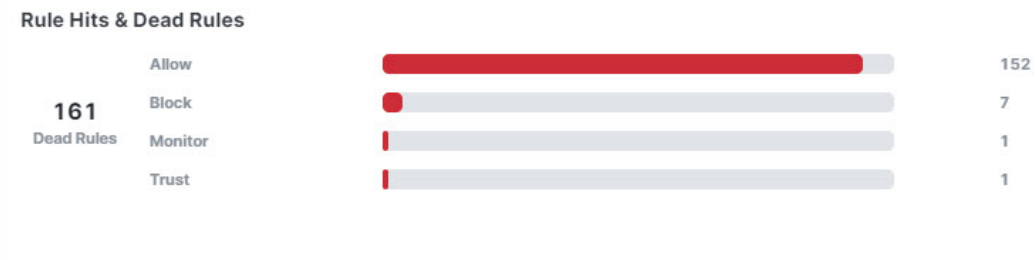
Access control policy analysis summary

When analysis completes, select an access control policy to review the right-pane summary and click **View analysis details and optimize**.

Alternatively, you can click the ellipse button associated with a policy and select **View details** to see the right-pane summary.



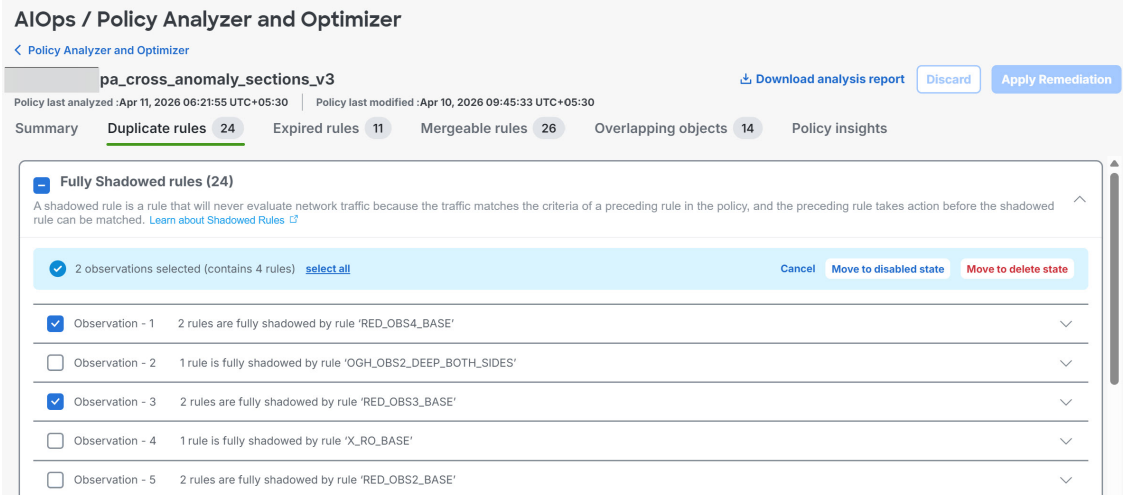
Overall summary—provides insights on how many rules are healthy, disabled, expired, and contain anomalies, using a pie chart for the selected access control policy. You can also hover over the part of the pie to view the percentage of rules.



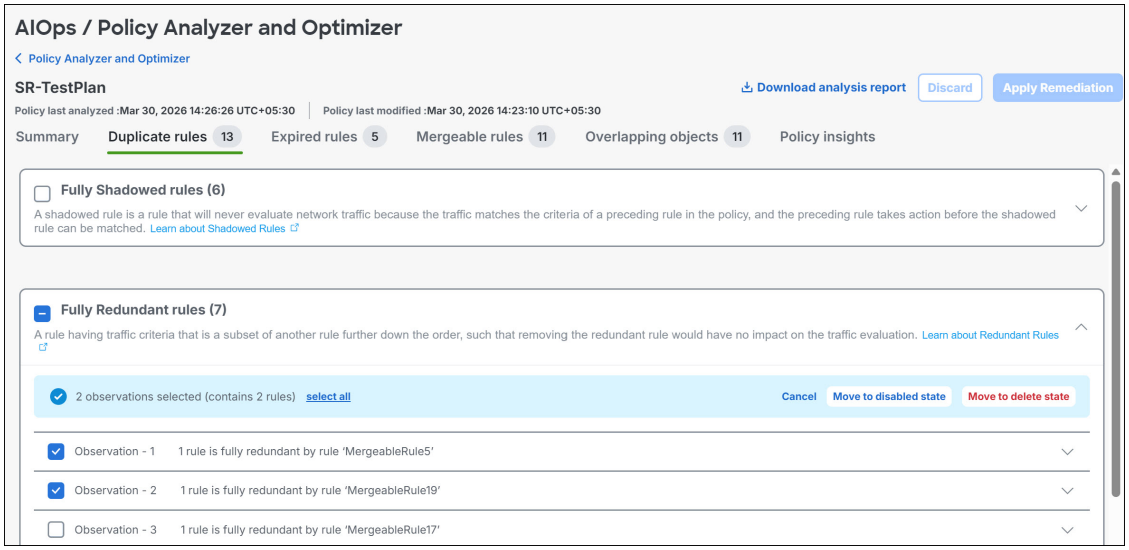
Rule usage history—shows how recently rules were used, with time periods.

Rules with Anomalies—provides insights on how many rules have anomalies.

Hits rules & dead rules—provides insights on hitcount of expired rules, for rule types including allow, block, monitor, and trust.



In remediation tabs such as **Duplicate rules**, **Expired rules**, **Mergeable rules**, **Overlapping objects**, and **Policy insights** you can select the check box next to a category to stage all observations in that category, or expand the category and select specific observations or rules. Available actions depend on the anomaly type.



Analyze duplicate rules in access control policy

The **Duplicate Rules** tab lists shadowed and redundant rules with anomalies:

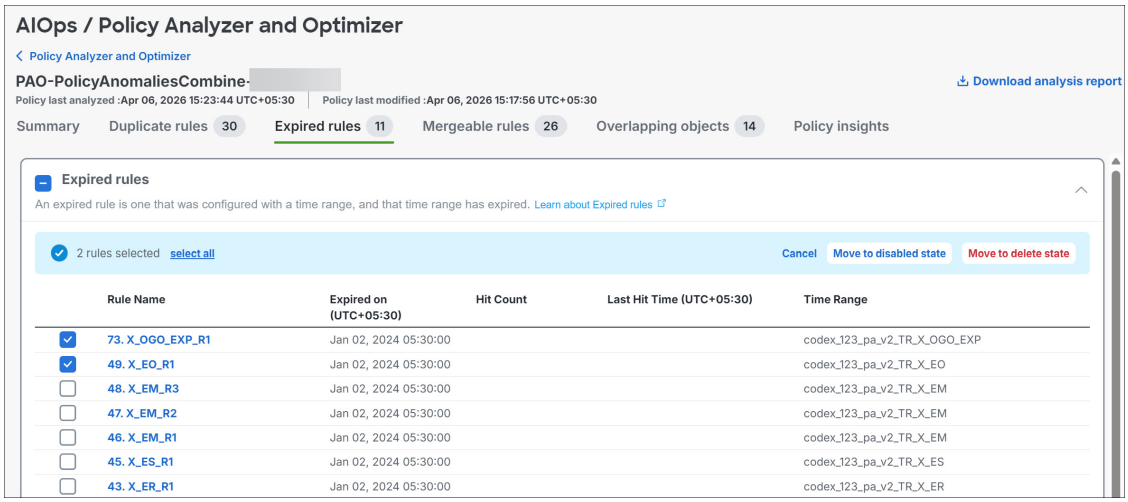
- A **Fully Shadowed rules** is one that will never evaluate network traffic because another rule that precedes it over shadows this rule.

- A **Fully Redundant rules** is one that is just a part of another larger rule, such that removing this redundant rule does not have an impact on the network traffic, because the traffic evaluation that this rule must perform is already performed by another rule.

You can remediate all duplicate-rule observations in a category, selected fully shadowed or fully redundant observations, or individual rules within an expanded observation. For selected duplicate rules, choose **Move to disabled state** or **Move to delete state**. Disable rules first when you want to measure the impact before deleting them.

Note Expand each observation to review the affected rules before you stage a remediation. Each rule in the list is displayed with a set of attributes; click the settings button on the top right to select which rule attributes you want to display along with the rule.

When duplicate-rule remediation removes shadowed or redundant rules and retains a base rule, Policy Analyzer and Optimizer adds a standardized comment to the retained rule. The comment identifies the retained rule and the removed rules, which helps you audit the cleanup.

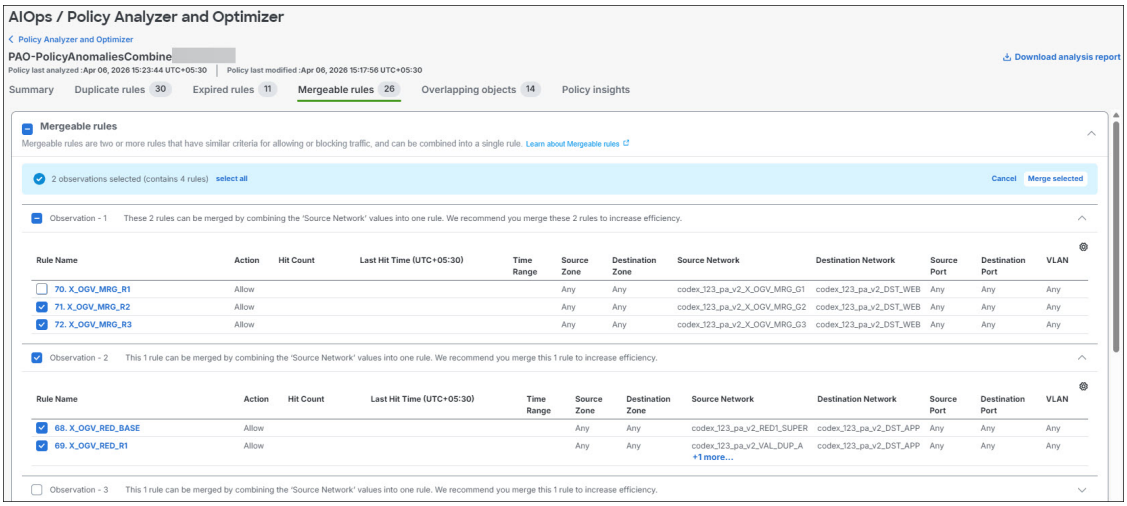


After you stage the selected duplicate-rule remediations, you can still **Undo** them before clicking **Apply Remediation**. It is recommended that you disable rules first to measure the impact and delete them later, because deleting them permanently removes them.

You can enable the disabled rules any time by navigating to the Cloud-Delivered Firewall Management Center or the On-Premises Firewall Management Center on which the rules are present.

Analyze expired rules in access control policy

The **Expired Rules** tab lists rules that were configured with a time range and the time range has expired. You can also see rule information such as the date on which the rule expired, hit count, last hit time, and the time range.

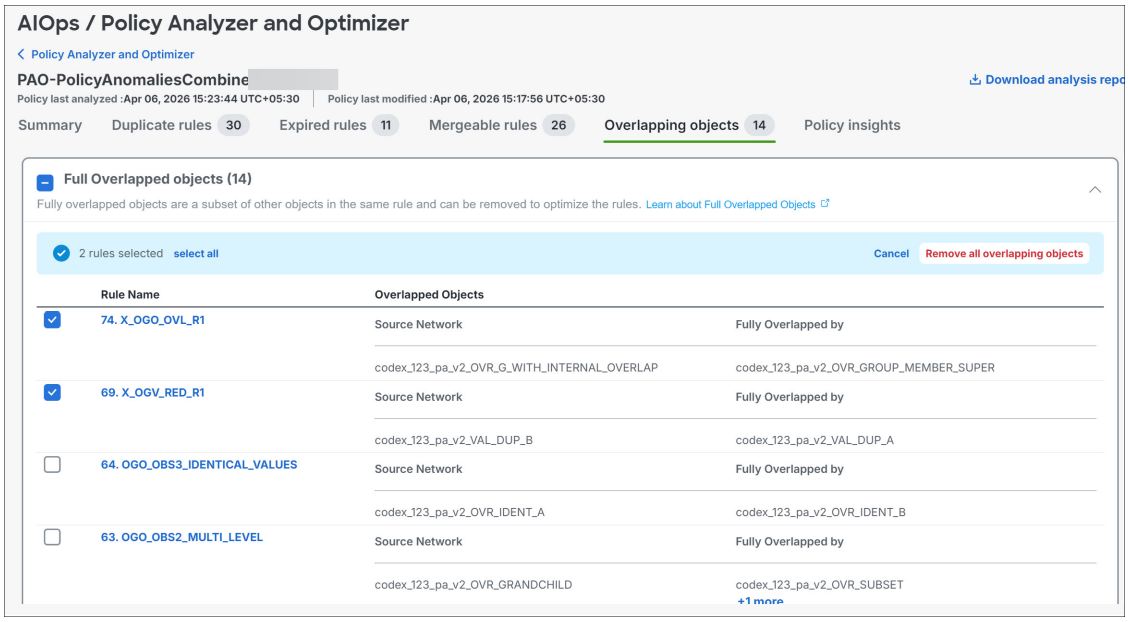


You can remediate all expired-rule observations in the category, selected expired-rule observations, or selected expired rules. For selected expired rules, choose **Move to disabled state** or **Move to delete state**. Only selected rules are changed when you apply remediation.

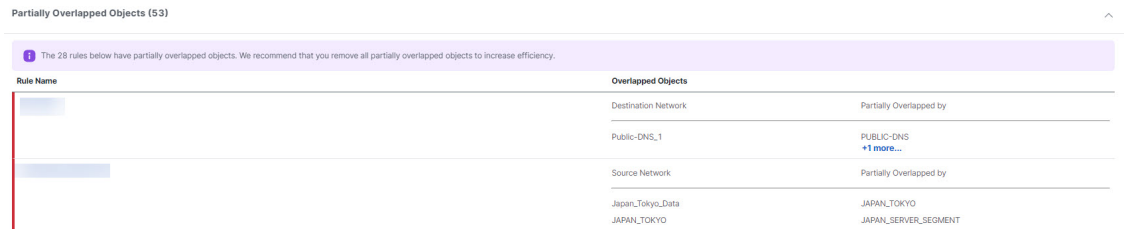
Analyze mergeable rules in access control policy

The **Mergeable Rules** tab lists the rules that have similar allow and block settings and can be merged into a single rule.

Review the mergeable-rule observations and stage remediation for the entire category, selected observations, or individual rules within an expanded observation. Click **Merge Selected** to merge only the staged items. Unselected mergeable-rule observations remain unchanged until you stage and apply remediation for them.



Note When you select individual rules to merge, select only consecutive rules. The first selected rule in the sequence is updated with the merged rule criteria, and the remaining selected rules are removed. You can start the merge from any rule in a consecutive set. The first rule in the observation does not need to be selected.

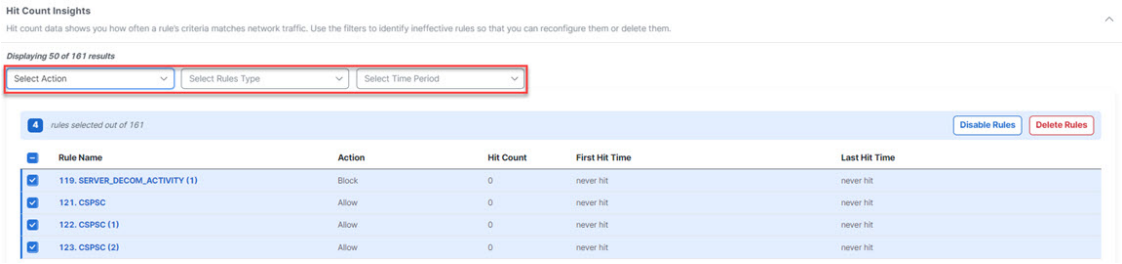


Analyze overlapping objects in access control policy

The **Overlapping Objects** tab lists objects that are either fully overlapping (the IP addresses or port numbers are either the same or a complete subset) or partially overlapping (some subset of IP addresses are repeated, but not all).

For example, if a rule contains an object for 192.168.1.1 and another for 192.168.1.0/24, the 192.168.1.1 object is fully overlapped by the other object and is not needed in the rule. For fully overlapped objects, you can remediate all fully overlapped observations in the category, selected observations, or selected rules. Click **Remove All Fully Overlapped Objects from Rules** to remove fully overlapped objects only from the staged items. For partial overlaps, evaluate each occurrence and edit the objects directly.

For partial overlaps, you need to evaluate each occurrence, determine if any changes can be made, and implement those changes directly by editing the objects.



Analyze policy insights in access control policy

The **Policy Insights** tab has a **Hit Count** section that initially lists any rules that have never been triggered (**Never Hit Rules**). The hit count information is from all devices that are assigned to the policy. You can change criteria and see other hit count information, for example, **Not Hit Rules** for the past six months, or **Hit Rules** over a selected time period. You can filter the rules using the actions set in the rules, hit information, and time period:

- **Never Hit Rules**—Rules that have never been hit from the time they were created.
- **Hit Rules**—Rules that have been hit in the selected time period.
- **Not Hit Rules**—Rules that have not been hit in the selected time period.

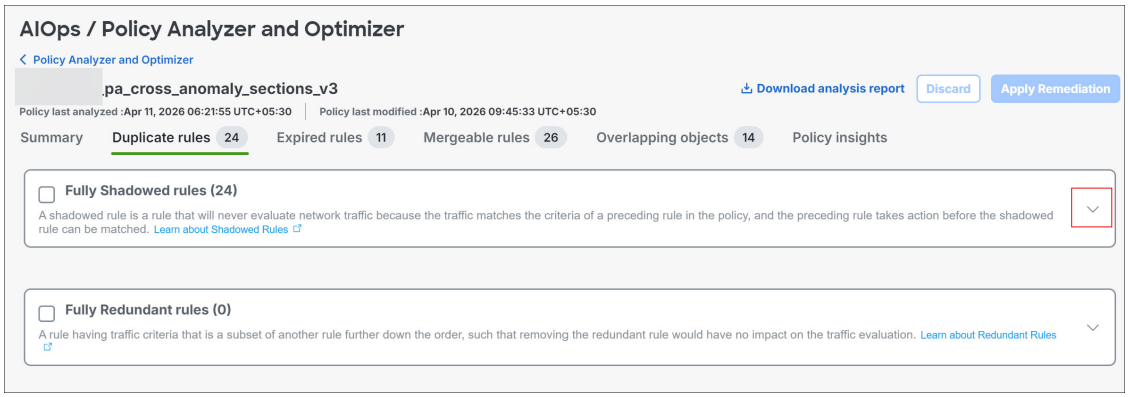
Select the rules that you want to disable or delete, and select **Disable Rules** or **Delete Rules**. These changes are staged until you select **Apply Remediation**. First, disable the rules when you want to measure their impact before deleting them.

Access control policy remediation

Policy Analyzer and Optimizer stages remediation changes before it updates the policy. You can stage remediation for an entire anomaly category, selected observations, or individual rules within an expanded observation. Before you apply remediation, unselected observations and rules remain unchanged and available for later selection in the same analysis report.

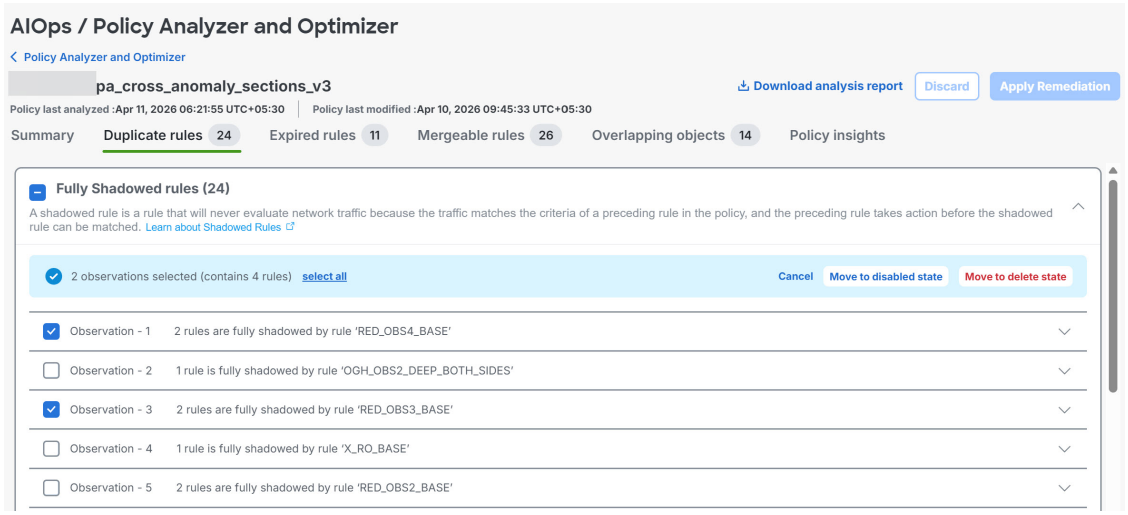
Review staged changes before you select **Apply Remediation**. After you apply remediation, you cannot apply more changes from the same analysis report. To remediate remaining anomalies, run policy analysis again on the updated policy and use the new report.

Before you begin



- Back up all policies before you apply remediation.
- Ensure that at least one remediation is staged. If no remediation is staged, **Apply Remediation** is disabled.
- Verify the **Policy Last Modified** and **Policy Last Analyzed** timestamps, and review the number of rules that are staged for remediation.

Procedure



Step 1 In the **Policy Analyzer and Optimizer** page, select the policy to see details about the analysis on the right pane and click **View analysis details & optimize**.

Step 2 Click the remediation tab that contains the anomalies that you want to fix.

Step 3 Expand a remediation category. Select the check box for the category to stage all observations, or select the check boxes for specific observations or rules to stage only those items. Repeat this step in other remediation tabs, as needed.

Step 4 Select the remediation action that applies to the staged items, such as **Move to disabled state**, **Move to delete state**, **Merge Selected**, **Remove All Fully Overlapped Objects from Rules**, **Disable Rules**, or **Delete Rules**.

Step 5 Review the staged remediation. If you need to change the staged remediation before applying it, use the available undo or discard action.

Step 6 Click **Apply Remediation**.

Step 7 Read the confirmation message, which summarizes the remediations that will be applied. Confirm that the selected policy and staged remediation are correct.

Step 8 Click **Apply**.

Note
For an On-Premises Firewall Management Center in which the Change Management Workflow is enabled, when policy remediations are applied, an internal workflow ticket is created and the changes are staged. The changes take effect only when the ticket is submitted or approved. See Change Management in *Cisco Secure Firewall Management Center Administration Guide* for more information.

After remediation is complete, the selected rules are updated. Policy Analyzer and Optimizer automatically analyzes the updated policy and generates a refreshed summary that shows any remaining issues. Verify the intended changes in the corresponding access control policy.

Download access control analysis report

The access control analysis report is a PDF summary of completed remediations for a selected policy. It includes only the remediation categories that apply to the changes you selected and applied. Each section lists the rule name, remediation action, and related comments. For example, if no duplicate rules were remediated, the report excludes the duplicate-rule remediation section.

The report includes only the remediation sections and rule details for remediations that you selected and applied. Unselected anomalies are not included in the report.

1. In the Policy Analyzer and Optimizer page, click **Access control**.
2. Select an access control policy, and in the right pane, click **Download analysis report**.

The report can include these sections:

- Remediation Summary
- Hit Count Remediation
- Expired Rules Remediation
- Duplicate Rules Remediation
- Mergeable Rules Remediation

Note To determine whether a policy is remediated by the Policy Analyzer and Optimizer, navigate to **Policies** > **Access Policies** and edit a policy to view the rules in the **Policy Editor**. When a policy is remediated, a comment is added to the rules that are optimized.

You can also filter all the optimized rules using "updated by Policy Analyzer and Optimizer" to view all the remediated rules.

During duplicate rule remediation, the retained rule is updated with a comment specifying which rule was preserved and which were removed.

Network Address Translation policy analysis

Use the **Network Address Translation** (NAT) tab when you want to analyze NAT policies and find rules that are shadowed or redundant. NAT Policy Analyzer and Optimizer helps you identify rules that are not contributing to effective NAT behavior, understand which rule owns the conflict, and download a NAT analysis report for review.

NAT Policy Analyzer and Optimizer requirements

- NAT Policy Analyzer and Optimizer is available only when AIOps is enabled for the tenant and for the selected data source.
- For On-Premises Firewall Management Center, NAT Policy Analyzer and Optimizer requires Version 7.6 or later.

- If NAT Policy Analyzer and Optimizer is disabled in AIOps settings, NAT Policy Analyzer and Optimizer operations are blocked for all data sources.
- When AIOps is enabled for a data source, Policy Analyzer and Optimizer initiates the initial NAT synchronization and analysis for onboarded data sources.
- NAT Policy Analyzer and Optimizer performs analysis at the management center level, not on a per-device basis.

Note Disabled NAT rules are excluded from being analyzed by the Policy Analyzer and Optimizer.

Analyze NAT policies

Network Address Translation (NAT) Policy Analyzer and Optimizer analyzes Cloud-Delivered Firewall Management Center and On-Premises Firewall Management Center NAT policies and categorizes NAT findings into shadowed rules and redundant rules.

NAT Policy Analyzer and Optimizer reports these NAT finding types.

Table 149:

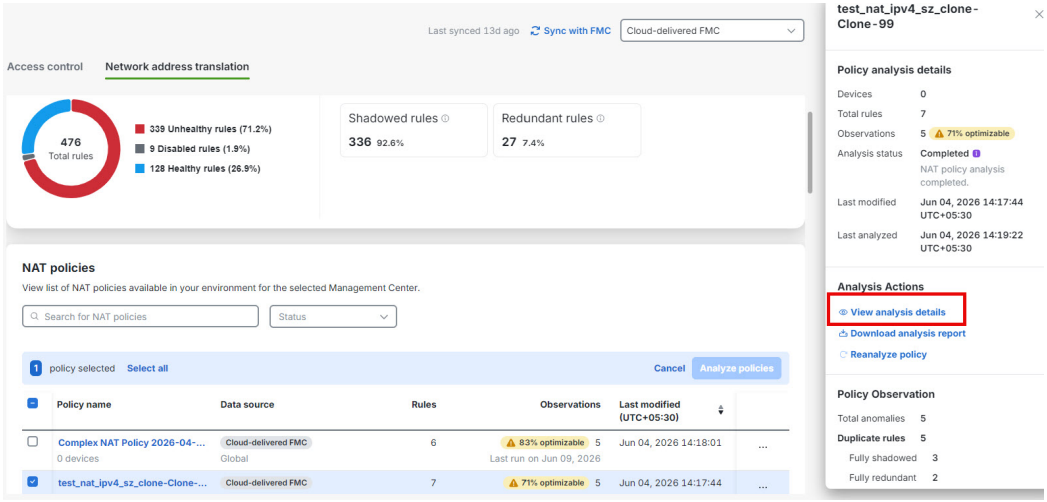
NAT finding	Meaning	How to interpret it
Shadowed NAT rule	A rule that will never evaluate network traffic because another rule that precedes it over shadows this rule.	Review the shadowing rule and the shadowed rules together. A rule is marked shadowed only when the overlap is complete for the compared dimensions.
Redundant NAT rule	A rule can be removed without changing the final NAT behavior because another rule can handle the traffic with the same effective NAT action.	Policy Analyzer and Optimizer checks the translated action for redundancy. Matching traffic criteria alone is not enough when translated source, destination, service, or PAT behavior differs.

NAT rule sections and comparison behavior

NAT Policy Analyzer and Optimizer follows the high-level NAT evaluation model used by Cisco Secure Firewall NAT policies. NAT rules are evaluated in section order: Manual NAT before Auto NAT, Auto NAT, and Manual NAT after Auto NAT.

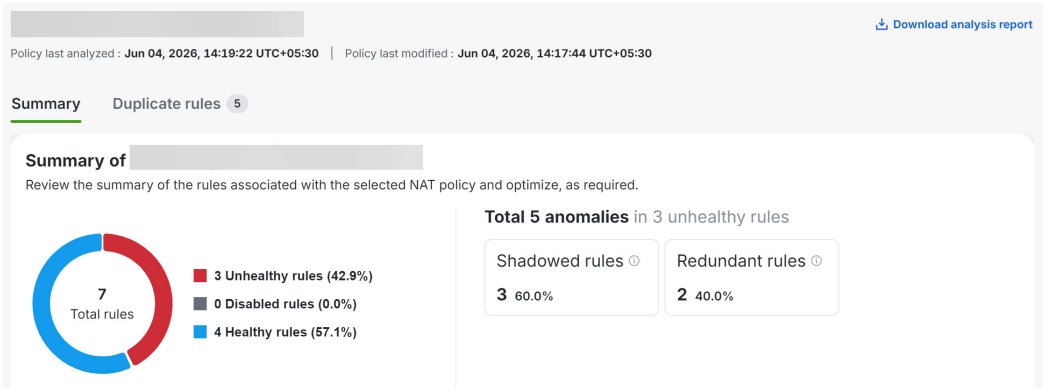
The NAT section determines the rule comparisons that can be reported by NAT Policy Analyzer and Optimizer.

NAT section	What it contains	NAT Policy Analyzer and Optimizer comparison behavior
Manual NAT before Auto NAT	Manual or twice NAT rules evaluated before Auto NAT.	Rules in this section can be compared with rules in the same section, Auto NAT, and Manual NAT after Auto NAT.
Auto NAT	Object NAT rules whose device order is determined internally.	Auto NAT rules can participate in comparisons with Manual NAT before or after sections. NAT Policy Analyzer and Optimizer does not report shadowed or redundant rules within the same Auto NAT section.
Manual NAT after Auto NAT	Manual or twice NAT rules evaluated after Auto NAT.	Rules in this section can be compared with rules in the same section and with rules from earlier comparable sections.



Supported NAT address families for Policy Analyzer and Optimizer

NAT Policy Analyzer and Optimizer supports these address-family flows.



Flow	Traffic family	Notes
NAT44	IPv4 to IPv4	Supported for standard IPv4 NAT and PAT behavior.
NAT66	IPv6 to IPv6	Supported for IPv6 NAT behavior.
NAT64	IPv6 to IPv4	Supported when cross-family behavior is explicitly configured.
NAT46	IPv4 to IPv6	Supported when cross-family behavior is explicitly configured.

NAT policy analysis summary

When analysis completes, select a NAT policy to review the right-pane summary and click **View analysis details**.

The policy-specific page displaying the anomaly details is shown.

- **Overall summary**—provides insights on how many rules are unhealthy, disabled, healthy, using a pie chart for the selected NAT policy. You can also hover over the part of the pie to view the percentage of rules.
- **Total anomalies**—shows the number of rule anomalies detected in the selected NAT policy. Also indicates how many unhealthy rules contain those anomalies.

Download NAT analysis report

The NAT analysis report is available after NAT policy analysis is complete and can be downloaded as a PDF. The PDF report includes policy metadata, analysis timestamps, summary charts, counts for healthy, disabled, shadowed, and redundant rules, and tabular observation details.

1. In the Policy Analyzer and Optimizer page, click **Network address translation**.
2. Select a NAT policy, and in the right pane, click **Download analysis report**.

The detailed rule information can include NAT section, rule type, direction, source and destination interface objects, original source, original destination, original service, translated source, translated destination, and translated service. Use these details to evaluate whether changes are needed in the management center. NAT Policy Analyzer and Optimizer does not apply NAT remediations in this release.

NAT policy remediation

Policy Analyzer and Optimizer stages NAT remediation changes before it updates the policy. You can stage remediation for individual rules or for all rules in a duplicate-rule observation.

The available actions depend on the NAT rule type:

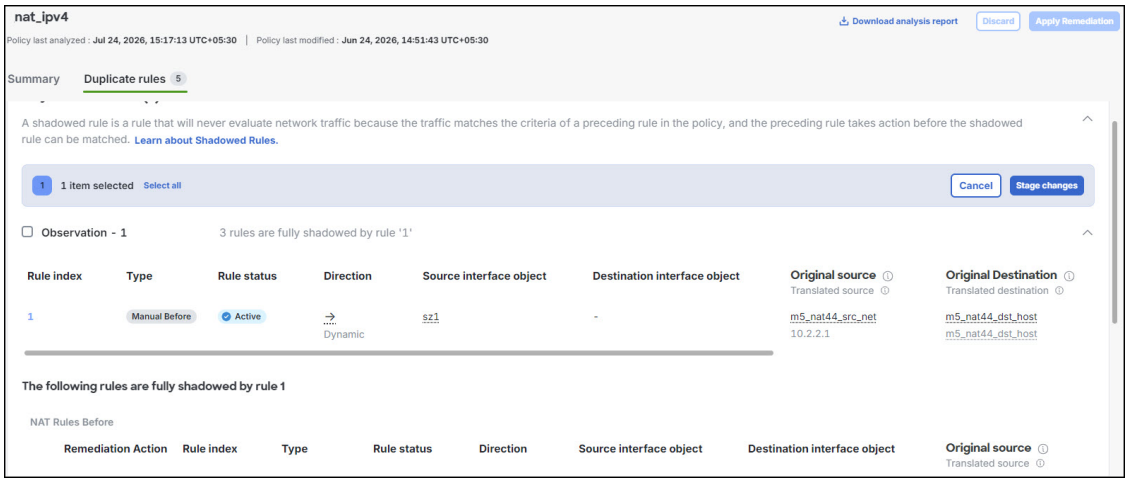
- Manual NAT rules: You can delete or disable selected manual rules
- Auto NAT rules: You can only delete Auto NAT rules, but you cannot disable them.

Note Back up your policy before applying any remediation. The changes made modify the NAT policy and cannot be automatically reverted.

Before you begin

- Ensure that NAT policy analysis is complete and that duplicate-rule observations are available.
- Verify the **Policy last analyzed** and **Policy last modified** values for the policy that you want to remediate.

Procedure



Step 1 In Policy Analyzer and Optimizer, select the NAT policy and under **Analysis Actions**, click **View analysis details** to open its analysis details.

Step 2 Click **Duplicate rules** and expand fully shadowed or redundant rules section that contains anomalies.

Step 3 Expand the observation that contains the rules that you want to remediate.

You can select the rules or select the observation to stage all rules in that observation.

Figure 396: NAT rule remediation

Step 4 Click **Stage changes**.

Step 5 In **Select rules to remediate**, select the action for each rule type:

NAT rule type	Available action
Manual rules	**Delete all selected** or **Disable all selected**
Auto NAT Rules	**Delete all selected**. You cannot disable **Auto NAT** rules.

Step 6 Select **Confirm staging**. The staged changes are only for review purposes and are not applied yet.

Note
Staged changes are visible to any user who opens the policy in Policy Analyzer and Optimizer. They remain until a user selects **Discard** or **Apply Remediation**, or until a new analysis runs after the policy is edited.

Click **View details** to inspect and review the staged changes. You can click **Undo** or **Discard** to revise the staged remediation.

Step 7 Select **Apply Remediation**.

Step 8 On the **Apply NAT duplicate-rule remediation** page, verify the policy and the number of rules to modify, and then select **Apply remediation**.

After you apply the remediation, Policy Analyzer and Optimizer updates the selected NAT rules and automatically starts a new analysis because the previous analysis is stale. While the new analysis runs, the **Observations** column for the NAT policy shows In progress. After analysis completes, review the refreshed duplicate-rule observations and policy status. If no analyzed anomalies remain, the policy can show a healthy status.

NAT remediation history

After you apply remediation to a NAT policy, Policy Analyzer and Optimizer records the remediation as a version in remediation history. Use remediation history to review when the remediation ran, the job that ran it, the user who started it, the remediation status, and the report for that version. The history lists the latest version first.

Note Remediation history records changes applied to the NAT policy. It does not indicate whether the updated policy has been deployed to managed devices. Deploy the policy separately as required.

Before you begin

Apply remediation to the NAT policy. Remediation history is available after the policy has at least one remediation version.

Procedure

Step 1 Open Policy Analyzer and Optimizer and click the Network address translation tab.

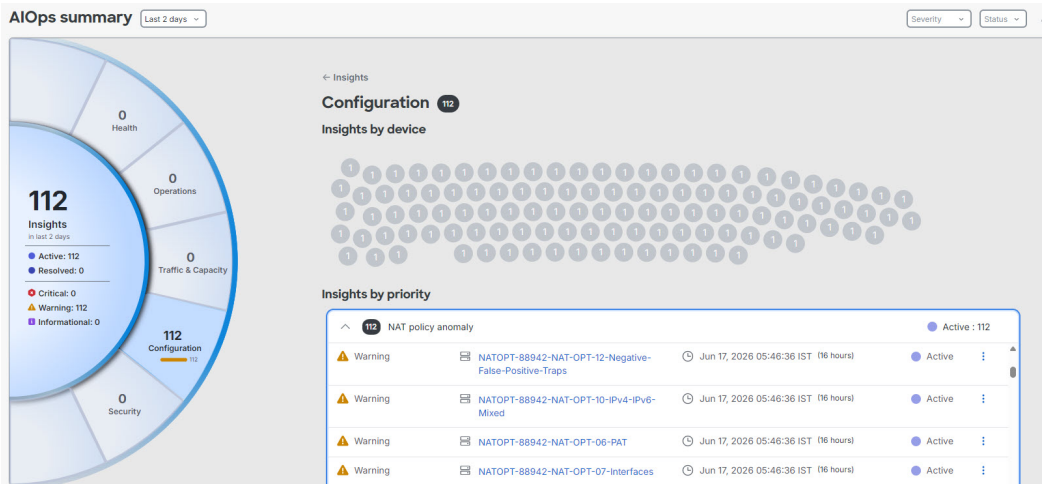
Step 2 Select the NAT policy that you want to review. The policy analysis details open.

Step 3 Under **Remediation Actions**, select **View remediation history**. The link shows the number of remediation versions that are available.

Step 4 Review the remediation history. The list displays the latest remediation version first and then the older versions.

Step 5 Review the date and time, Job ID, user, download option, and Remediation Status for each version.

For a completed remediation, select **Download** to download the remediation report.



The remediation report is a PDF that summarizes the selected NAT remediation, its status, and the resulting changes to the policy.

Note
Policy Analyzer and Optimizer displays up to 10 remediation versions, from the latest version to the oldest available version.

NAT Policy Analyzer and Optimizer and AgenticOps insights

When NAT Policy Analyzer and Optimizer analysis detects NAT policy anomalies, AgenticOpscan raise a NAT policy anomaly insight. From AIOps Insights, you can review NAT anomaly counts by data source, open the affected data source or policy, and navigate back to the NAT Policy Analyzer and Optimizer analysis details.

Navigation: **Insights & Reports** > **Summary**.

If you dismiss a NAT anomaly insight, it is dismissed for the current insight occurrence. A later scheduled analysis can raise the insight again if NAT anomalies are detected again.

Troubleshooting Policy Analyzer and Optimizer

Read the following sections to troubleshoot any issues with the Policy Analyzer and Optimizer:

Policy Analyzer and Optimizer Does Not Analyze Policies

If you notice that Policy Analyzer and Optimizer is not analyzing policies despite clicking **Analyze Policy**, try the following:

Procedure

Step 1 Navigate **Administration** > **Integrations** > **Firewall Management Center**.

Step 2 Select the On-Premises Firewall Management Center or **Cloud-Delivered FMC** for which the policy analysis is not happening and choose **Workflows** under **Actions** on the right pane.

Step 3 If you see that the latest workflow's **Current State** shows up as **Error**, expand the workflow and scroll to the last action whose **END STATE** is **ERROR**.

Step 4 Click **Error Message** under the **RESULT** column to see a detailed error message or click **Stack Trace** to see the series of exceptions that occurred, which caused the error.

Step 5 Resolve the error or contact Cisco TAC for assistance.

Policy Analyzer and Optimizer Does Not Fetch Policies

If policies on your On-Premises Firewall Management Center are not displayed on the Policy Analyzer and Optimizer page on Security Cloud Control, do the following:

Procedure

Step 1 On the On-Premises Firewall Management Center, navigate **Integration** > **Cisco Security Cloud**.

Step 2 Ensure that the **Enable Policy Analyzer and Optimizer** checkbox is checked.

Step 3 (Optional) In the left navigation pane of your Security Cloud Control tenant, navigate **Administration** > **Integrations** > **Firewall Management Center**, and ensure that the On-Premises Firewall Management Center is active and reachable.

Frequently Asked Questions About Policy Analyzer and Optimizer

Can Cisco AI Assistant analyze and remediate policies instead of manually doing it using Policy Analyzer and Optimizer?

The Cisco AI Assistant collaborates with Policy Analyzer and Optimizer to scrutinize policies with anomalies and notify users. However, the AI Assistant cannot automatically analyze and remediate policies.

Can Policy Analyzer and Optimizer detect new changes to an already-analyzed policy and run analysis again on the same policy?

No, the Policy Analyzer and Optimizer can analyze policies only when manually triggered or at a 24-hour scheduled policy analysis run.

For a shared policy, does the Policy Analyzer and Optimizer provide individual device-based reports?

No. The Policy Analyzer and Optimizer provides reports only based on the access policy analysis data.

I am an On-Premises Firewall Management Center user. Should I purchase the Security Cloud Control base license to use the Policy Analyzer and Optimizer?

No. The Policy Analyzer and Optimizer comes as part of an existing or a newly created Security Cloud Control tenant during the Cisco Security Cloud integration.

I provisioned a Security Cloud Control tenant when I integrated my On-Premises Firewall Management Center with the Cisco Security Cloud. What other features, except Policy Analyzer and Optimizer, can I leverage in Security Cloud Control?

You can only leverage Policy Analyzer and Optimizer capabilities of this Security Cloud Control tenant. To use other features of Security Cloud Control, you need to purchase the Security Cloud Control base license and other device-specific licenses.

For an On-Premises Firewall Management Center on which the change management workflow is enabled and there are policies with pending changes to be approved, can the Policy Analyzer and Optimizer still apply remediations those policies?

No. The remediation will be hindered with an error saying the policies are locked for use.

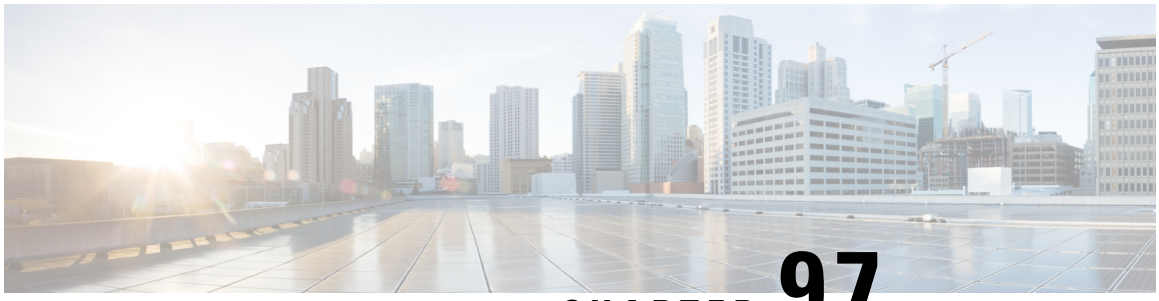
Is there a maximum number of rules that Policy Analyzer and Optimizer can analyze in a policy?

There are no such limits. The Policy Analyzer and Optimizer can analyze any number of policies and rules. However, when the policies have more number of rules, the analysis takes a long time too.

What is the difference between disable rules and delete rules? Which is the better option?

Deleting a rule removes the rule completely from the device memory. However, disabling a rule keeps it in the device memory as a backup and does not get deployed to the device.

If a policy remediation fails when it is partially done, are the changes automatically revoked by Policy Analyzer and Optimizer?



No. In such a case, you get a failure notification and a remediation report. You can read the report to know which rules were impacted by the half-done remediation, manually revoke the changes, and start the remediation all over again.

PART XXI

Custom Intrusion Policies for Access Control

- Intrusion Prevention , on page 2775
- Migrate from Snort 2 to Snort 3, on page 2799
- Intrusion Policies, on page 2819
- Intrusion Prevention Performance Tuning, on page 2865
- Network Analysis Policies, on page 2879
- Advanced Access Control settings for Network Analysis and Intrusion Policies, on page 2917

CHAPTER 97

Intrusion Prevention

The Snort inspection engine is an integral part of the Firewall Threat Defense. In most cases, the system-provided policies are all you need. For advanced users with specific needs, you can create custom rules. To configure custom Snort 3 rules, see Custom Snort 3 Intrusion Policies for Access Control.

Note To configure custom Snort 2 rules, see Custom Snort 2 Intrusion Policies for Access Control.

- Intrusion prevention, on page 2775
- Snort inspection engine, on page 2777
- Snort 3, on page 2777
- Multi-layer inspection, on page 2781
- Guidelines and limitations for network analysis and intrusion policies, on page 2784
- Prerequisites for network analysis and intrusion policies, on page 2784
- How policies examine traffic for intrusions, on page 2785
- System-provided and custom network analysis and intrusion policies, on page 2790

Intrusion prevention

Network analysis and intrusion policies work together as part of the intrusion detection and prevention feature.

- The term 'intrusion detection' generally refers to the process of passively monitoring and analyzing network traffic for potential intrusions and storing attack data for security analysis. This is sometimes referred to as "Intrusion Detection System (IDS)."
- The term 'intrusion prevention' includes the concept of intrusion detection, but adds the ability to block or alter malicious traffic as it travels across your network. This is sometimes referred to as "Intrusion Prevention System (IPS)."
- uses network analysis and intrusion policies working together to provide comprehensive packet inspection and threat protection.

Intrusion prevention components and operation

In an intrusion prevention deployment, when the system examines packets:

- A **network analysis policy** governs how traffic is *decoded* and *preprocessed* so it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.
- An **intrusion policy** uses *intrusion and preprocessor rules* (sometimes referred to collectively as *intrusion rules*) to examine the decoded packets for attacks based on patterns. Intrusion policies are paired with *variable sets*, which allow you to use named values to accurately reflect your network environment.

Both network analysis and intrusion policies are invoked by a parent access control policy, but at different times. As the system analyzes traffic, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (additional preprocessing and intrusion rules) phase. Together, network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect, alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

The system is delivered with several similarly named network analysis and intrusion policies (for example, Balanced Security and Connectivity) that complement and work with each other. By using system-provided policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and inspector rule states, as well as provides the initial configurations for inspectors and other advanced settings.

You can also create custom network analysis and intrusion policies. You can tune settings in custom policies to inspect traffic in the way that matters most to you so that you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

You create, edit, save, and manage network analysis and intrusion policies using similar policy editors in the web interface. When you are editing either type of policy, a navigation panel appears on the left side of the web interface; the right side displays various configuration pages.

Refer to the videos for additional support and information:

- Snort 3 Condensed Overview
- Snort 3 Extended Overview

Attention Detection mode deprecation: From management center Version 7.4.0, for a network analysis policy (NAP), the Detection inspection mode is deprecated and will be removed in an upcoming release.

The Detection mode was intended to be used as a test mode so that you can enable inspections and see how they behave in your network before setting it to drop traffic, that is, to show traffic that would be dropped.

This behavior is improved where all inspector drops are controlled by the rule state, and you can set each one to generate events. This is done to test them before configuring the rule state to drop traffic. As we now have granular control over traffic drops in Snort 3, the Detection mode only adds more complexity to the product and is not needed, so the detection mode is deprecated.

If you change a NAP in Detection mode to Prevention, the NAP that processes the traffic of intrusion events and have the result "will be dropped" will now be "dropped" and the corresponding traffic will drop the traffic from these events. This is applicable for rules whose GIDs are not 1 or 3. GIDs 1 and 3 are text/compiled rules (typically provided by Talos or from your custom/imported rules) and all other GIDs are inspections for anomalies. These are more uncommon rules to trigger in a network. Changing to Prevention mode is unlikely to have any impact on the traffic. You need to just disable the intrusion rule that is applicable for the dropped traffic and set it to just generate or disable.

We recommend you choose Prevention as the inspection mode, but if you choose Prevention, you cannot revert to Detection mode.

Snort inspection engine

A Snort inspection engine is an integral traffic analysis component that

- analyzes traffic in real time to provide deep packet inspection,
- operates as part of the Secure Firewall Threat Defense (formerly Firepower Threat Defense) device, and
- enables network analysis and intrusion policies to detect and protect against intrusions.

Snort 3

Snort 3 is a network inspection engine that

- provides vast improvements compared to the earlier version of Snort,
- offers more efficient operation with better performance and scalability, and
- is architecturally redesigned to inspect more traffic with equivalent resources when compared to Snort 2.

Snort 3 changes and improvements

The older version of Snort is Snort 2. Snort 3 provides simplified and flexible insertion of traffic parsers. Snort 3 also provides new rule syntax that makes rule writing easier and shared object rule equivalents visible.

The other significant changes with Snort 3 are:

- Unlike Snort 2, which uses multiple Snort instances, Snort 3 associates multiple threads with a single Snort instance. This uses less memory, improves Snort reload times, and supports more intrusion rules and a larger network map. The number of Snort threads varies by platform and is the same as the number of Snort 2 instances for each platform. Usage is virtually transparent.
- Snort version per Firewall Threat Defense—The Snort inspection engine is Firewall Threat Defense specific and not Cloud-Delivered Firewall Management Center (formerly Firepower Management Center) specific. Cloud-Delivered Firewall Management Center can manage several Firewall Threat Defenses, each with either versions of Snort (Snort 2 and Snort 3). Although the Cloud-Delivered Firewall Management Center's intrusion policies are unique, the system applies Snort 2 or Snort 3 version of an intrusion policy for intrusion protection depending on the device's selected inspection engine.
- Decoder rules—Packet decoder rules fire only in the default intrusion policy. The system ignores decoder rules that you enable in other policies.
- Shared object rules—Snort 3 supports some, but not all, shared object (SO) intrusion rules (rules with a generator ID (GID) of 3). Enabled shared object rules that are not supported do not trigger.
- Multi-layer inspection for Security Intelligence—Snort 3 detects the innermost IP address regardless of the layer.
- Platform support—Snort 3 requires Firewall Threat Defense version 7.0 or later. It is not supported with ASA FirePOWER or NGIPSv.
- Managed Devices—An Cloud-Delivered Firewall Management Center with version 7.0 can simultaneously support versions 6.4, 6.5, 6.6, 6.7, and 7.0 Snort 2 Firewall Threat Defenses, and version 7.0 Snort 3 Firewall Threat Defenses.
- Traffic interruption when switching Snort versions—Switching Snort versions interrupts traffic inspection and a few packets might drop during deployment.
- Unified policies—Irrespective of the underlying Snort engine version that is enabled in the managed Firewall Threat Defenses, the access control policies, intrusion policies, and network analysis policies configured in the Cloud-Delivered Firewall Management Center work seamlessly in applying the policies. All intrusion policies in Cloud-Delivered Firewall Management Center version 7.0 and above have two versions available, Snort 2 version and Snort 3 version. The intrusion policy is unified, which means that it has a common name, base policy, and inspection mode, although there are two versions of the policy (Snort 2 version and Snort 3 version). The Snort 2 and the Snort 3 versions of the intrusion policy can be different in terms of the rule settings. However, when the intrusion policy is applied on a device, the system automatically identifies the Snort version enabled on the device and applies the rule settings configured for that version.
- Lightweight Security Package (LSP)—Replaces the Snort Rule Updates (SRU) for Snort 3 next-generation intrusion rule and configuration updates. Downloading updates downloads both the Snort 3 LSP and the Snort 2 SRU.

  LSP updates provide new and updated intrusion rules and inspector rules, modified states for existing rules, and modified default intrusion policy settings for Cloud-Delivered Firewall Management Center and Firewall Threat Defense versions 7.0 or above. When you upgrade an Cloud-Delivered Firewall Management Center from version 6.7 or lower to 7.0, it supports both LSPs and SRUs. LSP updates may also delete system-provided rules, provide new rule categories and default variables, and modify default variable values. For more information on LSP updates, see the *Update Intrusion Rules* topic in the latest version of the *Firepower Management Center Configuration Guide*.

- Mapping of Snort 2 and Snort 3 rules and presets—Snort 2 and Snort 3 rules are mapped and the mapping is system-provided. However, it is not a one-to-one mapping. The system-provided intrusion base policies are pre-configured for both Snort 2 and Snort 3, and they provide the same intrusion prevention although with different rule sets. The system-provided base policies for Snort 2 and Snort 3 are mapped with each other for the same intrusion prevention settings.
- Synchronizing Snort 2 and Snort 3 rule override—When a Firewall Threat Defense is upgraded to 7.0, you can upgrade the inspection engine of the Firewall Threat Defense to the Snort 3 version. Cloud-Delivered Firewall Management Center maps all the overrides in the existing rules of the Snort 2 version of the intrusion policies to the corresponding Snort 3 rules using the mapping provided by Talos. However, if there are additional overrides performed after the upgrade or if you have installed a new Firewall Threat Defense of version 7.0, they have to be manually synchronized.
- Custom intrusion rules—You can create custom intrusion rules in Snort 3. You can also import the custom intrusion rules that exist for Snort 2 to Snort 3.
- Rule groups—The Cloud-Delivered Firewall Management Center groups all Snort 3 rules into rule groups. Rule groups are logical groups of rules that provide an easy management interface to enhance rule accessibility, rule navigation, and better control over the rule group security level.

  From Cloud-Delivered Firewall Management Center 7.3.0, rule navigation for several levels of rule groups is supported that provides more flexibility and logical grouping of rules. The MITRE framework is added that enables you to navigate through rules using the MITRE framework. MITRE is just another category of rule groups and is a part of Talos rule groups.

Note See https://attack.mitre.org for information about MITRE.

  A rule can be part of multiple rule groups, such as multiple MITRE ATT&CK rule groups, a rule category rule group, multiple "asset type" rule groups, a malware campaign, and others. The available rule groups are listed in the intrusion policy editor and can be selected to enhance policies.

  With this multi-level hierarchical structure, you can traverse down to the last element, which is the "leaf rule group." These rule groups contain sets of rules that are related to each other, such as a specific type of vulnerability, a similar target system, or a similar threat category. Rule groups have four security levels associated with them. You can change the security level, add or remove rule groups, and you can change the rule action for rules that match traffic seen on the network. This is done to bring a satisfactory balance between security, performance, and false positive resistance.
- Switching between Snort 2 and Snort 3 engines—Firewall Threat Defenses that support Snort 3 can also support Snort 2. Switching from Snort 3 to Snort 2 is not recommended from the efficacy perspective.

Important Although you can switch Snort versions freely, intrusion rule changes in one version of Snort will not be updated in the other version automatically. If you change the rule action for a rule in one version of Snort, ensure you replicate the change in the other version before switching the Snort version. System provided synchronization option only synchronizes the changes in the Snort 2 version of the intrusion policy to the Snort 3 version, and not the other way around.

Snort 3 multi-process support

Snort 3 multi-process support is a feature that:

- associates multiple threads with two Snort instances on Secure Firewall 6160 and 6170 devices running Secure Firewall version 10.0,
- automatically configures each Snort 3 instance with the threads as required during deployment, and
- results in reduced memory load, reduced lock contention, and shorter core generation times for improved resiliency, performance, and scalability.

Snort 3 multi-process architecture

Individual Snort 3 instances provide several advantages. Any Snort instance failure results in minimal traffic impact and you can also restart a single Snort process, if required.

Snort threads are distributed over NUMA nodes where each node is considered as an independent processor. This ensures that memory boundaries are maintained. For example, Snort instance 0 uses the memory of node 0, and instance 1 uses the memory of node 1.

The CLI outputs of commands such as **show coredump** and **show perfstats** have been enhanced to display information on both the Snort instances. On the Management Center, navigate to **Troubleshooting > Monitor > Devices** to view the **Overview > Critical Processes** and the **Memory** sections for information on both the Snort instances. If there are any rule profiling errors, the Snort instance number is displayed with the error.

Disable snort 3 multi-process support

This task disables Snort 3 multi-process support.

Disabling multi-process support is intended for debugging purposes only and requires a manual deployment to take effect.

Procedure

Step 1 Use the **configure snort multi-process disable** command to disable Snort 3 multi-process support.

Example:

```
> configure snort multi-process disable
----------------------------------------------------------------------
Caution: this command is intended for debugging purposes only.
A deployment is required after enabling/disabling multi-process and will cause a Snort
restart and temporary traffic interruption.
----------------------------------------------------------------------
Do you still want to continue?
Please enter 'YES' or 'NO': YES
Please perform a manual deployment to disable multi-process.
```

Note
This command causes the Snort engine to restart and will also lead to traffic interruption during the next deployment when Snort is changing from the multi-process state to a single-process state.

Step 2 Redeploy the configuration to ensure that the Snort 3 multi-process support is disabled.

Multi-layer inspection

The multi-layer inspection feature in Snort 3 enables you to inspect traffic across multiple protocol layers within the same session.

Snort 3 can simultaneously inspect the following layers:

- Network layer (L3): IP addresses, fragmentation
- Transport layer (L4): TCP or UDP ports, flags, session tracking
- Application layer (L7): HTTP, DNS, SMTP, TLS, SIP, and others.
- File and payload layer: File extraction, malware signatures, embedded content

Snort 3 supports decoding for a wide range of protocols. It inspects encapsulated protocols and evaluates packet headers to determine policy actions during advanced threat inspection.

Header inspection

On versions earlier than 7.6.4

For encapsulation protocols not supported by Lina, the system initially matches traffic based on the outer IP header. The subsequent evaluation depends on the rule criteria:

- Rules without Layer 7 (L7) criteria: If the matched rule does not include L7 criteria (such as URL, application ID, or user identity), the system applies the rule based on the outer IP header.
- Rules with Layer 7 (L7) criteria: If the rule includes L7 criteria, the system uses the outer-IP header match as a starting point and then performs an additional evaluation using the innermost header.

This behavior can lead to unexpected results, such as a non-L7 rule matching the outer-IP header taking precedence over a rule matching the inner-IP header located lower in the rule set.

On version 7.6.4 and later

- Snort 3 always inspects the innermost header for protocols not supported by Lina, regardless of the presence of Layer 7 rules.
- Outer header-based rules alone are not sufficient for policy enforcement for protocols such as VXLAN. Snort 3 disregards connection details for action in such cases, using the actual packet content instead.
- For protocols supported by Lina, policy action continues to be based on the innermost header.
- If you currently manage encapsulated traffic for protocols not supported by Lina (such as VXLAN) using only outer-IP rules, be aware that on version 7.6.4 or later, this traffic will be handled by the default access control rule. In such a scenario, if your default policy action is set to Block, this may result in the traffic being dropped. We recommend that you review and update access control policies to match the inner IP header for such protocols, in addition to any existing outer IP header configurations.

Layer 7 features

For encapsulated traffic in Layer 7 features, only the innermost IP header must be matched in rules. Outer header-only rules will not apply.

Example scenarios

The following table lists examples based on different parameters.

Protocol	Version	Outer IP rule	Inner IP rule	L7 rule needed	Result
VXLAN (not supported by LINA)	7.6.2	Yes	No	No	Traffic allowed if outer header matches
VXLAN (not supported by LINA)	7.6.4	No	Yes	No	Traffic allowed if inner header matches
GRE (supported by LINA)	7.6.2 and 7.6.4	No	Yes	No	Traffic allowed if inner header matches
VXLAN + L7 feature	7.6.2 and 7.6.4	No	Yes	Yes	Inner header rule required

Note An outer IP rule matches traffic based on the tunnel endpoints. It evaluates:

- Source IP address of the encapsulating device
- Destination IP address of the encapsulating device

An inner IP rule matches traffic based on the original IP packet inside the tunnel. It evaluates:

- The real client IP address
- The real destination server IP address

Encapsulation layer limits and inspection behavior

When managing encapsulated traffic, it is important to understand the processing limits of the system's two primary inspection engines, Lina and Snort.

- LINA: Supports decoding up to 2 layers of encapsulation.
- Snort: Supports decoding up to 255 layers of encapsulation (with a default limit of 40).

Supported protocols and inspection capabilities of LINA and Snort 3

LINA

LINA supports decoding for the following protocols across the Data Link (L2), Network (L3), and Transport (L4) layers.

Layer	Supported protocols and headers
Layer 2	Cisco MetaData (CMD), IEEE 802.1Q, IEEE 802.1ad (DOT1AD), and Q-in-Q (EtherTypes 0x9100 and 0x9200). Supports up to three levels of VLAN headers.
Layer 3	IPv4, IPv6
Layer 4	ICMP (v4/v6), ESP, VXLAN, Geneve, GRE, IP-in-IP, and IPv6-in-IPv6. Supports up to 1 level of encapsulation.

GRE-specific support

For GRE traffic, the system supports decoding for the following protocol types:

- Point-to-Point Tunneling Protocol (PPTP)
- Web Cache Communication Protocol (WCCP)

ERSPAN handling

The system decodes GRE and ERSPAN (types 1, 2, and 3). To facilitate dispatch layer load-balancing, the system internally skips to the inner headers. Consequently, other modules are unable to inspect ERSPAN headers.

Snort 3

While Snort 3 supports a vast array of protocols, the following list highlights common encapsulation and tunneling protocols supported for inspection:

- VXLAN
- GRE
- Teredo
- GTP
- MPLS
- Geneve
- IP-in-IP
    - IPv4-in-IPv4
    - IPv6-in-IPv4
    - IPv4-in-IPv6
    - IPv6-in-IPv6

Note This list is not exhaustive. Snort 3 is designed to decode a wide range of industry-standard protocols.

Guidelines and limitations for network analysis and intrusion policies

Feature Limitations of Snort 3 for Firewall Management Center-Managed Firewall Threat Defense

The table lists the features that are supported on Snort 2 but not supported on Snort 3 for Firewall Management Center-managed Firewall Threat Defense devices.

Table 150: Feature Limitations of Snort 3

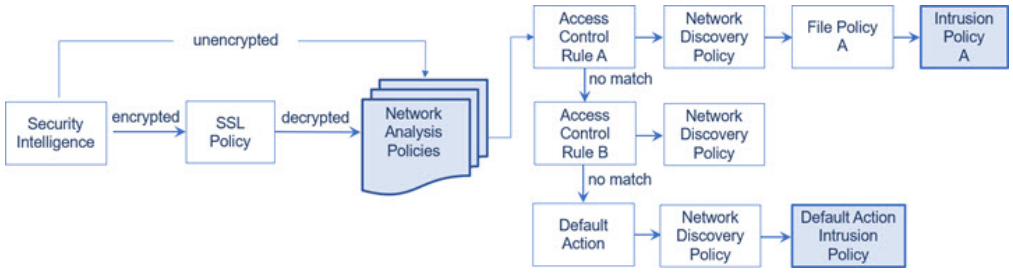
Policy/Area	Features not supported
Access Control Policy	The following application settings: • Safe Search • YouTube EDU
Intrusion Policy	• Global rule thresholding • Logging configuration: • SNMP • SRU rule updates as Snort 3 supports only LSP rule updates
Other features	Event logging with fully qualified domain name (FQDN).

Prerequisites for network analysis and intrusion policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the Intrusion Prevention System (IPS) license enabled for the Firewall Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

How policies examine traffic for intrusions



When the system analyzes traffic as part of your access control deployment, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (intrusion rules and advanced settings) phase.

Summary

The key components involved in examining traffic for intrusions are:

- Security Intelligence: Performs initial traffic filtering and blocking
- SSL policy: Handles encrypted traffic inspection and decryption
- Network analysis policies: Conduct decoding and preprocessing of traffic
- Access control rules: Determine which policies to apply to traffic
- Intrusion policies: Examine traffic for security threats and intrusions
- File policies: Analyze files for malware and threats
- Network discovery policy: Passively inspects packets for network mapping

Workflow

These stages describe how the system examines traffic for intrusions in an inline deployment:

1. The system processes traffic through multiple policy layers in a specific order, with network analysis and intrusion policy selection phases highlighted in the deployment.

   In an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs), the system can block traffic without further inspection at almost any step in the illustrated process. Security Intelligence, the SSL policy, network analysis policies, file policies, and intrusion policies can all either drop or modify traffic. Only the network discovery policy, which passively inspects packets, cannot affect the flow of traffic.

2. At each step of the process, a packet could cause the system to generate an event. Intrusion and preprocessor events (sometimes referred to collectively as *intrusion events*) are indications that a packet or its contents may represent a security risk.

Tip The diagram does not reflect that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

3. Note that for a single connection, although the system selects a network analysis policy before an access control rule as shown in the diagram, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

Decoding, normalizing, and preprocessing: Network analysis policies

Without decoding and preprocessing, the system cannot appropriately evaluate traffic for intrusions because protocol differences would make pattern matching impossible. Network analysis policies govern these traffic-handling tasks

- after traffic is filtered by Security Intelligence,
- after encrypted traffic is decrypted by an optional SSL policy, and
- before traffic can be inspected by file or intrusion policies

A network analysis policy governs packet processing in phases. First the system decodes packets through the first three TCP/IP layers, then continues with normalizing, preprocessing, and detecting protocol anomalies:

- The packet decoder converts packet headers and payloads into a format that can be easily used by the inspectors and later, intrusion rules. Each layer of the TCP/IP stack is decoded in turn, beginning with the data link layer and continuing through the network and transport layers. The packet decoder also detects various anomalous behaviors in packet headers.
- In inline deployments, the inline normalization preprocessor reformats (normalizes) traffic to minimize the chances of attackers evading detection. It prepares packets for examination by other inspectors and intrusion rules, and helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.
- Various network and transport layers inspectors detect attacks that exploit IP fragmentation, perform checksum validation, and perform TCP and UDP session preprocessing.

  Note that some advanced transport and network inspector settings apply globally to all traffic handled by the target devices of an access control policy. You configure these in the access control policy rather than in a network analysis policy.
- Various application-layer protocol decoders normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently, and to obtain meaningful results.
- The Modbus, DNP3, CIP, and s7commplus SCADA inspectors detect traffic anomalies and provide data to intrusion rules. Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport, and shipping systems.

- Several inspectors allow you to detect specific threats, such as Back Orifice, portscans, SYN floods and other rate-based attacks.

  Note that you configure the sensitive data inspector, which detects sensitive data such as credit card numbers and Social Security numbers in ASCII text, in intrusion policies.

Note When TLS Server Identity is disabled, Snort 3 does not perform SNI mismatch detection. It only evaluates the SNI in the Client Hello packet and bypasses the validation of the certificate's Common Name (CN) in the Server Hello packet.

In a newly created access control policy, one default network analysis policy governs preprocessing for all traffic for all intrusion policies invoked by the same parent access control policy. Initially, the system uses the Balanced Security and Connectivity network analysis policy as the default, but you can change it to another system-provided or custom network analysis policy. In a more complex deployment, advanced users can tailor traffic preprocessing options to specific security zones, networks, and VLANs by assigning different custom network analysis policies to preprocess matching traffic.

Note For an access control policy with rule action as Trust and a prefilter rule with action as Fastpath with logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

Access control rules: Intrusion policy selection

Intrusion policy selection is a traffic evaluation process that—

- evaluates traffic after initial preprocessing using access control rules,
- applies matching access control rule to handle traffic through monitor, trust, block, or allow actions,
- inspects allowed traffic for discovery data, malware, prohibited files, and intrusions in that order, and
- handles non-matching traffic using the access control policy's default action.

In most cases, the first access control rule that a packet matches is the rule that handles that traffic; you can monitor, trust, block, or allow matching traffic.

Traffic evaluation process

When you allow traffic with an access control rule, the system can inspect the traffic for discovery data, malware, prohibited files, and intrusions, in that order. Traffic not matching any access control rule is handled by the access control policy's default action, which can also inspect for discovery data and intrusions.

Note All packets, **regardless** of which network analysis policy preprocesses them, are matched to configured access control rules, making them potentially subject to inspection by intrusion policies in top-down order.

The diagram in How policies examine traffic for intrusions, on page 2785 shows the flow of traffic through a device in an inline, intrusion prevention and AMP for Networks deployment—

- Access Control Rule A allows matching traffic to proceed. The traffic is then inspected for discovery data by the network discovery policy, for prohibited files and malware by File Policy A, and then for intrusions by Intrusion Policy A.
- Access Control Rule B also allows matching traffic. However, in this scenario, the traffic is not inspected for intrusions (or files or malware), so there are no intrusion or file policies associated with the rule. Note that by default, traffic that you allow to proceed is inspected by the network discovery policy; you do not need to configure this.
- In this scenario, the access control policy's default action allows matching traffic. The traffic is then inspected by the network discovery policy, and then by an intrusion policy. You can (but do not have to) use a different intrusion policy when you associate intrusion policies with access control rules or the default action.

The example in the diagram does not include any blocking or trusting rules because the system does not inspect blocked or trusted traffic.

Intrusion inspection: Intrusion policies, rules, and variable sets

Intrusion inspection is a security mechanism that

- uses intrusion policies to govern how the system inspects traffic for security violations and can block or alter malicious traffic in inline deployments
- employs intrusion and preprocessor rules to analyze network traffic against specified criteria and detect attempts to exploit vulnerabilities, and
- utilizes variable sets to define values commonly used in intrusion rules for identifying source and destination IP addresses and ports.

Intrusion and inspector rules

An intrusion rule is a specified set of keywords and arguments that detects attempts to exploit vulnerabilities on your network; the system uses an intrusion rule to analyze network traffic to check if it matches the criteria in the rule. The system compares packets against the conditions specified in each rule and, if the packet data matches all the conditions specified in a rule, the rule triggers.

The system includes these types of rules created by Cisco Talos Intelligence Group (Talos):

- *shared object intrusion rules*, which are compiled and cannot be modified, except for rule header information such as source and destination ports and IP addresses
- *standard text intrusion rules*, which can be saved and modified as new custom instances of the rule.
- *preprocessor rules*, which are rules associated with inspectors and packet decoder detection options in the network analysis policy. You cannot copy or edit inspector rules. Most inspector rules are disabled by default; you must enable them to use inspectors to generate events and, in an inline deployment, drop offending packets.

When the system processes packets according to an intrusion policy, first a rule optimizer classifies all activated rules in subsets based on criteria such as: transport layer, application protocol, direction to or from the protected network, and so on. Then, the intrusion rules engine selects the appropriate rule subsets to apply to each packet.

Finally, a multi-rule search engine performs three different types of searches to determine if the traffic matches the rule:

- The protocol field search looks for matches in particular fields in an application protocol.
- The generic content search looks for ASCII or binary byte matches in the packet payload.
- The packet anomaly search looks for packet headers and payloads that, rather than containing specific content, violate well-established protocols.

In a custom intrusion policy, you can tune detection by enabling and disabling rules, as well as by writing and adding your own standard text rules. You can also use Cisco recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

Note When there are insufficient packets to process specific traffic against a block rule, the system continues to evaluate the remaining traffic against other rules. If any of the remaining traffic matches a rule which is set to block, then the session is blocked. However, if the system analyses the remaining traffic to be passed, then the traffic status shows pending on the rule which is stuck for want of complete packets.

Variable Sets

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Most variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

The system provides a single default variable set, which is comprised of predefined default variables. Most system-provided shared object rules and standard text rules use these predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Tip Even if you use system-provided intrusion policies, Cisco **strongly** recommends that you modify key default variables in the default set. When you use variables that accurately reflect your network environment, processing is optimized and the system can monitor relevant systems for suspicious activity. Advanced users can create and use custom variable sets for pairing with one or more custom intrusion policies.

Important If you are creating a custom variable set, do not use a number as the first character in a custom variable set name (for example, 3Snort). This will cause Snort 3 validation to fail when you deploy a configuration to Firewall Threat Defense firewall on the Cloud-Delivered Firewall Management Center.

Intrusion event generation

Intrusion event generation is a security mechanism that:

- identifies possible intrusions through packet decoding, preprocessing, and rules engine analysis,
- generates *intrusion or preprocessor events* (sometimes collectively called *intrusion events*) when threats are detected, and
- transmits events from managed devices to the Firewall Management Center for aggregated analysis and network asset protection.

Event composition and data collection

Each intrusion event in the database includes an event header and contains information about the event name and classification; the source and destination IP addresses; ports; the process that generated the event; and the date and time of the event, as well as contextual information about the source of the attack and the target. For packet-based events, the system also logs a copy of the decoded packet header and payload for the packet or packets that triggered the event.

As the database accumulates intrusion events, you can begin your analysis of potential attacks. The system provides you with the tools you need to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.

Event generation scenarios

The packet decoder, the preprocessors, and the intrusion rules engine can all cause the system to generate an event. For example:

- If the packet decoder (configured in the network analysis policy) receives an IP packet that is less than 20 bytes, which is the size of an IP datagram without any options or payload, the decoder interprets this as anomalous traffic. If, later, the accompanying decoder rule in the intrusion policy that examines the packet is enabled, the system generates a inspector event.
- If the IP defragmentation preprocessor encounters a series of overlapping IP fragments, the inspector interprets this as a possible attack and, when the accompanying inspector rule is enabled, the system generates a inspector event.
- Within the intrusion rules engine, most standard text rules and shared object rules are written so that they generate intrusion events when triggered by packets.

System-provided and custom network analysis and intrusion policies

Network analysis and intrusion policies are security mechanisms that

- examine traffic through preprocessing and intrusion prevention phases,
- provide system-provided default configurations for immediate deployment, and
- allow custom policy creation for tailored security requirements.

Default policy behavior in access control deployments

By default, a newly created access control policy invokes system-provided network analysis and intrusion policies to examine traffic.

This diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic:

The traffic flow demonstrates these characteristics:

- A default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided *Balanced Security and Connectivity network analysis policy* is the default.
- The default action of the access control policy allows all non-malicious traffic, as determined by the system-provided *Balanced Security and Connectivity intrusion policy*. Because the default action allows traffic to pass, the discovery feature can examine it for host, application, and user data before the intrusion policy can examine and potentially block malicious traffic.
- The policy uses default Security Intelligence options (global Block and Do Not Block lists only), does not decrypt encrypted traffic with an SSL policy, and does not perform special handling and inspection of network traffic using access control rules.

A simple step you can take to tune your intrusion prevention deployment is to use a different set of system-provided network analysis and intrusion policies as your defaults. Cisco delivers several pairs of these policies with the system.

Or, you can tailor your intrusion prevention deployment by creating and using custom policies. You may find that the inspector options, intrusion rule, and other advanced settings configured in those policies do not address the security needs of your network. By tuning your network analysis and intrusion policies, you can control at a very granular level how the system processes and inspects traffic on your network for intrusions.

System-provided network analysis and intrusion policies

System-provided network analysis and intrusion policies are security configurations that

- leverage the experience of the Cisco Talos Intelligence Group (Talos) for intrusion and inspector rule states and advanced settings,
- provide starting points for well tuned defensive policies covering common network setups, and
- receive automatic updates through Lightweight Security Package (LSP) releases for new vulnerabilities.

Key characteristics and usage

No system-provided policy covers every network profile, traffic mix, or defensive posture. Each covers common cases and network setups that provide a starting point for a well-tuned defensive policy. Although you can use system-provided policies as-is, Cisco strongly recommends that you use them as the base for custom policies that you tune to suit your network.

Tip Even if you use system-provided network analysis and intrusion policies, you should configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify key default variables in the default set.

As new vulnerabilities become known, Talos releases intrusion rule updates, also known as *Lightweight Security Package* (LSP). These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and inspector rules, modified states for existing rules, and modified default policy settings. Rule updates may also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

If a rule update affects your deployment, the web interface marks affected intrusion and network analysis policies as out of date, as well as their parent access control policies. You must re-deploy an updated policy for its changes to take effect.

For your convenience, you can configure rule updates to automatically re-deploy affected intrusion policies, either alone or in combination with affected access control policies. This allows you to easily and automatically keep your deployment up-to-date to protect against recently discovered exploits and intrusions.

To ensure up-to-date preprocessing settings, you **must** re-deploy access control policies, which also deploys any associated SSL, network analysis, and file policies that are different from those currently running, and can also update default values for advanced preprocessing and performance options.

Cisco delivers the system-provided network analysis and intrusion policies:

- Balanced Security and Connectivity network analysis and intrusion policies — These policies are built for both speed and detection. Used together, they serve as a good starting point for most organizations and deployment types. The system uses the Balanced Security and Connectivity policies and settings as defaults in most cases.
- Connectivity Over Security network analysis and intrusion policies — These policies are built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.
- Security Over Connectivity network analysis and intrusion policies — These policies are built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.
- Maximum Detection network analysis and intrusion policies — These policies are built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits.
- No Rules Active intrusion policy — In the No Rules Active intrusion policy, all intrusion rules, and all advanced settings except intrusion rule thresholds, are disabled. This policy provides a starting point if you want to create your own intrusion policy instead of basing it on the enabled rules in one of the other system-provided policies.

Note Depending on the system-provided base policy that is selected, the settings of the policy vary. To view the policy settings, click the **Edit** icon next to the policy and then click the **Base Policy** drop-down menu.

Benefits of custom network analysis and intrusion policies

Custom network analysis and intrusion policies are security configurations that:

- improve system performance in your specific environment,
- provide a focused view of malicious traffic and policy violations occurring on your network, and
- allow granular configuration of how the system processes and inspects network traffic for intrusions.

Custom policy structure

You may find that the inspector options, intrusion rules, and other advanced settings configured in the system-provided network analysis and intrusion policies do not fully address the security needs of your organization.

All custom policies have a base policy, also called a base layer, which defines the default settings for all configurations in the policy. A layer is a building block that you can use to efficiently manage multiple network analysis or intrusion policies.

In most cases, you base custom policies on system-provided policies, but you can use another custom policy. However, all custom policies have a system-provided policy as the eventual base in a policy chain. Because rule updates can modify system-provided policies, importing a rule update may affect you even if you are using a custom policy as your base. If a rule update affects your deployment, the web interface marks affected policies as out of date.

Custom network analysis policy benefits

Custom network analysis policies:

- enable tuning preprocessing to match specific traffic characteristics and monitoring requirements,
- reduce system processing overhead by disabling unnecessary inspectors, and
- allow tailored preprocessing for different security zones, networks, or VLANs in complex deployments.

By default, one network analysis policy preprocesses all unencrypted traffic handled by the access control policy. That means that all packets are decoded and preprocessed according to the same settings, regardless of the intrusion policy (and therefore intrusion rule set) that later examines them.

Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default. A simple way to tune preprocessing is to create and use a custom network analysis policy as the default.

Tuning options available vary by inspector, but some of the ways you can tune inspectors and decoders include:

- You can disable inspectors that do not apply to the traffic you are monitoring. For example, the HTTP Inspect inspector normalizes HTTP traffic. If you are confident that your network does not include any web servers using Microsoft Internet Information Services (IIS), you can disable the inspector option that looks for IIS-specific traffic and thereby reduce system processing overhead.

Note If you disable an inspector in a custom network analysis policy, but the system needs to use that inspector to later evaluate packets against an enabled intrusion or inspector rule, the system automatically enables and uses the inspector although the inspector remains disabled in the network analysis policy web interface.

- Specify ports, where appropriate, to focus the activity of certain inspectors. For example, you can identify additional ports to monitor for DNS server responses, encrypted SSL sessions, or ports on which you decode telnet, HTTP, and RPC traffic.

If you are an advanced user with a complex deployment, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs. (Note that ASA FirePOWER modules cannot restrict preprocessing by VLAN.)

Note Tailoring preprocessing using custom network analysis policies—especially multiple network analysis policies—is an advanced task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful to allow the network analysis and intrusion policies examining a single packet to complement each other.

Benefits of custom intrusion policies

Custom intrusion policies are security configurations that

- enable tailored traffic inspection through multiple specialized intrusion policies
- manage which intrusion and inspector rules are enabled and how they are configured, and
- allow access control rules to specify which policy inspects which traffic based on multiple criteria.

In a newly created access control policy initially configured to perform intrusion prevention, the default action allows all traffic, but first inspects it with the system-provided Balanced Security and Connectivity intrusion policy. Unless you add access control rules or change the default action, all traffic is inspected by that intrusion policy.

To customize your intrusion prevention deployment, you can create multiple intrusion policies, each tailored to inspect traffic differently. Then, configure an access control policy with rules that specify which policy inspects which traffic. Access control rules can be simple or complex, matching and inspecting traffic using multiple criteria including security zone, network or geographical location, VLAN, port, application, requested URL, or user.

The main function of intrusion policies is to manage which intrusion and inspector rules are enabled and how they are configured, as follows:

- Within each intrusion policy, you should verify that all rules applicable to your environment are enabled, and improve performance by disabling rules that are not applicable to your environment. You can specify which rules should drop or modify malicious packets.
- Cisco recommendations allow you to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

- You can modify existing rules and write new standard text rules as needed to catch new exploits or to enforce your security policies.

Other customizations you might make to an intrusion policy include:

- The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text. Note that other inspectors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.
- Global thresholds cause the system to generate events based on how many times traffic matching an intrusion rule originates from or is targeted to a specific address or address range within a specified time period. This helps prevent the system from being overwhelmed with a large number of events.
- Suppressing intrusion event notifications and setting thresholds for individual rules or entire intrusion policies can also prevent the system from being overwhelmed with a large number of events.
- In addition to the various views of intrusion events within the web interface, you can enable logging to syslog facilities or send event data to an SNMP trap server. For each policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events. Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

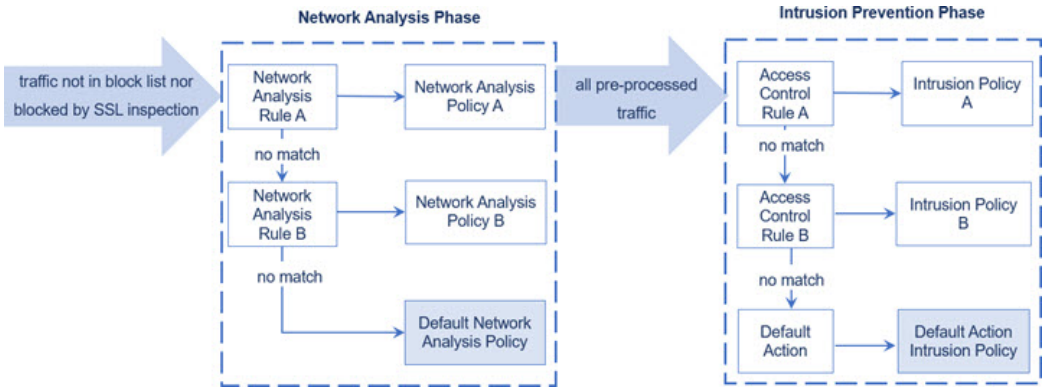
Limitations of custom policies

Because preprocessing and intrusion inspection are so closely related, you **must** be careful that your configuration allows the network analysis and intrusion policies processing and examining a single packet to complement each other.

By default, the system uses one network analysis policy to preprocess all traffic handled by managed devices using a single access control policy. This diagram shows how a newly created access control policy in an inline intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

Notice how a default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default.

You can tune preprocessing by creating and using a custom network analysis policy as the default. However, if you disable a inspector in a custom network analysis policy but the system needs to evaluate preprocessed packets against an enabled intrusion or inspector rule, the system automatically enables and uses the inspector although it remains disabled in the network analysis policy web interface.



Note In order to get the performance benefits of disabling an inspector, you **must** make sure that none of your intrusion policies have enabled rules that require that inspector.

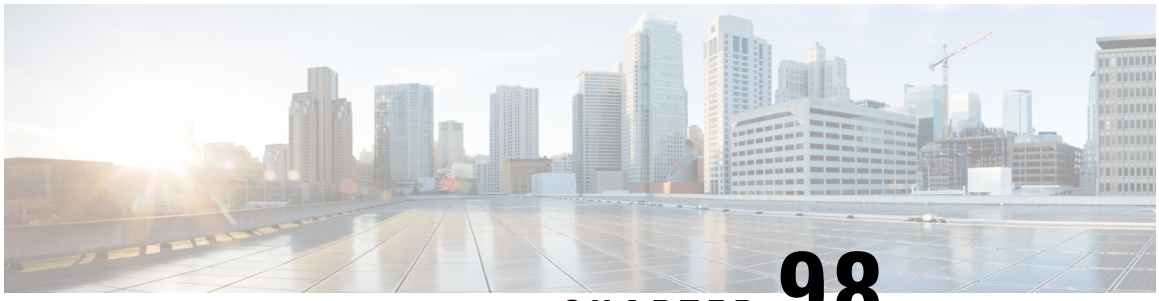
An additional challenge arises if you use multiple custom network analysis policies. For advanced users with complex deployments, you can tailor preprocessing to specific security zones, networks, and VLANs by assigning custom network analysis policies to preprocess matching traffic. (Note that ASA FirePOWER cannot restrict preprocessing by VLAN.) To accomplish this, you add custom *network analysis rules* to your access control policy. Each rule has an associated network analysis policy that governs the preprocessing of traffic that matches the rule.

Tip You configure network analysis rules as an advanced setting in an access control policy. Unlike other types of rules, network analysis rules invoke network analysis policies, rather than being contained by them.

The system matches packets to any configured network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rule is preprocessed by the default network analysis policy. While this allows you a great deal of flexibility in preprocessing traffic, keep in mind that all packets, **regardless** of which network analysis policy preprocessed them, are subsequently matched to access control rules—and thus to potential inspection by intrusion policies—in their own process. In other words, preprocessing a packet with a particular network analysis policy does **not** guarantee that the packet will be examined with any particular intrusion policy. You **must** carefully configure your access control policy so it invokes the correct network analysis and intrusion policies to evaluate a particular packet.

The diagram shows in detail how the network analysis policy (preprocessing) selection phase occurs before and separately from the intrusion prevention (rules) phase. For simplicity, the diagram eliminates the discovery and file or malware inspection phases. It also highlights the default network analysis and default-action intrusion policies.

In this scenario, an access control policy is configured with two network analysis rules and a default network analysis policy:



- Network Analysis Rule A preprocesses matching traffic with Network Analysis Policy A. Later, you want this traffic to be inspected by Intrusion Policy A.
- Network Analysis Rule B preprocesses matching traffic with Network Analysis Policy B. Later, you want this traffic to be inspected by Intrusion Policy B.
- All remaining traffic is preprocessed with the default network analysis policy. Later, you want this traffic to be inspected by the intrusion policy associated with the default action of the access control policy.

After the system preprocesses traffic, it can examine the traffic for intrusions. The diagram shows an access control policy with two access control rules and a default action:

- Access Control Rule A allows matching traffic. The traffic is then inspected by Intrusion Policy A.
- Access Control Rule B allows matching traffic. The traffic is then inspected by Intrusion Policy B.
- The default action of the access control policy allows matching traffic. The traffic is then inspected by the default action's intrusion policy.

Each packet's handling is governed by a network analysis policy and intrusion policy pair, but the system does **not** coordinate the pair for you. Consider a scenario where you misconfigure your access control policy so that Network Analysis Rule A and Access Control Rule A do not process the same traffic. For example, you could intend the paired policies to govern the handling of traffic on a particular security zone, but you mistakenly use different zones in the two rules' conditions. This could cause traffic to be incorrectly preprocessed. For this reason, tailoring preprocessing using network analysis rules and custom policies is an **advanced** task.

Note that for a single connection, although the system selects a network analysis policy before an access control rule, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

CHAPTER 98

Migrate from Snort 2 to Snort 3

Starting with Version 7.0, Snort 3 is the default inspection engine for new Firewall Threat Defense deployments with Cloud-Delivered Firewall Management Center. If you are still using the Snort 2 inspection engine, switch to Snort 3 now for improved detection and performance.

Upgrading Firewall Threat Defense to Version 7.2 through 7.6 also upgrades eligible Snort 2 devices to Snort 3. For devices that are ineligible because they use custom intrusion or network analysis policies, manually upgrade to Snort 3 as described here.

Although you can switch individual devices back, you should not. Snort 2 will be deprecated in a future release and will eventually prevent Firewall Threat Defense upgrade.

- Snort 3 inspection engine, on page 2799
- Snort 2 versus Snort 3, on page 2800
- Migrating from Snort 2 to Snort 3, on page 2800
- View Snort 2 and Snort 3 base policy mapping, on page 2804
- Synchronize Snort 2 rules with Snort 3, on page 2805
- Deploy configuration changes, on page 2806
- Examples for migration, on page 2808

Snort 3 inspection engine

Snort 3 is a network inspection engine that

- serves as the default inspection engine for newly registered Firewall Threat Defense devices on version 7.0 or later,
- requires explicit enablement after upgrading Firewall Threat Defense devices to version 7.0 or later, and
- activates the Snort 3 version of the intrusion policy, which is applied through access control policies, for all traffic passing through the device.

For Firewall Threat Defense devices on version 6.x or earlier, Snort 2 is the default inspection engine.

Version switching and rule mapping

You can switch Snort versions when required. Snort 2 and Snort 3 intrusion rules are mapped and the mapping is system-provided. However, you may not find a one-to-one mapping of all the intrusion rules in Snort 2 and Snort 3. If you change the rule action for one rule in Snort 2, that change will not be retained if you switch to

Snort 3 without first synchronizing Snort 2 with Snort 3. For more information on synchronization, see Synchronize Snort 2 rules with Snort 3, on page 2805.

Snort 2 versus Snort 3

Snort 3 has been architecturally redesigned to inspect more traffic with equivalent resources when compared to Snort 2. Snort 3 provides simplified and flexible insertion of traffic parsers. Snort 3 also provides new rule syntax that makes rule writing easier and shared object rule equivalents visible.

This table lists the differences between the Snort 2 and the Snort 3 versions in terms of the inspection engine capabilities.

Feature	Snort 2	Snort 3
Packet threads	One per process	Any number per process
Configuration memory use	Number of processes * *x* GB	*x* gigabytes (GB) in total; more memory available for packets
Configuration reload	Slower	Faster; one thread can be pinned to separate cores
Rule syntax	Inconsistent and requires line escapes	Uniform system with arbitrary whitespace
Rule comments	Comments only	#, #begin and #end marks; C language style

Additional reference: Differences between Snort 2 and Snort 3 in Firepower.

Migrating from Snort 2 to Snort 3

Migrating from Snort 2 to Snort 3 requires you to switch the inspection engine of the Firewall Threat Defense device from Snort 2 to Snort 3.

Summary

Depending on your requirements, go through the stages listed in the workflow to complete the migration of your device from Snort 2 to Snort 3.

Workflow

These are the stages of migrating from Snort 2 to Snort 3:

1. Enable Snort 3 on the device.
   - Enable Snort 3 on an individual device, on page 2801
   - Enable Snort 3 on multiple devices, on page 2802
2. Convert Snort 2 custom rules to Snort 3.

- Convert all Snort 2 custom rules across all intrusion policies to Snort 3, on page 2803
- Convert Snort 2 custom rules of a single intrusion policy to Snort 3, on page 2804

3. Synchronize Snort 2 rules with Snort 3.
   - Synchronize Snort 2 rules with Snort 3, on page 2805

Prerequisites for migrating from Snort 2 to Snort 3

Consider the recommended prerequisites before migrating your device from Snort 2 to Snort 3.

- Have a working knowledge of Snort. To learn about the Snort 3 architecture, see Snort 3 Adoption.
- Back up your management center. See Backup the Management Center.
- Back up your intrusion policy. See Exporting Configurations.
- Clone your intrusion policy. To do this, you can use an existing policy as the base policy to create a copy of your intrusion policy. In the **Intrusion Policies** page, click **Create Policy** and choose an existing intrusion policy from the **Base Policy** dropdown list.

Enable Snort 3 on an individual device

Enable Snort 3 on an individual device to take advantage of enhanced security capabilities.

Use this procedure when you need to upgrade a specific device from Snort 2 to Snort 3 inspection engine. The system will automatically convert policy configurations during deployment to ensure compatibility with the selected Snort version.

Important During the deployment process, there could be a momentary traffic loss because the current inspection engine needs to be shut down.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the device to go to the device home page.

Note
The device is marked as Snort 2 or Snort 3, showing the current version on the device.

Step 3 Click the **Device** tab.

Step 4 In the Inspection Engine section, click **Upgrade**.

Note
In case you want to disable Snort 3, click **Revert to Snort 2** in the Inspection Engine section.

Step 5 Click **Yes**.

What to do next

Deploy the changes on the device. See Deploy configuration changes, on page 2806.

The system converts your policy configurations during the deployment process to make them compatible with the selected Snort version.

Enable Snort 3 on multiple devices

This task enables Snort 3 on multiple devices to provide enhanced intrusion detection capabilities.

To enable Snort 3 on multiple devices, ensure all the required Firewall Threat Defense devices are on version 7.0 or later.

Important During the deployment process, there could be a momentary traffic loss because the current inspection engine needs to be shut down.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Select all the devices on which you want to enable or disable Snort 3.

Note
The devices are marked as Snort 2 or Snort 3, showing the current version on the device.

Step 3 Click the **Select Bulk Action** dropdown list and choose **Upgrade to Snort 3**.

Step 4 Click **Yes**.

What to do next

Deploy the changes on the device. See Deploy configuration changes, on page 2806.

Convert Snort 2 Custom IPS Rules to Snort 3

Snort 2 to Snort 3 custom IPS rule conversion is a migration process that transforms custom intrusion prevention system rules from Snort 2 format to Snort 3 format.

Conversion requirements and resources

If you are using a rule set from a third-party vendor, contact that vendor to confirm that their rules successfully convert to Snort 3 or to obtain a replacement rule set written natively for Snort 3. If you have custom rules that you have written yourself, familiarize yourself with writing Snort 3 rules prior to conversion so that you

can update your rules to optimize Snort 3 detection after conversion. See the links to learn more about writing rules in Snort 3.

- https://blog.snort.org/2020/08/how-rules-are-improving-in-snort-3.html
- https://blog.snort.org/2020/10/talos-transition-to-snort-3.html

You can refer to other blogs at https://blog.snort.org/ to learn more about Snort 3 rules.

See these procedures to convert Snort 2 rules to Snort 3 rules using the system-provided tool.

- Convert all Snort 2 custom rules across all intrusion policies to Snort 3, on page 2803
- Convert Snort 2 custom rules of a single intrusion policy to Snort 3, on page 2804

Important Snort 2 network analysis policy (NAP) settings *cannot* be copied to Snort 3 automatically. NAP settings have to be manually replicated in Snort 3.

Convert all Snort 2 custom rules across all intrusion policies to Snort 3

Convert legacy Snort 2 custom rules to the updated Snort 3 format to ensure compatibility with current intrusion detection systems.

This task migrates existing Snort 2 custom rules to Snort 3 format, allowing you to maintain your custom rule configurations while upgrading to the latest intrusion detection engine. You can either import the converted rules directly or download them for review before importing.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Ensure **All Rules** is selected in the left pane.

Step 4 Click the **Tasks** drop-down list and choose:

- **Convert Snort 2 rules and import**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.
- **Convert Snort 2 rules and download**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and download them into your local system.

Step 5 Click **OK**.

Note

- If you selected **Convert and import** in the previous step, then all the converted rules are saved under a newly created rule group **All Snort 2 Converted Global** under **Local Rules**.
- If you selected **Convert and download** in the previous step, then save the rules file locally. You can review the converted rules in the downloaded file and later upload them by following the steps in Add custom rules to rule groups, on page 2846.

Refer to the video Converting Snort 2 Rules to Snort 3 for additional support and information.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Convert Snort 2 custom rules of a single intrusion policy to Snort 3

Convert Snort 2 custom rules in an intrusion policy to Snort 3 format to maintain compatibility with Snort 3 environments.

When migrating to Snort 3, existing Snort 2 custom rules need to be converted to maintain their functionality. This task allows you to convert custom rules for a specific intrusion policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click **Show Snort 3 Sync status**.

Step 3 Click the **Sync** icon **Snort out-of-Sync** ( ) of the intrusion policy.

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in green**Snort in-Sync** ( ). It indicates that there are no custom rules to be converted.

Step 4 Read the summary and click the **Custom Rules** tab.

Step 5 Choose:

- **Import converted rules to this policy**: To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.
- **Download converted rules**: To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and download them into your local system. You can review the converted rules in the downloaded file and later upload the file by clicking the upload icon.

Step 6 Click **Re-Sync**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

View Snort 2 and Snort 3 base policy mapping

This task allows you to view the mapping between Snort 3 and Snort 2 intrusion policies.

Note Snort 2 is not supported on threat defense version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Cloud-Delivered Firewall Management Center guide that matches your Firewall Threat Defense version.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **IPS Mapping**.

Step 4 In the **IPS Policy Mapping** dialog box, click **View Mappings** to view the Snort 3 to Snort 2 intrusion policy mapping.

Step 5 Click **OK**.

Synchronize Snort 2 rules with Snort 3

This task helps ensure that Snort 2 rule override settings and custom rules are replicated on Snort 3, allowing you to start with similar coverage when transitioning between versions.

To ensure that the Snort 2 version settings and custom rules are retained and carried over to Snort 3, the Firewall Management Center provides the synchronization functionality. Synchronization helps Snort 2 rule override settings and custom rules, which you may have altered and added over the last few months or years, to be replicated on the Snort 3 version. This utility helps to synchronize Snort 2 version policy configuration with Snort 3 version to start with similar coverage.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Cloud-Delivered Firewall Management Center guide that matches your Firewall Threat Defense version.

If the Firewall Management Center is upgraded from 6.7 or earlier to 7.0 or later version, the system synchronizes the configuration. If the Firewall Management Center is a fresh 7.0 or later version, you can upgrade to a higher version, and the system will not synchronize any content during upgrade.

Before upgrading a device to Snort 3, if changes are made in Snort 2 version, you can use this utility to have the latest synchronization from Snort 2 version to Snort 3 version so that you start with a similar coverage.

Note When you move to Snort 3, manage the Snort 3 version of the policy independently. Do not use this utility as a regular operation.

Important

- Only the Snort 2 rule overrides and custom rules are copied to Snort 3 and not the other way around. You may not find a one-to-one mapping of all the intrusion rules in Snort 2 and Snort 3. Your changes to rule actions for rules that exist in both versions are synchronized when you perform the following procedure.
- Synchronization *does not* migrate the threshold and suppression settings of any custom or system-provided rules from Snort 2 to Snort 3.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **Show Snort 3 Sync status**.

Step 4 Identify the intrusion policy that is out-of-sync.

Step 5 Click the **Sync** icon **Snort out-of-Sync** ( ).

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in green**Snort in-Sync** ( ).

Step 6 Read the summary. Download a copy of the summary if required.

Step 7 Click **Re-Sync**.

Note
- The synchronized settings will be applicable on the Snort 3 intrusion engine only if it is applied on a device, and after a successful deployment.
- Snort 2 custom rules can be converted to Snort 3 with the system-provided tool. If you have any Snort 2 custom rules, click the Custom Rules tab and follow the on-screen instructions to convert the rules. For more information, see Convert Snort 2 custom rules of a single intrusion policy to Snort 3, on page 2804.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Deploy configuration changes

Deploy configuration changes to ensure that modifications made to device configurations take effect on the affected devices.

After you change configurations, deploy them to the affected devices.

Note This topic covers the basic steps involved in deploying configuration changes. We *strongly* recommend that you refer to the *Deploy Configuration Changes* topic in the latest version of the *Cisco Secure Firewall Management Center Device Configuration Guide* to understand the prerequisites and implications of deploying the changes before proceeding with the steps.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic.

Procedure

Step 1 On the Cloud-Delivered Firewall Management Center menu bar, click **Deploy** and choose **Deployment**.

The GUI page lists the devices with out-of-date configurations having **Pending** status.

- The **Modified By** column lists the users who have modified the policies or objects. Expand the device listing to view the users who have modified the policies for each policy listing.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption might occur in the device during deployment.

  If this column is blank for a device, it indicates that there will be no traffic inspection interruptions on that device during deployment.

- The **Last Modified Time** column specifies the last time you made configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment.

Step 2 Identify and choose the devices on which you want to deploy configuration changes.

- Search: Search for the device name, type, domain, group, or status in the search box.
- Expand: Click **Expand Arrow** ( ) to view device-specific configuration changes to be deployed.

  If you select a checkbox next to a device, all changes made to that device and listed for the device, are included in the deployment. However, you can use **Policy selection** ( ) to select individual policies or specific configurations to deploy while withholding the remaining changes without deploying them.

  Note
  - When the status in the **Inspect Interruption** column indicates (**Yes**) that deploying will interrupt inspection, and perhaps traffic, on a Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).

- When there are changes to interface groups, security zones, or objects, the impacted devices are shown as out-of-date on the Firewall Management Center. To ensure that these changes take effect, the policies with these interface groups, security zones, or objects, also need to be deployed along with these changes. The impacted policies are shown as out-of-date on the **Preview**page on the Firewall Management Center.

Step 3 Click **Deploy**.

Step 4 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy: Continue deploying without resolving warning conditions. You cannot proceed if the system identifies errors.
- Close: Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

Configuration changes are deployed to the selected devices and take effect according to the deployment settings.

What to do next

During deployment, if there is a deployment failure, there is a possibility that the failure may impact traffic. However, it depends on certain conditions. If there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For details, see the Deploy Configuration Changes topic in the latest version of the *Cisco Secure Firewall Management Center Device Configuration Guide*.

Examples for migration

Migrate from Snort 2 to Snort 3

Migrating from Snort 2 to Snort 3

- involves converting and adapting the Snort 2 rules to the Snort 3 rule syntax,
- optimizes the rules for improved detection and performance, and
- allows organizations to leverage the enhanced features and capabilities of Snort 3.

Organizations with Threat Defense devices managed by the Secure Firewall Management Center can opt for a hybrid deployment approach during the migration from Snort 2 to Snort 3. This approach allows for a gradual transition and minimizes potential disruptions, if any.

Benefits of migrating to snort 3

Snort 3 provides

- **Enhanced protocol support**: Snort 3 provides improved protocol support, allowing you to detect and monitor threats across a wide range of modern protocols, including encrypted traffic.
- **Streamlined rule management**: Snort 3 offers a more user-friendly rule language and rule management system, making it easier to create, modify, and manage rules effectively.
- **Improved performance**: Snort 3 has been optimized to handle higher traffic volumes more efficiently, ensuring timely threat detection and reducing the risk of performance bottlenecks.

Sample business scenario

This sample business scenario is an illustrative situation that

- demonstrates how organizations evaluate network security inspection engine migrations,
- shows the roles and motivations of security analysts and network administrators in technology decisions, and
- highlights the benefits of upgrading from legacy to modern security monitoring solutions.

Organizational migration scenario

Alice works as a security analyst in a large organization that heavily relies on the Snort inspection engine to monitor and protect their network infrastructure. The organization has been using Snort Version 2 for several years, but they have encountered some limitations and challenges.

Bob, the network administrator, is looking to migrate from Snort 2 to Snort 3 to overcome these issues and enhance his organization's network security capabilities.

This migration will also improve network security monitoring, enhance performance, and streamline rule management.

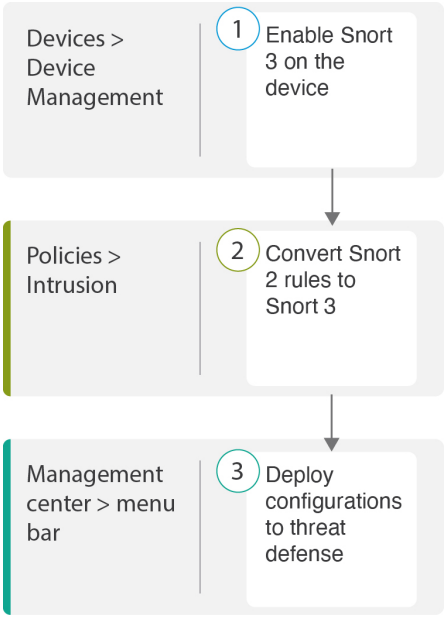
Best practices for migrating from Snort 2 to Snort 3

Follow these best practices when migrating from Snort 2 to Snort 3 to ensure data integrity and maintain security coverage.

- Back up your intrusion policy before performing the migration. See the Export Configurations task in the *Cisco Secure Firewall Management Center Administration Guide*.
- Before upgrading a device to Snort 3, if changes are made in Snort 2, use the synchronize utility to include the latest synchronization from Snort 2 to Snort 3 so that you can start with a similar coverage. See Synchronize Snort 2 rules with Snort 3, on page 2805.
- Snort 2 custom rules are not automatically converted to Snort 3 and must be manually migrated. See Convert Snort 2 Custom IPS Rules to Snort 3, on page 2802.
- Synchronization does not migrate Snort 2 rules with thresholds or suppressions. These rules must be created again in Snort 3.

Prerequisites for migration

Complete these prerequisites before starting the migration process to ensure system readiness and data protection.



- Have a working knowledge of Snort. To learn about the Snort 3 architecture, see Snort 3 Adoption.
- Back up your management center. See Backup the Management Center.
- Back up your intrusion policy. See Exporting Configurations.

End-to-end migration workflow

Summary

Depending on your requirements, go through the stages listed in the workflow to complete the migration of your device from Snort 2 to Snort 3.

Workflow

These are the stages of migrating Snort 2 to Snort 3:

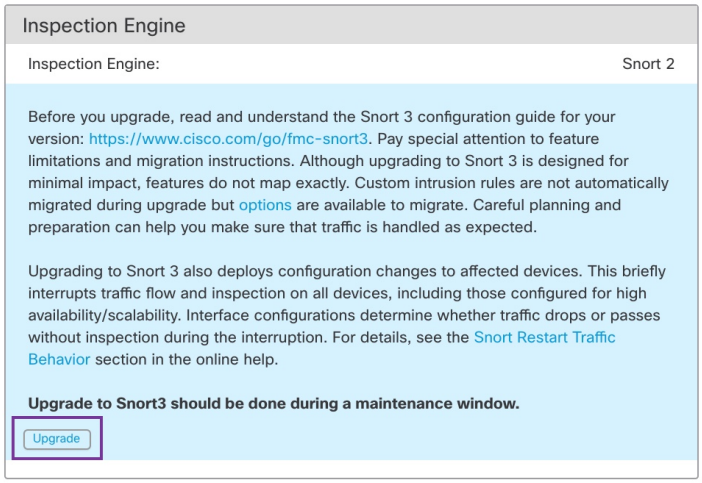
1. Enable Snort 3 on the device. See Enable Snort 3 on Threat Defense device, on page 2811.
2. Convert Snort 2 rules to Snort 3. See Convert Snort 2 rules of a single intrusion policy to Snort 3, on page 2812.
3. Deploy configuration. See Deploy configuration changes, on page 2806.

Enable Snort 3 on Threat Defense device

Enable Snort 3 on your Threat Defense device for enhanced security capabilities.

Use this procedure to upgrade from Snort 2 to Snort 3 on your Threat Defense device.

Attention During the deployment process, there could be a momentary traffic loss because the current inspection engine needs to be shut down.



Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the corresponding device to go to the device home page.

Step 3 Click the **Device** tab.

Step 4 In the **Inspection Engine** section, click **Upgrade**.

Step 5 Click **Yes**.

What to do next

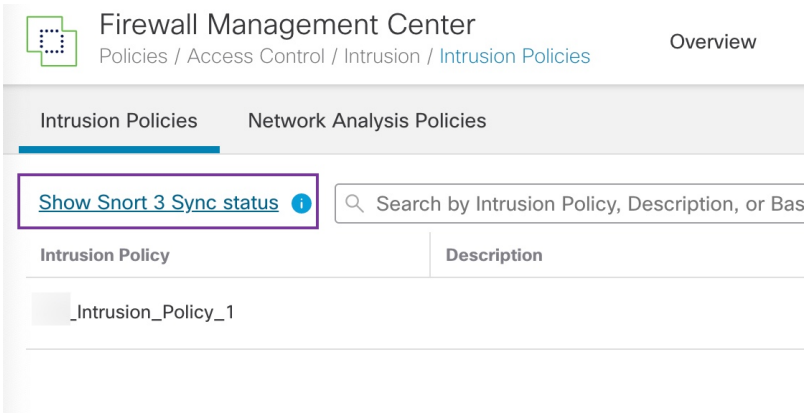
Deploy the changes on the device. See Deploy configuration changes, on page 2806.

The system converts your policy configurations during the deployment process to make them compatible with the selected Snort version.

Convert Snort 2 rules of a single intrusion policy to Snort 3

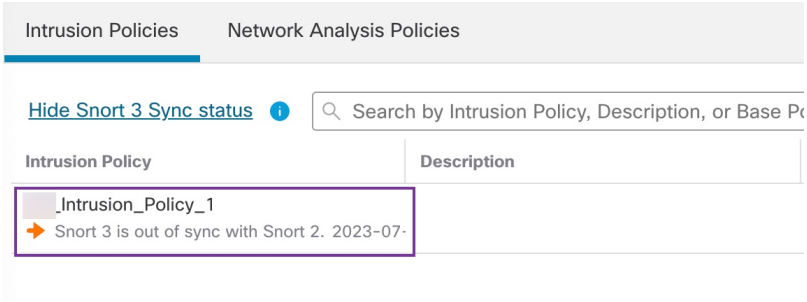
This task synchronizes and converts Snort 2 intrusion policy rules to Snort 3 format, ensuring that custom rules, thresholds, and suppressions are properly migrated to maintain security policy effectiveness when using Snort 3 engines.

When intrusion policies display an orange arrow indicator, the Snort 2 and Snort 3 versions are not synchronized. The synchronization process uses the snort2Lua tool to convert rules and may require manual intervention for custom rules, thresholds, and suppressions that cannot be automatically migrated.



Before you begin

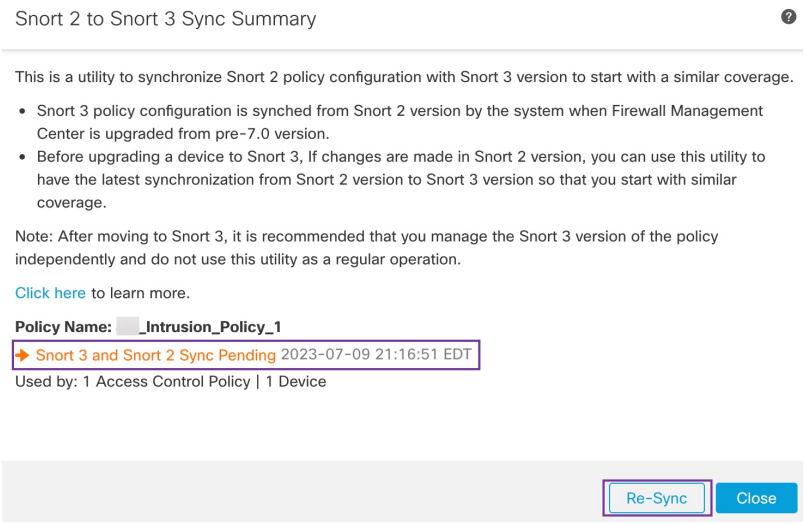
Follow these steps to convert Snort 2 rules of a single intrusion policy to Snort 3:



Procedure

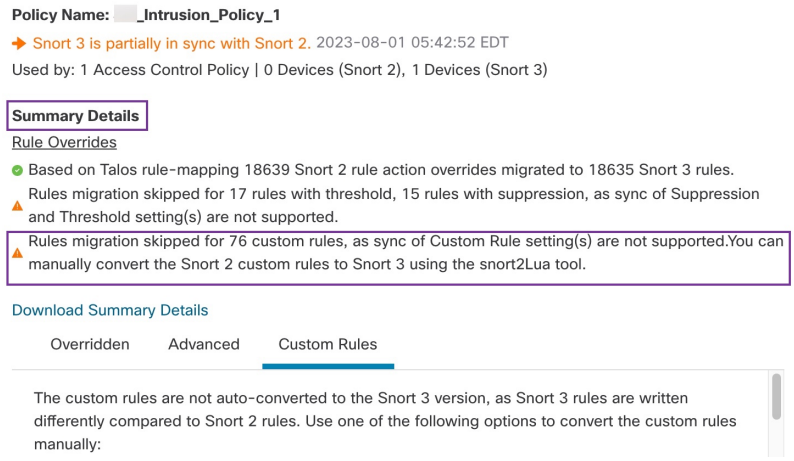
Step 1 Choose **Policies** > **Access Control heading** > **Intrusion** > **Intrusion Policies**.

a) In the **Intrusion Policies** tab, click **Show Snort 3 Sync status**.

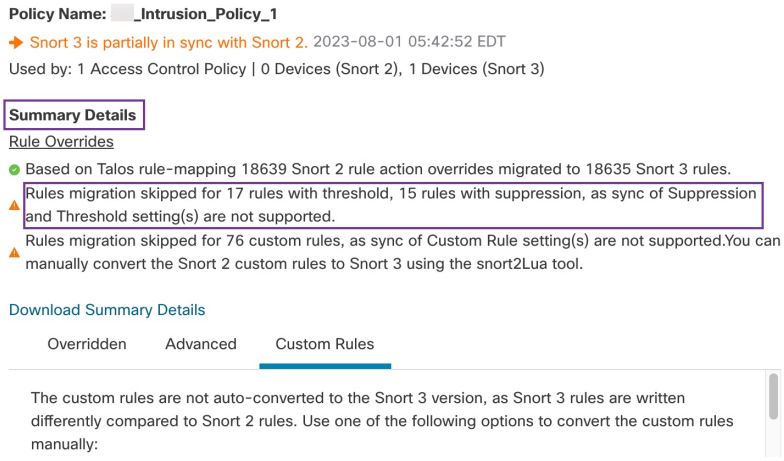


If your policy displays an orange arrow, it indicates that the Snort 2 and the Snort 3 versions of the intrusion policy are not synchronized.

b) Click the orange arrow.



The **Snort 2 to Snort 3 Sync Summary** page displays that the Snort 2 to Snort 3 sync is pending.

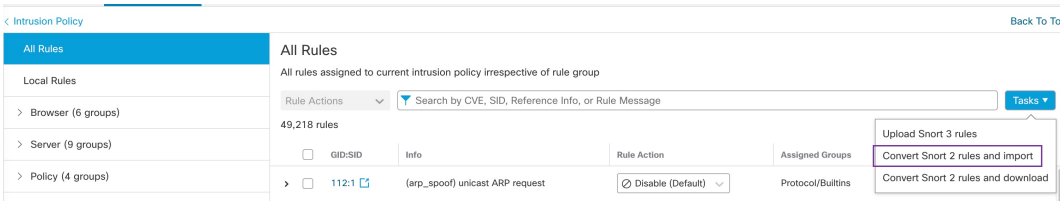


c) Click **Re-Sync** to start the synchronization.

Note
When you click **Re-Sync**, the snort2Lua tool converts the rules from Snort 2 to Snort 3.

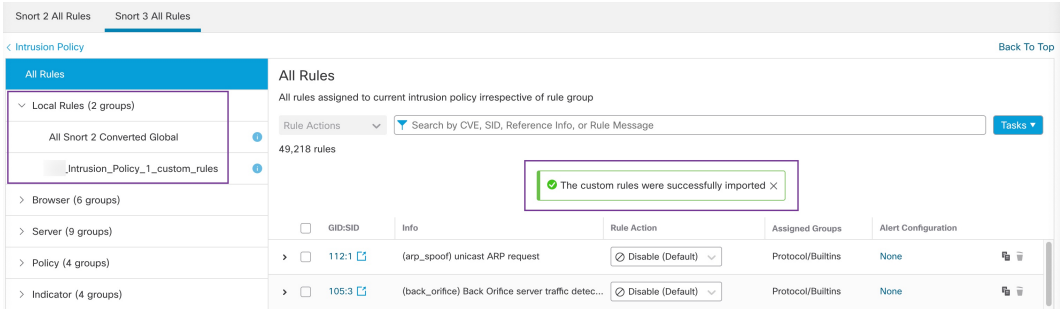
The **Summary Details** section lists the rules that were migrated or skipped. In our use case, there are 76 custom Snort 2 rules, 17 rules with thresholds, and 15 rules with suppression that were skipped during the sync process. To migrate the custom rules, go to the next step.

To migrate rules with thresholds and suppressions, go to Step 6.



Step 2 To migrate the 76 custom rules, perform either one of these steps:

- In the **Custom Rules** tab, click the **Import** icon to convert and auto-import the local rules to the Snort 3 version of the policy.



A confirmation message is displayed after the rules are successfully imported.

- Choose **Objects** > **Intrusion Rules** and click **Snort 3 All Rules**.
  - **a.** Click **Local Rules** in the left panel to check if any rules have been migrated. Notice that no custom rules from Snort 2 have been migrated.
  - **b.** From the **Tasks** drop-down list, choose **Convert Snort 2 rules and import**.

  - **c.** Click **OK**.

A rule group named (**All Snort 2 Converted Global**) is now created under **Local Rules** in the left panel.

Notice that all 76 custom rules have been migrated, as shown in the following figure.

Alternatively, you can select the **Convert Snort 2 rules and download** in the previous step to save the rules file locally. You can review the converted rules in the downloaded file and later upload them using the **Upload Snort 3 rules** option.

Step 3 Click the **Download Summary Details** link to download the rules in .txt format.

This is a sample of the summary that is displayed.

Example:

```
  "id": "00505691-15DC-0ed3-0000-004294988561",

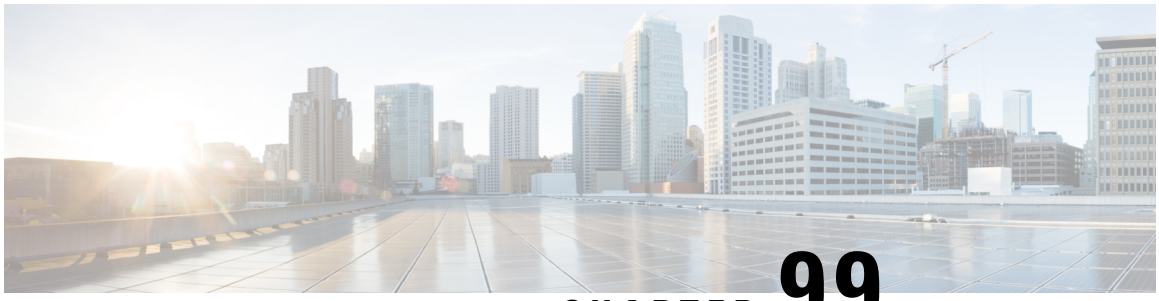
1:1000094=alert,1:1000113=disabled,1:1000147=alert,1:1000161=alert,1:1000105=disabled,1:1000140=alert,1:1000111=alert,
1:1000102=alert,1:1000129=disabled,1:1000108=alert,1:1000144=disabled,1:1000088=alert,1:1000091=alert,1:1000131=alert,
1:1000157=alert,1:1000120=alert,1:1000126=alert,1:1000165=alert,1:1000146=alert,1:1000162=alert,1:1000116=alert,1:1000142=alert,
1:1000170=disabled,1:1000169=alert,1:1000104=alert,1:1000099=disabled,1:1000171=alert,1:1000093=alert,1:1000087=alert,1:1000100=alert,
1:1000137=alert,1:1000158=alert,1:1000103=alert,1:1000098=alert,1:1000127=disabled,1:1000130=alert,1:1000164=alert,1:1000089=alert,
         1:1000109=alert,1:1000136=alert,1:1000117=alert,1:1000166=alert,1:1000168=alert",
        "type": "PolicyInfo",
        "description": "Corresponding Snort 2 policy overridden custom (local) rules."
      },
      {
        "type": "AssignedDevices",
        "status": "INFO",
        "description": "Snort3:0 , Snort2:0"
      },
      {
        "id": "122:6",
        "type": "Threshold",
        "status": "ERROR",
        "description": "PSNG_TCP_FILTERED_DECOY_PORTSCAN"
      },
      {
        "id": "122:15",
        "type": "Threshold",
        "status": "ERROR",
        "description": "PSNG_IP_PORTSWEEP_FILTERED"
       },
      {
        "id": "122:1",
        "type": "Threshold",
        "status": "ERROR",
        "description": "PSNG_TCP_PORTSCAN"
      },
```

Step 4 Click **Close** to close the **Sync Summary** dialog box.

Step 5 To check the rules with status: ERROR, choose **Policies** > **Access Control heading** > **Intrusion** and click the **Snort 2** version of the intrusion policy.

Step 6 Under **Policy Information**, click **Rules** and filter for the rule. For example, enter **PSNG_TCP_PORTSCAN** in the **Filter**field to find the rule.



Step 7 Click **Show Details** to view the detailed version of the rule.

Step 8 Create the rule again in Snort 3 using Snort 3 rule guidelines and save the file as a .txt or .rules file. For more information, see www.snort3.org.

Step 9 Upload the custom rule that you just created locally to the list of all the Snort 3 rules. See Add Custom Rules to Rule Groups.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

CHAPTER 99

Intrusion Policies

This chapter provides information on managing Snort 3 intrusion policies and access control rule configurations for intrusion detection and prevention.

- Intrusion policies, on page 2819
- Create a custom snort 3 intrusion policy, on page 2820
- Edit Snort 3 Intrusion Policies, on page 2821
- Change the base policy of an intrusion policy, on page 2826
- View Snort 2 and Snort 3 base policy mapping, on page 2827
- Synchronize Snort 2 rules with Snort 3, on page 2827
- Manage intrusion policies, on page 2829
- Access control rule configuration to perform intrusion prevention, on page 2830
- Tune Intrusion Policies using Rules, on page 2831
- Recommended rules, on page 2850
- Mitigate threats using MITRE framework in Snort 3 intrusion policies, on page 2854

Intrusion policies

An *intrusion policy* is a defined set of intrusion detection and prevention configurations that

- inspects traffic for security violations,
- can block or alter malicious traffic in inline deployments, and
- serves as the system's last line of defense before traffic is allowed to its destination.

At the heart of each intrusion policy are the intrusion rules. An enabled rule causes the system to generate intrusion events for (and optionally block) traffic matching the rule. Disabling a rule stops processing of the rule.

The system delivers several base intrusion policies, which enable you to take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and inspector rule states (enabled or disabled), as well as provides the initial configurations for other advanced settings.

Tip System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.

If you create a custom intrusion policy, you can:

- Tune detection by enabling and disabling rules, as well as by writing and adding your own rules.
- Use Secure Firewall recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

An intrusion policy can drop matching packets and generate intrusion events. To configure an intrusion or preprocessor drop rule, set its state to Block.

When tailoring your intrusion policy, especially when enabling and adding rules, keep in mind that some intrusion rules require that traffic first be decoded or preprocessed in a certain way. Before an intrusion policy examines a packet, the packet is preprocessed according to configurations in a network analysis policy. If you disable a required inspector, the system automatically uses it with its current settings, although the inspector remains disabled in the network analysis policy web interface.

Caution Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet **must** complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task.

After you configure a custom intrusion policy, you can use it as part of your access control configuration by associating the intrusion policy with one or more access control rules or an access control policy's default action. This forces the system to use the intrusion policy to examine certain allowed traffic before the traffic passes to its final destination. A variable set that you pair with the intrusion policy allows you to accurately reflect your home and external networks and, as appropriate, the servers on your network.

By default, the system disables intrusion inspection of encrypted payloads. This default reduces false positives and improves performance when an encrypted connection matches an access control rule with intrusion inspection enabled.

Refer to the video for additional support and information - Snort 3 Intrusion Policy Overview.

Create a custom snort 3 intrusion policy

Create a custom Snort 3 intrusion policy to tailor intrusion detection and prevention settings to your network security requirements.

Snort 3 intrusion policies define how the system inspects traffic and responds to potential threats. You can create custom policies based on existing system-provided policies or other custom policies to meet specific security needs.

Before you begin

Follow these steps to create a custom Snort 3 intrusion policy:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click **Create Policy**.

Step 3 Enter a unique **Name** and, optionally, a **Description**.

Step 4 Choose the **Inspection Mode**.

The selected action determines whether intrusion rules block and alert (**Prevention** mode) or only alert (**Detection** mode).

Note
Before selecting the prevention mode, you might want block rules to alert only so you can identify rules that cause many false positives.

Step 5 Choose the **Base Policy**.

You can use either a system-provided policy or an existing policy as your base policy.

Step 6 Click **Save**.

The new policy has the same settings as its base policy.

What to do next

To customize the policy, see Edit Snort 3 Intrusion Policies, on page 2821.

Edit Snort 3 Intrusion Policies

Use this task to understand how to access, modify, and manage Snort 3 intrusion policies in the Firewall Management Center, including editing policy settings, managing rule groups, and applying recommendations to protect your network.

While editing a Snort 3 policy, all the changes are saved immediately. No additional action is required to save the changes.

Before you begin

-

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion** .

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **Snort 3 Version** next to the intrusion policy you want to configure.

Step 4 Edit your policy:

- Change the mode—Click the **Mode** drop-down to change the inspection mode.

Caution
The inspection mode is changed only for the Snort 3 version of the policy. The existing inspection mode is retained in the Snort 2 version as is, which means that your Snort 2 and Snort 3 versions of the policy will have different inspection modes. We recommend that you use this option with caution.

- **Prevention** —Triggered Block rules create an event (alert) and drop the connection.
- **Detection** —Triggered Block rules create an alert.

  You can choose the detection mode before going for prevention. For example, before choosing the prevention mode, you might want block rules to alert only, so that you can identify rules that cause a lot of false positives.

Step 5 Click the **Base Policy** layer that defines the intrusion policy's default settings.

- Search rules—Use the search field to filter the display. You can enter the GID, SID, rule message, or reference info. For example, GID:1; SID:9621—to display only rule 1:962, SID:9621,9622,9623—to display multiple rules with different SIDs. You can also click inside the Search text box to choose any of the following options:
  - apply the filters **Action = Alert** , or **Action: Block**
  - apply the **Disabled Rules** filter
  - show **Custom/User Defined Rules**
  - filter by GID, SID, or GID:SID
  - filter by CVE
  - filter by comment
- View filtered rules—Click any of the **Presets** to view rules that are set to alert, block, disabled, and so on.

  Overridden rules indicate the rules where the rule action has been changed from the default action to a different action. Note that, once changed, the rule action status is Overridden even if you change it back to its original default action. However, if you select **Revert to default** from the **Rule Action** drop-down list, the Overridden status is removed.

  Advanced Filters provides filter options based on the Lightweight Security Package (LSP) releases, Classifications of intrusions, and Microsoft Vulnerabilities.
- View rule documentation—Click the rule ID or the **Rule Documentation** icon to display Talos documentation for the rule.
- View a rule details—Click the **Expand Arrow** ( ) icon in a rule row to view the rule details.
- Add rule comments—Click **Comment** ( ) under the Comments column to add comments for a rule.

Step 6 **Group Overrides** —Click the **Group Overrides** layer that lists all the categories of rule groups. The top-level parent rule group with Description, Overrides, Enabled Groups, and other details is displayed. Parent rule groups cannot be updated and are read-only. Only the leaf rule groups can be updated. In each rule group,

you can traverse up to the last leaf group. Across each group, you can override, include, and exclude rule groups. In the leaf rule groups, you can:

- Search rule groups—Use the search field to enter keywords and search for rule groups.
- In the left panel, you can choose any of the preset filter options to search for rule groups:
  - All—For displaying all rule groups.
  - Excluded—For excluded groups.
  - Included—For included groups.
  - Overridden—For rule group configuration that is overridden.
- Set the security level for a rule group—Navigate to the required rule group on the left pane and click it. Click **Edit** next to the **Security Level** of the rule group to increase or decrease the security level based on system-defined rule settings.

  In the **Edit Security Level** dialog box, you have the option to click **Revert to Default** , which reverts the changes you made.

  The Firewall Management Center automatically changes the action for the rules of the rule group for the configured security level. In the **Rule Overrides** layer, notice the count of Block Rules and Disabled Rules in the **Presets** every time you change the security level.
- You can make bulk changes to the security level to change the security level of all rule groups within a particular rule category. Bulk security level applies to rule groups that have more than one rule group. After a bulk update of rule groups, you can still update the security level of any of the associated rule groups within it.

  There can be **mixed** security levels within rule groups; **mixed** indicates that the child groups contain a mix of security levels within the parent rule group.
- Include or exclude rule groups—The rule groups displayed are the default rule groups associated with the system-provided base intrusion policy. You can include and exclude rule groups from the intrusion policy. An excluded rule group is removed from the intrusion policy and its rules are not applied on the traffic. For information on uploading custom rules in Firewall Management Center , see Add custom rules to rule groups, on page 2846 .

  To exclude a rule group:

  a. Navigate the Rule Groups pane and choose the rule group that you want to exclude.

  b. Click the **Exclude** hyperlink on the right-pane.

  c. Click **Exclude** .

  To include a new rule group or multiple rule groups with the uploaded custom rules or a previously excluded rule group:

  a. Click **Add** (+) next to the rule group filter dropdown list.

  b. Choose all the rule groups you want to add by checking the check box next to it.

  c. Click **Save** .

- For a leaf rule group, click the icon under the **Override** column header to see the rule action trail, which describes the sequence of overridden rule actions that can be assigned due to the base policy and group overrides for an intrusion rule. Rule actions can be obtained from either the base policy configurations or the user group override. The user group override takes the priority between the two; priority refers to the final overridden action that is assigned to the rule group.
- Click the rule count (number) under the **Rule Count** column header to see a summary of rules that are part of the rule group.

Step 7 **Recommendations** —Click the **Recommendations** layer if you want to generate and apply Cisco recommended rules. Recommendations use the host database to enable or disable rules, based on known vulnerabilities.

Step 8 **Rule Overrides** —Click the **Rule Overrides** layer to choose any of the presets to view rules, which are set to alert, block, disabled, overridden, rewrite, pass, drop, or reject.

- The **Set By** column shows the default set by state (Base Policy) or modified rule state by Group Overrides, Rule Overrides, or Recommendations. The **Set By** column in **All Rules** (in the left pane) shows the trail of rule action override actions based on priority order. The priority order of rule actions is Rule Override > Recommendations > Group Override > Base Policy.
- Modify **Rule Action** —To modify rule actions, choose either of the following:
  - Bulk edit—Choose one or more rules, then choose the required action from the **Rule Action** drop-down list; and click **Save** .

    Note
    Bulk rule action changes are supported only for the first 500 rules.

  - Single rule edit—Choose the action for the rule from the drop-down list in the **Rule Action** column.

  Rule actions are:

  - **Block** — Generates event, blocks current matching packet and all the subsequent packets in this connection.
  - **Alert** — Generates only events for matching packet and does not drop packet or connection.
  - **Disable** —Does not match traffic against this rule. No events are generated.
  - **Revert to default** —Reverts to the system default action.
  - **Pass** — No events are generated, allows packet to pass without further evaluation by any subsequent Snort rules.

    Note
    The Pass action is available only for custom rules and not for system-provided rules.

  - **Drop** — Generates event, drops matching packet and does not block further traffic in this connection.
  - **Reject** — Generates event, drops matching packet, blocks further traffic in this connection and sends TCP reset if it is a TCP protocol to source and destination hosts.

    Behavior of reject in different firewall modes and IP address or source or destination in relation to Client or Server : Snort sends RST packets to both client and server in cases of routed, inline, and bridged interfaces. Snort sends two RST packets. The RST packet in the client's direction will have the source set to the server's IP and the destination set to client's IP. The RST packet in the server's direction will have the source set to the client's IP and the destination set to the server's IP.

- **Rewrite** — Generates event and overwrites packet contents based on the replace option in the rule.

For IPS rule action logging, see Rule action logging, on page 2825 .

If there is a **React** rule, it is converted to an alert action.

Step 9 Click the **Summary** layer for a holistic view of the current changes to the policy. The policy summary page contains the following information:

- Rule distribution of the policy, that is, active rules, disabled rules, and similar categories.
- Option to export policy and generate report of the intrusion policy.
- Base policy details.
- Option to generate recommendations.
- Group overrides list the groups you have overridden.
- Rule overrides that shows the list of rules that you have overridden.
- In the **Summary** layer, click the ? icon to open a pop-up window that explains the Snort layering concepts.

To change the base policy, see Change the base policy of an intrusion policy, on page 2826 .

Note
You can navigate to **Objects** > **Intrusion Rules** and click the **Snort 3 All Rules** tab and traverse through all the intrusion rule groups. The parent rule group lists the associated child groups and rule count.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806 .

Rule group reporting

Rule group reporting feature reflects rule groups in generated intrusion events, includes MITRE tactics and techniques identification, and provides dedicated columns for both MITRE and non-MITRE rule groups in intrusion event displays.

To view the intrusion events in Cloud-Delivered Firewall Management Center, choose **Analysis** > **Unified Events**. In the **Unified Events** page, explicitly enable the **MITRE ATT&CK** column for rule group reporting.

Rule action logging

From Cloud-Delivered Firewall Management Center 7.2.0 onwards, in the **Intrusion Events** window, the event in the **Inline Result** column displays the same name as the IPS action applied to the rule, so that you can see the action that was applied on the traffic matching the rule.

For the IPS actions, the tables show the events that are displayed in the **Inline Result** column of the **Intrusion Events** window and **Action** column for **Intrusion Event Type** in the **Unified Events** window.

IPS Action for Snort 3	Inline Result - Cloud-Delivered Firewall Management Center 7.1.0 and earlier	Inline Result -Cloud-Delivered Firewall Management Center 7.2.0 onwards
Alert	Pass	Alert
Block	Dropped/Would Have Dropped/Partially Dropped	Block/Would Block/Partial Block
Drop	Dropped/Would have dropped	Drop/Would drop
Reject	Dropped/Would have dropped	Reject/Would reject
Rewrite	Allow	Rewrite

Important

- In case of a rule without the "Replace" option, the **Rewrite** action is displayed as **Would Rewrite**.
- The **Rewrite** action would also be displayed as **Would Rewrite** if the "Replace" option is specified, but the IPS policy is in Detection mode or the device is in Inline-TAP or Passive mode.

Note In case of backward compatibility (Cloud-Delivered Firewall Management Center 7.2.0 managing a Firewall Threat Defense 7.1.0 device), the events mentioned are applicable only to the Alert IPS action where **Pass** is displayed as **Alert** for events. For all the other actions, the events for Cloud-Delivered Firewall Management Center 7.1.0 are applicable.

Change the base policy of an intrusion policy

Change the base policy to use a different system-provided or custom policy as the foundation for your intrusion policy configuration.

You can choose a different system-provided or custom policy as your base policy. You can chain up to five custom policies, with four of the five using one of the other four previously created policies as its base policy; the fifth must use a system-provided policy as its base.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click **Edit** ( ) next to the intrusion policy you want to configure.

Step 3 Choose a policy from the **Base Policy** drop-down list.

Step 4 Click **Save**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

View Snort 2 and Snort 3 base policy mapping

This task allows you to view the mapping between Snort 3 and Snort 2 intrusion policies.

Note Snort 2 is not supported on threat defense version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Cloud-Delivered Firewall Management Center guide that matches your Firewall Threat Defense version.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **IPS Mapping**.

Step 4 In the **IPS Policy Mapping** dialog box, click **View Mappings** to view the Snort 3 to Snort 2 intrusion policy mapping.

Step 5 Click **OK**.

Synchronize Snort 2 rules with Snort 3

This task helps ensure that Snort 2 rule override settings and custom rules are replicated on Snort 3, allowing you to start with similar coverage when transitioning between versions.

To ensure that the Snort 2 version settings and custom rules are retained and carried over to Snort 3, the Firewall Management Center provides the synchronization functionality. Synchronization helps Snort 2 rule override settings and custom rules, which you may have altered and added over the last few months or years, to be replicated on the Snort 3 version. This utility helps to synchronize Snort 2 version policy configuration with Snort 3 version to start with similar coverage.

Note Snort 2 is not supported on threat defense Version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Cloud-Delivered Firewall Management Center guide that matches your Firewall Threat Defense version.

If the Firewall Management Center is upgraded from 6.7 or earlier to 7.0 or later version, the system synchronizes the configuration. If the Firewall Management Center is a fresh 7.0 or later version, you can upgrade to a higher version, and the system will not synchronize any content during upgrade.

Before upgrading a device to Snort 3, if changes are made in Snort 2 version, you can use this utility to have the latest synchronization from Snort 2 version to Snort 3 version so that you start with a similar coverage.

Note When you move to Snort 3, manage the Snort 3 version of the policy independently. Do not use this utility as a regular operation.

Important

- Only the Snort 2 rule overrides and custom rules are copied to Snort 3 and not the other way around. You may not find a one-to-one mapping of all the intrusion rules in Snort 2 and Snort 3. Your changes to rule actions for rules that exist in both versions are synchronized when you perform the following procedure.
- Synchronization *does not* migrate the threshold and suppression settings of any custom or system-provided rules from Snort 2 to Snort 3.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Ensure the **Intrusion Policies** tab is selected.

Step 3 Click **Show Snort 3 Sync status**.

Step 4 Identify the intrusion policy that is out-of-sync.

Step 5 Click the **Sync** icon **Snort out-of-Sync** ( ).

Note
If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in green**Snort in-Sync** ( ).

Step 6 Read the summary. Download a copy of the summary if required.

Step 7 Click **Re-Sync**.

Note

- The synchronized settings will be applicable on the Snort 3 intrusion engine only if it is applied on a device, and after a successful deployment.
- Snort 2 custom rules can be converted to Snort 3 with the system-provided tool. If you have any Snort 2 custom rules, click the Custom Rules tab and follow the on-screen instructions to convert the rules. For more information, see Convert Snort 2 custom rules of a single intrusion policy to Snort 3, on page 2804.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Manage intrusion policies

This task enables you to perform comprehensive management operations on your intrusion policies including creation, modification, deletion, export, deployment, and reporting.

On the Intrusion Policy window (**Policies** > **Access Control heading** > **Intrusion**) you can view your current custom intrusion policies, along with the following information:

- The number of access control policies and devices using the intrusion policy to inspect traffic.
- Indicates the domain where the policy was created in a multidomain deployment.

Note Snort 2 is not supported on threat defense version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the Cloud-Delivered Firewall Management Center guide that matches your Firewall Threat Defense version.

In a multidomain deployment, the system displays policies created in the current domain, which you can edit. It also displays policies created in ancestor domains, which you cannot edit. To view and edit policies created in a lower domain, switch to that domain.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Manage your intrusion policy:

- Create — Click **Create Policy**; see Create a custom snort 3 intrusion policy, on page 2820.
- Delete — Click **Delete** ( ) next to the policy you want to delete. The system prompts you to confirm and informs you if another user has unsaved changes in the policy. Click **OK** to confirm.

  If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Edit intrusion policy details — Click **Edit** ( ) next to the policy you want to edit. You can edit the **Name**, **Inspection Mode**, and the **Base Policy** of the intrusion policy.
- Edit intrusion policy settings — Click **Snort 3 Version**; see Edit Snort 3 Intrusion Policies, on page 2821.
- Export — If you want to export an intrusion policy to import on another Firewall Management Center, click Export; see the *Exporting Configurations* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.
- Deploy — Choose **Deploy** > **Deployment**; see Deploy configuration changes, on page 2806.

- Report — Click **Report**; see the *Generating Current Policy Reports* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*. Generates two reports, one for each policy version.

Access control rule configuration to perform intrusion prevention

An access control rule configuration to perform intrusion prevention is a security mechanism that

- enables multiple access control rules within an access control policy to be associated with intrusion policies,
- permits intrusion inspection for Allow or Interactive Block access control rules to match different intrusion inspection profiles against different types of traffic, and
- evaluates traffic before it reaches its final destination on the network.

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

System-provided and custom intrusion policies

Cisco delivers several intrusion policies with the system. By using system-provided intrusion policies, you can take advantage of the experience of the Cisco Talos Intelligence Group (Talos). For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for advanced settings. You can use system-provided policies as-is, or you can use them as the base for custom policies. Building custom policies can improve the performance of the system in your environment and provide a focused view of the malicious traffic and policy violations occurring on your network.

Connection and intrusion event logging

When an intrusion policy invoked by an access control rule detects an intrusion and generates an intrusion event, it saves that event to the Management Center. The system also automatically logs the end of the connection where the intrusion occurred to the Management Center database, regardless of the logging configuration of the access control rule.

Access control rule configuration and intrusion policies

The number of unique intrusion policies you can use in a single access control policy depends on the model of the target devices; more powerful devices can handle more. Every unique **pair** of intrusion policy and variable set counts as one policy. Although you can associate a different intrusion policy-variable set pair with each Allow and Interactive Block rule (as well as with the default action), you cannot deploy an access control policy if the target devices have insufficient resources to perform inspection as configured.

Configure an access control rule to perform intrusion prevention

Configure an access control rule to enable intrusion prevention inspection on network traffic, allowing you to detect and prevent malicious activities based on intrusion signatures and policies.

You must be an Admin, Access Admin, or Network Admin to perform this task.

Follow these steps to configure an access control rule to perform intrusion prevention:

Procedure

Step 1 In the access control policy editor, create a new rule or edit an existing rule; see the *Access Control Rule Components* topic in the latest version of the *Cisco Secure Firewall Management Center Configuration Guide*.

Step 2 Ensure the rule action is set to **Allow**, **Interactive Block**, or **Interactive Block with reset**.

Step 3 Click **Inspection**.

Step 4 Choose a system-provided or a custom intrusion policy, or choose **None** to disable intrusion inspection for traffic that matches the access control rule.

Step 5 If you want to change the variable set associated with the intrusion policy, choose a value from the **Variable Set** drop-down list.

Step 6 Click **Save** to save the rule.

Step 7 Click **Save** to save the policy.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Tune Intrusion Policies using Rules

This section provides information on custom rules in Snort 3, intrusion rule action, intrusion event notification filters in an intrusion policy, converting Snort 2 custom rules to Snort 3, and adding rule groups with custom rules to an intrusion policy.

Tuning intrusion rules

Tuning intrusion rules is a configuration process that

- enables rule state modification for shared object rules, standard text rules, and inspector rules,
- controls event generation and traffic processing based on rule configuration, and
- allows filtering of rules to display specific subsets for targeted configuration changes.

Rule state configuration

You enable a rule by setting its rule state to Alert or to Block. Enabling a rule causes the system to generate events on traffic matching the rule. Disabling a rule stops processing of the rule. You can also set your intrusion policy so that a rule set to Block generates events on, and drops, matching traffic.

You can filter rules to display a subset of rules, enabling you to select the exact set of rules where you want to change rule states or rule settings.

When an intrusion rule or rule argument requires a disabled inspector, the system automatically uses it with its current configuration even though it remains disabled in the web user interface (UI) of the network analysis policy.

Note We recommend that you do not modify shared object rules and you only enable or disable these rules for your threat defense device. To create custom Snort rules, contact Cisco support.

Intrusion rule types

An intrusion rule is a specified set of keywords and arguments that the system uses to detect attempts to exploit vulnerabilities in your network. As the system analyzes network traffic, it compares packets against the conditions specified in each rule, and triggers the rule if the data packet meets all the conditions specified in the rule.

- *intrusion rules*, which are subdivided into *shared object rules* and *standard text rules*
- *inspector rules*, which are associated with a detection option of the packet decoder or with one of the inspectors included with the system.

Rule type attributes and characteristics

This table summarizes attributes of these rule types:

Table 151: Intrusion rule types

Type	Generator ID (GID)	Snort ID (SID)	Source	Can Copy?	Can Edit?
shared object rule	3	lower than 1,000,000	Cisco Talos Intelligence Group (Talos)	yes	limited
standard text rule	1 (Global domain or legacy GID)	lower than 1,000,000	Talos	yes	limited
	1,000-2,000 (descendant domain)	1,000,000 or higher	Created or imported by user	yes	yes

Type	Generator ID (GID)	Snort ID (SID)	Source	Can Copy?	Can Edit?
preprocessor rule	decoder- or preprocessor-specific	lower than 1,000,000	Talos	no	no
		1,000,000 or higher	Generated by the system during option configuration	no	no

You cannot save changes to any rule created by Talos, but you can save a copy of a modified rule as a custom rule. You can modify either variables used in the rule or rule header information (such as source and destination ports and IP addresses). In a multidomain deployment, rules created by Talos belong to the Global domain. Administrators in descendant domains can save local copies of the rules, which they can then edit.

For the rules it creates, Talos assigns default rule states in each default intrusion policy. Most preprocessor rules are disabled by default and must be enabled if you want the system to generate events for preprocessor rules and, in an inline deployment, drop offending packets.

Custom rules in Snort 3

A custom rule in Snort 3 is an intrusion detection rule that

- enables users to create custom threat detection by importing local rule files with `.txt` or `.rules` extensions,
- belongs to rule groups and can be included in multiple groups simultaneously, and
- receives a unique rule number in `GID:SID:Rev` format with system-generated identifiers.

Rule number format

When you create a custom intrusion rule, the system assigns it a unique rule number, which has the format `GID:SID:Rev`. The elements of this number are:

- **GID**—Generator ID. For custom rules, it is not necessary to specify the GID. The system automatically generates the GID based on whether you are in the Global domain or a sub-domain while uploading the rules. For all standard text rules, this value is 2000 for a Global domain.
- **SID**—Snort ID. Indicates whether the rule is a local rule of a system rule. When you create a new rule, assign a unique SID to the rule.

  SID numbers for local rules start at 1,000,000, and the SID for each new local rule is incremented by one.
- **Rev**—The revision number. For a new rule, the revision number is one. Each time you modify a custom rule the revision number should be incremented by one.

In a custom standard text rule, you set the rule header settings and the rule keywords and arguments. You can use the rule header settings to focus the rule to only match traffic using a specific protocol and traveling to or from specific IP addresses or ports.

To check whether a SID is enabled or disabled, verify the entries in the snort.lua file located in the `./file-contents/ngfw/var/sf/detection_engines/<ID>/IPS/<ID>` directory.

- If the SID is disabled by default, no entry will be present in the file.

- If the SID is manually enabled, you will see an entry with **enable:yes**.
- If the SID is disabled after being manually enabled, the entry remains in the file and will display **enable:no**.

Note

- Snort 3 custom rules cannot be edited. Ensure that custom rules have a valid classification message for `classtype` within the rule text. If you import a rule without a classification or with an incorrect classification, delete and recreate the rule.
- You can create custom intrusion rules using Snort 3. However, support for tuning and troubleshooting these rules is currently not available.
- The *classtype* in a Snort rule assigns a classification to the rule indicating the type of attack that is associated with an event. A priority level of 1-4 is also associated with each *classtype*. However, the priority level for certain *classtypes* on the Threat Defense device do not match the open-source Snort *classtype* priority levels that are mentioned in the Snort documentation. For example, *tcp-connection* has a priority of 4 in open-source Snort while a priority of 3 is assigned to it on the Threat Defense device.

Sensitive data detection

Sensitive data such as social security numbers, credit card numbers, emails, and so on may be leaked onto the internet, intentionally or accidentally. Sensitive data detection is used to detect and generate events on possible sensitive data leakage. Events are generated only when a significant amount of Personally Identifiable Information (PII) is transferred. Sensitive data detection can mask PII in the output of events.

Use the `sd_pattern` IPS option to detect and filter PII. This information includes credit card numbers, U.S. Social Security numbers, phone numbers, and email addresses. A regular expression (regex) syntax is available for defining your own PII.

The sd_pattern option has the following settings:

- Pattern—An implicit, required setting that specifies the regular expression to look for in the PDU. The regex must be written in PCRE syntax.
- Threshold—An explicit, optional setting that specifies the number of matches in the PDU required to generate an event.

  The `sd_pattern` as IPS rule option is available in Snort with no requirements for additional inspectors. The syntax for the rule option is:

  ```
  sd_pattern: "<pattern>"[, threshold <count>];
  ```

  For example:

  ```
  sd_pattern:"credit_card", threshold 2;
  ```

There are five built-in patterns for sensitive data. To use the built-in patterns in the "pattern" setting, you must specify the name of the PII type that needs to be matched and the necessary regex is substituted for it. The PII name and regex mappings or patterns are described here:

Table 152: Built-in patterns

PII Name	Pattern
credit_card	`\d{4}\D?\d{4}\D?\d{2}\D?\d{2}\D?\d{3,4}`

PII Name	Pattern
us_social	`[0-8]\d{2}-\d{2}-\d{4}`
us_social_nodashes	`[0-8]\d{8}`
Email	`[a-zA-Z0-9!#$%&'*+\/=?^_`{\|}~-]+(?:\.[a-zA-Z0-9!#$%&'*+\/=?^_`{|}~-]+)*@(?:[a-zA-Z0-9](?:[a-zA-Z0-9-]*[a-zA-Z0-9])?\.)+[a-zA-Z0-9](?:[a-zA-Z0-9-]*[a-zA-Z0-9])?`
us_phone	`(?:\+?1[-\.\s]?)?\(?([2-9][0-8]\d)\)?[-\.\s]([2-9]\d{2})[-\.\s](\d{4})`

Masking for data matching these patterns only work with system-provided rules or built-in patterns for Credit Cards, U.S. Social Security numbers, emails, and U.S. phone numbers. Masking does not work for custom rules or user-defined PII patterns. Rules are available in the Lightweight Security Package (LSP) for sensitive data, gid:13. By default, they are not enabled in any system-provided policy.

The sensitive data rules in LSP cover all built-in patterns and have the following threshold values:

- credit_card: 2
- us_social: 2
- us_social_nodashes: 20
- email: 20
- us_phone: 20

You can use the sd_pattern option to create custom rules and modify existing rules. To do this, use the Snort 3 intrusion policy interface.

An example of a rule with sd_pattern with a custom pattern and threshold:

alert tcp (sid: 1000000001; sd_pattern:"[\w-\.]+@([\w-]+\.)+[\w-]{2,4}",threshold 4; msg: "email, threshold 4")

Examples

An example of custom rules using sensitive data detection:

Rule with built-in pattern

```
alert tcp (
        msg:"SENSITIVE-DATA Email";
        flow:only_stream;
        pkt_data;
        sd_pattern:"email", threshold 5;
        service:http, smtp, ftp-data, imap, pop3;
        gid:2000;
        sid:1000001;
)
```

Rule with custom pattern

```
alert tcp (
        msg:"SENSITIVE-DATA US phone numbers";
        flow:only_stream;
        file_data;
        sd_pattern:"+?3?8?(0[\s\.-]\d{2}[\s\.-]\d{3}[\s\.-]\d{2}[\s\.-]\d{2})", threshold
2;
        service:http, smtp, ftp-data, imap, pop3;
```

```
        gid:2000;
        sid:1000002;
)
```

Here are some more examples of complete Snort IPS rules with built-in sensitive data patterns:

- alert tcp (sid:1; msg:"Credit Card"; sd_pattern:"credit_card", threshold 2;)
- alert tcp (sid:2; msg:"US Social Number"; sd_pattern:"us_social", threshold 2;)
- alert tcp (sid:3; msg:"US Social Number No Dashes"; sd_pattern:"us_social_nodashes", threshold 2;)
- alert tcp (sid:4; msg:"US Phone Number"; sd_pattern:"us_phone", threshold 2;)
- alert tcp (sid:5; msg:"Email"; sd_pattern:"email", threshold 2;)

Disabling data masking is not supported in the Secure Firewall Management Center, and Secure Firewall Device Manager.

For information on how to add custom rules to rule groups, see Add custom rules to rule groups, on page 2846.

View Snort 3 intrusion rules in an intrusion policy

This task allows you to view and interact with Snort 3 intrusion rules within an intrusion policy, enabling you to manage rule display settings and access detailed rule information.

You can adjust how rules are displayed in the intrusion policy. You can also display the details for a specific rule to see rule settings, rule documentation, and other rule specifics.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click **Snort 3 Version** next to the policy.

Step 3 While viewing the rules, you can:

- Filter the rules.
- Choose a rule group to see rules related to that group.
- View an intrusion rule's details.
- View rule comments.
- View rule documentation.

See Edit Snort 3 Intrusion Policies, on page 2821 for details on performing these tasks.

Intrusion rule actions

An intrusion rule action is a policy configuration mechanism that

- enables or disables rules within individual intrusion policies,
- specifies which action the system takes if monitored conditions trigger the rule, and
- inherits default actions from the base policy used during intrusion policy creation.

Default action behavior

The Cisco Talos Intelligence Group (Talos) sets the default action of each intrusion and inspector rule in each default policy. For example, a rule may be enabled in the Security over Connectivity default policy and disabled in the Connectivity over Security default policy. Talos sometimes uses a rule update to change the default action of one or more rules in a default policy. If you allow rule updates to update your base policy, you also allow the rule update to change the default action of a rule in your policy when the default action changes in the default policy you used to create your policy (or in the default policy it is based on). Note, however, that if you have changed the rule action, the rule update does not override your change.

When you create an intrusion rule, it inherits the default actions of the rules in the default policy you use to create your policy.

Intrusion rule action options

In an intrusion policy, you can set a rule's action to specific values that determine how the system responds to matching traffic.

Alert

You want the system to detect a specific intrusion attempt and generate an intrusion event when it finds matching traffic. When a malicious packet crosses your network and triggers the rule, the packet is sent to its destination and the system generates an intrusion event. The malicious packet reaches its target, but you are notified through the event logging.

Block

You want the system to detect a specific intrusion attempt, drop the packet containing the attack, and generate an intrusion event when it finds matching traffic. The malicious packet never reaches its target, and you are notified through the event logging.

Disable

You do not want the system to evaluate matching traffic.

Note Choosing either the **Alert** or **Block** options enables the rule. Choosing **Disable** disables the rule.

We strongly recommend that you **do not** enable all the intrusion rules in an intrusion policy. The performance of your managed device is likely to degrade if all rules are enabled. Instead, tune your rule set to match your network environment as closely as possible.

Set intrusion rule action

Set intrusion rule actions to control how the system responds to detected threats, allowing you to configure rules to alert on or block specific intrusion attempts.

Intrusion rule actions are policy-specific.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click **Snort 3 Version** next to the policy you want to edit.

Tip
This page shows the total number of:

- disabled rules
- enabled rules set to Alert
- enabled rules set to Block
- overridden rules

Step 3 Choose the rule or rules where you want to set the rule action.

Step 4 Choose one of the rule actions from the **Rule Action** drop-down list. See Edit Snort 3 Intrusion Policies, on page 2821 for more information about the different rule actions.

Step 5 Click **Save**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Intrusion event notification filters in an intrusion policy

An intrusion event notification filter in an intrusion policy is a security mechanism that

- determines event importance based on frequency of occurrence or source and destination IP addresses,
- allows administrators to specify thresholds for when events require attention, and
- prevents system overwhelm by limiting notifications for widespread attacks.

Event notification filtering scenarios

The importance of an intrusion event can be based on frequency of occurrence, or on source or destination IP address. In some cases you may not care about an event until it has occurred a certain number of times. For example, you may not be concerned if someone attempts to log into a server until they fail a certain number of times. In other cases, you may only need to see a few occurrences to know there is a widespread problem. For example, if a DoS attack is launched against your web server, you may only need to see a few occurrences of an intrusion event to know that you need to address the situation. Your system is overwhelmed when it receives hundreds of the same event.

Intrusion event thresholds

An intrusion event threshold is a configuration setting that

- limits the number of times the system logs and displays an intrusion event based on how many times the event is generated within a specified time period,
- prevents you from being overwhelmed with a large number of identical events, and
- can be set per shared object rule, standard text rule, or inspector rule.

Set intrusion event thresholds

To set a threshold, first specify the thresholding type.

Table 153: Thresholding options

Option	Description
Limit	Logs and displays events for the specified number of packets (specified by the Count argument) that trigger the rule during the specified time period. For example, if you set the type to **Limit**, the **Count** to `10`, and the **Seconds** to `60`, and 14 packets trigger the rule, the system stops logging events for the rule after displaying the first 10 that occur within the same minute.
Threshold	Logs and displays a single event when the specified number of packets (specified by the Count argument) trigger the rule during the specified time period. Note that the counter for the time restarts after you hit the threshold count of events and the system logs that event. For example, you set the type to **Threshold**, **Count** to `10`, and **Seconds** to `60`, and the rule triggers 10 times by second 33. The system generates one event, then resets the Seconds and Count counters to 0. The rule then triggers another 10 times in the next 25 seconds. Because the counters reset to 0 at second 33, the system logs another event.
Both	Logs and displays an event once per specified time period, after the specified number (count) of packets trigger the rule. For example, if you set the type to **Both**, **Count** to two, and **Seconds** to `10`, these event counts result: • If the rule is triggered once in 10 seconds, the system does not generate any events (the threshold is not met) • If the rule is triggered twice in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time) • If the rule is triggered four times in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time, and subsequent events are ignored)

Secondly, specify tracking, which determines whether the event threshold is calculated per source or destination IP address.

Table 154: Thresholding IP options

Option	Description
Source	Calculates event instance count per source IP address.
Destination	Calculates event instance count per destination IP address.

Finally, specify the number of instances and time period that define the threshold.

Table 155: Thresholding Instance/Time options

Option	Description
Count	The number of event instances per specified time period per tracking IP address required to meet the threshold.

Option	Description
Seconds	The number of seconds that elapse before the count resets. If you set the threshold type to **limit**, the tracking to **Source IP**, the **count** to `10`, and the **seconds** to `10`, the system logs and displays the first 10 events that occur in 10 seconds from a given source port. If only 7 events occur in the first 10 seconds, the system logs and displays those; if 40 events occur in the first 10 seconds, the system logs and displays 10, then begins counting again when the 10-second time period elapses.

You can use intrusion event thresholding alone or combine it with rate-based attack prevention, the `detection_filter` keyword, or intrusion event suppression.

Tip You can also add thresholds from within the packet view of an intrusion event.

Set threshold for an intrusion rule in snort 3

Set a threshold for an intrusion rule to control when and how often alerts are generated based on event instances within a specified time period.

You can set a single threshold for a rule from the Rule Detail window. Adding a threshold overwrites any existing threshold for the rule. The threshold you set for an intrusion rule is applied to each packet thread. However, the configuration is fully applied only within the context of a unique flow. You might see more alerts on different network flows, but you will not see fewer alerts than the configured number.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 From an intrusion rule's Alert Configuration column, click the **None** link.

Step 4 Click **Edit** ( ).

Step 5 In the Alert Configuration window, click the **Threshold** tab.

Step 6 From the **Type** drop-down list, choose the type of threshold you want to set:

- Choose **Limit** to limit notification to the specified number of event instances per time period.
- Choose **Threshold** to provide notification for each specified number of event instances per time period.
- Choose **Both** to provide notification once per time period after a specified number of event instances.

Step 7 Choose **Source** or **Destination** in the **Track By** field to indicate whether you want the event instances tracked by source or destination IP address.

Step 8 Enter the number of event instances you want to use as your threshold in the **Count** field.

Step 9 Enter a number that specifies the time period, in seconds, for which event instances are tracked in the **Seconds** field.

Step 10 Click **Save**.

Refer to the video Snort 3 Suppression and Threshold for additional support and information.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 202.

View and delete intrusion event thresholds

This task allows you to view existing threshold settings for intrusion rules and delete them when they are no longer appropriate for your system configuration.

To view or delete an existing threshold setting for a rule, use the Rules Details view to display the configured settings for a threshold and see if they are appropriate for your system. If they are not, you can add a new threshold to overwrite the existing values.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Choose the rule with a configured threshold as shown in the **Alert Configuration** column (the **Alert Configuration** column displays **Threshold** as a link for the rule).

Step 4 To remove the threshold for the rule, click **Threshold** link in the **Alert Configuration** column.

Step 5 Click **Edit** ( ).

Step 6 Click **Threshold** tab.

Step 7 Click **Reset**.

Step 8 Click **Save**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Intrusion policy suppression configuration

Intrusion policy suppression configuration is a security mechanism that

- suppresses intrusion event notification when a specific IP address or range of IP addresses triggers a specific rule or inspector,
- eliminates false positives by allowing rules to trigger for all packets while only showing events for legitimate attacks, and
- is useful for scenarios such as mail servers that transmit packets resembling specific exploits.

Mail server suppression example

If you have a mail server that transmits packets that look like a specific exploit, you might suppress event notification for that event when it is triggered by your mail server. The rule triggers for all packets, but you only see events for legitimate attacks.

Intrusion policy suppression types

You can use intrusion event suppression alone or in any combination with rate-based attack prevention, the `detection_filter` keyword, or intrusion event thresholding.

Tip You can add suppressions from within the packet view of an intrusion event. You can also access suppression settings by using the **Alert Configuration** column on the intrusion rules editor page (**Objects** > **Intrusion Rules**, click **Snort 3 All Rules**).

Set suppression for an intrusion rule in Snort 3

This task allows you to configure one or more suppressions for a rule in your intrusion policy to reduce false positives and focus on relevant security events.

You can set one or more suppressions for a rule in your intrusion policy.

Before you begin

Ensure you create the required network objects to be added for source or destination suppression.

Follow these steps to set suppression for an intrusion rule in Snort 3:

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Click the **None** link in the Alert Configuration column for the intrusion rule.

Step 4 Click **Edit** ( ).

Step 5 From the **Suppressions** tab, click the add icon **Add** ( ) next to any of these options:

- Choose **Source Networks** to suppress events generated by packets originating from a specified source IP address.
- Choose **Destination Networks** to suppress events generated by packets going to a specified destination IP address.

Step 6 Select any of the preset networks in the **Network** drop-down list.

Step 7 Click **Save**.

Step 8 (Optional) Repeat steps 5, 6, and 7 if needed.

Step 9 Click **Save** in the Alert Configuration window.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

View and delete suppression conditions

View or delete existing suppression conditions to manage event notifications for specific network conditions.

You may want to view or delete an existing suppression condition. For example, you can suppress event notification for packets originating from a mail server IP address because the mail server normally transmits packets that look like exploits. If you then decommission that mail server and reassign the IP address to another host, you should delete the suppression conditions for that source IP address.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Choose the rule for which you want to view or delete suppressions.

Step 4 Click **Suppression** in the **Alert Configuration** column.

Step 5 Click **Edit** ( ).

Step 6 Click **Suppressions** tab.

Step 7 Remove the suppression by clicking **Clear** ( ) next to the suppression.

Step 8 Click **Save**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Add intrusion rule comments

Add comments to rules in your intrusion policy for documentation and management purposes.

You can add comments to rules in your intrusion policy. Comments added this way are specific to the policy. Comments you add to a rule in one intrusion policy are not visible in other intrusion policies.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click **Snort 3 Version** next to the policy you want to edit.

Step 3 In the right side of the page where all the rules are listed, choose the rule where you want to add a comment.

Step 4 Click **Comment** ( ) under the **Comments** column.

Step 5 In the **Comments** field, enter the rule comment.

Step 6 Click **Add Comment**.

Step 7 Click **Save**.

The system displays a **Comment** ( ) next to the rule in the Comments column.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Prepare custom rules for snort 3 conversion

Before converting from Snort 2 to Snort 3, make sure you are prepared to manage your custom rule set for Snort 3.

- If you are using a rule set from a third-party vendor, contact that vendor to confirm that their rules will successfully convert to Snort 3 or to obtain a replacement rule set written natively for Snort 3.
- If you have custom rules that you have written yourself, familiarize yourself with writing Snort 3 rules before converting, so you can update your rules to optimize Snort 3 detection after conversion.

Learn more about writing rules in Snort 3:

- https://blog.snort.org/2020/08/how-rules-are-improving-in-snort-3.html
- https://blog.snort.org/2020/10/talos-transition-to-snort-3.html

You can refer to other blogs at https://blog.snort.org/ to learn more about Snort 3 rules.

Important Snort 2 network analysis policy (NAP) settings *cannot* be copied to Snort 3 automatically. NAP settings must be manually replicated in Snort 3.

Convert all Snort 2 custom rules across all intrusion policies to Snort 3

Convert legacy Snort 2 custom rules to the updated Snort 3 format to ensure compatibility with current intrusion detection systems.

This task migrates existing Snort 2 custom rules to Snort 3 format, allowing you to maintain your custom rule configurations while upgrading to the latest intrusion detection engine. You can either import the converted rules directly or download them for review before importing.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Ensure **All Rules** is selected in the left pane.

Step 4 Click the **Tasks** drop-down list and choose:

- **Convert Snort 2 rules and import**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.
- **Convert Snort 2 rules and download**—To automatically convert all the Snort 2 custom rules across all the intrusion policies to Snort 3 and download them into your local system.

Step 5 Click **OK**.

Note

- If you selected **Convert and import** in the previous step, then all the converted rules are saved under a newly created rule group **All Snort 2 Converted Global** under **Local Rules**.
- If you selected **Convert and download** in the previous step, then save the rules file locally. You can review the converted rules in the downloaded file and later upload them by following the steps in Add custom rules to rule groups, on page 2846.

Refer to the video Converting Snort 2 Rules to Snort 3 for additional support and information.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Convert Snort 2 custom rules of a single intrusion policy to Snort 3

Convert Snort 2 custom rules in an intrusion policy to Snort 3 format to maintain compatibility with Snort 3 environments.

When migrating to Snort 3, existing Snort 2 custom rules need to be converted to maintain their functionality. This task allows you to convert custom rules for a specific intrusion policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click **Show Snort 3 Sync status**.

Step 3 Click the **Sync** icon **Snort out-of-Sync** ( ) of the intrusion policy.

Note

If the Snort 2 and the Snort 3 versions of the intrusion policy are synchronized, then the **Sync** icon is in green**Snort in-Sync** ( ). It indicates that there are no custom rules to be converted.

Step 4 Read the summary and click the **Custom Rules** tab.

Step 5 Choose:

- **Import converted rules to this policy**: To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and import them into Firewall Management Center as Snort 3 custom rules.

- **Download converted rules**: To convert the Snort 2 custom rules in the intrusion policy to Snort 3 and download them into your local system. You can review the converted rules in the downloaded file and later upload the file by clicking the upload icon.

Step 6 Click **Re-Sync**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Add custom rules to rule groups

Upload custom rules to add locally created Snort 3 rules to the list of all available rules in the system.

Uploading custom rules in the Firewall Management Center adds the custom rules that you have created locally to the list of all the Snort 3 rules.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Click the **Tasks** drop-down list.

Step 4 Click **Upload Snort 3 Rules**.

Step 5 Drag and drop the `.txt` or `.rules` file that contains the Snort 3 custom rules that you have created.

Step 6 Click **OK**.

Note
If there are any errors in the selected file, then you cannot proceed further. You can download the error file and **Replace File** link to upload version 2 of the file, after fixing the errors.

Step 7 Associate rules to a rule group to add the new rules to that group.

You can also create a new custom rule group (by clicking the **Create New Custom Rule Group** link) and then add the rules to the new group.

Note
If there are no existing local rule groups, then proceed by clicking **Create New Custom Rule Group to proceed**. Enter a **Name** for the new rule group and click **Save**.

Step 8 Choose either of these options:

- **Merge Rules** to merge the new rules that you are adding with the existing rules in the rule group.
- **Replace all rules in the group with file contents** to replace all the existing rules with the new rules that you are adding.

Note
If you chose more than one rule group in the previous step, then only the **Merge Rules** option is available.

Step 9 Click **Next**.

Review the summary to know the new rule IDs that are being added and optionally download it.

Step 10 Click **Finish**.

Important All uploaded rules are disabled by default. Change their state as needed to ensure the rules are active.

What to do next

- Uploading custom rules in the Firewall Management Center adds the custom rules that you have created to the list of all the Snort 3 rules. To enforce these custom rules on the traffic, add and enable these rules in the required intrusion policies. For information on adding rule groups with custom rules to an intrusion policy, see Add rule groups with custom rules to an intrusion policy, on page 2847. For information on enabling custom rules, see Manage custom rules in Snort 3, on page 2847.
- Deploy configuration changes. See Deploy configuration changes, on page 2806.

Add rule groups with custom rules to an intrusion policy

Enable custom rules in an intrusion policy to enforce these rules on network traffic.

Custom rules that are uploaded in the system have to be enabled in an intrusion policy to enforce those rules on the traffic. After uploading custom rules on Firewall Management Center, add the rule group with the new custom rules in the intrusion policy.

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 In the **Intrusion Policies** tab, click the **Snort 3 Version** of the intrusion policy.

Step 3 Click **Add** (+) next to the Rule Groups search bar.

Step 4 In the **Add Rule Groups** window, click the **Expand Arrow** (›) icon next to a rule group to expand the local rule group.

Step 5 Check the check box next to the uploaded custom rules group.

Step 6 Click **Save**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Manage custom rules in Snort 3

This task enables uploaded custom rules in intrusion policies to enforce rule monitoring on network traffic.

Custom rules that are uploaded in the system have to be added to an intrusion policy and enabled to enforce those rules on the traffic. You can enable the uploaded custom rules across all policies or selectively on individual policies.

Before you begin

Follow these steps to enable custom rules in one or many intrusion policies:

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Expand **Local Rules**.

Step 4 Select the required rule group.

Step 5 Select the rules by checking the check boxes next to them.

Step 6 Select **Per Intrusion Policy** from the **Rule Actions** drop-down list.

Step 7 Choose:

- **All Policies** to have the same rule actions for all the rules to be added.
- **Per Intrusion Policy** to have different rule actions for each intrusion policy.

Step 8 Set the rule actions:

- If you selected All Policies in the previous step, then select the required rule action from the **Select Override state** drop-down list.
- If you selected Per Intrusion Policy in the previous step, then select the **Rule Action** against the policy name. To add more policies, click **Add Another**.

Step 9 Optionally, add a comment in the **Comments** text box.

Step 10 Click **Save**.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Delete custom rules

Delete custom rules that are no longer needed from your intrusion rule configuration to maintain an organized and efficient rule set.

Use this procedure when you need to remove custom rules from the Local Rules section in the Snort 3 All Rules interface. Before deletion, all rules must be disabled to prevent configuration conflicts.

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Expand **Local Rules** in the left pane.

Step 4 Check the check boxes of the rules you want to delete.

Step 5 Ensure that the rule action for all the rules that you select is **Disable**.

If required, follow these steps to disable the rule action for multiple selected rules:

a) From the **Rule Actions** drop-down box, select **Per Intrusion Policy**.
b) Select **All Policies** radio button.
c) Select **Disable** from the **Select Override state** drop-down list.
d) Click **Save**.
e) Check the check boxes of the rules you want to delete.

Step 6 From the **Rule Actions** drop-down list, select **Delete**.

Step 7 Click **Delete** in the Delete Rules pop-up window.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Delete rule groups

Delete rule groups to remove unwanted or obsolete intrusion detection rules from your system configuration and maintain an organized rule structure.

Before deleting a rule group, you must exclude it from all intrusion policies and disable all rules within the group to prevent system conflicts.

Before you begin

Exclude the rule group you want to delete from all intrusion policies where you have included it. For steps on excluding a rule group from an intrusion policy, see Edit Snort 3 Intrusion Policies, on page 2821.

Follow these steps to delete rule groups:

Procedure

Step 1 Choose **Objects** > **Intrusion Rules**.

Step 2 Click **Snort 3 All Rules** tab.

Step 3 Expand **Local Rules** in the left pane.

Step 4 Select the rule group to be deleted.

Step 5 Ensure the rule action for all the rules in the group is set to **Disable** before proceeding.

If the rule action for any of the rules is anything other than **Disable**, then you cannot delete the rule group. If required, follow the steps below to disable the rule action for all the rules:

a) Check the check box below the **Rule Actions** drop-down list to select all the rules in the group.
b) From the **Rule Actions** drop-down box, select **Per Intrusion Policy**.
c) Select **All Policies** radio button.
d) Select **Disable** from the **Select Override state** drop-down list.
e) Click **Save**.

Step 6 Click the **Delete** ( ) next to the rule group.

Step 7 Click **OK** in the Delete Rule Group pop-up window.

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Recommended rules

This section provides an insight into Secure Firewall recommended rules and generating and applying Secure Firewall recommended rules.

Snort 3 rule changes in LSP updates

Snort 3 rule changes in LSP updates are modifications to system-defined intrusion rules that

- replace existing rules with new rules for better detection capabilities,
- combine multiple rules into a single rule or expand a single rule into multiple rules when better detection is possible, and
- remove existing system-defined rules for better management as part of the LSP update.

To get notifications for changes to any *overridden* system-defined rules during LSP updates, ensure that the **Retain user overrides for deleted Snort 3 rules** check box is checked.

To navigate to the **Retain user overrides for deleted Snort 3 rules** check box, click **System** ( ) > **Configuration** > **Intrusion Policy Preferences**.

By default this check box is checked. When this check box is checked, the system retains the rule overrides in the new replacement rules that are added as a part of the LSP update. The notifications are shown in the **Tasks** tab under the Notifications icon that is located next to **System** ( ).

Secure Firewall recommended rules

Secure Firewall recommended rules are intrusion rule recommendations that

- target vulnerabilities associated with host assets detected in the network, such as operating systems, servers, and client application protocols,
- allow you to tailor your intrusion policy to the specific needs of your monitored network, and

- provide individual recommendations for each intrusion policy. These typically apply to standard text rules and shared object rules, but recommendations can also include inspector and decoder rules.

Rule recommendation configuration options

When you generate rule state recommendations, you can use the default settings or configure advanced settings. Advanced settings allow you to:

- Redefine which hosts on your network the system monitors for vulnerabilities
- Influence which rules the system recommends based on rule overhead
- Specify whether to generate recommendations to disable rules

You can also choose to use the recommendations immediately or review the recommendations (and affected rules) before accepting them.

Choosing to use recommended rule states adds a read-only Secure Firewall Recommendations layer to your intrusion policy, and subsequently choosing not to use recommended rule states removes the layer.

You can schedule a task to generate recommendations automatically based on the most recently saved configuration settings in your intrusion policy.

The system does not change rule states that you set manually such as:

- Manually setting the states of specified rules *before* you generate recommendations prevents the system from modifying the states of those rules in the future.
- Manually setting the states of specified rules *after* you generate recommendations overrides the recommended states of those rules.

Tip The intrusion policy report can include a list of rules with rule states that differ from the recommended state.

While displaying the recommendation-filtered Rules page, or after accessing the Rules page directly from the navigation panel or the Policy Information page, you can manually set rule states, sort rules, and take any of the other actions available on the Rules page, such as suppressing rules, setting rule thresholds, and so on.

Note The Cisco Talos Intelligence Group (Talos) determines the appropriate state of each rule in the system-provided policies. If you use a system-provided policy as your base policy, and you allow the system to set your rules to the Secure Firewall recommended rule state, the rules in your intrusion policy match the settings recommended for your network assets.

Generate new Secure Firewall recommendations in Snort 3

Generate Secure Firewall recommendations to create new recommended rule settings in Snort 3.

Generate the Secure Firewall recommendations for the intrusion policy and then follow the steps that are listed here to create new recommended rule settings in Snort 3. Rule overheads are interpreted as **security levels**

based on the threshold policies you select in Snort 3. The recommended action depends on the selected security level. If it is higher than the base policy, the recommendation includes actions beyond only generating events.

Prior to setting the Secure Firewall recommendations you should ask which of the three points listed below closely matches the goal:

- Increased Protection —Enable additional rules based on vulnerabilities found in the host database and do not automatically disable any rules. This will likely result in a larger rule set.
- Focused Protection—Enable additional rules and disable existing rules based on vulnerabilities found in the host database. This can increase or decrease the number of rules depending on vulnerabilities discovered.
- Higher Efficiency—Use the currently enabled rule set and disable any rules for vulnerabilities not found in the host database. This will likely result in a smaller enabled rule set.

Based on the response, these are the recommended actions:

- Set recommendations to the next highest security level, and clear the option to disable rules.
- Set recommendations to the next highest security level, and select the option to disable rules.
- Set recommendations to the current security level, and select the option to disable rules.

Before you begin

Secure Firewall recommendations have the following requirements:

- Ensure that hosts are present in the system to generate recommendations.
- Protected networks configured for recommendations should map to the hosts present in the system

Follow these steps to generate new Secure Firewall recommendations in Snort 3:

Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click the **Snort 3 Version** button of the intrusion policy.

Step 3 Click the **Recommendations (Not in Use)** layer to configure the rule recommendations. Click **Start**.

In the Secure Firewall Rule Recommendations window you can set the following:

- **Security Level**: Click to select the security level. Optionally, you can check the **Accept Recommendation to Disable Rules** checkbox to disable rules that are not enabled at the input security level and in protected networks. Only enable this option if you need to trim your rule set due to a high number of alerts or to improve inspection performance. The security levels are:
  - Security level 1: Connectivity Over Security

    No Impact—No new rules are enabled and no existing rules are disabled. To increase the protection, select a higher security level.

    Lower Security (checkbox is checked)—All rules are disabled except for the rules in the Connectivity Over Security ruleset that match potential vulnerabilities on discovered hosts. It is recommended instead to adjust the Base Policy.

- Security level 2: Balanced Security Over Connectivity

  No Impact—No new rules are enabled and no existing rules are disabled. To increase the protection, select a higher security level.

  Higher Efficiency(checkbox is checked)—Keeps existing rules that match potential vulnerabilities on discovered hosts and disables rules for vulnerabilities not found on the network.

- Security level 3: Security Over Connectivity

  Increased Security—Enables additional rules that match potential vulnerabilities on discovered hosts based on the Maximum Detection ruleset.

  Focused Security(checkbox is checked)—Enables additional rules that match vulnerabilities on discovered hosts based on the Security Over Connectivity ruleset, while disabling existing rules that do not match potential vulnerabilities on discovered hosts.

- Security level 4 : Maximum Detection

  Increased Security—Enables additional rules that match potential vulnerabilities on discovered hosts based on the Security Over Connectivity ruleset.

  Focused Security (checkbox is checked)—Enables additional rules that match vulnerabilities on discovered hosts based on the Maximum Detection ruleset, while disabling existing rules that do not match potential vulnerabilities on discovered hosts.

  Note
  Maximum Detection enables a very high number of rules and may impact performance. We recommend you to review and test this setting before deploying into a production environment.

- **Protected Networks**: Specifies the monitored networks or individual hosts to examine for recommendations. You can select one or more system or custom defined network objects from the drop-down list. By default, any IPv4 or IPv6 networks are selected, if no selection is done.

  Important
  The Secure Firewall Rule Recommendations depend on network discovery. Protected Networks apply to any hosts discovered within the ranges configured in your Network Discovery policy. For more information, see the chapter Network Discovery Policies in the *Cisco Secure Firewall Management Center Device Configuration guide*.

  Click the **Add +** button to create a new network object of type Host or Network and click **Save**.

Step 4 Generate and apply recommendations:

- **Generate**: Generates the recommendations for an intrusion policy. This action lists the rules under Recommended Rules (Not in use).
- **Generate and Apply**: Generates and applies the recommendations for an intrusion policy. This action lists the rules under Recommended Rules (In use).

Recommendations are generated successfully. A new recommendation tab appears with all the recommended rules with their corresponding recommended actions. Rule action preset filters are also available for this tab, in addition with new recommendations.

Step 5 You can verify the recommendations and choose to apply them.

- **Accept**—Applies the previously generated recommendations for an Intrusion policy.

- **Refresh**—Regenerates and updates the rule recommendations for an Intrusion policy.
- **Edit**—It opens the Recommendations dialog box, you can provide the recommendation input values and then generate the recommendations.
- **Remove All**—Revert or remove the applied recommended rules from the policy and also removes the recommendation tab.

Under **All Rules**, there is a Recommended Rules section which displays the recommended rules.

Note
Final action for an Intrusion rule is applied based on the rule action priority order and following is the rule action priority order:

Rule Override > Generated Recommendations > Group Override > Base Policy Default Action

For enabled recommendations, Firewall Management Center considers the current state: group overrides, base policy, and recommendation configurations and priority order of actions is:

pass > block > reject > drop > rewrite > alert

What to do next

Deploy configuration changes. See Deploy configuration changes, on page 2806.

Mitigate threats using MITRE framework in Snort 3 intrusion policies

This section describes how to use the MITRE ATT&CK framework in Snort 3 intrusion policies to identify attack tactics and techniques, review rule coverage, and improve threat mitigation.

MITRE framework

The MITRE Adversarial Tactics, Techniques, and Common Knowledge (ATT&CK) framework is a comprehensive knowledge base that

- provides insights into the tactics, techniques, and procedures (TTPs) distributed by threat actors aiming to harm systems,
- incorporates groups to refer to threat groups, activity groups, or threat actors based on the set of tactics and techniques they employ, and
- is compiled as matrices, with each matrix representing an operating system or a particular platform.

Each technique includes information about execution, procedures, defenses, detections, and real-world examples.

Note See https://attack.MITRE.org for additional information about MITRE ATT&CK.

The management center uses the MITRE ATT&CK Framework to enhance threat detection and response, incorporating these capabilities:

- Intrusion events include TTPs, allowing administrators to manage traffic with greater granularity by grouping rules according to vulnerability type, target system, or threat category.
- Select malware events use TTPs, enhancing the ability to detect and respond to threats.

MITRE framework benefits

MITRE framework provides security advantages that

- enable administrators to act on traffic based on MITRE Tactics, Techniques, and Procedures (TTPs) added to intrusion events,
- allow viewing and handling traffic with more granularity through grouping rules by vulnerability type, target system, or threat category, and
- provide the ability to organize intrusion rules according to the MITRE ATT&CK framework for customized policies based on specific attacker tactics and techniques.

Sample business scenario for MITRE network

A sample business scenario for MITRE network is a security implementation example that

- uses Snort 3 as the primary intrusion detection and prevention system for a large corporate network,
- addresses the need for robust network security measures in a rapidly evolving threat landscape, and
- enables network administrators to determine if configured policies are finding traffic of interest and tracking known attack groups.

Network security considerations

Network administrators need to know if adversaries are attempting to take advantage of weaknesses in their systems or applications to cause unanticipated behavior. The weakness in the system can be a bug, a glitch, or a design vulnerability. The applications may be websites, databases, standard services, such as Server Message Block (SMB) or Secure Shell (SSH), network device administration and management protocols or applications, such as web servers and related services.

The insights provided by the MITRE framework provide administrators with a more precise opportunity to specify protection for specific assets and protect their network from specific threat groups.

Prerequisites for MITRE framework

Ensure that your system meets these requirements before implementing the MITRE framework:

- You must be running Secure Firewall Management Center and Secure Firewall Threat Defense Version 7.3.0 or later with Snort 3.
- You must have at least one intrusion policy. See Create a custom snort 3 intrusion policy, on page 2820.

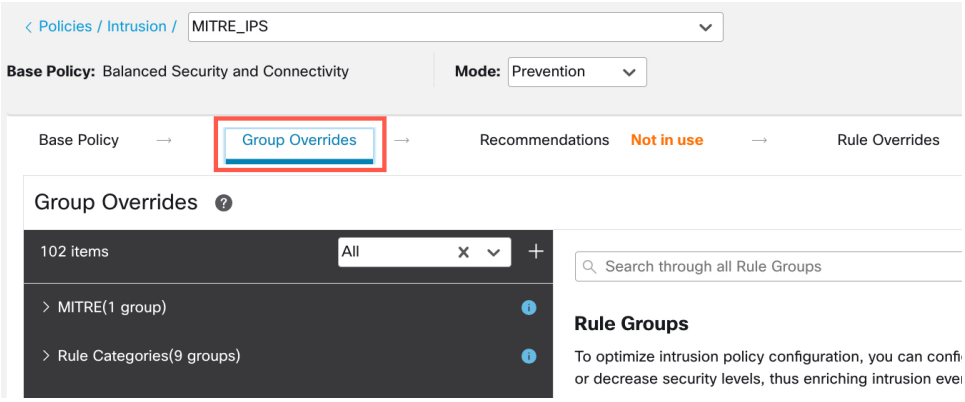
View and edit your Snort 3 intrusion policy

This task allows you to customize your Snort 3 intrusion policy by modifying rule groups, security levels, and accessing Cisco-recommended rules to enhance threat detection capabilities.

Snort 3 intrusion policies use a hierarchical rule group structure organized by the MITRE framework. You can drill down to specific rule categories and modify security levels for bulk changes or individual rule actions. The policy editor provides multiple layers, including Group Overrides, Rule Overrides, Recommendations, and Summary views.

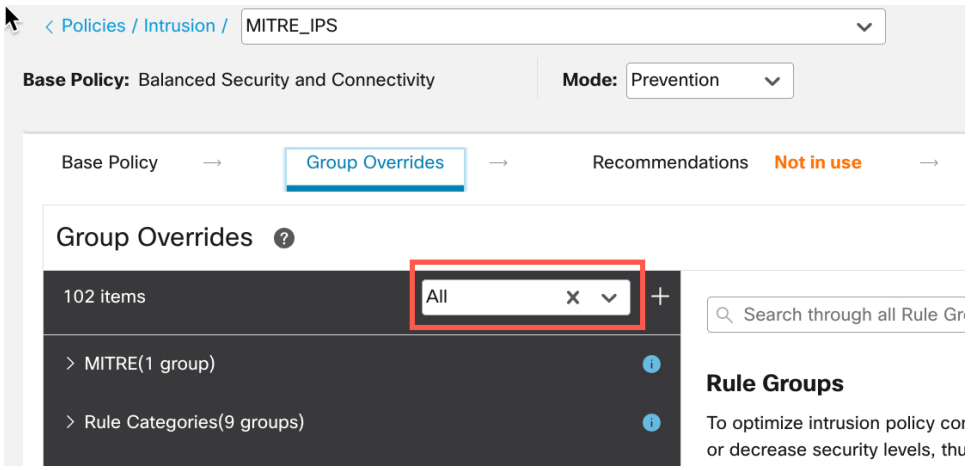
Procedure

Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.



Step 2 Ensure that the **Intrusion Policies** tab is chosen.

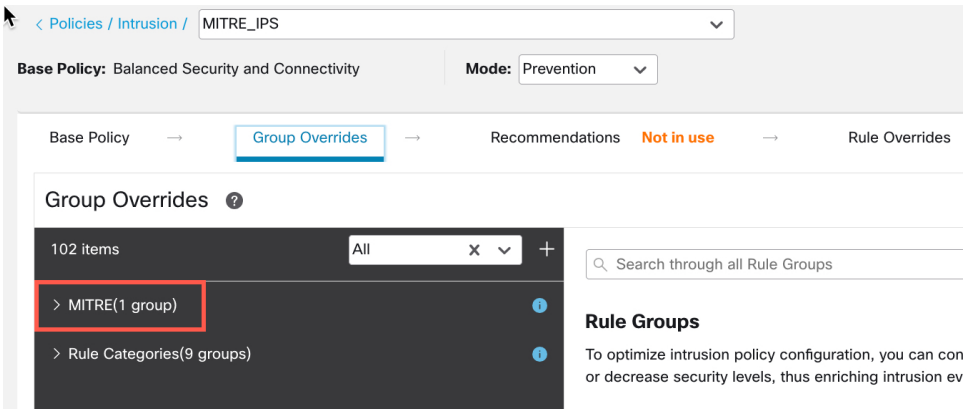
a) Click **Snort 3 Version** next to the intrusion policy that you want to view or edit.



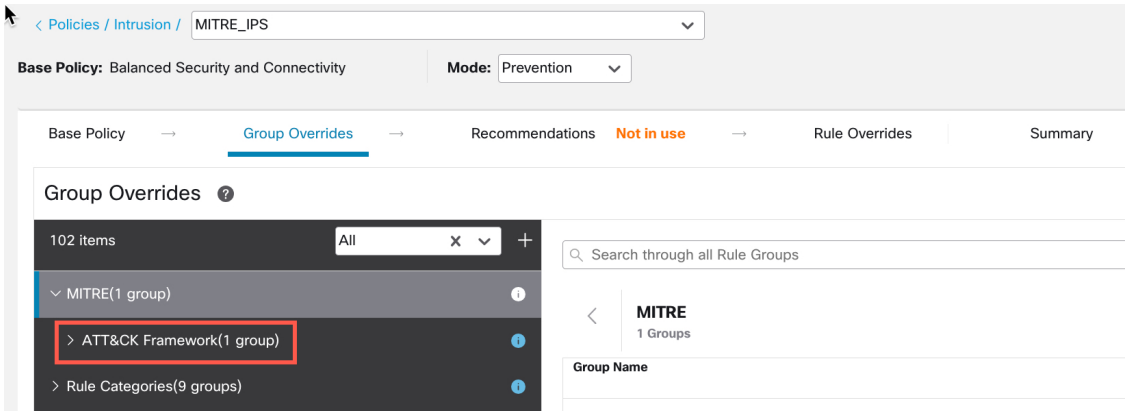
b) Close the Snort helper guide that is displayed.

Step 3 Click the **Group Overrides** layer.

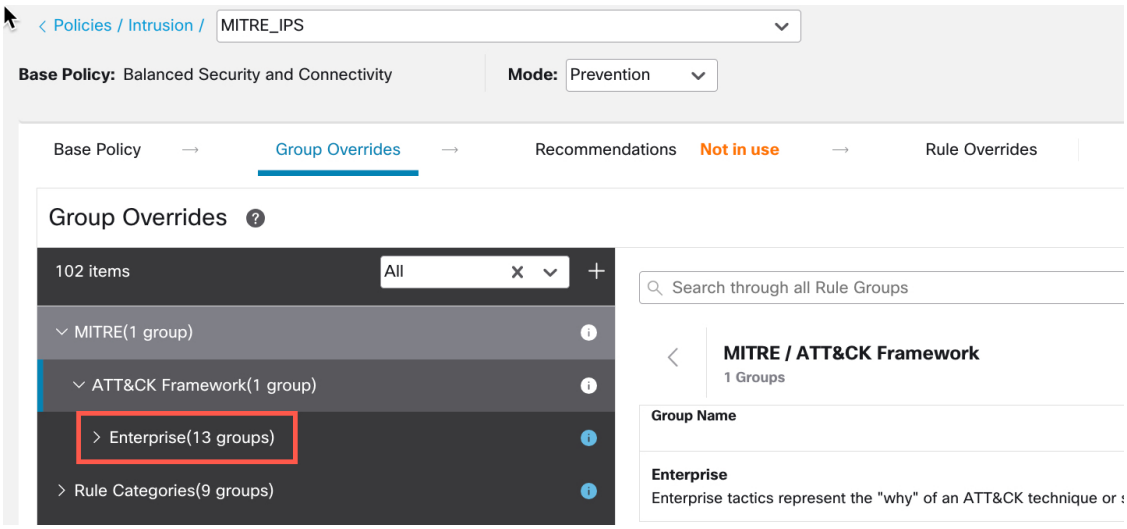
This layer lists all the categories of rule groups, in a hierarchical structure. You can drill down to the final leaf rule group under each rule group.



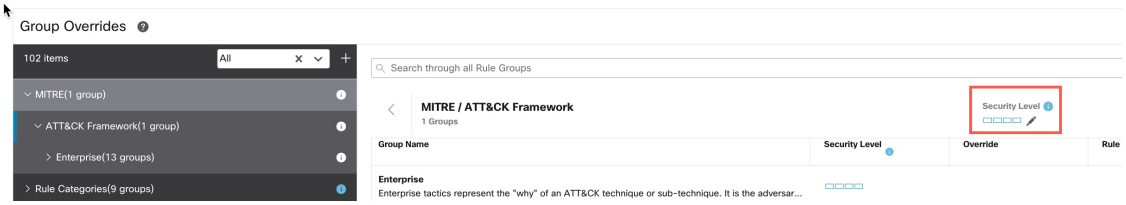
a) Under **Group Overrides**, ensure that **All** is chosen in the drop-down list, so that all the rule groups for the corresponding intrusion policy are visible in the left pane.



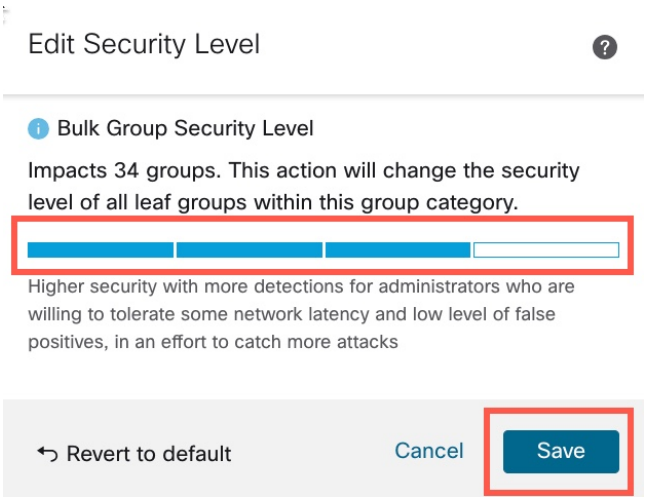
Step 4 Click **MITRE** in the left pane.



Note
Depending on your specific requirements, you can choose the **Rule Categories** rule group or any other rule group and subrule groups under it. All the rule groups use the MITRE framework.

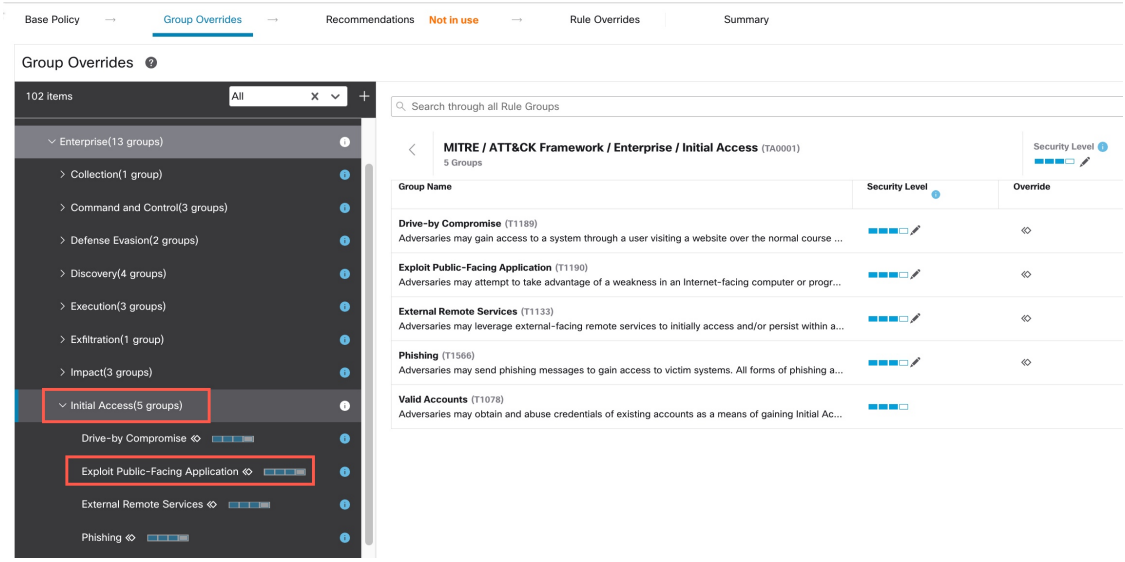


a) Under **MITRE**, click **ATT&CK Framework** to drill down.

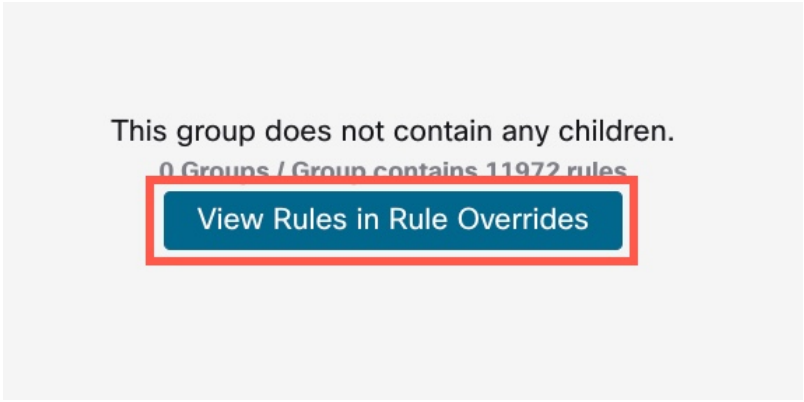


b) Under **ATT&CK Framework**, click **Enterprise** to expand it.

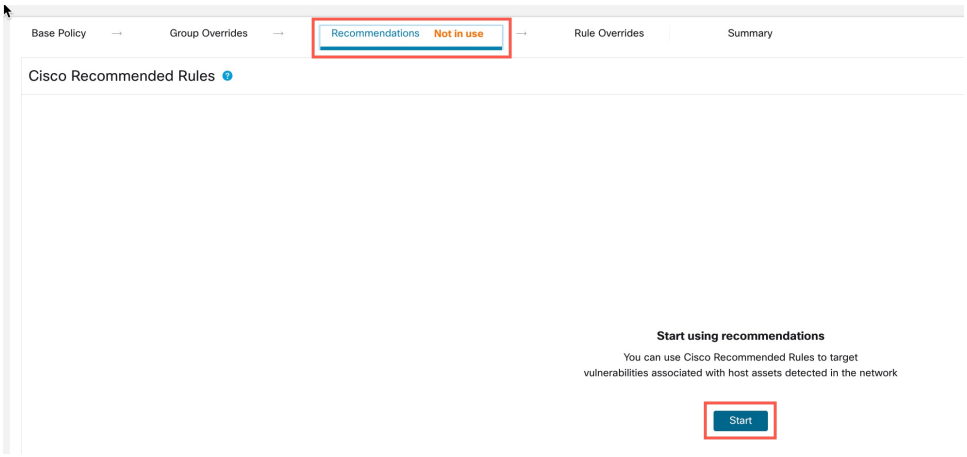
c) Click the **Edit** (✎) icon next to the **Security Level** of the rule group to make bulk changes to all associated rule group security levels under the **Enterprise** rule group category.



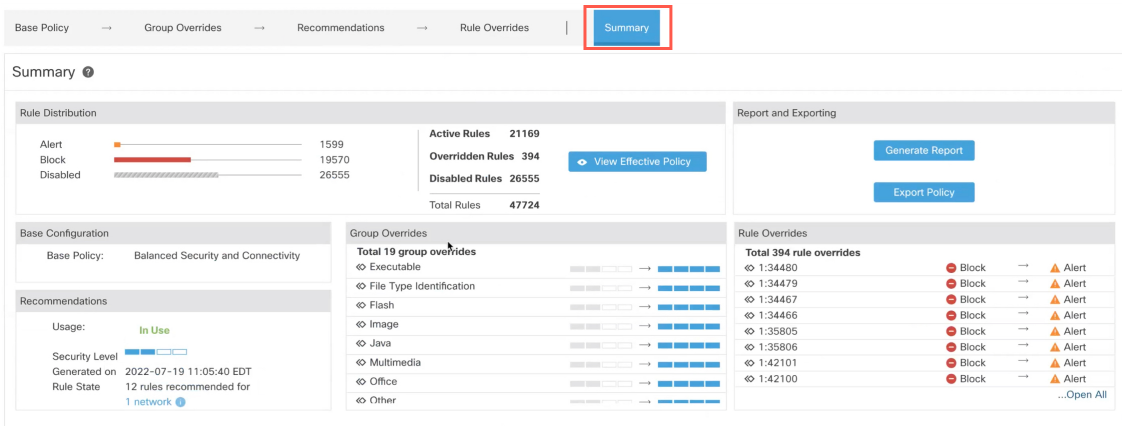
d) In the **Edit Security Level** window, choose a **Security Level** (in this example, **3**), and click **Save**.



Step 5 Under **Enterprise**, click **Initial Access** to expand it.



Step 6 Under **Initial Access**, click **Exploit Public-Facing Application**, which is the last leaf group.



Step 7 Click **View Rules in Rule Overrides** to view the available rules, their details, and actions. You can change the rule actions for one or multiple rules in the **Rule Overrides** layer.

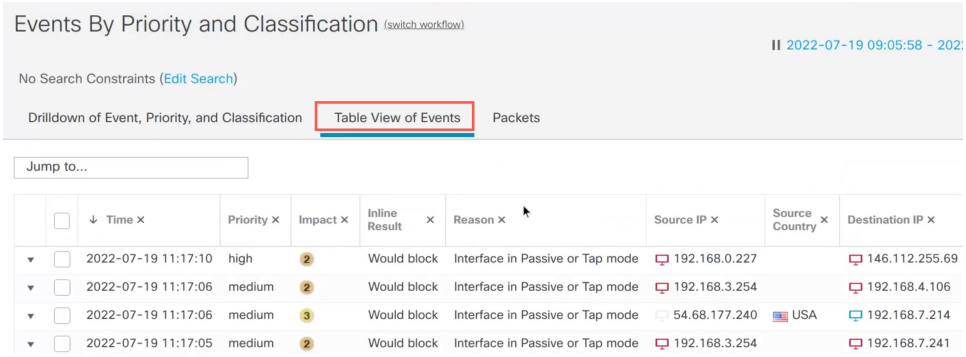
Step 8 Click the **Recommendations** layer and then click **Start** to start using Cisco-recommended rules. You can use the intrusion rule recommendations to target the vulnerabilities that are associated with the host assets detected in the network. For more information, see Generate new Secure Firewall recommendations in Snort 3, on page 2851.

Step 9 Click the **Summary** layer for a holistic view of the current changes to the policy. Based on the rule overrides, security-level changes, and generation of Cisco-recommended rules, you can view the rule distribution of the policy, group overrides, rule overrides, rule recommendations, and additional details to verify your changes.

What to do next

Deploy your intrusion policy to detect and log events that are triggered by the Snort rules. See Deploy configuration changes, on page 2806.

View intrusion events

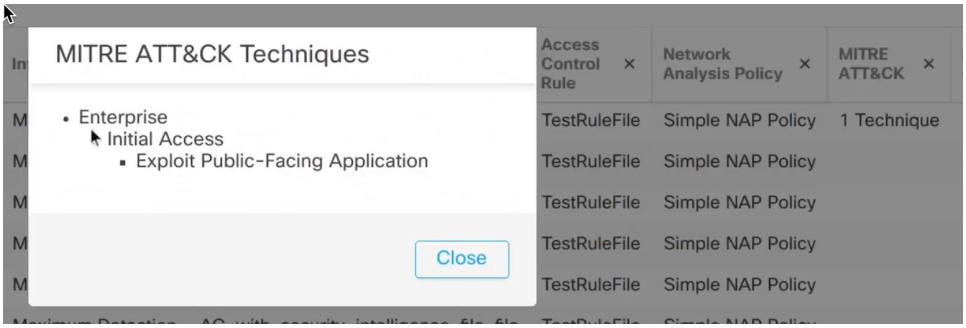


This task allows you to view MITRE ATT&CK techniques and rule groups associated with intrusion events, providing security context and attack pattern mapping for better threat analysis.

You can view the MITRE ATT&CK techniques and rule groups in the intrusion events on the **Classic Event Viewer** and **Unified Event Viewer** pages. Talos provides mappings from Snort rules (GID:SID) to MITRE ATT&CK techniques and rule groups. These mappings are installed as part of the Lightweight Security Package (LSP).

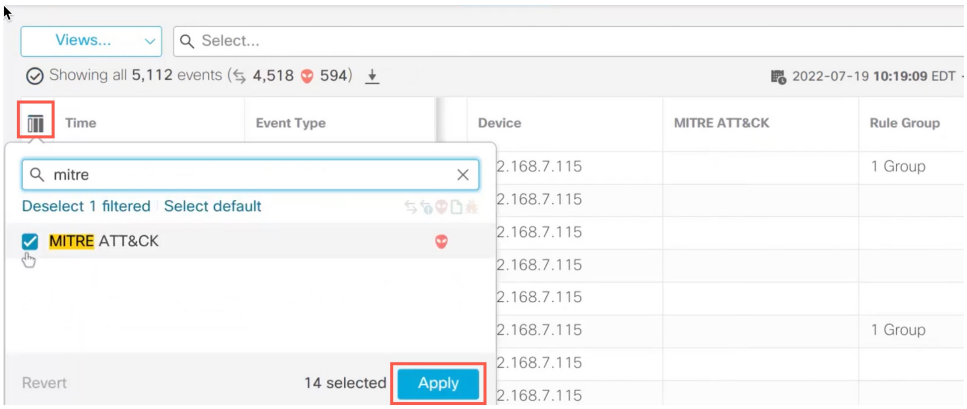
Procedure

Step 1 Click **Analysis** and select **Events** under **Intrusions**.

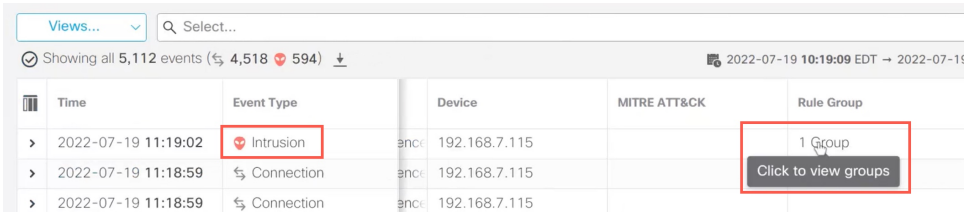


Step 2 Click the **Table View of Events** tab.

Step 3 Under **MITRE ATT&CK**, you can see the techniques for an intrusion event. Click **1 Technique** to view the MITRE ATT&CK techniques.

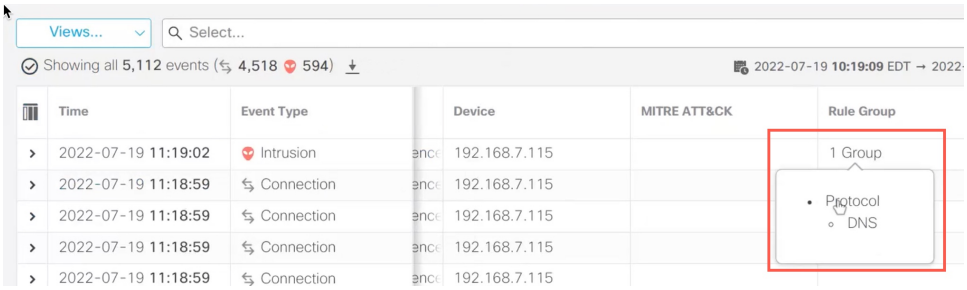


In this example, **Exploit Public-Facing Application** is the technique.

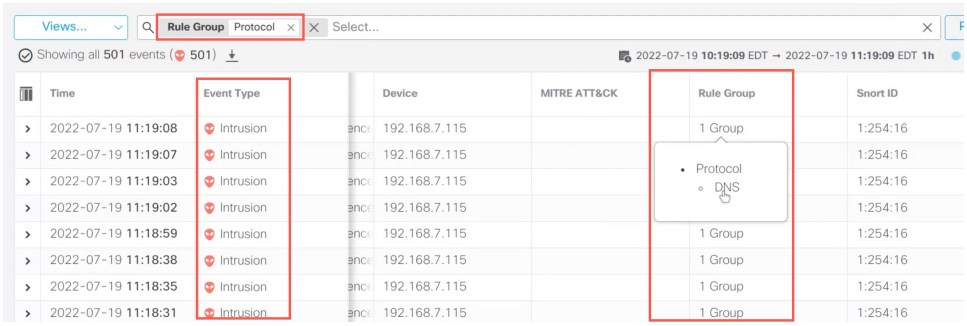


Step 4 Click **Close**.

Step 5 Click **Analysis** and select **Unified Events**.



Step 6 If not enabled, click the column selector icon to enable the **MITRE ATT&CK** and **Rule Group** columns.



Step 7 In this example, the intrusion event is triggered by an event that is mapped to one rule group. Click **1 Group** under the **Rule Group** column.

Step 8 You can view **Protocol**, which is the parent rule group, and the DNS rule group under it. Choose **Protocol** > **DNS** to search for all the intrusion events that have at least one rule group.

The search results are displayed.

- Configure intrusion performance statistic logging, on page 2878

Intrusion prevention performance tuning

Intrusion prevention performance tuning is a system optimization mechanism that

- improves performance while analyzing traffic for attempted intrusions,
- applies settings on a per-access control policy basis to all intrusion policies invoked by that parent access control policy, and
- balances security with the need to maintain device latency at an acceptable level.

Performance tuning features

Cisco provides several features for improving the performance of your system as it analyzes traffic for attempted intrusions. You can:

- specify the number of packets to allow in the event queue. You can also, before and after stream reassembly, enable or disable inspection of packets that will be rebuilt into larger streams.
- override default match and recursion limits on PCRE that are used in intrusion rules to examine packet payload content.
- elect to have the rules engine log more than one event per packet or packet stream when multiple events are generated, allowing you to collect information beyond the reported event.

- balance security with the need to maintain device latency at an acceptable level with packet and rule latency thresholding.
- configure the basic parameters of how devices monitor and report their own performance. This allows you to specify the intervals at which the system updates performance statistics on your devices.

License requirements for intrusion prevention performance tuning

This reference provides licensing information required for implementing intrusion prevention performance tuning on Cisco Secure Firewall devices, covering both Threat Defense and Classic licensing models.

Limiting pattern matching for intrusions

Limit pattern matching for intrusions to optimize system performance by controlling how many pattern states are analyzed per packet and managing content inspection before and after stream reassembly.

Pattern matching limits help balance security effectiveness with system performance. When processing high volumes of traffic, limiting the number of pattern states analyzed per packet can prevent performance degradation while maintaining essential intrusion detection capabilities.

Before you begin

Follow these steps to limit pattern matching for intrusions:

Procedure

Step 1 In the access control policy editor, click **Advanced** (**Policies** > **Access Control heading** > **Access Control**, click **Edit** and then click **Advanced Settings**).

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** ( ) next to **Performance Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Pattern Matching Limits** in the **Performance Settings** pop-up window.

Step 4 Enter a value for the maximum number of events to queue in the **Maximum Pattern States to Analyze Per Packet** field.

Step 5 To disable the inspection of packets that will be rebuilt into larger streams of data before and after stream reassembly in Snort 2, check the **Disable Content Checks on Traffic Subject to Future Reassembly** check box. Inspection before and after reassembly requires more processing overhead and may decrease performance.

Important
In Snort 3, the **Disable Content Checks on Traffic Subject to Future Reassembly** check box settings are:

- Checked—Indicates detecting TCP payload before reassembly. It includes inspection of packets before and after stream reassembly. This process requires more processing overhead and may decrease performance.
- Unchecked—Indicates detecting TCP payload after reassembly.

Step 6 Click **OK**.

Step 7 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Regular expression limits overrides for intrusion rules

The default regular expression limits ensure a minimum level of performance. Overriding these limits could increase security, but could also significantly impact performance by permitting packet evaluation against inefficient regular expressions.

Caution Do not override default PCRE limits unless you are an experienced intrusion rule writer with knowledge of the impact of degenerative patterns.

Table 156: Regular expression constraint options

Option	Description
Match Limit State	Specifies whether to override **Match Limit**. You have these options: • select **Default** to use the value configured for **Match Limit** • select **Unlimited** to permit an unlimited number of attempts • select **Custom** to specify either a limit of 1 or greater for **Match Limit**, or to specify 0 to completely disable PCRE match evaluations
Match Limit	Specifies the number of times to attempt to match a pattern defined in a PCRE regular expression.
Match Recursion Limit State	Specifies whether to override **Match Recursion Limit**. You have these options: • select **Default** to use the value configured for **Match Recursion Limit** • select **Unlimited** to permit an unlimited number of recursions • select **Custom** to specify either a limit of 1 or greater for **Match Recursion Limit**, or to specify 0 to completely disable PCRE recursions Note that for **Match Recursion Limit** to be meaningful, it must be smaller than **Match Limit**.
Match Recursion Limit	Specifies the number of recursions when evaluating a PCRE regular expression against the packet payload.

Override regular expression limits for intrusion rules

Override the default regular expression limits to customize performance settings for intrusion rules according to your network requirements.

Regular expression limits control the processing of pattern matching in intrusion rules. Modifying these limits can help optimize performance based on your specific environment and traffic patterns.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** ( ) next to **Performance Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Regular Expression Limits** in the **Performance Settings** pop-up window.

Step 4 You can modify any of the options as described in Regular expression limits overrides for intrusion rules, on page 2867.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Per packet intrusion event generation limits

When the intrusion rules engine evaluates traffic against rules, it places the events generated for a given packet or packet stream in an event queue, then reports the top events in the queue to the user interface. When configuring the intrusion event logging limits, you can specify how many events can be placed in the queue and how many are logged, and select the criteria for determining event order within the queue.

Table 157: Intrusion event logging limits options

Option	Description
Maximum events stored per packet	The maximum number of events that can be stored for a given packet or packet stream.
Maximum events logged per packet	The number of events logged for a given packet or packet stream. This cannot exceed the **Maximum Events Stored Per Packet** value.
Prioritize event logging by	The value used to determine event ordering within the event queue. The highest ordered event is reported through the user interface. You can select from: • `priority`, which orders events in the queue by the event priority. • `content_length`, which orders events by the longest identified content match. When events are ordered by content length, rule events always take precedence over decoder and preprocessor events.

Limiting intrusion events generated per packet

This task allows you to control the number of intrusion events generated per packet by configuring intrusion event logging limits in the access control policy performance settings.

Use this task when you need to manage intrusion detection system performance by limiting the number of events generated for each packet processed by the firewall.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** ( ) next to **Performance Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Intrusion Event Logging Limits** in the **Performance Settings** pop-up window.

Step 4 You can modify any of the options in Per packet intrusion event generation limits, on page 2869.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Packet and intrusion rule latency threshold configuration

Packet and intrusion rule latency threshold configuration is a performance management mechanism that

- uses thresholding to manage packet and rule processing performance in access control policies,
- measures elapsed time for packet and rule processing operations, and
- implements protective actions when configurable time thresholds are exceeded.

Processing mechanisms

This configuration includes two distinct processing mechanisms:

- **Packet latency thresholding**: Measures the total elapsed time taken to process a packet by applicable decoders, preprocessors, and rules, and ceases inspection of the packet if the processing time exceeds a configurable threshold.
- **Rule latency thresholding**: Measures the elapsed time each rule takes to process an individual packet, suspends the violating rule along with a group of related rules for a specified time if the processing time exceeds the rule latency threshold a configurable consecutive number of times, and restores the rules when the suspension expires.

Latency-based performance settings

Latency-based performance settings are a system configuration mechanism that

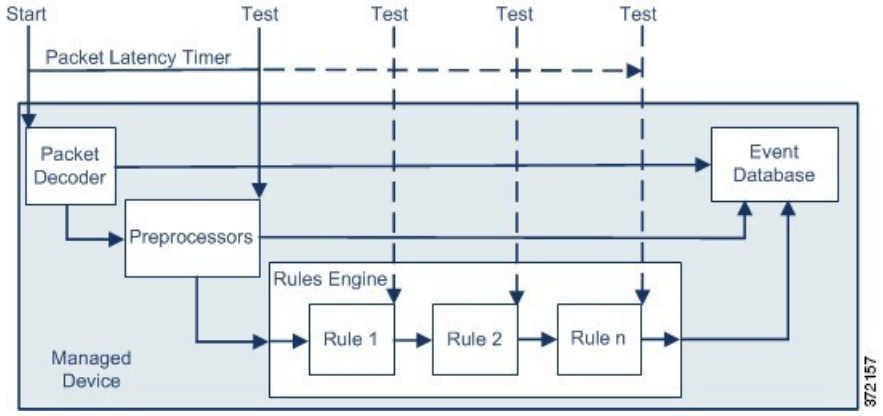
- takes performance settings from the latest intrusion rule update deployed on the system,
- applies settings based on the security level of the network analysis policy (NAP) associated with the access control policy, and
- evaluates the most secure network analysis policy among custom rules when multiple policies are configured.

Policy evaluation logic

The latency settings that are actually applied depend on the security level of the network analysis policy (NAP) associated with the access control policy. Generally, this is the default NAP policy. However, if custom network analysis rules are configured, and if any of these specify a NAP policy that is more secure than the default NAP policy, then latency settings are based on the most secure NAP policy among the custom rules. If the default NAP policy or any custom rules invoke a custom NAP policy, then the security level used in the evaluation is the system-provided base policy on which each custom NAP policy is based.

This policy evaluation logic applies regardless of whether the effective threshold and network analysis configurations are inherited or configured directly in the policy.

Packet latency thresholding



Packet latency thresholding is a software-based latency implementation that

- measures elapsed time, not just processing time, to more accurately reflect the actual time required for the rule to process a packet,
- does not enforce strict timing, and
- can improve system performance by stopping inspection of packets that require excessive processing time.

Packet latency thresholding operation

A timer starts for each packet when decoder processing begins. Timing continues either until all processing ends for the packet or until the processing time exceeds the threshold at a timing test point.

The trade-off for the performance and latency benefits derived from latency thresholding is that uninspected packets could contain attacks.

Packet latency timing is tested at these test points:

- after the completion of all decoder and preprocessor processing and before rule processing begins
- after processing by each rule

If the processing time exceeds the threshold at any test point, packet inspection ceases.

Tip Total packet processing time does not include routine TCP stream or IP fragment reassembly times.

Packet latency thresholding has no effect on events triggered by a decoder, preprocessor, or rule processing the packet. Any applicable decoder, preprocessor, or rule triggers normally until a packet is fully processed, or until packet processing ends because the latency threshold is exceeded, whichever comes first. If a drop rule detects an intrusion in an inline deployment, the drop rule triggers an event and the packet is dropped.

Note No packets are evaluated against rules after processing for that packet ceases because of a packet latency threshold violation. A rule that would have triggered an event cannot trigger that event, and for drop rules, cannot drop the packet.

Packet latency thresholding can improve system performance in both passive and inline deployments, and can reduce latency in inline deployments, by stopping inspection of packets that require excessive processing time. These performance benefits might occur when, for example:

- for both passive and inline deployments, sequential inspection of a packet by multiple rules requires an excessive amount of time
- for inline deployments, a period of poor network performance, such as when someone downloads an extremely large file, slows packet processing

In a passive deployment, stopping the processing of packets might not contribute to restoring network performance because processing simply moves to the next packet.

Packet latency thresholding notes

By default, the latency-based performance settings for packet handling are disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting. The information in this section applies only if you choose to specify custom values.

Enable packet latency thresholding

Enable packet latency thresholding to monitor and manage packet processing delays, which helps optimize network performance and identify potential bottlenecks.

Packet latency thresholding allows you to set performance parameters for packet processing. This feature is useful for monitoring network performance and ensuring optimal packet flow through the system.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** ( ) next to **Latency-Based Performance Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.

Step 3 Click **Packet Handling** in the **Latency-Based Performance Settings** pop-up window.

Step 4 Check the **Enabled** check box.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Configure packet latency thresholding

This task enables you to configure packet latency thresholding for latency-based performance settings.

By default, the latency-based performance settings for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** ( ) next to **Latency-Based Performance Settings**.

System (⚙) > **Monitoring** > **Statistics**

Step 3 If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 4 Click **Packet Handling** in the **Latency-Based Performance Settings** pop-up window.

By default, **Installed Rule Update** is selected. We recommend using this default.

The values displayed do not reflect the automated settings.

Step 5 If you choose to specify custom values:

- Check the **Enabled** check box, and see Packet latency thresholding notes, on page 2873 for recommended minimum **Threshold** settings.
- You must specify custom values in both the packet handling tab and the rule handling tab.

Step 6 Click **OK**.

Step 7 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Rule latency thresholding

Rule latency thresholding is a software-based latency implementation that

- measures elapsed time, not just processing time, to more accurately reflect the actual time required for the rule to process a packet,
- does not enforce strict timing, and
- temporarily suspends rules that exceed specified processing time thresholds to improve system performance.

Rule latency thresholding operations

A timer measures the processing time each time a packet is processed against a group of rules. Any time the rule processing time exceeds a specified rule latency threshold, the system increments a counter. If the number of consecutive threshold violations reaches a specified number, the system takes these actions:

- suspends the rules for the specified period
- triggers an event indicating the rules have been suspended
- re-enables the rules when the suspension expires
- triggers an event indicating the rules have been re-enabled

The system zeroes the counter when the group of rules has been suspended, or when rule violations are not consecutive. Permitting some consecutive violations before suspending rules lets you ignore occasional rule violations that might have negligible impact on performance and focus instead on the more significant impact of rules that repeatedly exceed the rule latency threshold.

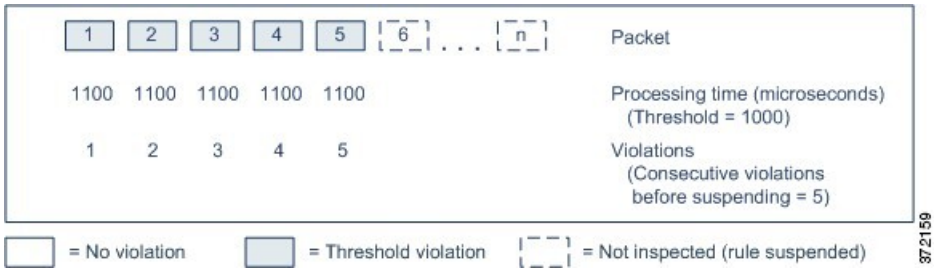
The trade-off for the performance and latency benefits derived from latency thresholding is that uninspected packets could contain attacks.

Rule latency thresholding has no effect on intrusion events triggered by the rules processing the packet. A rule triggers an event for any intrusion detected in the packet, regardless of whether the rule processing time exceeds the threshold. If the rule detecting the intrusion is a drop rule in an inline deployment, the packet is dropped. When a drop rule detects an intrusion in a packet that results in the rule being suspended, the drop rule triggers an intrusion event, the packet is dropped, and that rule and all related rules are suspended.

Note Packets are not evaluated against suspended rules. A suspended rule that would have triggered an event cannot trigger that event and, for drop rules, cannot drop the packet.

Rule latency thresholding can improve system performance in both passive and inline deployments, and can reduce latency in inline deployments, by suspending rules that take the most time to process packets. Packets are not evaluated again against suspended rules until a configurable time expires, giving the overloaded device time to recover. These performance benefits might occur when:

- hastily written, largely untested rules require an excessive amount of processing time
- a period of poor network performance, such as when someone downloads an extremely large file, causes slow packet inspection



Rule latency thresholding examples

This example shows five consecutive rule processing times that do not result in rule suspension.

In this example, the time required to process each of the first three packets violates the rule latency threshold of 1000 microseconds, and the violations counter increments with each violation. Processing of the fourth packet does not violate the threshold, and the violations counter resets to zero. The fifth packet violates the threshold and the violations counter restarts at one.

This example shows five consecutive rule processing times that do result in rule suspension.

In the second example, the time required to process each of the five packets violates the rule latency threshold of 1000 microseconds. The group of rules is suspended because the rule processing time of 1100 microseconds for each packet violates the threshold of 1000 microseconds for the specified five consecutive violations. Any subsequent packets, represented in the figure as packets 6 through n, are not examined against suspended rules until the suspension expires. If more packets occur after the rules are re-enabled, the violations counter begins again at zero.

Rule latency thresholding notes

Rule latency thresholding suspends rules for the time specified by **Suspension Time** when the time rules take to process a packet exceeds **Threshold** for the consecutive number of times specified by **Consecutive Threshold Violations Before Suspending Rule**.

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default.

The information in this topic applies only if you choose to specify custom values.

You can enable rule 134:1 to generate an event when rules are suspended, and rule 134:2 to generate an event when suspended rules are enabled.

Table 158: Rule latency thresholding options

Option	Description
Threshold	Specifies the time in microseconds that rules should not exceed when examining a packet.
Consecutive Threshold Violations Before Suspending Rule	Specifies the consecutive number of times rules can take longer than the time set for **Threshold** to inspect packets before rules are suspended.
Suspension Time	Specifies the number of seconds to suspend a group of rules.

Configure rule latency thresholding

Configure rule latency thresholding to customize how the system handles rules when latency conditions are detected, improving overall performance and system responsiveness.

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default.

Procedure

Step 1 In the access control policy editor, click **Advanced**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

Step 2 Click **Edit** ( ) next to **Latency-Based Performance Settings**.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Click **Rule Handling** in the **Latency-Based Performance Settings** pop-up window.

By default, **Installed Rule Update** is selected. We recommend using this default.

The values displayed do not reflect the automated settings.

Step 4 If you choose to specify custom values:

- You can configure any of the options in Rule latency thresholding notes, on page 2876.
- You must specify custom values in both the packet handling tab and the rule handling tab.

Step 5 Click **OK**.

Step 6 Click **Save** to save the policy.

What to do next

- If you want to generate events, enable latency rules 134:1 and 134:2.
- Deploy configuration changes.

Intrusion performance statistic logging configuration

This reference provides information about intrusion performance statistic logging configuration options, including sample time settings, minimum packet requirements, and troubleshooting options for logging session and protocol distribution data.

Sample time (seconds) and minimum number of packets

When the number of seconds specified elapses between performance statistics updates, the system verifies it has analyzed the specified number of packets. If it has, the system updates performance statistics. Otherwise, the system waits until it analyzes the specified number of packets.

Caution Configuring a very low value, such as one second, for the sample time can greatly impact the device. The device may experience disk space issues, and its operation may be affected by the volume of performance statistics logged. To avoid these issues, do not set a very low value.

Troubleshooting options: log session/protocol distribution

Support might ask you during a troubleshooting call to log protocol distribution, packet length, and port statistics.

Caution Do not enable **Log Session/Protocol Distribution** unless instructed to by Support.

Troubleshooting options: summary

Support might ask you during a troubleshooting call to configure the system to calculate the performance statistics only when the Snort process is shut down or restarted. To enable this option, you must also enable the **Log Session/Protocol Distribution** troubleshooting option.

Caution Do not enable **Summary** unless instructed to do so by Support.

Configure intrusion performance statistic logging

Configure intrusion performance statistic logging to customize how the system samples and logs performance statistics for monitoring and troubleshooting purposes.

Performance statistics logging allows you to monitor device performance by sampling statistics at defined intervals. Proper configuration ensures optimal device performance while providing necessary monitoring data.

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** ( ) next to **Performance Settings**.

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Click **Performance Statistics** in the pop-up window that appears.

Step 3 Modify the **Sample time** or **Minimum number of packets** as described in Intrusion performance statistic logging configuration, on page 2877.

Caution
Configuring a very low value, such as one second, for the **Sample time** can greatly impact the device. The device may experience disk space issues, and its operation may be affected by the volume of performance statistics logged. To avoid these issues, do not set a very low value.

Step 4 Optionally, expand the **Troubleshoot Options** section and modify those options only if asked to do so by Support.

Step 5 Click **OK**.

What to do next

- Deploy configuration changes.

CHAPTER 101

Network Analysis Policies

This chapter provides an insight into network analysis policy basics, prerequisites, and how to manage network analysis policies. It also provides information on custom network analysis policy creation and network analysis policy settings.

- Network analysis policies, on page 2879
- Manage network analysis policies, on page 2880
- Snort 3 definitions and terminologies for network analysis policies, on page 2881
- Custom network analysis policy creation for Snort 3, on page 2883
- Network analysis policy settings and cached changes, on page 2910
- Generate Snort 3 recommendations, on page 2911

Network analysis policies

A *network analysis policy* is a traffic preprocessing configuration that

- governs many traffic preprocessing options and is invoked by advanced settings in your access control policy,
- performs preprocessing after Security Intelligence matching and SSL decryption, and
- completes processing before intrusion or file inspection begins.

Default and custom network analysis policies

By default, the system uses the *Balanced Security and Connectivity* network analysis policy to preprocess all traffic handled by an access control policy. However, you can choose a different default network analysis policy to perform this preprocessing. For your convenience, the system provides a choice of several non-modifiable network analysis policies, which are tuned for a specific balance of security and connectivity by the Talos Intelligence Group. You can also create a custom network analysis policy with custom preprocessing settings.

Note System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules. Network analysis and intrusion policies work together to examine your traffic.

You can also tailor traffic preprocessing options to specific security zones, networks, and VLANs by creating multiple custom network analysis policies, then assigning them to preprocess different traffic.

Manage network analysis policies

This task allows you to perform various management operations on network analysis policies, including creation, editing, deletion, comparison, and report generation.

Under your user name in the toolbar, the system displays a tree of available domains. To switch domains, choose the domain you want to access.

Note Snort 2 is not supported on threat defense version 7.7. For information on Snort 2 features that are supported in versions earlier than 7.7, refer to the management center guide that matches your threat defense version.

Procedure

Step 1 Choose one of these paths to access the network analysis policy.

- **Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy**
- **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**

Note
If your custom user role limits access to the first path listed here, use the second path to access the policy.

Step 2 Manage your network analysis policy:

- Create—If you want to create a new network analysis policy, click **Create Policy**.

  Two versions of the network analysis policy are created, a **Snort 2 Version** and a **Snort 3 Version**.

  - For the Snort 2 version, see *Custom Network Analysis Policy Creation for Snort 2* in the *Cisco Secure Firewall Management Center Configuration Guide*.
  - For the Snort 3 version, see Custom network analysis policy creation for Snort 3, on page 2883.

- Delete—If you want to delete a network analysis policy, click the **Delete** icon, then confirm that you want to delete the policy. You cannot delete a network analysis policy if an access control policy references it.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Edit—If you want to edit an existing network analysis policy, click the **Edit** icon.

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Report—Click the **Report** icon; see *Generating Current Policy Reports* in the *Cisco Secure Firewall Management Center Configuration Guide*.

Snort 3 definitions and terminologies for network analysis policies

This table lists the Snort 3 concepts and terms used in the Network Analysis Policy.

Table 159: Snort 3 definitions and terminologies for network analysis policy

Term	Description
Inspectors	Inspectors are plugins that process packets (similar to the Snort 2 preprocessor).
Binder inspector	The binder inspector defines the flow when a particular inspector must be accessed and considered. When the traffic matches the conditions defined in the binder inspector, only then do the values and configurations for that inspector come into effect. For more information, see *Binder Inspector* in Custom network analysis policy creation for Snort 3, on page 2883.
Singleton inspectors	Singleton inspectors contain one instance. These inspectors do not support adding more instances like multiton inspectors. Settings for a singleton inspector apply to all traffic that matches the inspector, not just a specific traffic segment. For more information, see *Singleton Inspectors* in Custom network analysis policy creation for Snort 3, on page 2883.

Term	Description
Multiton inspectors	Multiton inspectors contain multiple instances which you can configure as needed. These inspectors support configuring settings based on specific conditions, such as network, port, and VLAN. One set of supported settings is called an instance. For more information, see *Multiton Inspectors* in Custom network analysis policy creation for Snort 3, on page 2883.
Schema	The schema file is based on the OpenAPI JSON specification, and it validates the content that you upload or download. You can download the schema file and open it using any third-party JSON editor, such as Swagger editor. The schema file helps you to identify what parameters can be configured for inspectors with their corresponding allowed values, range, and accepted patterns to be used. For more information, see Customize the network analysis policy, on page 2891.
Sample file	It is a pre-existing template that contains example configurations to help you with configuring the inspectors. You can refer to the example configurations included in the sample file and make any changes you require. For more information, see Customize the network analysis policy, on page 2891.
Full configuration	You can download the entire inspector configurations in a single file. All information regarding the inspector configuration is available in this file. The full configuration is a merged configuration of the default configuration (provided as part of the LSP updates by Cisco Talos) and the custom NAP inspector configurations. For more information, see Customize the network analysis policy, on page 2891.

Term	Description
Overridden configuration	In the **Snort 3 Version** of the network analysis policy page: • Under **Actions** > **Upload**, you can click **Overridden Configuration** to upload the JSON file that contains the overridden configuration. • Under **Actions** > **Download**, you can click **Overridden Configuration** to download the inspector configuration that has been overridden. If you have not overridden any inspector configuration, then this option is disabled. When you override the inspector configuration, then this option is enabled automatically to allow you to download. For more information, see Customize the network analysis policy, on page 2891.

Customize the network analysis policy, on page 2891
Network analysis policy mapping, on page 2889

Custom network analysis policy creation for Snort 3

A custom network analysis policy creation for Snort 3 is a data-driven configuration process that

- enables advanced users to customize the default network analysis policy for specific network requirements or to optimize performance, and
- utilizes JSON and JSON Schema based on the OpenAPI specification to configure inspectors and settings.

Network analysis policy customization overview

The default network analysis policy is tuned for typical network requirements and optimal performance. In most situations, you do not need to customize the policy. However, when you have a specific network requirement or when you are facing performance issues, the default network analysis policy can be customized. Note that customizing the network analysis policy is an advanced configuration that should only be done by advanced users or Cisco Support.

In Snort 3, the list of inspectors and settings are not in a one-to-one mapping with the Snort 2 list of preprocessors and settings. The number of inspectors and settings available in Firewall Management Center forms a subset of those that Snort 3 supports. See https://snort.org/snort3 for more information on Snort 3. See https://www.cisco.com/go/snort3-inspectors for more information on the inspectors available in Firewall Management Center.

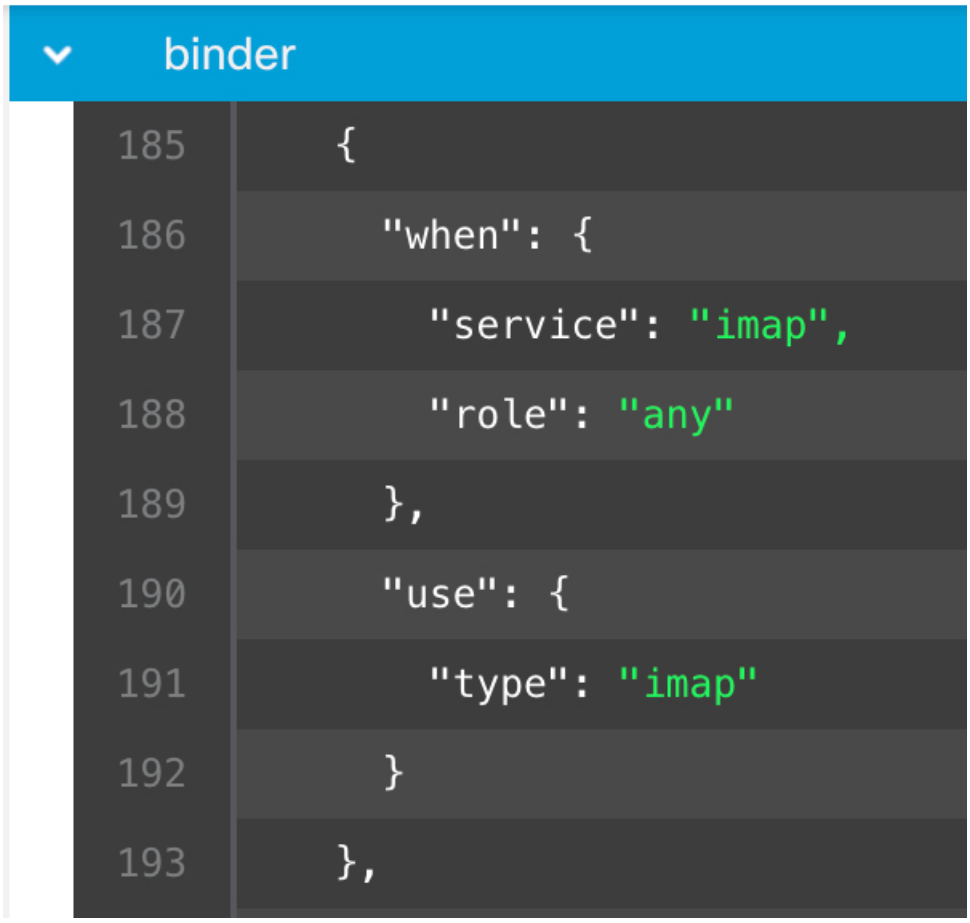
Note

- While upgrading the Firewall Management Center to the 7.0 release, the changes that were done in the Snort 2 version of the network analysis policy are not migrated to Snort 3 after the upgrade.
- Unlike the intrusion policy, there is no option to synchronize Snort 2 network analysis policy settings to Snort 3.

Default inspector updates

Lightweight Security Package (LSP) updates may contain new inspectors or modifications to integer ranges for existing inspector configurations. After you install an LSP, new inspectors or updated ranges will be available under **Inspectors** in the **Snort 3 Version** of your network analysis policy.

Binder inspector



Binder inspector defines the flow when a particular inspector has to be accessed and taken into consideration. When the traffic matches the conditions defined in the binder inspector, only then the values and configurations for that inspector come into effect. For example:

For the *imap* inspector, the binder defines the following condition when it has to be accessed. That is when:

- Service is equal to imap.
- Role is equal to any.

a

If these conditions are met, then use the type imap.

Singleton inspectors

Singleton inspectors contain a single instance. These inspectors do not support adding more instances like multiton inspectors. Settings of a singleton inspector apply to all traffic, not to a specific segment.

For example:

```
{
   "normalizer":{
      "enabled":true,
      "type":"singleton",
      "data":{
         "ip4":{
            "df":true
         }
      }
   }
}
```

Multiton inspectors

Multiton inspectors contain multiple instances which you can configure as needed. These inspectors support configuring settings based on specific conditions, such as network, port, and VLAN. One set of supported settings is called an instance. There is a default instance, and you can also add additional instances based on specific conditions. If the traffic matches that condition, the settings from that instance are applied. Otherwise,

the settings from the default instance are applied. Also, the name of the default instance is the same as the name of the inspector.

For a multiton inspector, when you upload the overridden inspector configuration, you also need to include and define a matching binder condition (conditions under when the inspector has to be accessed or used) for each instance in the JSON file, otherwise, the upload will result in an error. You can also create new instances. Ensure that you include a binder condition for each new instance you create to avoid errors.

For example:

- Multiton inspector where the default instance is modified.

```
{
   "http_inspect":{
      "enabled":true,
      "type":"multiton",
      "instances":[
         {
            "name":"http_inspect",
            "data":{
               "response_depth":5000
            }
         }
      ]
   }
}
```

- Multiton inspector where the default instance and default binder is modified.

```
{
   "http_inspect":{
      "enabled":true,
      "type":"multiton",
      "instances":[
         {
            "name":"http_inspect",
            "data":{
               "response_depth":5000
            }
         }
      ]
   },
   "binder":{
      "type":"binder",
      "enabled":true,
      "rules":[
         {
            "use":{
               "type":"http_inspect"
            },
            "when":{
               "role":"any",
               "ports":"8080",
               "proto":"tcp",
               "service":"http"
            }
         }
      ]
   }
}
```

- Multiton inspector where a custom instance and a custom binder is added.

```
{
   "http_inspect":{
      "enabled":true,
      "type":"multiton",
      "instances":[
         {
            "name":"http_inspect1",
            "data":{
               "response_depth":5000
            }
         }
      ]
   },
   "binder":{
      "type":"binder",
      "enabled":true,
      "rules":[
         {
            "use":{
               "type":"http_inspect",
               "name":"http_inspect1"
            },
            "when":{
               "role":"any",
               "ports":"8080",
               "proto":"tcp",
               "service":"http"
            }
         }
      ]
   }
}
```

Common Industrial Protocol safety

Common Industrial Protocol (CIP) safety is a set of extensions to the CIP that

- enables the safe operation of devices,
- provides fail-safe communication between different nodes on a CIP network, and
- comprises two main components for safety parameter exchange and safety information transmission.

CIP safety protocol components

The CIP safety protocol comprises two main components:

- CIP safety segments—Used in Forward Open messages to exchange safety parameters for the subsequent safety session.
- CIP safety messages—Used to exchange actual safety information.

The CIP inspector detects and identifies:

- CIP as a service and client
- Payloads, such as CIP Read, CIP Admin, CIP Infrastructure, and CIP Write

The CIP inspector can parse the CIP segments and detect the CIP Safety segments in the Forward Open requests.

To test the CIP safety feature, you must enable the CIP inspector. See Detect and block safety segments in CIP packets, on page 2888.

Detect and block safety segments in CIP packets

This task enables detection and blocking of CIP safety segments while allowing other CIP packets to pass through.

Use this procedure to detect and block CIP safety segments while allowing other CIP packets:

- Create a custom network analysis policy called **cip_safety**.
- Create access control rules in your access control policy to block CIP safety and to allow all other packets.

To test the CIP safety feature, enable the CIP inspector in the management center and assign it to an access control policy.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click the **Snort 3 Version** of the network analysis policy **cip_safety** that you created.

Step 3 Under **Inspectors**, click **CIP** to expand it.

The default configuration appears in the left column and the overridden configuration appears in the right column under the inspector.

Step 4 Under **Overridden Configuration** on the right column, click the **Edit Inspector** icon and change the "enabled" field in **CIP** from false (default) to true.

Step 5 Click **OK** and then click **Save**.

Step 6 To assign the **CIP** inspector to the access control policy, choose **Policies** > **Access Control heading** > **Access Control**, click **Edit** and choose the **Advanced Settings** option from the **More** drop-down arrow at the end of the packet flow line.

Step 7 Click **Edit** () next to **Network Analysis and Intrusion Policies**.

Step 8 In the **Network Analysis and Intrusion Policies** window, choose the access control policy **cip_safety** that you created from the **Default Network Analysis Policy** drop-down list.

The CIP inspector is now enabled in the management center and you can create the custom access control rules to block CIP safety and to allow all other CIP packets.

Step 9 After you send live traffic containing CIP safety packet flows, go to **Unified Events** to verify that the payload is the expected payload that contains CIP safety packet logs for the detection and block use case as mentioned in this procedure.

CIP is detected as an application protocol and client (see the **Application Protocol** and **Client Application** fields), and **CIP Safety** is shown under the **Web Application** field.

Network analysis policy mapping

Network analysis policy mapping is a correlation mechanism that

- provides mapping information for network analysis policies,
- finds the corresponding Snort 2 version of policies for the Snort 3 version, and
- ensures that the Snort 3 version of policies has its equivalent Snort 2 version.

View network analysis policy mapping

View which Snort 3 network analysis policies are automatically mapped to their Snort 2 equivalent policies in the system.

Network analysis policy mapping allows you to see the relationship between Snort 3 and Snort 2 policies when transitioning between versions or managing both simultaneously.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click **NAP Mapping**.

Step 3 Expand the arrow for **View Mappings**.

The Snort 3 network analysis policies that are automatically mapped to a Snort 2 equivalent policy are displayed.

Step 4 Click **OK**.

Create a network analysis policy

Create a new network analysis policy that provides both Snort 2 and Snort 3 versions for network traffic inspection and analysis.

All the existing network analysis policies are available in Firewall Management Center with their corresponding Snort 2 and Snort 3 versions. When you create a new network analysis policy, it is created with both the Snort 2 version and the Snort 3 version.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click **Create Policy**.

Step 3 Enter the **Name** and **Description**.

Step 4 Select a **Base Policy** and click **Save**.

The new network analysis policy is created with its corresponding **Snort 2 Version** and **Snort 3 Version**.

Modify the network analysis policy

This task allows you to update the configuration of an existing network analysis policy by modifying its properties such as name, description, or base policy settings.

You can modify the network analysis policy to change its name, description, or the base policy.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Click **Edit** to change the name, description, inspection mode, or the base policy.

Note
If you edit the network analysis policy name, description, base policy, and inspection mode, the edits are applied to both the Snort 2 and Snort 3 versions. If you want to change the inspection mode for a specific version, then you can do that from within the network analysis policy page for that respective version.

Step 3 Click **Save**.

Search for an inspector on the Network Analysis Policy window

This task allows you to quickly locate specific inspectors within the network analysis policy interface by using search functionality.

On the Snort 3 version of the network analysis policy window, you may need to search for an inspector by entering any relevant text in the search bar.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Enter the name of an inspector or any relevant text to search for in the **Search** bar.

All the inspectors matching the text you search for are displayed.

For example, if you enter `pop`, then the pop inspector and the binder inspector are shown as matching results on the screen.

Copy the inspector configuration

This task describes how to copy inspector configurations.

You can copy the inspector configuration for the Snort 3 version of the network analysis policy according to your requirements.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to copy the configuration.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

Step 4 Click the **Copy to clipboard** icon to copy the inspector configuration to the clipboard for one or both of these options.

- **Default Configuration** in the left column
- **Overridden Configuration** in the right column

Step 5 Paste the copied inspector configuration to a JSON editor to make any edits you may require.

Related Topics

Customize the network analysis policy, on page 2891

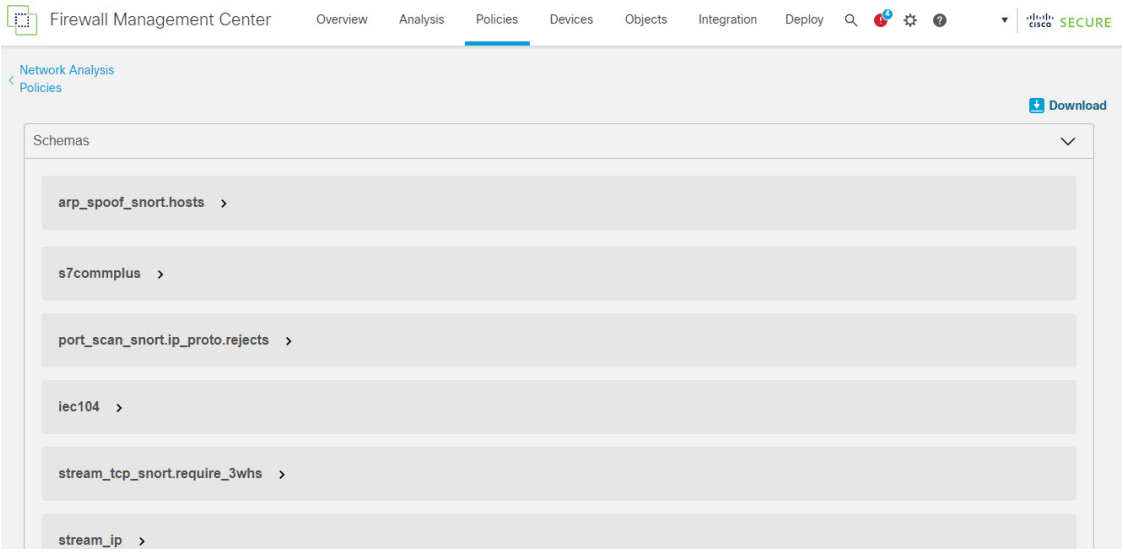
Customize the network analysis policy

Customize the network analysis policy to adapt Snort 3 configurations according to your security requirements.

You can customize the Snort 3 version of the network analysis policy according to your requirements.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.



Step 2 Go to the **Snort 3 Version** of the network analysis policy.

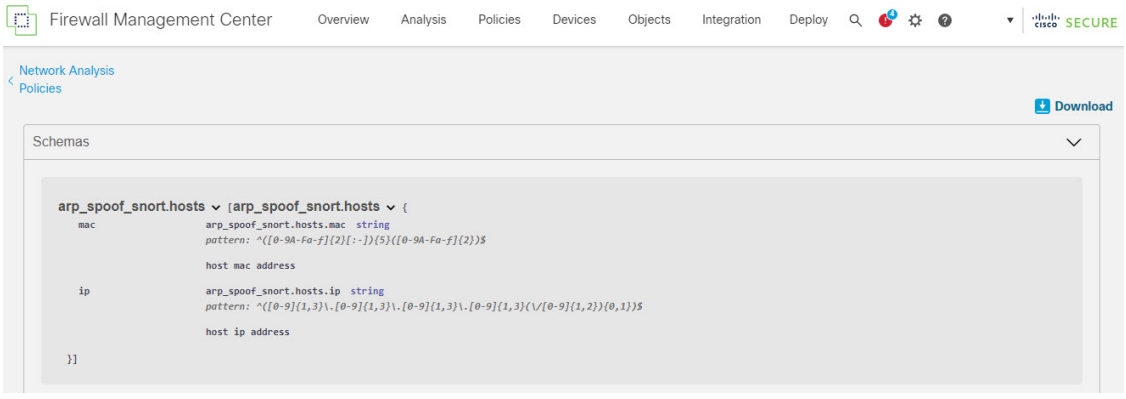
Step 3 Click the **Actions** dropdown menu.

The following options are displayed:

- View Schema
- Download Schema / Download Sample File / Template
- Download Full Configuration
- Download Overridden Configuration
- Upload Overridden Configuration

Step 4 Click **View Schema** to open the schema file directly in a browser.

Step 5 You can download the schema file, sample file / template, full configuration, or overridden configuration as needed.



These options provide you an insight about the allowed values, range, and patterns, existing and default inspector configurations, and overridden inspector configurations.

a) Click **Download Schema** to download the schema file.

The schema file validates the content that you upload or download. You can download the schema file and open it using any third-party JSON editor. The schema file helps you identify which parameters can be configured for inspectors, along with their allowed values, ranges, and accepted patterns.

For example, for the *arp_spoof_snort* inspector, you can configure the hosts. The hosts include the *mac* and *ip* address values. The schema file shows the following accepted pattern for these values.

- **mac** – `pattern: ^([0-9A-Fa-f]{2}[:-]){5}([0-9A-Fa-f]{2})$`
- **ip** – `pattern: ^([0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}.[0-9]{1,3}(/[0-9]{1,2}){0,1})$`

You must provide the values, range, patterns according to the accepted ones in the schema file to be able to successfully override the inspector configuration, otherwise, you get an error message.

b) Click **Download Sample File / Template** to use a pre-existing template that contains example configurations to help you with configuring the inspectors.

You can refer to the example configurations included in the sample file and make any changes that you may require.

c) Click **Download Full Configuration** to download the entire inspector configurations in a single JSON file.

You can download the full configuration to find the information you need, rather than expanding the inspectors separately. This file contains all information about the inspector configuration.

d) Click **Download Overridden Configuration** to download the inspector configuration that has been overridden.

Step 6 To override the existing configuration, follow these steps.

You can choose to override an inspector configuration using these ways.

- Make inline edits for an inspector directly on the Firewall Management Center. See the topic **Make Inline Edit for an Inspector to Override Configuration** in the **Getting Started with Network Analysis Policies** chapter of the *Cisco Secure Firewall Management Center Snort 3 Configuration Guide*.
- Continue to follow the current procedure of using the **Actions** dropdown menu to upload the overridden configuration file.

If you chose to make inline edits directly in the Firewall Management Center, then you do not need to complete this procedure any further. Otherwise, you must complete this procedure completely.

a) Under **Inspectors**, expand the required inspector for which you want to override the default configuration.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

You may need to search for an inspector by entering any relevant text in in the search bar.

b) Click the **Copy to clipboard** icon to copy the default inspector configuration to the clipboard.
c) Create a JSON file and paste the default configuration in it.
d) Keep the inspector configuration that you want to override, and remove all other configuration and instances from the JSON file.

You can also use the **Sample File / Template** to understand how to override the default configuration. This is a sample file that includes JSON snippets explaining how you can customize the network analysis policy for Snort 3.

e) Make changes to the inspector configuration as needed.

Validate the changes and make sure they conform to the schema file. For multiton inspectors, make sure that the binder conditions for all instances are included in the JSON file. See *Multiton Inspectors* in the topic **Custom Network Analysis Policy Creation for Snort 3** in the *Cisco Secure Firewall Management Center Snort 3 Configuration Guide* for more information.

f) If you are copying any further default inspector configurations, add the inspector configuration to the existing file that contains the overridden configuration.

Note
The copied inspector configuration must comply with the JSON standards.

g) Save the overridden configuration file to your system.

Step 7 From the **Actions** dropdown menu, choose Upload Overridden Configuration to upload the JSON file that contains the overridden configuration.

Caution
Upload only the changes that you require. You should not upload the entire configuration as it makes the overrides sticky in nature and therefore, any subsequent changes to the default configuration as part of the LSP updates would not be applied.

You can drag and drop a file or click to browse to the JSON file saved in your system that contains the overridden inspector configuration.

- **Merge inspector overrides** – Content in the uploaded file is merged with the existing configuration if there is no common inspector. If there are common inspectors, then the content in the uploaded file (for common inspectors) takes precedence over the previous content, and it replaces the previous configuration for those inspectors.
- **Replace inspector overrides** – Removes all previous overrides and replaces them with the new content in the uploaded file.

  Attention
  Choosing this option deletes all the previous overrides. Review your choice carefully before using this option to override the configuration.

If any error occurs while uploading the overridden inspectors, you see the error in the **Upload Overridden Configuration File** pop-up window. You can also download the file with the error, fix the error, and reupload the file.

Step 8 In the **Upload Overridden Configuration File** pop-up window, click **Import** to upload the overridden inspector configuration.

After you upload the overridden inspector configuration, you will see an orange icon next to the inspector that signifies that it is an overridden inspector.

Also, the **Overridden Configuration** column under the inspector shows the overridden value.

You can also view all the overridden inspectors using the **Show Overrides Only** checkbox adjacent to the Search bar.

Note
Make sure that you always download the overridden configuration, open the JSON file, and append any new changes/overrides to the inspector configurations to this file. This action is needed so that you do not lose the old overridden configurations.

Step 9 (Optional) Take a backup of the overridden configuration file on your system before making any new inspector configuration changes.

Tip
We recommend that you take a backup from time to time as you override the inspector configuration.

Make inline edit for an inspector to override configuration

This task allows you to make inline edits for inspector configurations to override the default configuration according to your requirements in the Snort 3 version of the network analysis policy.

For the Snort 3 version of the network analysis policy, you can make an inline edit for the inspector configuration to override the configuration according to your requirements.

Alternatively, you can also use the **Actions** drop-down menu to upload the overridden configuration file. See Customize the network analysis policy, on page 2891 for more information.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to override the default setting.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

Step 4 Under the **Overridden Configuration** in the right column, click **Edit Inspector** (Pencil) icon to make changes to the inspector configuration.

The Override Configuration pop-up appears where you can make the required edits.

Note

- Make sure that you keep only those settings that you want to override. If you leave a setting with the same value, that field becomes sticky. This means if that setting is changed in the future by Talos, the current value will be retained.
- If you are adding or deleting any custom instance, make sure that you add or delete a binder rule for that instance in the binder inspector as well.

Step 5 Click **OK**.

If there are any errors according to the JSON standards, it shows you an error message.

Step 6 Click **Save** to save the changes.

If the changes conform to the OpenAPI schema specification, the Firewall Management Center allows you to save the configuration, otherwise, the **Error saving overridden configuration** pop-up appears that shows the errors. You can also download the file with the errors.

Revert unsaved changes during inline edits

This task allows you to revert any unsaved changes made during inline edits to override the configuration for an inspector, returning to the most recently saved value.

While making inline edits to override the configuration for an inspector , you can revert any unsaved changes. Note that this action reverts all unsaved changes to the most recently saved value, but does not revert the configuration to the default configuration for an inspector.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to revert the unsaved changes.

The default configuration is displayed in the left column and the overridden configuration is displayed in the right column under the inspector.

Step 4 Under the **Overridden Configuration** on the right column, click the **Cross** ✕ icon to revert any unsaved changes for the inspector.

Alternatively, you can click **Cancel** to cancel the changes.

If you do not have any unsaved changes to the inspector configuration, then this option is not visible.

Revert overridden configuration to default configuration

Revert any changes that you made to override the default configuration for an inspector, restoring the original default settings.

You can revert any changes that you made to override the default configuration for an inspector. This action reverts the overridden configuration to the default configuration for an inspector.

Procedure

Step 1 Go to **Policies** > **Access Control heading** > **Intrusion** > **Network Analysis Policies**.

Step 2 Go to the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Inspectors**, expand the required inspector for which you want to revert the overridden configuration.

The overridden inspectors are shown with the orange icon next to their name.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector. Under the **Overridden Configuration** on the right column, click **Revert to default configuration** (back arrow) icon to revert the overridden configuration for the inspector to the default configuration.

If you did not make any changes to the default configuration for the inspector, then this option is disabled.

Step 4 Click **Revert** to confirm the decision.

Step 5 Click **Save** to save the changes.

If you do not want to save the changes, you can click **Cancel** or the **Cross** ✕ icon.

Validate Snort 3 policies

This task validates Snort 3 policies to ensure they work correctly with current and previous device versions, handling version-specific configurations and inspector settings.

To validate the Snort 3 policies, here is a list of basic information that you can make note of:

- Current version of the Cloud-Delivered Firewall Management Center can manage multiple Firewall Threat Defense versions.
- Current version of Cloud-Delivered Firewall Management Center supports network analysis policy (NAP) configurations which are not applicable to previous version of Firewall Threat Defense devices.
- Current NAP Policy and validations will work based on the current version support.
- Changes may include content which is not valid for previous versions of Firewall Threat Defenses.

- Policy configuration changes are accepted if they are valid for the current version and performed using the current Snort 3 binary and NAP schema.
- For previous version Firewall Threat Defenses, validation is performed during deployment using NAP schema and Snort 3 binary for that specific version. If there is any configuration which is not applicable for the given version, the user is informed or warned that the configuration not supported on the given version will not be deployed, while the remaining configuration will be deployed.

In this procedure, when we associate the NAP policy to an Access Control Policy and deploy it on a device, for example any inspector like rate filter configuration is applied to validate the Snort 3 policies.

Procedure

Step 1 **Steps to Override NAP Policy Configuration:** Under **Inspectors** in the **Snort 3 Version** of the network analysis policy, expand the required inspector for which you want to override the default setting.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

a) Under the **Overridden Configuration** on the right column, click **Edit Inspector** (Pencil) icon to make changes to any inspector like rate_filter.

The Override Configuration pop-up appears where you can make the required edits to the rate_filter inspector. Click **OK**.

b) Click **Save** to save the changes.

Alternatively, you can use the **Actions** dropdown menu to upload the overridden configuration file.

Step 2 Click the **Actions** dropdown menu in the **Snort 3 Version** of the network analysis policy.

Step 3 Under **Upload**, you can click **Overridden Configuration** to upload the JSON file that contains the overridden configuration.

Caution
Upload only the changes that you require. You should not upload the entire configuration as it causes the overrides to remain persistent, so any subsequent changes to the default configuration from LSP updates will not be applied.

You can drag and drop a file or click to browse to the JSON file saved in your system that contains the overridden inspector configuration.

- **Merge inspector overrides**: Content in the uploaded file is merged with the existing configuration if there is no common inspector. If there are common inspectors, then the content in the uploaded file (for common inspectors) takes precedence over the previous content, and it replaces the previous configuration for those inspectors.
- **Replace inspector overrides**: Removes all previous overrides and replaces them with the new content in the uploaded file.

Note
As choosing this option deletes all the previous overrides, make an informed decision before overriding the configuration using this option.

If any error occurs while uploading the overridden inspectors, you see the error on the **Upload Overridden Configuration File** pop-up window. You can also download the file with the error, then fix the error and reupload the file.

Step 4 **Steps to Associate NAP Policy to Access Control Policy:** In the access control policy editor, click **Advanced**, then click **Edit** next to the Network Analysis and Intrusion Policies section.

a) From the **Default Network Analysis Policy** drop-down list, select a default network analysis policy.

If you choose a user-created policy, you can click **Edit** to edit the policy in a new window. You cannot edit system-provided policies.

b) Click **OK** and then click **Save** to save the policy.

Step 5 Alternatively, in the access control policy editor, click **Advanced**, then click **Edit** next to the Network Analysis and Intrusion Policies section.

a) Click **Add Rule**.
b) Configure the rule's conditions by clicking the options you want to add.
c) Click **Network Analysis** and choose the **Network Analysis Policy** you want to use to preprocess the traffic matching this rule.
d) Click **Add**.

Step 6 **Deployment:** On the Cloud-Delivered Firewall Management Center menu bar, click **Deploy** and then select **Deployment**.

Step 7 Identify and choose the devices on which you want to deploy configuration changes.

- Search: Search for the device name, type, domain, group, or status in the search box.
- Expand: Click **Expand Arrow** to view device-specific configuration changes to be deployed.

By selecting the device check box, all changes for that device listed under it are pushed for deployment. Alternatively, you can use the **Policy Selection** to select individual policies or configurations to deploy, withholding the rest.

Optionally, use **Show or Hide Policy** to selectively view or hide the associated unmodified policies.

Step 8 Click **Deploy**.

Step 9 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

Note
It displays a warning that Snort 3 network analysis policy contains inspectors or attributes not valid for this Firewall Threat Defense version. Invalid settings will be skipped during deployment. Invalid inspectors are: ["rate_filter"] only for devices lower than 7.1 version.

Examples of custom network analysis policy configuration

This is a sample file that includes JSON snippets explaining how you can customize the network analysis policy for Snort 3. You can choose to override an inspector configuration using the following ways:

- Make inline edits for an inspector directly on the Firewall Management Center. See Make inline edit for an inspector to override configuration, on page 2894.

- Use the **Actions** drop-down menu to upload the overridden configuration file. See Customize the network analysis policy, on page 2891.

Before you choose any of these options, review all the details and examples to help you define the network analysis policy overrides successfully. To avoid risks and errors, read and understand the scenarios provided here.

If you choose to override an inspector configuration from the **Actions** drop-down menu, you need to construct a JSON file for the network analysis policy overrides and upload the file.

For overriding an inspector configuration in the network analysis policy, you must upload only the changes that you require. You should not upload the entire configuration because it makes the overrides sticky in nature and therefore, any subsequent changes to the default values or configuration as part of the LSP updates would not be applied.

Here are the examples for various scenarios:

Enabling a Singleton Inspector when the Default State in the Base Policy is Disabled

```
{
  "rate_filter": {
    "enabled": true,
    "type": "singleton",
    "data": []
  }
}
```

Disabling a Singleton Inspector when the Default State in the Base Policy is Enabled

```
{
  "rate_filter": {
    "enabled": false,
    "type": "singleton",
    "data": []
  }
}
```

Enabling a Multiton Inspector when the Default State in the Base Policy is Disabled

```
{
  "ssh": {
    "enabled": true,
    "type": "multiton",
    "instances": []
  }
}
```

Disabling a Multiton Inspector when the Default State in the Base Policy is Enabled

```
{
  "ssh": {
    "enabled": false,
    "type": "multiton",
    "instances": []
  },
  "iec104": {
    "type": "multiton",
    "enabled": false,
    "instances": []
```

```
  }
}
```

Overriding the Default Value of Specific Setting(s) for Singleton Inspector

```
{
  "normalizer": {
    "enabled": true,
    "type": "singleton",
    "data": {
      "tcp": {
        "block": true
      },
      "ip6": true
    }
  }
}
```

Overriding Specific Setting(s) of a Default Instance (where Instance Name Matches with Inspector Type) in Multiton Inspector

```
{
  "http_inspect": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "data": {
          "unzip": false
        },
        "name": "http_inspect"
      }
    ]
  }
}
```

Adding Binder Rule for a Default Instance with Required Changes

Note Default binder rules cannot be edited; they are always appended at the end.

```
{
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "use": {
          "type": "http_inspect"
        },
        "when": {
          "role": "server",
          "service": "http",
          "dst_nets": "10.1.1.0/24"
        }
      }
    ]
  }
}
```

Adding a New Custom Instance

Note Corresponding binder rule entry must be defined in the binder inspector.

```
{
  "telnet": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "name": "telnet_my_instance",
        "data": {
          "encrypted_traffic": true
        }
      }
    ]
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_my_instance"
        }
      }
    ]
  }
}
```

Overriding a Singleton Instance, Multiton Default Instance, and Creating a New Multiton Instance in a Single JSON Override

Example to show the following in a single JSON override:

- Overriding a Singleton instance (**`normalizer`** inspector)
- Overriding a Multiton default instance (**`http_inspect`** inspector)
- Creating a new Multiton instance (**`telnet`** inspector)

```
{
  "normalizer": {
    "enabled": true,
    "type": "singleton",
    "data": {
      "tcp": {
        "block": true
      },
      "ip6": true
    }
  },
  "http_inspect": {
    "enabled": true,
```

```
      "type": "multiton",
      "instances": [
        {
          "data": {
            "unzip": false,
            "xff_headers": "x-forwarded-for true-client-ip x-another-forwarding-header"
          },
          "name": "http_inspect"
        }
      ]
    },
    "telnet": {
      "enabled": true,
      "type": "multiton",
      "instances": [
        {
          "name": "telnet_my_instance",
          "data": {
            "encrypted_traffic": true
          }
        }
      ]
    },
    "binder": {
      "enabled": true,
      "type": "binder",
      "rules": [
        {
          "when": {
            "role": "any",
            "service": "telnet"
          },
          "use": {
            "type": "telnet",
            "name": "telnet_my_instance"
          }
        },
        {
          "use": {
            "type": "http_inspect"
          },
          "when": {
            "role": "server",
            "service": "http",
            "dst_nets": "10.1.1.0/24"
          }
        }
      ]
    }
}
```

Note You do not need to provide the **name** attribute for the default instance in binder rules.

Configuring arp_spoof

Example for configuring **arp_spoof**:

The **arp_spoof** inspector does not have any default configurations for any attributes. This demonstrates the case where you can provide the overrides.

```
{
  "arp_spoof": {
    "type": "singleton",
    "data": {
      "hosts": [
        {
          "ip": "1.1.1.1",
          "mac": "ff:0f:f1:0f:0f:ff"
        },
        {
          "ip": "2.2.2.2",
          "mac": "ff:0f:f2:0f:0f:ff"
        }
      ]
    },
    "enabled": true
  }
}
```

Configuring rate_filter

```
{
  "rate_filter": {
    "data": [
      {
        "apply_to": "[10.1.2.100, 10.1.2.101]",
        "count": 5,
        "gid": 135,
        "new_action": "alert",
        "seconds": 1,
        "sid": 1,
        "timeout": 5,
        "track": "by_src"
      }
    ],
    "enabled": true,
    "type": "singleton"
  }
}
```

Configuring Binder Rules when Multi-Hierarchy Network Analysis Policy is Used

This example illustrates adding a new custom instance in child policy and the way binder rules should be written. Binder rules are defined as a list and therefore, it is important to pick up the rules defined in the parent policy and build the new rules on top of it as rules will not be merged automatically. The binder rules available in child policy are a source of truth in totality.

On the Firewall Threat Defense, the default Cisco Talos policy rules are appended on these user-defined overrides.

Parent Policy:

We have defined a custom instance by the name **`telnet_parent_instance`** and the corresponding binder rule.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": true
```

```
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

Child Policy:

This network analysis policy has the aforementioned policy as its base policy. We have defined a custom instance by the name **telnet_child_instance** and have also defined the binder rules for this instance. The binder rules from parent policy need to be copied here, and then child policy binder rules can be prepended or appended on top of it based on the nature of the rule.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": false
        },
        "name": "telnet_child_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet",
          "nets": "10.2.2.0/24"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_child_instance"
        }
      },
      {
        "when": {
          "role": "any",
          "service": "telnet"
```

```
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

Configuring List Inspector Attribute in General

While changing overrides for any attribute of type list, it is important to pass the full contents rather than partial override. This means if a base policy attributes are defined as:

```
{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1"
      }
    },
    {
      "entry2": {
        "key2": "value2"
      }
    }
  ]
}
```

If you want to modify **value1** to **value1-new**, the override payload must look like the following:

Correct Way:

```
{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1-new"
      }
    },
    {
      "entry2": {
        "key2": "value2"
      }
    }
  ]
}
```

Incorrect Way:

```
{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1-new"
      }
    }
  ]
}
```

You can understand this configuration by taking the trimmed values of the **alt_max_command_line_len** attribute in the **smtp** inspector. Suppose the default (base) policy configuration for **smtp** inspector is as follows:

```
{
  "smtp": {
    "type": "multiton",
    "instances": [
      {
        "name": "smtp",
        "data": {
          "decompress_zip": false,
          "normalize_cmds": "ATRN AUTH BDAT CHUNKING DATA DEBUG EHLO
           EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL
           NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SOML STARTTLS TICK
           TIME TURN TURNME VERB VRFY X-ADAT XADR XAUTH XCIR X-DRCP X-
           ERCP XEXCH50 X-EXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE
           XSTA XTRN XUSR",
          "ignore_data": false,
          "max_command_line_len": 512,
          "max_header_line_len": 1000,
          "log_rcptto": false,
          "decompress_swf": false,
          "max_response_line_len": 512,
          "b64_decode_depth": -1,
          "max_auth_command_line_len": 1000,
          "log_email_hdrs": false,
          "xlink2state": "alert",
          "binary_data_cmds": "BDAT XEXCH50",
          "auth_cmds": "AUTH XAUTH X-EXPS",
          "log_filename": false,
          "uu_decode_depth": -1,
          "ignore_tls_data": false,
          "data_cmds": "DATA",
          "bitenc_decode_depth": -1,
          "alt_max_command_line_len": [
            {
              "length": 255,
              "command": "ATRN"
            },
            {
              "command": "AUTH",
              "length": 246
            },
            {
              "length": 255,
              "command": "BDAT"
            },
            {
              "length": 246,
              "command": "DATA"
            }
          ],
          "log_mailfrom": false,
          "decompress_pdf": false,
          "normalize": "none",
          "email_hdrs_log_depth": 1464,
          "valid_cmds": "ATRN AUTH BDAT CHUNKING DATA DEBUG EHLO
           EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL
           NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SOML STARTTLS TICK
           TIME TURN TURNME VERB VRFY X-ADAT XADR XAUTH XCIR X-DRCP X-
           ERCP XEXCH50 X-EXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE
           XSTA XTRN XUSR",
          "qp_decode_depth": -1
        }
      }
    ],
    "enabled": true
```

```
  }
}
```

Now, if you want to add two more objects to the **alt_max_command_line_len** list:

```
{
    "length": 246,
    "command": "XEXCH50"
},
{
    "length": 246,
    "command": "X-EXPS"
}
```

Then the custom network analysis policy override JSON would look like the following:

```
{
  "smtp": {
    "type": "multiton",
    "instances": [
      {
        "name": "smtp",
        "data": {
          "alt_max_command_line_len": [
            {
              "length": 255,
              "command": "ATRN"
            },
            {
              "command": "AUTH",
              "length": 246
            },
            {
              "length": 255,
              "command": "BDAT"
            },
            {
              "length": 246,
              "command": "DATA"
            },
            {
              "length": 246,
              "command": "XEXCH50"
            },
            {
              "length": 246,
              "command": "X-EXPS"
            }
          ]
        }
      }
    ],
    "enabled": true
  }
}
```

Configuring Overrides when Multi-Hierarchy Network Analysis Policy is used in Multiton Inspector

This example illustrates overriding attributes in child policy and how the merged configuration will be used in the child policy for any instance. Any overrides defined in the child policy will be merged with the parent policy. Thus, if attribute1 and attribute2 are overridden in parent policy and attribute2 and attribute3 are overridden in the child policy, the merged configurations are for child policy. This means that attribute1

(defined in parent policy), attribute2 (defined in child policy), and attribute3 (defined in child policy) will be configured on the device.

Parent Policy:

Here we have defined a custom instance by the name **`telnet_parent_instance`** and overridden 2 attributes namely, **`normalize`** and **`encrypted_traffic`** in the custom instance.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": false
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

Child Policy:

This network analysis policy has the aforementioned policy as its base policy. We have overridden attribute **`encrypted_traffic`** from parent policy and also overridden new attribute **`ayt_attack_thresh`**.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "encrypted_traffic": true,
          "ayt_attack_thresh": 1
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  }
}
```

With the above policy JSON, when you deploy the network analysis policy the following merged JSON will be configured on the device.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": true,
          "ayt_attack_thresh": 1
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

This example illustrates details for the custom network analysis policy. The same behavior is also exhibited in the default instance. Also, a similar merging would be done for Singleton inspectors.

Removing all the Inspector Overrides for the Network Analysis Policy

Whenever you want to remove all the overrides for a specific network analysis policy, you can upload an empty JSON. While uploading the overrides, choose the option **Replace inspector overrides**.

Network analysis policy settings and cached changes

When you create a new network analysis policy, it has the same settings as its base policy.

When tailoring a network analysis policy, especially when disabling inspectors, keep in mind that some inspectors and intrusion rules require that traffic first be decoded or preprocessed in a certain way. If you disable a required inspector, the system automatically uses it with its current settings, although the inspector remains disabled in the network analysis policy web interface.

Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet **must** complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task.

The system caches one network analysis policy per user. While editing a network analysis policy, if you select any menu or other path to another page, your changes stay in the system cache even if you leave the page.

Generate Snort 3 recommendations

Snort 3 rule recommendations

Snort 3 rule recommendations are a security tuning feature that

- automatically tune your intrusion policy with rules specific to the host environment,
- enable additional rules or tune the current rule set by disabling rules for vulnerabilities not present in your network, and
- use the host database to determine rules that apply to your environment.

How rule recommendations work

The management center builds a database of hosts on your network with details such as the IP address, hostname, operating system, services, users, and client applications through passive discovery. Based on this information, the system maps vulnerabilities to each discovered host. The recommendations feature uses this host database to determine the rules that apply to your environment.

In Snort 3, there are four security levels, each corresponding to a specific Talos policy:

- Level 1–Connectivity Over Security
- Level 2–Balanced Security and Connectivity
- Level 3–Security Over Connectivity
- Level 4–Maximum Detection

Check the **Accept Recommendations to Disable Rules** check box to disable rules for vulnerabilities not found on the hosts in your network. Check this option only if you have to trim your rule set because of a high number of alerts, or to improve inspection performance.

For more information, see Secure Firewall recommended rules, on page 2850.

Benefits

- By configuring recommendations, you can tailor your intrusion policy to detect specific types of threats more effectively using rules that are specific to the host environment.
- Recommendations contribute to a more efficient and effective incident response process by reducing false positives and false negatives.

Sample business scenario

A sample business scenario is a network security implementation that demonstrates how a large corporate network uses Snort 3 as its primary intrusion detection and prevention system to enhance incident response capabilities through vulnerability-based rule generation and intrusion policy optimization.

Business scenario details

In this scenario, a large corporate network adopts robust network security measures in a rapidly evolving threat landscape. The security team wants to enhance their incident response capabilities by generating recommendations or rule sets based on the vulnerabilities detected in the host network. This helps to optimize their intrusion policies, thereby safeguarding the network more effectively.

Best practices

- You must have high-quality, accurate host data.

  Because of the passive nature of network discovery, your threat defense devices must be positioned as close as possible to your protected hosts. This allows the threat defense devices to watch network traffic to and from these hosts, giving you accurate data about applications, services, and vulnerabilities on your network.

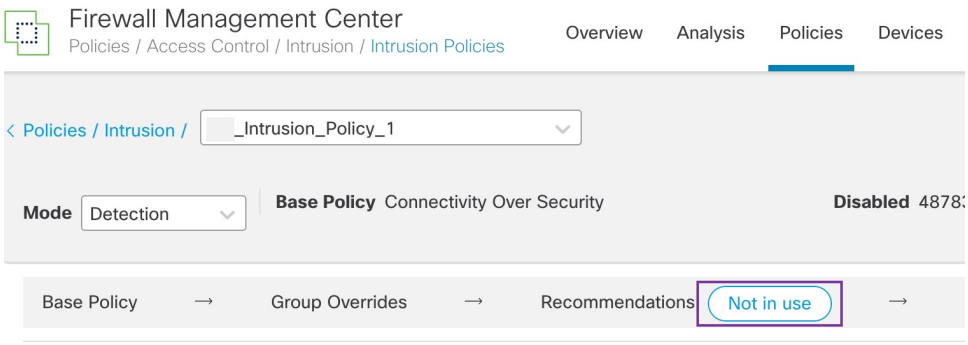
- Devices should have visibility to east–west traffic flows as well as north–south traffic flows to build an accurate host profile.
- You can create a scheduled task to update recommendations automatically.

Prerequisites for generating recommendations

- Ensure that hosts are present in the system to generate recommendations.
- Protected networks configured for recommendations should map to the hosts present in the system.

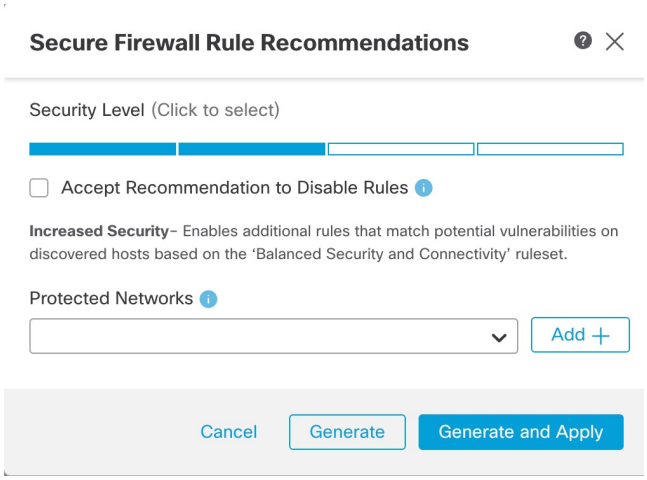
Generate Snort 3 recommendations

Generate and apply Snort 3 rule recommendations to optimize your intrusion policy based on your network configuration and security requirements.



Snort 3 recommendations help you configure intrusion policies with rules that are tailored to your network environment. The system analyzes your protected networks and suggests appropriate security levels and rule configurations.

Procedure



Step 1 Choose **Policies** > **Access Control heading** > **Intrusion**.

Step 2 Click the **Snort 3 Version** button of the corresponding intrusion policy.

Step 3 Click the **Recommendations (Not in Use)** layer to configure the rule recommendations.

In the **Cisco Recommended Rules** window, you can set the security level.

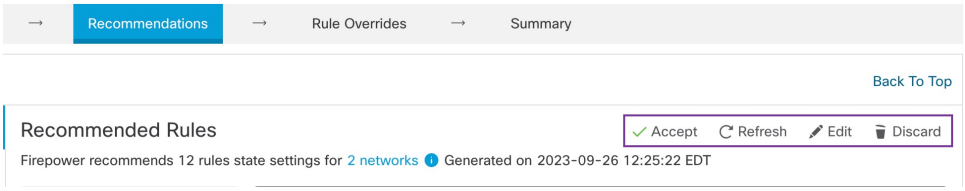
Step 4 Click to select the security level.

Step 5 (Optional) Check the **Accept Recommendation to Disable Rules** check box to disable the rules written for vulnerabilities not found on the hosts in your network.

Use this option, only if you have to trim your rule set because of a high number of alerts or to improve inspection performance.

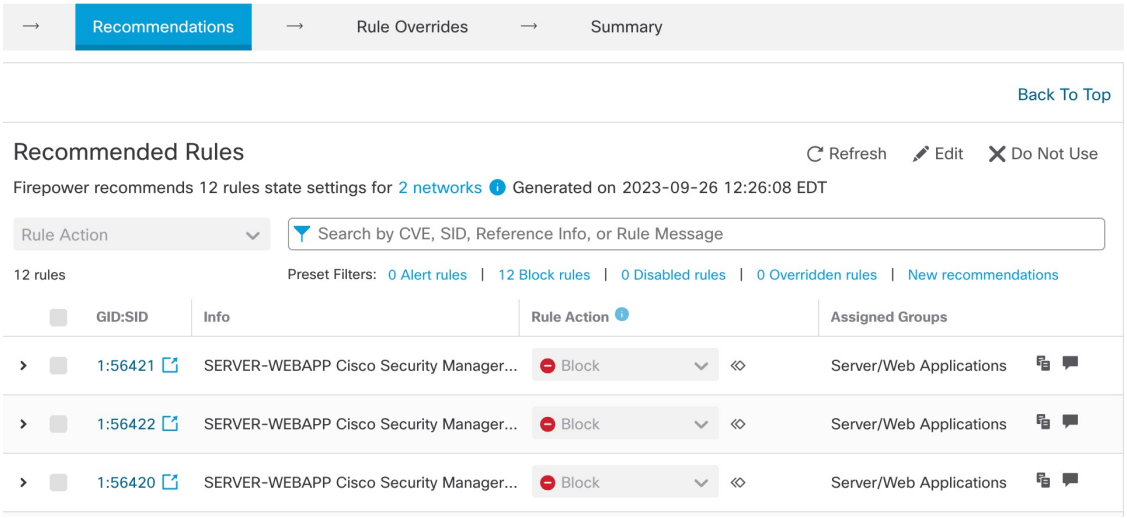
Step 6 From the **Protected Networks** drop-down list, choose the network objects that must be examined by the recommendations. By default, any IPv4 or IPv6 networks are selected if you do not make a selection.

Click **Add +** to create a new network object of type **Host** or **Network** and click **Save**.



Step 7 Generate and apply recommendations:

- **Generate**—Generates the recommendations for an intrusion policy. This action lists the rules under **Recommended Rules (Not in use)**.
- **Generate and Apply**—Generates and applies the recommendations for an intrusion policy. This action lists the rules under **Recommended Rules (Not in use)**.

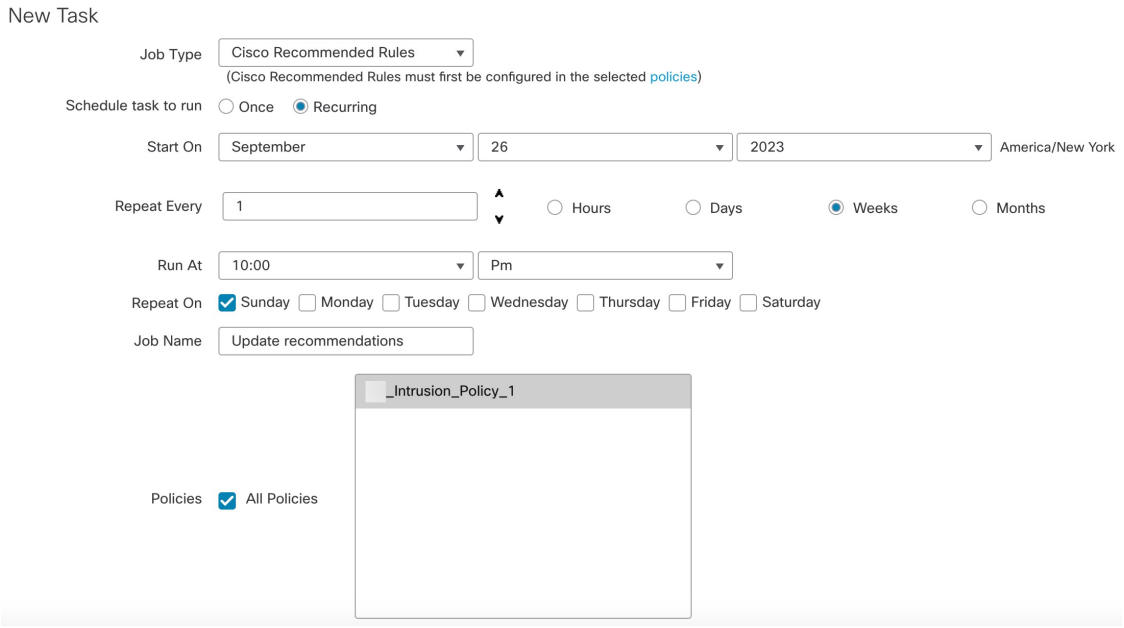


Recommendations are generated successfully. A new recommendation tab appears with all the recommended rules and their corresponding recommended actions. Rule action preset filters are also available for this tab, in addition to new recommendations.

Step 8 Verify the recommendations and then apply them accordingly:

- **Accept**—Applies the previously generated recommendations for an intrusion policy.
- **Refresh**—Regenerates and updates the rule recommendations for an intrusion policy.
- **Edit**—Opens the **Recommendations** dialog box where you can provide the recommendation input values and then generate the recommendations.
- **Discard**—Either reverts or removes the applied recommended rules from the policy; also removes the **Recommendations** tab.

Under **All Rules**, the Recommended Rules section displays the recommended rules.



Step 9 To effectively use recommendations, they must be updated periodically. Follow these steps:

a. Choose **System** (⚙) > **Tools** > **Scheduling**.

b. Click **Add Task**.

c. Choose **Cisco Recommended Rules** from the **Job Type** drop-down list.

d. Update the required fields, as needed.

e. Click **Save**.

What to do next

Deploy configuration changes. Refer to Deploy configuration changes, on page 2806.

CHAPTER 102

Advanced Access Control settings for Network Analysis and Intrusion Policies

This chapter describes how to configure advanced settings for network analysis and intrusion policies.

- Advanced access control settings for network analysis and intrusion policies, on page 2917
- Advanced access control settings for network analysis and intrusion policies, on page 2917
- Requirements and prerequisites for advanced access control settings for network analysis and intrusion policies, on page 2918
- Inspection of packets that pass before traffic is identified, on page 2918
- Advanced settings for network analysis policies, on page 2920

Advanced access control settings for network analysis and intrusion policies

Advanced access control settings are intrusion detection and prevention configurations that

- require specific expertise to configure,
- typically require little or no modification, and
- are not common to every deployment.

Version compatibility

Advanced access control settings for network analysis and intrusion policies

Advanced access control settings are intrusion detection and prevention configurations that

- require specific expertise to configure,
- typically require little or no modification, and
- are not common to every deployment.

Version compatibility

Requirements and prerequisites for advanced access control settings for network analysis and intrusion policies

This reference provides the system requirements, software prerequisites, and configuration dependencies needed to implement advanced access control settings for network analysis and intrusion detection policies in Cisco Secure Firewall environments.

Model support

- Network Admin

Inspection of packets that pass before traffic is identified

Inspection of packets that pass before traffic is identified is a network security process that

- allows a few packets to pass initially for connection establishment and traffic identification,
- enables features like URL filtering, application detection, rate limiting, and Intelligent Application Bypass to function properly, and
- requires explicit configuration in access control policies to inspect, prevent, and generate events for these initial packets.

Configuration requirements

You must explicitly configure your access control policy to inspect these packets, prevent them from reaching their destination, and generate any events.

As soon as the system identifies the access control rule or default action that should handle the connection, the remaining packets in the connection are handled and inspected accordingly.

Best practices for handling packets that pass before traffic identification

The default action specified for an access control policy is NOT applied to these packets.

Use these guidelines to choose a value for the **Intrusion Policy used before Access Control rule is determined** setting in the Advanced settings of the access control policy.

- You can choose a system-created or custom intrusion policy. For example, you can choose **Balanced Security and Connectivity**.
- For performance reasons, unless you have good reason to do otherwise, this setting should match the default action set for your access control policy.
- If your system does NOT perform intrusion inspection (for example, in a discovery-only deployment), select **No Rules Active**. The system will NOT inspect these initial packets, and they will be allowed to pass.
- By default, this setting uses the default variable set. Ensure that this is suitable for your purposes. For information, see Variable sets, on page 3040.
- The network analysis policy associated with the first matching network analysis rule preprocesses traffic for the policy you select. If there are no network analysis rules, or none match, the default network analysis policy is used.

Specify a policy to handle packets that pass before traffic identification

This task explains how to specify the system's behavior for network traffic during the period before traffic identification is complete.

Note This setting is sometimes referred to as the *default intrusion policy*. (This is distinct from the default action for an access control policy.)

Before you begin

Review best practices for these settings. See Best practices for handling packets that pass before traffic identification, on page 2918.

Follow these steps to specify a policy to handle packets that pass before traffic identification:

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** ( ) next to the **Network Analysis** and **Intrusion Policies** section.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Select an intrusion policy from the **Intrusion Policy used before Access Control rule is determined** drop-down list.

If you choose a user-created policy, you can click **Edit** ( ) to edit the policy in a new window. You cannot edit system-provided policies.

Step 3 Optionally, select a different variable set from the **Intrusion Policy Variable Set** drop-down list. You can also select **Edit** (✎) next to the variable set to create and edit variable sets. If you do not change the variable set, the system uses a default set.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Variable sets, on page 3040

Advanced settings for network analysis policies

A *network analysis policy* is a traffic preprocessing configuration that governs how traffic is decoded and preprocessed so that it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.

Advanced configuration concepts

This traffic preprocessing occurs after Security Intelligence matching and traffic decryption, but before intrusion policies inspect packets in detail. By default, the system-provided Balanced Security and Connectivity network analysis policy is the default network analysis policy.

Tip The system-provided Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.

A simple way to tune preprocessing is to create and use a custom network analysis policy as the default. If you are an advanced user with a complex deployment, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs.

To accomplish this, you add custom *network analysis rules* to your access control policy. A network analysis rule is simply a set of configurations and conditions that specifies how you preprocess traffic that matches those qualifications. You create and edit network analysis rules in the advanced options in an existing access control policy. Each rule belongs to only one policy.

Each rule has:

- a set of rule conditions that identifies the specific traffic you want to preprocess
- an associated network analysis policy that you want to use to preprocess traffic that meets all the rules' conditions

When it is time for the system to preprocess traffic, it matches packets to network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rules is preprocessed by the default network analysis policy.

Set the default network analysis policy

Setting a default network analysis policy establishes the baseline preprocessing behavior for network traffic analysis within your access control policy.

You can choose a system- or user-created policy.

Note If you disable a preprocessor but the system needs to evaluate preprocessed packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although it remains disabled in the network analysis policy web interface. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful that you allow the network analysis and intrusion policies examining a single packet to complement each other.

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** ( ) next to the Network Analysis and Intrusion Policies section.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 From the **Default Network Analysis Policy** drop-down list, select a default network analysis policy.

If you choose a user-created policy, you can click **Edit** ( ) to edit the policy in a new window. You cannot edit system-provided policies.

Step 3 Click **OK**.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Related Topics

Limitations of custom policies

Network analysis rules

A network analysis rule is a preprocessing configuration component that

- tailors preprocessing configurations to network traffic within access control policy advanced settings,

- matches packets in top-down order by ascending rule number, starting at 1, and
- preprocesses traffic according to the first rule where all conditions match.

Network analysis rule conditions and matching

You can add zone, network, and VLAN tag conditions to a rule. If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a network condition but no zone condition evaluates traffic based on its source or destination IP address, regardless of its ingress or egress interface. Traffic that does not match any network analysis rules is preprocessed by the default network analysis policy.

Network analysis policy rule conditions

Network analysis policy rule conditions are configuration parameters that enable you to fine-tune your network analysis policy to target the users and networks you want to control.

Related Topics

Security zone rule conditions, on page 2202
Network rule conditions, on page 1701
VLAN tag rule conditions, on page 2070

Security zone rule conditions

A security zone rule condition is a network traffic control mechanism that

- segments your network to help you manage, classify, and decrypt traffic flow by grouping interfaces across multiple devices,
- controls or decrypts traffic by its source and destination security zones, and
- requires all interfaces in a zone to be of the same type (all inline, passive, switched, or routed).

Zone condition traffic matching

If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

All zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Tip Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

Network rule conditions

A network condition is a traffic matching criterion that

- controls or decrypts traffic based on source and destination IP addresses using inner packet headers,
- enables administrators to specify exact IP addresses or blocks for granular policy enforcement, and
- can be built using predefined network objects or by manually entering IP addresses or address blocks.

Network rule condition restrictions

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

VLAN tag rule conditions

VLAN tags rule conditions are filtering mechanisms that

- control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic
- use the innermost VLAN tag to filter VLAN traffic, with the exception of prefilter policy which uses the outermost VLAN tag, and
- apply only to inline sets and do not match traffic on firewall interfaces.

VLAN tag rule conditions configuration details

Note VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note this Q-in-Q support:

- Firewall Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Firewall Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

Configure network analysis rules

Network analysis rules allow you to specify which network analysis policy should preprocess traffic that matches specific conditions, providing granular control over traffic inspection before intrusion detection.

Network analysis rules are configured within the advanced settings of an access control policy. You can create custom rules to apply different network analysis policies based on traffic conditions such as source, destination, ports, or applications.

Before you begin

Follow these steps to configure network analysis rules:

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** ( ) next to the Network Analysis and Intrusion Policies section.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Tip
Click **Network Analysis Policy List** to view and edit existing custom network analysis policies.

Step 2 Next to **Network Analysis Rules**, click the statement that indicates how many custom rules you have.

Step 3 Click **Add Rule**.

Step 4 Configure the rule's conditions by clicking the conditions you want to add.

Step 5 Click **Network Analysis** and choose the **Network Analysis Policy** you want to use to preprocess the traffic matching this rule.

Click **Edit** ( ) to edit a custom policy in a new window. You cannot edit system-provided policies.

Step 6 Click **Add**.

What to do next

- Deploy configuration changes.

Manage network analysis rules

Network analysis rules allow you to control how traffic preprocessing occurs by defining specific conditions and configurations that determine traffic handling methods.

A network analysis rule is simply a set of configurations and conditions that specifies how you preprocess traffic that matches those qualifications. You create and edit network analysis rules in the advanced options in an existing access control policy. Each rule belongs to only one policy.

Procedure

Step 1 In the access control policy editor, click **Advanced**, then click **Edit** ( ) next to the Intrusion and Network Analysis Policies section.

If **View** ( ) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Next to **Network Analysis Rules**, click the statement that indicates how many custom rules you have.

Step 3 Edit your custom rules. You have the following options:

- To edit a rule's conditions, or change the network analysis policy invoked by the rule, click **Edit** ( ) next to the rule.
- To change a rule's order of evaluation, click and drag the rule to the correct location. To select multiple rules, use the Shift and Ctrl keys.
- To delete a rule, click **Delete** ( ) next to the rule.

Tip
Right-click a rule to display a context menu that lets you cut, copy, paste, edit, delete, or add new network analysis rules.

Step 4 Click **OK**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

- Prefix lists, on page 3015
- Configure a route map, on page 3017
- Security intelligence, on page 3021
- Sinkhole objects, on page 3033
- Configure an SLA monitor, on page 3034
- Time ranges, on page 3036
- Time zones, on page 3038
- Tunnel zones, on page 3038
- URLs, on page 3038

- Variable sets, on page 3040
- VLAN tags, on page 3057
- VPN, on page 3057

Objects

An object is a configuration element that

- associates a name with a value for increased flexibility and ease of use in the web interface,
- enables reuse of configurations across policies, rules, event searches, reports, and dashboards, and
- can be managed, grouped, and overridden as needed within the system.

Object management and usage

The system uses named objects to simplify configuration and management. Use the object manager to create and manage objects. Many configurations that use objects also allow you to create objects as needed. The object manager enables you to:

- View the policies, settings, and other objects where a network, port, VLAN, or URL object is used; see View objects and their usage, on page 2935.
- Group objects to reference multiple objects with a single configuration; see Object groups, on page 2937.
- Override object values for selected devices; see Object overrides, on page 2939.

After editing an object used in an active policy, you must redeploy the changed configuration for your changes to take effect. You cannot delete an object that is in use by an active policy.

Note The system configures an object on a managed device only when a policy assigned to that device uses the object. If you remove an object from all policies assigned to a given device, the object is also removed from the device configuration on the next deployment, and subsequent changes to the object are not reflected in the device configuration.

Object types

This table lists the objects you can create in the system, and indicates whether each object type can be grouped or configured to allow overrides.

Object type	Groupable?	Allows overrides?
Network	yes	yes
Port	yes	yes
Interface: • Security Zone • Interface Group	no	no

Object type	Groupable?	Allows overrides?
Tunnel Zone	no	no
Application Filter	no	no
VLAN Tag	yes	yes
External Attribute: Security Group Tag (SGT) and Dynamic Object	no	no
URL	yes	yes
Geolocation	no	no
Time Range	no	no
Variable Set	no	no
Security Intelligence: Network, DNS, and URL lists and feeds	no	no
Sinkhole	no	no
File List	no	no
Cipher Suite List	no	no
Distinguished Name	yes	no
Public Key Infrastructure (PKI): • Internal and Trusted CA • Internal and External Certs	yes	no
Key Chain	no	yes
DNS Server Group	no	no
SLA Monitor	no	no
Prefix List: IPv4 and IPv6	no	yes
Route Map	no	yes
Access List: Standard and Extended	no	yes
AS Path	no	yes
Community List	no	yes
Policy List	no	yes
FlexConfig: Text and FlexConfig objects	no	yes

Use the object manager

The object manager provides capabilities for creating and managing objects and object groups, viewing them in paginated lists, filtering results, and refreshing the displayed information.

- The object manager enables creation and management of objects and object groups.
- The object manager displays 20 objects or groups per page. If you have more than 20 of any type of object or group, use the navigation links at the bottom of the page to view additional pages. You can also go to a specific page or click **Refresh** ( ) to refresh your view.
- Access the page using **Objects** > **Object Management**. You can alternatively access the page using **Objects** > **Other FTD Objects**.
- By default, objects and groups are listed alphabetically by name. You can filter objects by name or value.

Import objects

Import objects into the system by uploading a properly formatted comma-separated values file. This task enables bulk addition of supported object types, streamlining object management.

Objects can be quickly imported into the system using a properly formatted CSV file. Up to 1000 objects can be imported in a single operation. The format and required columns vary depending on object type.

Object TYPE	Rules

Individual object	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DN
	• Both NAME and DN column entries are mandatory to import an entry.
	• You can import individual objects directly into an existing distinguished NAME object group.

Object TYPE	Rules

Network object	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • TYPE
	  • VALUE
	  • LOOKUP
	• To import a host, range, or network object type, provide entries for both NAME and VALUE columns.
	• For an FQDN object, specify "FQDN" in the TYPE column entry, and enter "IPv4," "IPv6," or "IPv4/IPv6" in the LOOKUP column entry.
	• If you leave the LOOKUP column entry for the FQDN object empty, the system saves the object with ipv4_ipv6 as the VALUE.

PORT	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • PROTOCOL
	  • PORT
	  • ICMPCODE
	  • ICMPTYPE
	• The NAME column entry is mandatory.
	• The PORT column entry is mandatory for 'tcp' and 'udp' PROTOCOL types.
	• The ICMPCODE and ICMPTYPE column entries are mandatory for 'icmp' and 'icmp6' PROTOCOL types.

Object TYPE	Rules

URL	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • URL
	• You must provide entries for the NAME and URL columns to import an object.

VLAN TAG	• The column header must be mentioned in capital letters.
	• The file must have these columns headers:
	  • NAME
	  • DESCRIPTION
	  • TAG
	• The NAME and TAG column entries are mandatory to import an entry.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose one of these object types from the left pane:

- **Distinguished Name** > **Individual Objects**
- **Network Object**
- **PORT**
- **URL**
- **VLAN TAG**

Step 3 Choose **Import Object** from the **Add [Object TYPE]** drop-down list.

Note
If you have selected **Individual Objects** in the previous step, click **Import**.

Step 4 Click **Browse**.

Step 5 Locate and select the comma-separated file on your system.

Step 6 Click **Open**.

Note

While importing **Distinguished Name** objects, you can optionally check the **Add imported Distinguished Name objects to the below object group** check box and select the group name from the drop-down box to import the objects directly to an existing distinguished name object group.

Step 7 Click **Import**.

Edit objects

Edit network objects and groups to update their settings or manage variable sets as required for your deployment.

See caveats related to network objects and groups at Networks, on page 2982.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose an object type from the list; see Objects, on page 2930.

Step 3 Click **Edit** ( ) next to the object you want to edit.

If **View** ( ) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

Step 4 Modify the object settings as desired.

Step 5 If you are editing a variable set, manage the variables in the set; see Manage variables, on page 3054.

Step 6 For objects that can be configured to allow overrides:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941. You can change this setting only for objects that belong to the current domain.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2942.

Step 7 Click **Save**.

Step 8 If you are editing a variable set, and that set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

What to do next

- If an active policy references your object, deploy configuration changes.

View objects and their usage

This task enables you to view where objects are used within your system, helping you understand object dependencies and usage across policies and settings.

You can view usage details of objects on the Object Management page. Cloud-Delivered Firewall Management Center provides this functionality for many object types. However, some object types are not supported.

Before you begin

No prerequisites are required to view object usage details.

Follow these steps to view objects and their usage:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose one of the following supported object types:

- Access List > Extended
- Access List > Standard
- AS Path
- Community List
- Interface
- Network
- Policy List
- Port
- Prefix List > IPv4 Prefix List
- Prefix List > IPv6 Prefix List
- Route Map
- SLA Monitor
- URL
- VLAN Tag

Step 3 Click the **Find Usage** () icon next to the object.

The Object Usage window displays a list of all the policies, objects, and other settings where the object is in use. Click any of the listed items to know more about the object usage. For policies and some other settings where the object is used, you can click the corresponding links to visit the respective UI pages.

After completing these steps, you will be able to see where each object is used within your system, allowing you to manage and audit object usage efficiently.

Filter objects or object groups

Use this task when working with large configurations or when you need to identify and manage unused objects or object groups.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Enter your filter criteria in the **Filter** field.

The page updates as you type to display matching items.

You can use these wildcards:

- The asterisk (*) matches zero or more occurrences of a character.
- The caret (^) matches content at the beginning of a string.
- The dollar sign ($) matches content at the end of a string.

Step 3 To identify and review unused objects or object groups, check the **Show Unused Object** check box.

Note

- If an object is a part of an unused object group, the object is considered as used. However, the unused object group is displayed when the **Show Unused Object** check box is checked.
- The **Show Unused Object** check box is available only for network, port, URL, and VLAN tag object types.

Object groups

An object group is a configuration grouping that

- enables referencing multiple objects with a single configuration,
- allows objects and object groups to be used interchangeably in the web interface, and
- supports grouping of network, port, VLAN tag, URL, and PKI objects.

Object group usage and management

The system allows you to use objects and object groups interchangeably in the web interface. For example, anywhere you would use a port object, you can also use a port object group.

Network object groups can be nested. You can add a network object group to another network object group, up to 10 levels deep.

Objects and object groups of the same type cannot have the same name.

Edit an object group used in a policy, such as a network object group in an access control policy. Then, re-deploy the configuration for your changes to take effect.

Deleting a group does not delete the objects in the group; only their association with each other. Additionally, you cannot delete a group that is in use in an active policy. For example, you cannot delete a VLAN tag group that is used in a VLAN condition in a saved access control policy.

Object references and literal entries in object groups

Object groups can contain either object references or literal entries.

- Object references are links to existing Host/Network Objects. When the original object is modified (for example, an IP address change), all object groups containing references to that object are automatically updated to reflect the change.
- Literal entries are manually created entries within an object group. Unlike object references, literal entries are independent configuration entities and are not dynamically linked to existing Host/Network Objects. Therefore, changes made to a Host/Network Object do not propagate to object groups containing literal entries.

For example, an administrator may manually add a literal entry with the same name and IP address as an existing Host/Network Object. Although the entries appear identical, the literal entry remains independent of the original object. If the original Host/Network Object is modified, only object groups containing a reference to that object are updated.

Modifying a Host/Network Object updates only those object groups that contain a reference to that object. Object groups containing literal entries continue to display their original configuration unless the literal entries are manually modified.

Group reusable objects

Group reusable objects to simplify configuration and management in Secure Firewall Management Center.

- Organize object types such as Network, Port, URL, VLAN Tag, Distinguished Name, and PKI into groups for easier policy application.

This task is relevant when you need to manage multiple reusable objects and apply them efficiently in firewall policies.

Grouping objects allows for streamlined configuration and reduces manual effort when deploying or updating policies.

- Use this task when creating or editing object groups for policy deployment in Secure Firewall Management Center.

Before you begin

No explicit prerequisites are stated. Ensure you have access to Secure Firewall Management Center and the necessary permissions to manage objects.

- Identify the object types you want to group before starting the task.

Follow these steps to group reusable objects:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 If the object type you want to group is **Network**, **Port**, **URL**, or **VLAN Tag**:

a) Choose the object type from the list of object types.

b) Choose **Add Group** from the **Add [Object Type]** drop-down list.

Step 3 If the object type you want to group is **Distinguished Name**:

a) Expand the **Distinguished Name** node.
b) Choose **Object Groups**.
c) Click **Add Distinguished Name Group**.

Step 4 If the object type you want to group is **PKI**:

a) Expand the **PKI** node.
b) Choose one of the following:

- **Internal CA Groups**
- **Trusted CA Groups**
- **Internal Cert Groups**
- **External Cert Groups**

c) Click **Add [Object Type] Group**.

Step 5 Enter a unique **Name**.

Step 6 Choose one or more objects from the list, and click **Add**.

You can also:

- Use the filter field **Search** ( ) to search for existing objects to include, which updates as you type to display matching items. Click **Reload** ( ) above the search field or click **Clear** ( ) in the search field to clear the search string.
- Click **Add** ( ) to create objects on the fly if no existing objects meet your needs.

Step 7 Optionally for **Network**, **Port**, **URL**, and **VLAN Tag** groups:

- Enter a **Description**.
- Check the **Allow Overrides** check box to allow overrides for this object group; see Allow object overrides, on page 2941.

Step 8 Click **Save**.

After completing these steps, the object group is created and available for use in firewall policies. You can reference the group in active policies and deploy configuration changes as needed.

What to do next

- If an active policy references your object group, deploy configuration changes; see Deploy configuration changes, on page 202.

Object overrides

An object override is a configuration mechanism that

- enables the definition of alternate values for objects, which the system applies to specified devices,

- lets administrators create a smaller set of shared policies that can be used across devices without losing the flexibility to modify policies for individual devices, and
- allows modifications to an object for devices or domains that require different definitions.

Object override usage and supported object types

Administrators can create an object whose definition works for most devices and use overrides to specify modifications for those devices needing different definitions. You may also need to override an object for all devices. This approach allows you to create a single policy that applies everywhere. Object overrides allow you to use fewer shared policies and customize them for individual devices when necessary.

You can target overrides to a specific domain. The override value applies to all devices in that domain unless you set a device-specific override. The object manager enables selection of objects that can be overridden and allows listing device-level or domain-level overrides for each object.

Supported object types for overrides include:

- Network
- Port
- VLAN tag
- URL
- SLA Monitor
- Prefix List
- Route Map
- Access List
- AS Path
- Community List
- Policy List
- Cert Enrollment (PKI)
- Key Chain

In the object manager, the **Override** column flags objects that support overrides:

- Green checkmark: Overrides can be created, and none have been added yet.
- Red X: Overrides are not supported for the object.

- Number: Indicates the count of overrides added for the object (for example, "2" means two overrides have been defined).

Object override example

For example, to deny ICMP traffic to different departments, each connected to a different network, you can define an access control policy that includes a network object called Departmental Network. By enabling overrides for this object, it's possible to create policy variations on each relevant device that specify the actual network associated with that device.

Manage object overrides

Object overrides are used when you need to adjust the behavior of reusable objects for specific use cases, such as applying different values in different domains or policies. Use this task when you want to add, allow, delete, or edit object overrides in the Secure Firewall Management Center.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose from the list of object types; see Objects, on page 2930.

Step 3 Click **Edit** ( ) next to the object you want to edit.

If **View** ( ) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

Step 4 Manage the object overrides:

- Add—Add object overrides; see Add object overrides, on page 2942.
- Allow—Allow object overrides; see Allow object overrides, on page 2941.
- Edit—Edit object overrides; see Edit an object override, on page 2942.
- Delete—In the object editor, click **Delete** ( ) next to the override you want to remove.

Step 5 Click **Save**.

Allow object overrides

Enable the Allow Overrides option for an object so that you can specify override values as required for different use cases.

Procedure

Step 1 In the object editor, check the **Allow Overrides** check box.

Step 2 Click **Save** to apply your changes.

What to do next

Add object override values; see Add object overrides, on page 2942.

Add object overrides

Add or adjust object overrides so that network objects or groups can have different values assigned in specific domains or to specific devices, making configuration more flexible without modifying the base object.

Use this task when you need to assign different settings or values to the same object across multiple domains or devices—for example, when different parts of your organization require different configurations for the same network object.

For caveats when working with network objects or groups, see Networks, on page 2982.

Before you begin

Ensure that object overrides are allowed in your environment. See Allow object overrides, on page 2941.

Procedure

Step 1 In the object editor, expand the **Override** section.

Step 2 Click **Add**.

Step 3 On **Targets**, choose domains or devices in the **Available Devices and Domains** list and click **Add**.

Step 4 On the Override tab, enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 Enter an override value.

Example:

```
For a network object, enter a network value.
```

Step 7 Click **Add**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Edit an object override

This task enables you to edit the description and value of an existing object override to update its configuration as needed.

You can modify the description and the value of an existing override, but you cannot modify the existing target list. Add a new override with new targets to replace the existing override.

For caveats when working with network objects or groups, see Networks, on page 2982..

Procedure

Step 1 In the object editor, expand the **Override** section.

Step 2 Click **Edit** ( ) next to the override you want to modify.

Step 3 Optionally, modify the **Description**.

Step 4 Modify the override value.

Step 5 Click **Save** to save the override.

Step 6 Click **Save** to save the object.

What to do next

- If an active policy references your object, deploy configuration changes.

AAA servers

An AAA server is a network authentication, authorization, and accounting component that

- enables centralized management of user credentials
- supports policy enforcement, and
- provides accounting for user activities.

Add a RADIUS server group

RADIUS Server Group objects contain one or more references to RADIUS servers. These servers are used to authenticate users logging in through Remote Access VPN connections.

You can apply these objects to compatible Firewall Threat Defense devices.

Before you begin

Note You cannot override RADIUS Server Group Objects.

Procedure

Step 1 Select **Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**.

All currently configured RADIUS Server Group objects will be listed. Use the filter to narrow down the list.

Step 2 Choose and edit a listed RADIUS Server Group object, or add a new one.

See Configure RADIUS server options, on page 2945 and RADIUS server group configuration options, on page 2944 to configure this object.

Step 3 Click **Save**.

RADIUS server group configuration options

The configuration options for a RADIUS server group enable integration with identity policies and VPN authentication. This topic lists each option and describes its purpose, required settings, and usage notes.

Navigation path

Objects > **Object Management** > **AAA Server** > **RADIUS Server Group**. Choose and edit a configured RADIUS Server Group object or add a new one.

Fields

- **Name** and **Description**—Enter a name and optionally, a description to identify this RADIUS Server Group object.
- **Group Accounting Mode**—Defines how accounting messages are sent to the RADIUS servers. Choose one of these:
  - **Single**—Sends accounting messages to a single server (default).
  - **Multiple**—Sends accounting messages to all servers in the group simultaneously.
- **Retry Interval**—Sets the interval (1–10 seconds) between attempts to contact RADIUS servers.
- **Realms**(Optional)—Specify the Active Directory (AD) realm associated with this RADIUS server group. The selected realm is referenced in identity policies to determine VPN authentication identity sources for relevant traffic flows. This realm effectively provides a bridge from the identity policy to this RADIUS server group. If no realm is associated with this RADIUS server group, the RADIUS server group cannot be reached to determine the VPN authentication identity source for a traffic flow in an identity policy.

Note This field is mandatory if you use remote access VPN with User Identity and RADIUS as the identity source.

- **Enable authorize only**—If the group is used only for authorization or accounting (not authentication), enable authorize-only mode. This mode omits the RADIUS server password from Access-Request messages; the configured password for individual RADIUS servers is ignored.
- **Enable interim account update** and **Interval**—Enables the generation of interim accounting update messages to notify the RADIUS server of newly assigned IP addresses. The Interval option sets the period (1 to 120 hours; default is 24 hours) between updates.
- **Enable Dynamic Authorization** and **Port**— Enables the RADIUS dynamic authorization or change of authorization (CoA) services for this RADIUS server group. Specify the listening port for RADIUS CoA requests in the **Port** field. The valid range is 1024 to 65535 and the default value is 1700. Once defined, the corresponding RADIUS server group will be registered for CoA notification and it listens to the port for the CoA policy updates from the Cisco Identity Services Engine (ISE).

- **Merge Downloadable ACL with Cisco AV Pair ACL**—Enables merging a downloadable access control list (dACL) with a Cisco attribute-value (AV) pair ACL.

  A downloadable ACL defines and updates access control lists in Cisco ISE. Administrators can then download the updated ACLs to all applicable controllers. For more information about using dACLs in Cisco ISE, see the chapter on Segmentation, section on authorization policies, in the *Cisco ISE Administrator Guide*.

  A Cisco AV pair ACL can be utilized to define specific authentication, authorization, and accounting elements for each individual session. For more information about using dACLs in Cisco ISE, see the chapter on Segmentation, section on authorization profile settings, in the *Cisco ISE Administrator Guide*.

  If you select **Merge Downloadable ACL with Cisco AV Pair ACL**, you can choose the following options:

  - **After Cisco AV Pair ACL**—Place downloadable ACL entries after AV pair entries.
  - **Before Cisco AV Pair ACL**—Place downloadable ACL entries before AV pair entries.

- **RADIUS Servers**—For server-specific configuration options, see Configure RADIUS server options, on page 2945.

Related Topics

Add a RADIUS server group, on page 2943

Configure RADIUS server options

Use this topic to configure a RADIUS server, including authentication, accounting, connectivity, and security settings.

Navigation path

Objects > **Object Management** > **AAA Server** > **RADIUS Server Group**. Choose and edit a listed RADIUS Server Group object, or add a new one. In the RADIUS Server Group dialog, choose and edit a RADIUS Server or add a new server.

Fields

- **IP Address/Hostname**—Specify the hostname or IP address (IPv4 or IPv6) of the RADIUS server that receives authentication requests. Only one server may be selected. To add servers, add more RADIUS Server entries to the RADIUS Server Group list.
- **RADIUS Server-Enabled Message Authenticator**—Message authenticators safeguard server-to-client communication and are required for a secure connection between your RADIUS server and firewall devices. Disabling message authenticators may expose your firewalls to potential attacks.

  Your RADIUS server must support and be configured for Message-Authenticator. Requires Firewall Threat Defense Version 7.2.10+, 7.4.3+, or 7.6.1+. For the Firepower 4100/9300, this feature may require an FXOS upgrade; for minimum builds, see *Cisco Secure Firewall Threat Defense Compatibility Guide*.
- **Authentication Port**—The port on which RADIUS authentication and authorization are performed. The default is 1812.
- **Key** and **Confirm Key**—Enter the shared secret to encrypt data between the managed device (client) and the RADIUS server.

The key is a case-sensitive, alphanumeric string of up to 127 characters. Special characters are permitted.

Enter the same key in this field and on the RADIUS server. Enter the shared secret again in the Confirm field.

- **Accounting Port**—Enter the port number for RADIUS accounting. The default port is 1813.
- **Timeout**—Specify the session timeout for authentication.

  Set the timeout value to 60 seconds or more for RADIUS two-factor authentication. The default timeout value is 10 seconds.
- **Connect Using** —Select the method to connect the device to a RADIUS server using either a route lookup or a specific interface.
  - Click the **Routing** radio button to use the routing table.
  - Click the **Specific Interface** radio button and choose a security zone/interface group or the Management interface (the default) from the drop-down list. If you want to use Management, you must choose it specifically; it is not available when using a route lookup. You cannot specify any other management-only interface as the RADIUS source.You can also choose a loopback interface group.
- **Redirect ACL**—Select the redirect ACL from the list or add a new one.

  Use the ACL name from the device to control redirected traffic. The Redirect ACL name here must be the same as the *redirect-ACL* name in ISE server. When you configure the ACL object, ensure that you select Block action for ISE and DNS servers, and Allow action for the rest of the servers.

RADIUS server group configuration options, on page 2944

Add a single sign-on server

Add a single sign-on (SSO) server to integrate SAML-based authentication for remote access VPN users. This task enables secure user authentication through your identity provider.

Use this task when you need to configure SAML single sign-on for remote access VPN, allowing users to authenticate using an external identity provider. You typically need to perform this configuration when you integrate with SAML IdPs, such as Microsoft Azure.

Before you begin

Obtain the following from your SAML identity provider:

- Identity Provider Entity ID URL
- Sign-in URL
- Sign-out URL
- Identity provider certificate and enroll the certificate in Firewall Threat Defense using the Cloud-Delivered Firewall Management Center web interface (**Devices** > **Certificates**)

For more information, see Configuring a SAML Single Sign-On Authentication, on page 1908.

Follow these steps to add a single sign-on server:

Procedure

Step 1 Choose **Objects** > **Object Management** > **AAA Server** > **Single Sign-on Server**.

Step 2 Click **Add Single Sign-on Server** and provide the following details:

Field	Description
Name	Enter the name for the SAML single sign-on server object.
Identity Provider Entity ID	Enter the URL that the SAML IdP defines to uniquely identify a service provider. Enter the URL for a metadata XML page that describes how the SAML Issuer responds to requests.
SSO URL	Enter the URL for signing in to the SAML identity provider server.
Logout URL	Enter the URL for signing out of the SAML identity provider server.
Base URL	Enter the URL that redirects users back to Firewall Threat Defense after the identity provider authenticates them. This should be the access interface URL configured for the Firewall Threat Defense remote access VPN.
Identity Provider Certificate	Enter the IdP certificate enrolled into the Firewall Threat Defense to verify the signed messages. Select an identity provider certificate from the list or click **Add** to create a new certificate enrollment object. For more information, see Manage Firewall Threat Defense certificates, on page 3080. You must enroll all of the Microsoft Azure registered application CA certificates as Trustpoints on the Firewall Threat Defense. The Microsoft Azure SAML identity provider is configured on Firewall Threat Defense for the initial application. All connection profiles are mapped to the configured MS Azure SAML identity provider. For each of the MS Azure applications (other than the default), you can choose the required trustpoint(CA certificate) in the connection profile configuration of the remote access VPN. For details, see Configure AAA Settings for Remote Access VPN, on page 1835.
Service Provider Certificate	Firewall Threat Defense certificate, which will be used to sign the requests and build circle of trust with IdP. If you have not enrolled internal Firewall Threat Defense certificates, click + to add and enroll a certificate. For more information, see Manage Firewall Threat Defense certificates, on page 3080.
Request Signature	Select the encryption algorithm to sign the SAML single sign-on requests. The signatures are listed from weakest to strongest: SHA1, SHA256, SHA384, SHA512. Select None to disable encryption.

Field	Description
Request Timeout	Specify how long users can complete the single sign-on request (SAML assertion validity duration). The SAML IdP has two time outs: *NotBefore* and *NotOnOrAfter*. The Firewall Threat Defense validates if its current time is within the time range of (lower limit) *NotBefore* and (upper limit) the smaller of *NotBefore* plus *timeout* and *NotOnOrAfter*. Thus, if you set a timeout longer than the IdP's *NotOnOrAfter* timeout, the specified timeout is ignored and the *NotOnOrAfter* timeout is selected. If the sum of the specified timeout and the *NotBefore* timeout is less than the *NotOnOrAfter* time, Firewall Threat Defense timeout overrides the timeout. The timeout range is 1-7200 seconds; the default is 300 seconds.
Enable IdP only accessible on Internal Network	Select this option if the SAML IdP resides on the internal network. Firewall Threat Defense acts as a gateway and establishes communication between the users and IdP using an anonymous webvpn session.
Request IdP re-authentication on Login	Select this option to authenticate user at each login even if the previous IdP session is valid.
Allow Overrides	Select this check box to allow overrides for this single sign-on server object.

Step 3 Click **Save**.

The single sign-on server is added and configured for SAML authentication. Users can now authenticate to the remote access VPN using the specified identity provider.

Access lists

An access list is a traffic selection object that

- identifies and selects traffic to which a service will apply
- is used when configuring features such as route maps for Firewall Threat Defense devices, and
- distinguishes between allowed and blocked traffic, where blocked traffic is excluded from the service but not necessarily dropped altogether.

Types of access lists

You can configure these types of ACL:

- Extended: Identifies traffic based on source and destination address and ports. Supports IPv4 and IPv6 addresses, which you can mix in a given rule.
- Standard: Identifies traffic based on destination address only. Supports IPv4 only.

Each access list is composed of one or more access control entries (ACEs), or rules. The order of ACEs is important.

1. When the ACL is evaluated, a packet is tested against each ACE in the order listed.

2. After a match is found, no more ACEs are checked.
3. Place more specific rules at the top of an ACL for correct behavior.

Place the most specific rules at the top of the ACL so it works as expected

Configure an extended ACL object

Configure extended ACL objects to define traffic classification rules based on source and destination addresses, protocols, ports, application groups, or IPv6 traffic. This enables granular control over network traffic for security and policy enforcement.

Use extended ACL objects when you want to match traffic based on source and destination addresses, protocol and port, application group, or if the traffic is IPv6. These objects are useful for policy-based routing and direct internet access scenarios, and provide flexibility in defining access control entries for various network requirements.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Access List** > **Extended** from the table of contents.

Step 2 Do one of the following:

- Click **Add Extended Access List** to create a new object.
- Click **Edit** ( ) to edit an existing object.

Step 3 In the **New Extended Access List Object** dialog box, enter a name for the object (no spaces allowed) and configure the access control entries:

a) Do one of the following:

- Click **Add** to create a new entry.
- Click **Edit** ( ) to edit an existing entry.

b) Select the **Action**, whether to Allow (match) or Block (not match) the traffic criteria.

Note
The **Logging**, **Log Level**, and **Log Interval** options are used for access rules only (ACLs attached to interfaces or applied globally). Because ACL objects are not used for access rules, leave these values at their defaults.

c) Configure the source and destination addresses on the **Network** tab using any of the following techniques:

- Select the desired network objects or groups from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. You can mix IPv4 and IPv6 addresses.
- Type an address in the edit box below the source or destination list and click **Add**. You can specify a single host address (such as 10.100.10.5 or 2001:DB8::0DB8:800:200C:417A), or a subnet (in 10.100.10.0/24 or 10.100.10.0 255.255.255.0 format, or for IPv6, 2001:DB8:0:CD30::/60).

d) Click the **Port** tab and configure the service using any of the following techniques.

- Select the desired port objects from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. The object can specify TCP/UDP ports, ICMP/ICMPv6 message types, or other protocols (including "any"). However, the source port, which you typically would leave empty, accepts TCP/UDP only. You cannot select port groups.

  For TCP/UDP, note that you must use the same protocol in both the source and destination fields, if you specify both. For example, you cannot specify a UDP source port and a TCP destination port.

- Type or select a port or protocol in the edit box below the source or destination list and click **Add**.

Note
To get an entry that applies to all IP traffic, select a destination port object that specifies "all" protocols.

e) Click the **Application** tab and choose the applications that are to be grouped for the direct internet access policy.

Important
- You cannot configure applications for cluster devices. Hence, this tab is not applicable for cluster devices.
- Use extended ACL with applications only in policy-based routing. Do not use it in other policies as its behavior is unknown and not supported. Ensure migration of the realm/ISE configuration for policy-based routing that uses User Identity and SGT in extended ACL.

Note
- The **Available Applications** list displays a fixed set of pre-defined applications. This list is a subset of the applications that are available on the Access Control policy as only they can be detected by their first packet (FQDN end-points resolved to IP addresses and port). The application definitions are updated through the VDB updates and are pushed to Firewall Threat Defense during subsequent deployments.
- User-defined custom applications or group of applications are not supported.
- Currently, Cloud-Delivered Firewall Management Center neither supports user-defined custom applications or group of applications nor allows you to modify the pre-defined applications list.
- You can use the filter options provided under the **Application Filters** to refine this list.

f) Click the **Users** tab and choose the users, user groups, or both that are to be classified for the Policy Based Routing (PBR).

Important
Use extended ACL with users, user groups, or both only for Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

Note
- The **Available Realms** list displays the configured active directory/LDAP realms. For information on creation of realm and managing them, see Create an LDAP realm or an Active Directory realm and realm directory, on page 2325 and Manage a realm, on page 2341 respectively.

  Note
  Local realms and Azure AD realms are not supported.

- The **Available Users** list displays the downloaded users and user groups of the selected AD/LDAP realms. To download the users, user groups, or both, navigate to **Integrations** > **Other Integrations** > **Realms**, and then click **Download** against the relevant active directory/LDAP realms.

  Note
  Threat defense can support a maximum of 512 user groups and 64000 user-IP mappings.

- The user to IP mapping and user group membership information are updated and pushed to the Firewall Threat Defense from the Cloud-Delivered Firewall Management Center during the user login or logouts, and changes in the group memberships.

g) Click the **Security Group Tag** tab and choose the source SGT tags to be classified for the direct internet access policy.

Important
Use extended ACL with SGTs only for Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

Note
- The **Available Security Group Tags** list displays the configured security group tags. You can choose to use the ISE SGTs or create custom SGTs.
- To use ISE SGTs, ensure that ISE is integrated with Cloud-Delivered Firewall Management Center with **Session Directory Topic** and SXP Topic subscribed.

  Note
  The supported ISE versions are 3.2, 3,1, 3.0, and 2.7 patch 2+.

- For information on creating custom SGTs, see Create a security group tag object, on page 2972.

Important
You can configure **Users** and **Security Group Tag** for Secure Firewall 4200 devices only.

h) Select the required application, and click **Add to Rule**.

Note
- Do not configure destination networks and applications in the extended ACL object.
- The selected applications (Network Service objects) in each of the access control entries, form a Network Service Group (NSG) and this group is deployed on the Firewall Threat Defense. The NSG is used in direct internet access to classify traffic based on the match with the selected application group.

i) Click **Add** to add the entry to the object.

Troubleshooting Tips

If necessary, click and drag the entry to move it up or down in the rule order to the desired location. Repeat the process to create or edit additional entries in the object.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 5 Click **Save**.

Configure a service access object

This task enables you to configure a service access object, which defines the conditions that traffic must meet to access a service, such as remote access VPN on the Firewall Threat Defense device.

Service access objects allow you to manage access based on geolocations and ensure that only traffic from approved regions can access specified services.

A service access object defines conditions as multiple rules to be executed in order. Each service access rule has an Allow or Deny action and a set of match criteria such as country, continent, or user-defined geolocation objects.

These rules are used to manage access to services, such as remote access VPN, and enforce security policies based on the source location of the traffic. If the traffic does not match any rules, the default action is enforced.

Use this task when you need to enforce or restrict access based on geographic or custom geolocation objects.

Before you begin

- Configure geolocation objects. For more information, see Geolocation objects, on page 2979.
- Configure a remote access VPN policy. For more information, see Create a New Remote Access VPN Policy, on page 1822.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Access List** > **Service Access**.

Step 2 Click **Add Service Access Object** to create a new object.

Step 3 In the **Add Service Access Object** dialog box, configure the following parameters:

a) In the **Name** field, enter a name for the object.

b) Click **Add Rule** to add a rule for the service access object. In the **Add Service Access Rule** dialog box, configure the following parameters:

1. Choose an action as **Allow** or **Deny** from the drop-down list.
2. From **Available Countries**, select countries, continents, or user-defined geolocation objects and move them to the **Selected Geolocation** list.
3. Click **Add**.

After you create a service access rule, a sequence number is assigned to the rule. This number determines the execution order of the rule. You cannot reorder these rules.

Step 4 From the **Default Action** drop-down list, choose **Allow All Countries** or **Deny All Countries**.

Step 5 (Optional) Check the **Allow Overrides** check box and click + to configure overrides for the service access object for devices.

Note

When you define an override for a device or a domain, whenever the system configures this object on the device or domain, it uses the override value instead of the value defined in the original object.

Step 6 (Optional) In the **Add Service Access Override** dialog box, configure these parameters:

a) From the **Target Devices and Domains** drop-down list, choose the required devices or domains for the override.

b) Verify if you require the existing rules. Otherwise, delete them.

c) Click **Add Rule** to create service access rules for this object override.

1. Choose an action as **Allow** or **Deny** from the drop-down list.
2. From **Available Countries**, select countries, continents, or user-defined geolocation objects and move them to the **Selected Geolocation** list.
3. Click **Add**.

d) From the **Default Action** drop-down list, choose **Allow All Countries** or **Deny All Countries**.

e) Click **Add**.

Step 7 Click **Save**.

What to do next

Configure the Service Access object in the remote access VPN policy. For more information, see Configure Access Interfaces for Remote Access VPN, on page 1851.

Configure a standard ACL object

Use standard ACL objects when you only need to match traffic based on destination IPv4 address. Extended ACLs allow more granularity if needed.

Procedure

Step 1 Select **Objects** > **Object Management** > **Access List** > **Standard** from the table of contents.

Step 2 Do one of the following:

- Click **Add Standard Access List** to create a new object.
- Click **Edit** (✎) to edit an existing object.

Step 3 In the **New Standard Access List Object** dialog box, enter a name for the object (no spaces allowed), and configure the access control entries:

a) Do one of the following:

- Click **Add** to create a new entry.
- Click **Edit** (✎) to edit an existing entry.

b) For each access control entry, configure the following properties:

- **Action**—Whether to allow (match) or block (not match) the traffic criteria.
- **Network**—Add the IPv4 network objects or groups that identify the destination of the traffic.

c) Click **Add** to add the entry to the object.
d) If necessary, click and drag the entry to move it up or down in the rule order to the desired location.

Repeat the process to create or edit additional entries in the object.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 5 Click **Save**.

Configure address pools

You can configure IP address pools for both IPv4 and IPv6 that can be used for clustering or for VPN remote access profiles. For clustering in Individual interface mode, you can also configure MAC address pools.

Procedure

Step 1 Select **Objects** > **Object Management** > **Address Pools**.

Step 2 Click **IPv4 Pools** and then **Add IPv4 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters.
- **Description**—Add an optional description for this pool.
- **IP Address**—Enter a range of addresses available in the pool. Use dotted decimal notation and a dash between the beginning and the end address, for example: 10.10.147.100-10.10.147.177.
- **Mask**—Identifies the subnet on which this IP address pool resides.
- **Allow Overrides**—Check this check box to enable object overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object overrides, on page 2939 for more information.

Step 3 Click **Save**.

Step 4 Click **IPv6 Pools** and then **Add IPv6 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **IPv6 Address**—Enter the first IP address available in the configured pool and the prefix length in bits. For example: 2001:DB8::1/64.
- **Number of Addresses**—Identifies the number of IPv6 addresses, starting at the Starting IP Address, that are in the pool.

- **Allow Overrides**—Check this check box to enable overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object overrides, on page 2939 for more information.

Step 5 Click **Save**.

Step 6 Click **MAC Address Pool** and then **Add MAC Address Pool**, and configure the following fields.

For clustering in Individual interface mode, you can configure a MAC address pool for the interface. It is not common to manually configure MAC addresses for an interface, but if you have special needs to do so, then this pool is used to assign a unique MAC address to each interface. See Configure the MAC address, on page 1110.

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **MAC Address Range**—Enter a range of MAC addresses available in the pool. Use a dash between the beginning and the end address, for example: 000C.F142.4CD1-000C.F142.4CD7.
- **Allow Overrides**—Check this check box to enable overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object overrides, on page 2939 for more information.

Create an application filter

An application filter is a reusable object that allows you to organize and manage applications efficiently for use in policies that require application matching.

An application filter does these:

- Simplifies application control and policy management.
- Groups applications based on type, risk, business relevance, category, and tags.
- Supports policies such as access control, QoS, intelligent application bypass, and decryption.

Application filter configuration options

- Use the system-provided filters to find applications. Select the desired applications and click **Add to Rule**.
- To remove an application from the filter, click the delete icon next to it.
- Click the info icon next to an application to view its information.

For detailed information on application characteristics, refer to Application rule conditions, on page 1701.

Configure an AS PATH object

Enable control over BGP routing updates and filtering by specifying a sequence of autonomous system (AS) numbers.

An AS Path is a mandatory attribute to set up BGP. It is a sequence of AS numbers through which a network can be accessed. AS path is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Neighboring autonomous systems (ASes) use BGP to exchange and update messages about how to reach different AS prefixes. After each router makes a new local decision on the best route to a destination, it sends the route and associated path information, including distance metrics and path attributes, to its peers. As this information travels through the network, each router along the path prepends its unique AS number to a list of ASes in the BGP message. This list is the route's AS-PATH.

An AS path, along with an AS prefix, provides a specific handle for a one-way transit route through the network. Use the Configure AS Path page to create, copy, and edit autonomous system (AS) path policy objects. Create AS path objects to use when configuring route maps, policy maps, or BGP Neighbor Filtering. An AS path filter allows you to filter the routing update message by using regular expressions.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Choose **Objects** > **Object Management** > **AS Path** from the table of contents.

Step 2 Click **Add AS PATH**.

Step 3 Enter a name for the AS PATH object in the **Name** field. Valid values are between 1 and 500.

Step 4 Click **Add** on the **New AS PATH Object** window.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) Specify the regular expression that defines the AS PATH filter in the **Regular Expression** field.
c) Click **Add**.

Step 5 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 6 Click **Save**.

Configure a BFD template

Configure a BFD template to define BFD interval values and authentication settings for single-hop or multi-hop sessions. This enables flexible and reusable BFD configurations across interfaces.

The BFD template specifies a set of BFD interval values. BFD interval values as configured in the BFD template are not specific to a single interface. You can also configure authentication for single-hop and multi-hop sessions. Echo mode is disabled by default. You can enable Echo mode on single-hop only.

Before you begin

No prerequisites are required to configure a BFD template.

Procedure

Step 1 In the Cloud-Delivered Firewall Management Center, choose **Objects** > **Object Management** > **BFD Template**.

Step 2 Click **Add BFD Template** or **Edit**.

Note
If you are editing a template, you cannot modify its name and type.

Step 3 On the **Template** tab, configure the following:

- **Template Name**—The name of this BFD template. You must assign a name in order to configure the rest of the parameters in the template. The template name cannot have spaces and cannot have only numbers.
- **Type**—Click the **Single-Hop** or **Multi-Hop** radio button.
- **Enable Echo**—(Optional) Enables Echo for the single-hop template.

If the Echo function is not negotiated, BFD control packets are sent at a high rate to meet the detection time. If the Echo function is negotiated, BFD control packets are sent at a slower, negotiated rate and self-directed echo packets are sent at a high rate. We recommend that you use Echo mode, if possible.

Step 4 On the **Interval** tab, configure the following:

a) From the **Interval Type** drop-down list, select **Microseconds** or **Milliseconds**.
b) In the **Multiplier** field, enter the value to be used for computing the hold down time. This value indicates the number of consecutive BFD control packets that must be missed from a BFD peer before BFD declares that the peer is unavailable and the Layer 3 BFD peer is informed of the failure. The range is 3 to 50. The default is 3.
c) In the **Minimum Transmit** field, enter the minimum transmit interval capability. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.
d) In the **Minimum Receive** field, enter the minimum receive interval capability. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.

Step 5 On the **Authentication** tab, configure the following:

- **Authentication Type**—Select **NONE**, **md5**, **meticulous-sha-1**, **meticulous-md5**, or **sha-1** from the drop-down list.
- **Encrypted Password**—(Optional) Enables encryption of the authentication password.
- **Password**—The authentication password that must be sent and received in the packets using the routing protocol being authenticated. The valid value is a string containing 1 to 29 uppercase and lowercase alphanumeric characters, except that the first character cannot be a digit or a digit followed by a whitespace. For example, '1password' or '0 password' is invalid.
- **Key ID**—The shared key ID that matches the key value. The range is 0 to 255.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the BFD template configuration.

The BFD template is configured with the specified interval values, authentication settings, and echo mode options. The template can now be applied to interfaces as needed.

Cipher suite lists

A cipher suite list is an object that

- contains several cipher suites,
- enables negotiation of SSL or TLS encrypted sessions, and
- can be used in SSL rules to control encrypted traffic based on the negotiated cipher suite.

Usage of cipher suite lists in SSL rules

You can use cipher suites and cipher suite lists in SSL rules to control encrypted traffic. These rules evaluate whether the client and server negotiated the SSL session using that cipher suite. If you add a cipher suite list to an SSL rule, and if an SSL session negotiates with any cipher suite from the list, the rule matches the session.

Note You can use cipher suites in the web interface wherever you use cipher suite lists. However, you cannot add, change, or remove cipher suites.

Create a cipher suite list

Create a custom cipher suite list to control which cipher suites are available for use in your environment.

Use this task when defining or updating the set of cipher suites to align with security policies or updated encryption standards.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Cipher Suite List** from the list of object types.

Step 2 Click **Add Cipher Suites**.

Step 3 Enter a **Name**.

Step 4 Choose one or more cipher suites from the **Available Ciphers** list.

Step 5 Click **Add**.

Step 6 Optionally, click **Delete** ( ) next to any cipher suites in the **Selected Ciphers** list that you want to remove.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Configure a community list

Configure a community list to group BGP destinations that share common attributes for route tagging and policy enforcement. This task enables you to create, copy, and edit community list policy objects for use in route maps or policy maps.

Community lists allow marking sets of prefixes for common routing policies, such as filtering or assigning local preference.

A community is an optional transitive BGP attribute used for route tagging. Communities are numerical values assigned to prefixes. They are advertised to neighbors. Upstream providers use these markers to apply routing policies, such as filtering or modifying attributes.

Use the Configure Community Lists page to create, copy, and edit community list policy objects. You can use this object with Firewall Threat Defense devices.

Community lists are used in match clauses of route maps and consist of ordered matching statements. Each destination is compared against the rules. The system stops processing further rules when it finds a match.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Community List** from the table of contents.

Step 2 Click **Add Community List**.

Step 3 In the **Name** field, specify a name for the community list object.

Step 4 Click **Add** on the **New Community List Object** window.

Step 5 Select the **Standard** radio button to indicate the community rule type.

Standard community lists are used to specify well-known communities and community numbers.

Note
You cannot have entries using Standard and entries using Expanded community rule types in the same Community List object.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) In the **COMMUNITIES** field, specify a community number. Valid values can be from 1 to 4294967295 or from 0:1 to 65534:65535.
c) Select the appropriate **Route Type**.

- Internet—Select to specify the Internet well-known community. Routes with this community are advertised to all peers (internal and external).
- No Advertise—Select to specify the no-advertise well-known community. Routes with this community are not advertised to any peer (internal or external).
- No Export—Select to specify the no-export well-known community. Routes with this community are advertised to only peers in the same autonomous system or to only other sub-autonomous systems within a confederation. These routes are not advertised to external peers.

Step 6 Select the **Expanded** radio button to indicate the community rule type.

Expanded community lists filter communities with regular expressions, which specify patterns used to match community attributes.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) Specify the regular expression in the **Expressions** field.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 9 Click **Save**.

Configure an extended community list

Create an extended community list to organize destinations by shared attributes, enabling precise BGP route filtering and policy object use.

An extended community is a larger group of destinations that share some common attribute. The BGP extended community list has attributes that can be used to mark a set of prefixes that share a common attribute. These markers are used in the match clause of a route map to filter the routes for implementing route leaks among virtual routers. You can also define policy list objects with the extended community list for filtering. Matching statements are organized in an ordered list within the extended community list. Routes are matched against the rules until a match is found with the specified route target (standard rule type) or regular expression (expanded rule type). Create and edit extended community list policy objects using the Extended Community page.

Note The extended community lists are applicable only for configuring import or export of routes.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Select **Objects** > **Object Management** > **Community List** > **Extended Community**, and then click **Add Extended Community List**.

Step 2 In the **Name** field, specify a name for the extended community list object. You can enter up to 80 characters for the name.

Step 3 Select the extended community rule type:

- To specify one or more route targets, click the **Standard** radio button .
- To specify regular expressions, click the **Expanded** radio button.

Note
Use either Standard or Expanded extended community rule type in each Extended Community List object.

Step 4 Click **Add**.

Step 5 If you have selected **Standard** as the extended community rule type, specify the following:

a) In the **Sequence No** field, enter the order in which you want the rule to be executed.

The sequence number must be unique in the list.

b) From the **Action** drop-down list, if you want to permit routes that have matching route target that is specified here, select **Allow**; if you want to deny routes that have matching route target that is specified here, select **Block**.

c) In the **Route Target** field, specify a route target.

- You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.
- Valid values can be from 1:1 to 65534:65535.
- You can have a maximum of 8 route targets in an entry.
- You cannot have redundant route target set across multiple entries. For example, say you want to configure *seq1* with *1:200,100:100,1:300* route targets, and *seq2* with *1:300,100:100,1:200* route targets. This results in redundant route target set and cannot be deployed.

Step 6 If you have selected **Expanded** as the extended community rule type, specify the following:

a) In the **Sequence No** field, enter the order in which you want the rule to be executed.

The sequence number must be unique in the list.

b) From the **Action** drop-down list, if you want to permit routes that have matching regular expression that is specified here, select **Allow**; if you want to deny routes that have matching regular expression that is specified here, select **Block**.

c) Specify the regular expression in the **Expressions** field.

- You can add a single route target or a set of route targets separated by a space in a single entry. For example, *^((16) | (18)):(.)$*.
- You can add a maximum of 16 regular expressions to an entry.
- You cannot have redundant regular expression set across multiple entries. For example, say you want to configure *seq1* with *^((16) | (18)):(.)$ ^4_[0-9]*$* route targets, and *seq2* with *^4_[0-9]*$ ^((16) | (18)):(.)$* route targets. This results in redundant regular expression set and cannot be deployed.

For details on BGP regular expressions, see here.

Step 7 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 8 Click **Save**.

The extended community list can be referenced in the match clause of the Route Map object or Policy List object:

- In the Route Map object, the name of the extended community list is displayed in the **Add Route Map Entry** > **Match Clause** > **BGP** > **Community List** > **Add Extended Community List** dialog. For more details on configuring BGP settings in a route map, see Configure a route map, on page 3017.
- In the Policy List object, the name of the extended community list is displayed in the **Add Policy List** > **Community Rule** > **Add Extended Community List** dialog. For more details on configuring BGP settings in a policy list, see Configure a policy list, on page 3012.

DHCP IPv6 pools

A DHCP IPv6 pool is a configuration element that

- defines a range of IPv6 addresses for DHCP assignment,
- is referenced when configuring DHCPv6 services, and
- enables address allocation to IPv6 clients.

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 prefix delegation client, on page 1093), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

To add a pool, see Create a DHCP IPv6 pool, on page 1229.

Distinguished names

A distinguished name is a certificate attribute that

- represents the subject or issuer for a public key certificate,
- can be used in rules to control encrypted traffic based on certificate negotiation, and
- consists of attributes such as country code, common name, organization, and organizational unit.

A *distinguished name group* is a named collection of existing distinguished name objects.

Distinguished name attributes and usage

Distinguished name objects and distinguished name groups can be used in TLS/SSL rules to control encrypted traffic based on whether the client and server negotiated the TLS/SSL session using a server certificate with the distinguished name as subject or issuer.

A distinguished name can include a country code, common name, organization, and organizational unit. In most cases, the certificate includes only a common name. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. The certificate can include multiple Subject Alternative Names (SANs). You can use these names as distinguished names (DNs) in a rule condition. For detailed information about SANs, see RFC 5280, section 4.2.1.6.

The format of a distinguished name object that references a common name is `CN=`*`name`*. If you add a DN rule condition without `CN=`, the system prepends `CN=` before saving the object.

The system uses Server Name Indication (SNI) to match the DN in the TLS/SSL rule whenever possible.

You can also add a distinguished name with one of each of the attributes listed in this table, separated by commas.

Table 160: Distinguished name attributes

Attribute	Description	Allowed Values
C	Country Code	two alphabetic characters
CN	Common Name	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces
O	Organization	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces
OU	Organizational Unit	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces

DN rule conditions

- When the system first detects an encrypted session to a new server, DN data is not available for ClientHello processing. As a result, the first session might not be decrypted.

  If the server requests TLS 1.3, the setting for TLS server identity discovery can help by making sure the server certificate is known before making decryption policy decisions. For more information, see TLS server identity discovery, on page 2692.

- You *cannot* configure a distinguished name condition if you also choose the **Decrypt - Known Key** action. Because that action requires you to choose a server certificate to decrypt traffic, the certificate already matches the traffic.

Wildcard examples

You can define one or more asterisks (*) as wildcards in an attribute. In a common name attribute, you can define one or more asterisks per domain name label. Wildcards match only in that label, but you can define multiple labels with wildcards. See this table for examples.

Table 161: Common name attribute wildcard examples

Attribute	Matches	Does not match
CN=*ample.com	example.com	mail.example.com example.text.com ampleexam.com
CN=exam*.com	example.com	mail.example.com example.text.com ampleexam.com
CN=*xamp*.com	example.com	mail.example.com example.text.com ampleexam.com

Attribute	Matches	Does not match
CN=*.example.com	mail.example.com	www.myhost.example.com example.com example.text.com ampleexam.com

Note The DN object `CN=amp.cisco.com` would *not* match a CN like `CN=auth.amp.cisco.com`, which is why wildcards are recommended in these cases.

For more information and examples, see Conditions for distinguished name rules in decryption policies, on page 2208.

Related Topics

Conditions for distinguished name rules in decryption policies, on page 2208

Create a distinguished name object

Enables you to create distinguished name objects, which uniquely identify and reference network entities within Secure Firewall Management Center.

Distinguished name objects are used to specify unique identifiers for certificates or access policies. Perform this task when configuring objects that require a distinguished or common name for identification.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Distinguished Name** node, and choose **Individual Objects**.

Step 3 Click **Add Distinguished Name**.

Step 4 Enter a **Name**.

Step 5 In the **DN** field, enter a value for the distinguished name or common name. You have the following options:

- If you add a distinguished name, you can include one of each attribute listed in Distinguished names, on page 2962 separated by commas.
- If you add a common name, you can include multiple labels and wild cards.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

DNS server groups

A DNS server group is a network configuration object that

- contains multiple Domain Name System (DNS) servers
- resolves fully qualified domain names (FQDNs), such as `www.example.com`, to IP addresses, and
- enables efficient domain name resolution within a network.

Create a DNS server group object

Create and manage a group of DNS servers for use in network policies to simplify DNS server assignments.

DNS server group objects allow you to define multiple DNS servers that can be referenced by other configuration elements. Use this task to centralize DNS server assignments for interfaces or policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **DNS Server Group** from the network objects list.

Step 2 Click **Add DNS Server Group**.

Step 3 Enter a **Name**.

Step 4 Optionally, enter the **Default Domain** that will be used to append to the host names that are not fully-qualified.

This setting is only used for the default server group.

Step 5 The default **Timeout** and **Retries** values are pre-populated. Change these values if necessary.

- Retries—Specify how many times (0 to 10) to retry contacting DNS servers if there is no response. Default is 2.
- Timeout—Specify how many seconds (1 to 30) to wait before trying the next DNS server. Default is 2 seconds; this timeout doubles with each retry.

Step 6 Enter the **DNS Servers** IP addresses (IPv4 or IPv6), separated by commas. *(Maximum of 6 servers per group.)*

Step 7 Click **Save**.

What to do next

Assign the configured DNS server group to interface objects in the DNS platform settings. For more information, see Configure DNS server settings, on page 1246.

External attributes

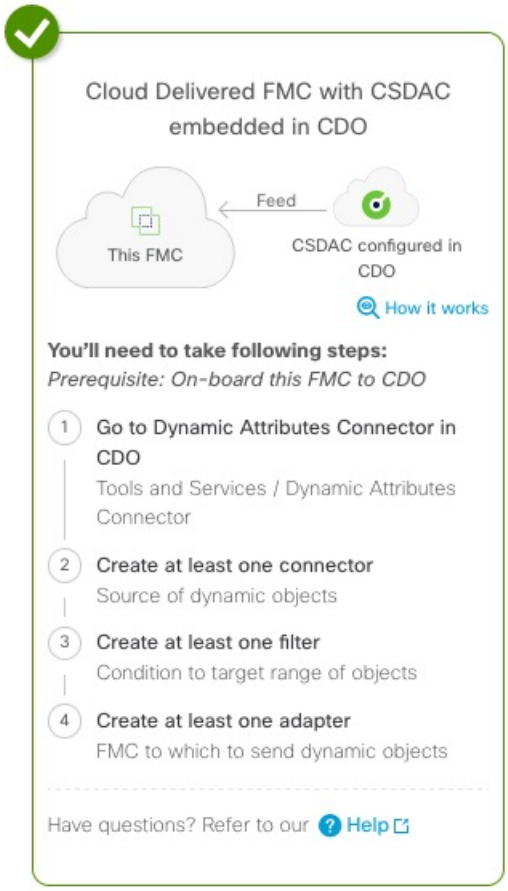
Dynamic objects

A dynamic object is a network object that

- specifies one or many IP addresses retrieved using REST API calls or the Dynamic Attributes Connector from cloud sources,
- can be used in access control or DNS rules without deploying dynamic changes, and
- automatically updates object values on managed devices after being pushed by the Dynamic Attributes Connector.

Kinds of dynamic objects

There are these kinds of dynamic objects:



- Connector-created dynamic objects: The system pushes dynamic objects created using the dynamic attributes connector to the Cloud-Delivered Firewall Management Center as soon as you create them. The system updates them at regular intervals.
- API-created dynamic objects have the following characteristics:
  - Are IP addresses, with or without classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.
  - Do not support fully-qualified domain names or address ranges.
  - You must update these objects using an API.

For more information about API-created dynamic objects, see API-created dynamic objects, on page 2971.

Note Unlike most other objects, dynamic objects do not have to be deployed to managed devices to take effect. Add a dynamic object to the **Dynamic Attributes** tab in a rule and deploy the rule. The object values are automatically updated on the managed device as soon as possible after being pushed by the Dynamic Attributes Connector.

Create dynamic objects with Cloud-Delivered Firewall Management Center

This page appears if you indicated that you are configuring the Dynamic Attributes Connector with Cloud-Delivered Firewall Management Center in Security Cloud Control.

A dynamic object is a firewall configuration element that

- enables automatic retrieval of IP addresses from cloud services,
- allows for dynamic updates within access control rules, and
- provides integration with external systems for adaptive security policies.

To deploy this feature:

1. Configure connectors: Retrieve IP addresses from supported cloud services for automatic policy updates.

   For more details, see Connectors, on page 2631.
2. Configure dynamic attributes filters: Specify which IP addresses should be sent to the management center.

   For more details, see Create dynamic attributes filters, on page 2455.
3. Configure a Cloud-Delivered Firewall Management Center adapter: Ensure that the retrieved IP addresses are sent to the correct device.
4. Access **Administration** > **Firewall Management Center**: Use the Tools menu to select **Cloud-Delivered FMC**.
5. View your dynamic objects: Navigate to **Objects** > **Object Management** > **External Attributes** > **Dynamic Object** to see the list.

6. Use dynamic objects in access control rules: In access control policies, use the **Dynamic Attributes** tab to add dynamic objects.

   You can also use the objects in DNS rules.

Create Dynamic Objects with Cloud-Delivered Firewall Management Center and On-Premises Dynamic Attributes Connector

Dynamic objects are automated network objects that synchronize IP addresses from cloud services to your management center via the dynamic attributes connector.

This page appears when you choose to configure an on-premises Dynamic Attributes Connector with Cloud-Delivered Firewall Management Center in Security Cloud Control.

Figure 397: Cloud-Delivered FMC and Dynamic Attributes Connector Integration

1. Install the Dynamic Attributes Connector on a supported Linux virtual machine.
2. Configure connectors. These connectors retrieve IP addresses from cloud services.
3. Configure adapters. These adapters send IP addresses to your Cloud-Delivered Firewall Management Center.
4. Configure dynamic attributes filters. These filters determine what IP addresses to send to the management center.

5. Click **Administration** > **Firewall Management Center** and choose **Cloud-Delivered FMC**.
6. View your dynamic objects at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object**.
7. Use dynamic objects in access control rules (**Policies** > **Access Control heading** > **Access Control**, then click the **Dynamic Attributes** tab).

   You can also use the objects in DNS rules.

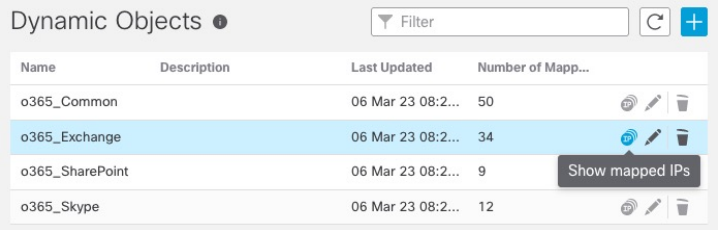
Dynamic objects page features

The Dynamic Objects page displays all dynamic objects created using the API or the Cisco Secure Dynamic Attributes Connector. You can edit, delete, or view IP address mappings on this page. The page enables you to view or download IP addresses associated with each object.

The page available at **Objects** > **Object Management** > **External Attributes** > **Dynamic Object** is displayed similar to this if you have already configured some dynamic objects.

This page displays information about each dynamic object and enables you to view or download IP addresses associated with that object. For more information, see Dynamic object mappings, on page 2970.

Dynamic object mappings



A dynamic object mapping is a configuration feature that

- enables connectors to send IPs matching dynamic attribute filters to the Cloud-Delivered Firewall Management Center,
- allows users to view or download a current list of mapped IP addresses, and
- updates IP addresses dynamically over time to reflect changes in access control rules.

Mapped IP address information

If you configured dynamic objects through the API or by using the dynamic attributes connector, the connectors send IPs that match dynamic attribute filters to the Cloud-Delivered Firewall Management Center at regular intervals.

To view or download a current list of these IP addresses, click **Show Mapped IDs** in the Cloud-Delivered Firewall Management Center, as illustrated.

IP addresses are added dynamically over time. Review the mapped IP addresses regularly, especially if the access control rules do not behave as expected.

Related topics

- API-created dynamic objects, on page 2971
- About the Dynamic Attributes Connector , on page 2621

API-created dynamic objects

An API-created dynamic object is a network object that

- specifies one or more IP addresses retrieved using REST API calls or the Dynamic Attributes Connector,
- can be used in access control or DNS rules without deploying dynamic changes to the objects, and
- updates IP addresses from cloud sources.

For more information about the dynamic attributes connector, see the information later in this guide.

Differences between dynamic objects and network objects

- Dynamic objects created using the dynamic attributes connector are pushed to the Cloud-Delivered Firewall Management Center as soon as they are created. These objects are then updated at regular intervals.
- API-created dynamic objects:
  - are IP addresses, with or without classless inter-domain routing (CIDR), that can be used in access control rules much like a network object,
  - do not support fully-qualified domain names or address ranges, and
  - must be updated using an API.

Add or edit an API-created dynamic object

This task enables you to add or edit a dynamic object using the API, allowing you to group IP addresses for use in access control rules. Dynamic objects help automate address management and streamline policy configuration.

A dynamic object is a group of IP addresses, with or without classless inter-domain routing (CIDR). You can use dynamic objects in access control rules much like a network object. This procedure is relevant when you need to manage dynamic address groups via the API instead of manually creating static objects.

Note This procedure is not necessary if you use the Dynamic Attributes Connector because it automatically creates dynamic objects for you.

Before you begin

Consult the *Firepower Management Center REST API Quick Start Guide* for information about how to use the object services REST API to populate the IP object with an address. Dynamic objects do not require deployment.

Follow these steps to add or edit an API-created dynamic object:

Procedure

Step 1 Click **Objects** > **Object Management**.

Step 2 Click **External Attributes** > **Dynamic Objects**.

Step 3 Click **Add Dynamic Object** or **Edit** ( ).

Step 4 Enter a **Name** for the object and an optional **Description**.

Step 5 From the **Type** list, click **IP**.

What to do next

If necessary, update the dynamic object using the API. Deployment is not required.

Security group tags

A security group tag is a network security object that

- specifies a single SGT value,
- is used in rules to control traffic with SGT attributes not assigned by Cisco ISE, and
- cannot be grouped or overridden.

Related Topics

Autotransition from custom SGTs to ISE SGTs
Custom SGT conditions
ISE SGTs versus custom SGT rule conditions

Create a security group tag object

This task allows you to add a security group tag object to enforce network access policies based on SGT.

You can create security group tag objects only in the global domain. A Control license is required for Classic devices. Any Smart License provides coverage for Smart Licensed devices.

Before you begin

- Disable ISE or ISE-PIC connections because custom SGT objects cannot be created if either is used as an identity source.

  Click **Integration** > **Other Integrations** > **Identity Sources**, click **None**, then click **Save**.

- See Best practices for ISE/ISE-PIC integration, on page 2376 for guidelines for using the identity source.

Follow these steps to create a security group tag object:

Procedure

Step 1 Click **Objects** > **Object Management**.
Step 2 Click **External Attributes** > **Security Group Tag**.
Step 3 Click **Add Security Group Tag**.
Step 4 Enter a **Name**.
Step 5 Optionally, enter a **Description**.
Step 6 In the **Tag** field, enter a single SGT.
Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

File lists

A file list is a threat management feature that

- allows you to manually specify files using unique SHA-256 hash values,
- overrides AMP cloud verdicts to improve detection accuracy within your environment, and
- supports categorization into clean or custom detection lists, enabling precise control over file treatment.

If you use malware defense and the AMP cloud incorrectly identifies a file's disposition, you can add the file to a file list to improve future detection. Specify these files using SHA-256 hash values. You can add up to 10,000 unique SHA-256 values in each file list.

File list categories

File lists are organized into two predefined categories.

- **Clean list**: If you add a file to this list, the system treats it as if the AMP cloud assigned a clean disposition.
- **Custom detection list**: If you add a file to this list, the system treats it as if the AMP cloud assigned a malware disposition.

Because you manually specify the blocking behavior for the files included in these lists, the system does not query the AMP cloud for these files' dispositions. You must configure a rule in the file policy with either the **Malware Cloud Lookup** or **Block Malware** action and a matching file type to calculate a file's SHA value.

Caution Do **not** include malware on the clean list. The clean list overrides both the AMP cloud disposition and the custom detection list.

Source files for file lists

Source files allow you to add multiple SHA-256 values to a file list by uploading a comma-separated value (CSV) file. The system validates the contents and populates the file list with valid SHA-256 values. Upload source files must meet the following requirements:

- The source file must be a simple text file with a .CSV extension.
- Any header must start with a pound sign; it is treated as a comment and will not be uploaded.
- Each entry should contain a single SHA-256 value followed by a description, and must end with either LF or CR+LF newline character.
- The system ignores any additional information present in the entry.

Note the following behaviors and limitations:

- Deleting a source file from the file list also removes all associated SHA-256 hashes from the list.
- You cannot upload multiple files to a file list if the upload would result in more than 10,000 distinct SHA-256 values in the list.
- The system truncates descriptions exceeding 256 characters to the first 256 characters when uploading. If the description contains commas, you must use an escape character (`\,`). If no description is provided, the source file name is used instead.
- All non-duplicate SHA-256 values are added to the file list. If a SHA-256 value already exists, it is not modified by subsequent uploads. Any threat name or description is derived from the individual SHA-256 value in related events.
- Invalid SHA-256 values in a source file are not uploaded.
- If multiple uploaded source files contain entries for the same SHA-256 value, the system uses the most recent value.
- If a source file contains multiple entries for the same SHA-256 value, the system uses the last entry.
- You cannot edit a source file directly within the object manager. To make changes, edit your local source file, delete the existing file from the system, then upload the revised file.
- The number of entries associated with a source file refers to the number of distinct SHA-256 values. Deleting a source file decreases the file list's SHA-256 entries by the number of valid entries in the deleted file.

Add individual SHA-256 values to file lists

Add unique SHA-256 values to file lists to enhance file detection and management within the system.

You must have the Malware Defense license for this procedure.

Adding SHA-256 values identifies files for detection and prevents duplicates by ensuring only unique values are included.

Before you begin

- Right-click a file or malware event from the event view, choose **Show Full Text** in the context menu, and copy the full SHA-256 value for pasting into the file list.

Follow these steps to add individual SHA-256 values to file lists:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to add a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Choose `Enter SHA Value` from the **Add by** drop-down list.

Step 5 Enter a description of the source file in the **Description** field.

Step 6 Enter or paste the file's entire value in the **SHA-256** field. The system does not support matching partial values.

Step 7 Click **Add**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Note After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

Upload an individual file to a file list

You must have the Malware Defense license for this procedure.

If you have a copy of the file you want to add to a file list, you can upload the file to the Cloud-Delivered Firewall Management Center for analysis. The system automatically calculates the file's SHA-256 value on upload. No file size limit applies for SHA-256 calculation.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to add a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 From the **Add by** drop-down list, choose **Calculate SHA**.

Step 5 (Optional) Enter a description of the file in the **Description** field. If you leave this field blank, the file name becomes the description during upload.

Step 6 Click **Browse**, and choose a file to upload.

Step 7 Click **Calculate and Add SHA** to upload the file and calculate the SHA-256 value.

Step 8 Click **Save**.

After completing these steps, the file is uploaded, its SHA-256 value is calculated, and the file is added to the selected file list for analysis.

What to do next

- If an active policy references your object, deploy configuration changes.

Note After you deploy configuration changes, the system no longer queries the AMP cloud for files on the list.

Upload source files to file lists

This task enables you to upload source files to file lists, allowing for efficient management and use of file data within the system.

You must have the Malware Defense license for this procedure.

Use this task when you need to add values from a source file to an existing file list in the system.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **File List**.

Step 3 Click **Edit** ( ) next to the file list where you want to add values from a source file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 In the **Add by** drop-down list, choose `List of SHAs`.

Step 5 (Optional) Enter a description of the source file in the **Description** field. If you do not enter a description, the system uses the file name.

Step 6 Click **Browse** to browse to the source file, then click **Upload and Add List**.

Step 7 Click **Save**.

After you complete these steps, the system uploads the source file and adds its values to the selected file list.

What to do next

- If an active policy references your object, deploy configuration changes.

Note After you deploy the policies, the system stops querying the AMP cloud for files on the list.

Edit SHA-256 values in file lists

You must have the Malware Defense license for this procedure.

You can edit or delete individual SHA-256 values on a file list. However, you cannot directly edit a source file within the object manager. To make changes, first modify your source file, delete the copy on the system, and then upload the modified file.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **File List**.

Step 3 Click **Edit** () next to the clean list or custom detection list where you want to modify a file.

If **View** () appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 You can:

- Click **Edit** () next to the SHA-256 value you want to change, and modify the **SHA-256** or **Description** values as desired.
- Click **Delete** () next to the SHA-256 value you want to delete.

Step 5 Click **Save** to update the file entry in the list.

Step 6 Click **Save** to save the file list.

What to do next

- If an active policy references your object, deploy configuration changes.

Note After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

Download source files from a file list

This task allows you to download source files from file lists, enabling you to obtain files for analysis or operational needs.

You must have the Malware Defense license for this procedure.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to download a source file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Next to the source file you want to download, click **View** ( ).

Step 5 Click **Download SHA List** and follow the prompts to save the source file.

Step 6 Click **Close**.

FlexConfig objects

A FlexConfig object is a configuration element that

- provides customized configuration of features on Firewall Threat Defense devices
- enables configuration of features not otherwise available through Cloud-Delivered Firewall Management Center, and
- uses policy objects in FlexConfig policies to customize device behavior.

FlexConfig object types

You can configure these types of objects for FlexConfig.

- **Text objects** define free-form text strings used as variables in a FlexConfig object. These objects can have a single value or multiple values. Several predefined text objects are included in FlexConfig objects. To customize device behavior, edit the contents of the text object when using a FlexConfig object. When editing a predefined object, create device overrides for each device instead of changing the default values. This helps prevent configuration issues for other users who use the same FlexConfig object. For information on configuring text objects, see Configure FlexConfig text objects, on page 1337.

- **FlexConfig objects** include device configuration commands, variables, and scripting language instructions. During deployment, the system processes these instructions to create configuration commands with customized parameters for the target devices. You can add instructions at the beginning (prepended) of the configuration or at the end (appended), based on your requirements. Append any FlexConfig that depends on Cloud-Delivered Firewall Management Center-configured objects (for example, a network object) to the configuration deployment. This ensures the necessary objects are configured before the FlexConfig refers to them. For more information on configuring FlexConfig objects, see Configure FlexConfig objects, on page 1333.

Geolocation objects

A geolocation object is a network policy element that

- represents one or more countries or continents identified as the source or destination of traffic on your monitored network,
- can be used in various places in the system's web interface, including access control policies, SSL policies, remote access VPN, and event searches, and
- enables you to write access control rules that block traffic to or from certain countries.

Geolocation database updates

To ensure that you are using up-to-date information to filter your network traffic, we strongly recommend that you regularly update your Geolocation Database (GeoDB).

Create a geolocation object

Create a geolocation object to define groups of countries and continents for use in security policies.

Use geolocation objects in access control and policy rules to manage network traffic based on geographic criteria.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Geolocation** from the list of object types.

Step 3 Click **Add Geolocation**.

Step 4 Enter a **Name**.

Step 5 Select the countries and/or continents to include.

- Selecting a continent includes all countries within that continent, including future additions via GeoDB updates.
- You can select any combination of countries and continents.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Interfaces

An interface is a network connection point that

- can be assigned to a *security zone*, an *interface group*, or both,
- enables application of security policies based on zones or groups, and
- supports flexible traffic control between different network segments.

Security zone and interface group assignments

Each interface can be assigned to a *security zone*, an *interface group*, or both. Apply your security policy based on zones or groups. For example, assign the "inside" interface to the "inside" zone and the "outside" interface to the "outside" zone. Configure the access control policy to allow traffic from inside to outside and block traffic from outside to inside. Some policies support only security zones. Other policies support both zones and groups.

For more information about interface objects, see Security zones and interface groups, on page 999.

To add interface objects, see Create security zone and interface group objects, on page 1002.

Key chains

Key chains help you rotate authentication keys for IGP peers to enhance data security, prevent unauthorized users from guessing routing protocol authentication keys, and maintain uninterrupted, secure communication by allowing overlapping key lifetimes.

Key chain authentication and key management

Use rotating keys in key chains, with a duration of 180 days or less, to protect your devices and data. Rotating keys apply only to the OSPFv2 protocol.

Note Only the MD5 cryptographic algorithm is used for authentication.

Each key in a key chain has two lifetimes:

- Accept lifetime: The time interval within which the device accepts the key during key exchange with another device.
- Send lifetime: The time interval within which the device sends the key during key exchange with another device.

During a key's send lifetime, the device sends routing update packets using that key. If the key is not within the accept lifetime, the device does not accept communication from other devices.

If lifetimes are not configured, the system treats the configuration as using an MD5 authentication key without defined timelines.

When configuring authentication for routing protocols that provide key chains, configure the keys in your key chain with overlapping lifetimes to prevent losing secure communication if no active key is available.

Key selection in a key chain is determined as follows:

- When a key chain has more than one valid key, OSPF selects the key with the longest lifetime.
- The system prefers a key with an infinite lifetime.
- If keys have the same lifetime, then key with the higher key ID is preferred.

Create a key chain object

Create key chain objects that securely manage and organize authentication keys for devices on your network.

Use this task when you need to define and manage key chains for secure authentication. Key chains enable secure key exchange, helping prevent unauthorized access and ensuring reliable communication between devices.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Key Chain** from the list of object types, and then click **Add Key Chain**.

Step 3 In the Add Key Chain Object dialog box, do the following:

a. Enter a name for the key chain in the **Name** field.

The name must start with an underscore or letter, followed by alphanumeric characters or one of the following special characters: hyphen, underscore, plus sign, or period.

b. Add a key to the key chain, click **Add**.

c. Specify the key identifier (between 0 and 255; use 0 only to signal an invalid key) in the **Key ID** field.

d. The **Algorithm** field and the **Crypto Encryption Type** field displays the supported algorithm and the encryption type, namely MD5 and Plain Text.

e. Enter the password in the **Crypto Key String** field and confirm it in the appropriate field. Passwords can be up to 80 characters and must not be a single digit or start with a digit followed by a space (e.g., "0 pass" or "1" are invalid).

f. Set the **Accept Lifetime** and **Send Lifetime** values to define the time intervals for key exchange. The times default to UTC. When specifying start and end lifetimes, ensure that the start is earlier than the end and is never left blank if the end is entered.

g. Click **Add** to create keys. Create at least two keys with overlapping lifetimes to prevent loss of secure communication.

Repeat steps 3b to 3g to create keys.

Step 4 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2942.

Step 5 Click **Save**.

After you save, you can use the key chain object in device authentication and secure communication configurations.

What to do next

- If an active policy references your object, deploy configuration changes.

Networks

A network object is a network entity that

- represents one or more IP addresses,
- can be used in access control policies, network variables, identity rules, network discovery rules, event searches, and reports, and
- is filtered automatically to show only valid objects for each configuration option.

Network object types

You can define a network object as one of these types:

- **Host**: A single IP address.

  IPv4 example:

  `209.165.200.225`

  IPv6 example:

  `2001:DB8::0DB8:800:200C:417A` or `2001:DB8:0:0:0DB8:800:200C:417A`

- **Range**: A range of IP addresses.

  IPv4 example:

  `209.165.200.225-209.165.200.250`

  IPv6 example:

  `2001:db8:0:cd30::1-2001:db8:0:cd30::1000`

- **Network**: An address block, also known as a subnet.

  IPv4 example:

  `209.165.200.224/27`

IPv6 example:

```
2001:DB8:0:CD30::/60
```

Note Security Intelligence ignores IP address blocks using a `/0` netmask.

- **FQDN**: A single fully-qualified domain name (FQDN). You can limit FQDN resolution to IPv4 address only, IPv6 address only, or both types. FQDNs must begin and end with a digit or letter. They can contain only letters, digits, and hyphens internally.

  Example:

  ```
  www.example.com
  ```

Note You can use FQDN objects in access control rules and prefilter rules, or manual NAT rules, only. The rules match the IP address obtained for the FQDN through a DNS lookup. To use an FQDN network object, ensure you have configured the DNS server settings in DNS server groups, on page 2965 and the DNS platform settings in Configure DNS server settings, on page 1246.

You *cannot* use FDQN network objects in identity rules.

- **Group**: A group of network objects or other network object groups. You can create nested groups by adding a network object group to another. Nesting is supported up to 10 levels.

Note You can add up to 100 network literals in a network object. Each nested network object group contains up to 100 network literals.

If you are using Cloud-Delivered Firewall Management Center

When you create a network object or group, it is replicated in the **Objects > FTD Network Objects** page in Security Cloud Control and vice-versa.

You can use the objects when specifying networks while configuring other Security Cloud Control-managed products, such as ASA or FDM.

Changes made to network objects or groups in either list are reflected in both. Deleting an object or group from either list also deletes its corresponding object or group from the other list.

Exception: If an object created on the Security Cloud Control list has the same name as an existing object on the Cloud-Delivered Firewall Management Center list, the object will not be replicated on the Cloud-Delivered Firewall Management Center list.

Network wildcard masks

A network wildcard mask is an IP address mask that

- uses a discontinuous mask of bits to define network objects,
- enables you to create network objects with expanded subnet IP addresses, and
- appears as **Network Wildcard** in the **Type** column of the network object list.

Network wildcard mask usage and support

You can create and manage wildcard mask objects from the Network Wildcard Mask page in **Objects** > **Object Management** .

Standard network objects use contiguous masks, while wildcard network objects use discontinuous masks.

This table shows examples of IP addresses and indicates whether they are considered network wildcard objects:

Table 162: Network wildcard mask examples

Example IP address	Network wildcard?	Object type
192.0.0.0/8	No	Network
10.10.0.0/255.255.0.0	No	Network
10.10.0.10/255.255.0.255	Yes	Network Wildcard
72.0.240.10/255.255.240.255	Yes	Network Wildcard

Note Network wildcard objects and groups containing network wildcard objects are allowed only when configuring these policies:

- Prefilter policy
- Access control policy
- NAT policy

Guidelines and limitations

- To create network wildcard objects, in the Cloud-Delivered Firewall Management Center UI, choose **Objects** > **Object Management** > **Network** and click **Add Network** and then **Add Object**. Select the **Network** option and enter the value as expanded subnet mask fotmat, such as 10.0.10.10 or 255.255.0.255.
- Features supported: Object override, group object support, group object override, wildcard literals, and wildcard object import.
- Network wildcard objects are supported only for IPv4 addresses.
- Network wildcard objects are supported from Cloud-Delivered Firewall Management Center and Firewall Threat Defense versions 7.1 onwards.
- Network wildcard objects are supported only for Snort-3.

Create a network object

Create network objects to define network addresses, address ranges, or groups that can be used in security policies and access rules.

Network objects allow you to efficiently manage and reuse network definitions across your security policies. This task is relevant when you need to add, clone, or modify network objects in your management center.

Procedure

Step 1 If you are accessing network objects from Security Cloud Control, choose **Objects**.

Step 2 Choose **Objects** > **Object Management**, and then Choose **Network** from the list of object types.

Step 3 Choose **Add Object** from the **Add Network** drop-down menu.

Step 4 Alternatively, you can clone an existing network object and edit the parameters to create a new network object. Click the **Clone** icon on the existing network object that you want to clone.

Step 5 Enter a **Name** and optionally, enter a **Description**.

Step 6 In the **Network** field, select the required option and enter an appropriate value; see Networks, on page 2982.

Note
You can add up to 100 network literals in a network object. Additionally, each nested network object group can contain a maximum of 100 network literals.

Step 7 (FQDN objects only) Select the DNS resolution from the **Lookup** drop-down menu to determine whether you want the IPv4, IPv6, or both IPv4 and IPv6 addresses associated with the FQDN.

Step 8 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2942.

Step 9 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Import network objects

For details on importing network objects, see Import objects, on page 2932.

Network objects and groups

A network object or group is a network management operation that

- modifies or removes network objects or groups from the Object Management page in Cloud-Delivered Firewall Management Center,

- automatically updates or deletes the corresponding network objects or groups replicated on the Objects page in Security Cloud Control, and
- ensures changes made to these objects on the Security Cloud Control objects page are reflected for the corresponding objects in Cloud-Delivered Firewall Management Center.

Caution When you edit or delete a network object or group from the Object Management page in Cloud-Delivered Firewall Management Center, this change also modifies or deletes the corresponding network object or group replicated on the Objects page in Security Cloud Control. Similarly, changes you make to these objects on the Security Cloud Control objects page are reflected for the corresponding objects in Cloud-Delivered Firewall Management Center.

PKI objects

PKI objects are public key certificates and paired private keys that

- represent the security components required to support your deployment
- consist of certificate authority certificates for internal and trusted CA objects
- consist of server certificates for internal and external certificate objects, and
- contain private keys paired with certificates for internal objects.

PKI object usage for applications and SSL rules

PKI objects support various security configurations across your network deployment.

You can use PKI objects for these applications:

- ISE/ISE-PIC identity source: Use trusted certificate authority objects and internal certificate objects to configure a connection to ISE/ISE-PIC as an identity source.
- Captive portal authentication: Use internal certificate objects to authenticate the identity of your captive portal device when connecting to users' web browsers.
- Secure LDAP or AD connections: Use trusted certificate authority objects to configure realms for secure connections to LDAP or AD servers.

If you use PKI objects in SSL rules, you can match traffic encrypted with:

- the certificate in an external certificate object
- a certificate either signed by the CA in a trusted CA object, or within the CA's chain of trust

If you use PKI objects in SSL rules, you can decrypt:

- outgoing traffic by re-signing the server certificate with an internal CA object
- incoming traffic using the known private key in an internal certificate object

You can manually input certificate and key information, upload a file containing that information, or in some cases, generate a new CA certificate and private key.

When you view a list of PKI objects in the object manager, the system displays the certificate's Subject distinguished name as the object value. Hover your pointer over the value to view the full certificate Subject distinguished name. To view other certificate details, edit the PKI object.

Note The Cloud-Delivered Firewall Management Center and managed devices encrypt all private keys stored in internal CA objects and internal certificate objects with a randomly generated key before saving them. If you upload private keys that are password protected, the appliance decrypts the key using the user-supplied password, then reencrypts it with the randomly generated key before saving it.

PKI objects for certificate enrollment

A certificate enrollment object is a PKI configuration item that

- contains the Certification Authority (CA) server information and enrollment parameters required for creating Certificate Signing Requests (CSRs)
- obtains identity certificates from the specified CA, and
- may include certificate revocation information.

Internal certificate authority objects

An internal certificate authority object is a security certificate object that

- represents the CA public key certificate of a CA your organization controls
- consists of the object name, CA certificate, and paired private key, and
- can be used in SSL rules to decrypt outgoing encrypted traffic by re-signing the server certificate with the internal CA.

Internal certificate authority object usage and management

You can create an internal certificate authority object in these ways:

- import an existing RSA-based or elliptic curve-based CA certificate and private key
- generate a new self-signed RSA-based CA certificate and private key
- generate an unsigned RSA-based CA certificate and private key. You must submit a certificate signing request (CSR) to another CA to sign the certificate before using the internal CA object.

Note If you reference an internal CA object in a **Decrypt - Resign** SSL rule and the rule matches an encrypted session, the user's browser may warn that the certificate is not trusted while negotiating the SSL handshake. To avoid this, add the internal CA object certificate to either the client or domain list of trusted root certificates.

After you create an internal CA object containing a signed certificate, you can download the CA certificate and private key. The system encrypts downloaded certificates and private keys with a user-provided password.

Whether system-generated or user-created, you can modify the internal CA object name, but cannot modify other object properties.

You cannot delete an internal CA object that is in use. Additionally, after you edit an internal CA object used in an SSL policy, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

CA certificates and private key import

A CA certificate and private key import is a security configuration process that

- enables uploading of X.509 v3 CA certificates and private keys,
- supports files encoded in DER or PEM formats, and
- validates that the certificate and key are properly paired before saving the object.

Supported file formats and import details

You can configure an internal CA object by importing an X.509 v3 CA certificate and private key. You can upload files encoded in one of these supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the private key file is password-protected, you can supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

The system only allows you to upload files that contain proper certificate or key information. It also ensures the certificate and key are paired with each other. The system validates the pair before saving the object.

Note If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's encryption algorithm type, in addition to any configured rule conditions. You must upload an elliptic curve-based CA certificate to decrypt outgoing traffic encrypted with an elliptic curve-based algorithm, for example.

Import a CA certificate and private key

Use this task when you need to add a new internal CA to your Secure Firewall Management Center for certificate management.

Administrators typically perform this task during initial setup or when updating trusted certificate authorities. It is relevant for those managing PKI infrastructure within Secure Firewall Management Center.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Import CA**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 Above the **Key** field, click **Browse** to upload a DER or PEM-encoded paired private key file.

Step 7 If the uploaded file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Generate a new CA certificate and private key

Generate a self-signed RSA-based CA certificate and accompanying private key by configuring an internal CA object.

Use this task to establish a trusted CA for your environment. The CA certificate enables secure signing and validation of other certificates and will be valid for ten years, with the **Valid From** date starting one week before creation.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Generate CA**.

Step 4 Enter a **Name**.

Step 5 Enter your identification attributes.

Step 6 Click **Generate self-signed CA**.

Signed certificates

A signed certificate is a digital security credential that

- is obtained from a certificate authority (CA)
- enables configuration of an internal CA object, and
- allows referencing the internal CA object in an SSL rule if it contains a signed certificate.

Certificate configuration steps

You can configure an internal CA object by obtaining a signed certificate from a CA. This process consists of these actions:

- Provide identification information to configure the internal CA object. This action generates an unsigned certificate, produces a paired private key, and creates a certificate signing request (CSR) to a specified CA.
- Upload the signed certificate issued by the CA to the internal CA object. The internal CA object now contains a signed certificate instead of the unsigned certificate.

Only reference an internal CA object in an SSL rule if it contains a signed certificate.

Create an unsigned CA certificate and CSR

Create an unsigned CA certificate and generate a certificate signing request (CSR) to enable secure certificate management in Secure Firewall Management Center.

Perform this task when you need to generate a new unsigned CA certificate and CSR, typically for setting up internal certificate authorities or renewing certificates for secure communications. Always complete this task before uploading a signed certificate issued by a certificate authority.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Generate CA**.

Step 4 Enter a **Name**.

Step 5 Enter the identification attributes.

Step 6 Click **Generate CSR**.

Step 7 Copy the CSR to submit to a CA.

Step 8 Click **OK**.

What to do next

- Upload a signed certificate issued by a CA as described in Upload a signed certificate issued in response to a CSR, on page 2990

Upload a signed certificate issued in response to a CSR

Perform this task after receiving a signed certificate from a certificate authority (CA) in response to a CSR generated by the system. Once uploaded, the certificate is available for referencing in SSL rules.

Before you begin

Obtain the signed certificate file (DER or PEM-encoded X.509 v3 CA certificate) that was issued in response to the CSR.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Edit** ( ) next to the CA object containing the unsigned certificate awaiting the CSR.

Step 4 Click **Install Certificate**.

Step 5 Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 If the uploaded file is password protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 7 Click **Save** to upload a signed certificate to the CA object.

What to do next

- If an active policy references your object, deploy configuration changes.

CA certificates and private key downloads

A CA certificate and private key download is a security operation that

- enables you to back up or transfer a CA certificate and its paired private key by downloading a file from an internal CA object,
- requires the system to decrypt the private key before creating the downloadable file, and
- uses a password provided by the user to encrypt the downloaded file for secure storage.

Encryption and storage of downloaded CA certificates and private keys

When you download a CA certificate and its private key, the system decrypts the private key before generating the file. Provide a password to encrypt the downloaded file. This helps keep it safe during storage and transfer. The system also encrypts the private key in the CA object with a randomly generated key before saving it to disk.

Caution Store downloaded key information in a secure location.

Caution If you download private keys as part of a system backup, they are decrypted and stored in the unencrypted backup file.

Download a CA certificate and private key

Obtain a CA certificate and private key required for certificate backup, migration, or integration within your secure firewall environment.

You can download CA certificates for both the current domain and ancestor domains. Use this task when you need to obtain the CA certificate and private key for backup, migration, or integration purposes.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Select the internal CA object whose certificate and private key you want to download. Click **Edit** ( ).

Step 4 Click **Download**.

Step 5 Enter an encryption password in the **Password** and **Confirm Password** fields.

Step 6 Click **OK**.

Trusted certificate authority objects

A trusted certificate authority object is a security configuration item that

- represents a CA public key certificate belonging to a trusted CA,
- consists of the object name and CA public key certificate, and
- can be used in SSL policy, realm configurations, and integration with ISE or ISE-PIC.

Usage scenarios for trusted certificate authority objects

You can use trusted certificate authority objects and groups in the following configurations:

- SSL policy: Control traffic encrypted with a certificate signed either by the trusted CA, or any CA within the chain of trust.
- Realm configurations: Establish secure connections to LDAP or Active Directory (AD) servers.
- ISE or ISE-PIC connection: Select trusted certificate authority objects for the pxGrid Server CA and MNT Server CA fields.

After you create the trusted CA object, you can modify the name and add certificate revocation lists (CRL), but cannot modify other object properties. There is no limit on the number of CRLs you can add to an object. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

Note Adding a CRL to an object has no effect when the object is used in your ISE or ISE-PIC integration configuration.

You cannot delete a trusted CA object that is in use. Additionally, after you edit a trusted CA object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

Trusted CA objects

A trusted CA object is a security object that:

- enables configuration of an external CA object by uploading an X.509 v3 CA certificate
- supports uploading files encoded in DER or PEM formats, and
- requires the system to validate the certificate before saving the object.

You can upload a file encoded in one of these supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate is encoded in the PEM format, you can also copy and paste the certificate information.

You can upload a CA certificate only if the file contains proper certificate information; the system validates the certificate before saving the object.

Add a trusted CA object

Add a trusted CA object so the system can validate certificates issued by a Certificate Authority (CA).

Use this task when you need to import a new trusted CA certificate into the system, such as when enabling secure communications or integrating with external certificate authorities.

Before you begin

- Have the DER or PEM-encoded X.509 v3 CA certificate file available.
- If the file is password-protected, ensure you have the password ready.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Trusted CAs**.

Step 3 Click **Add Trusted CAs**.

Step 4 Enter a **Name**.

Step 5 Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 If the file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 7 Click **Save**.

The trusted CA object is added and available for use in certificate validation processes.

What to do next

- If an active policy references your object, deploy configuration changes.

Certificate revocation lists in trusted CA objects

A certificate revocation list is a security file that

- can be uploaded to a trusted CA object
- enables control of encrypted traffic based on whether the issuing CA has revoked a certificate, and
- supports files encoded in Distinguished Encoding Rules (DER) or Privacy-enhanced Electronic Mail (PEM) formats.

Certificate revocation list usage in trusted CA objects

You can upload CRLs to a trusted CA object. If you reference that trusted CA object in an SSL policy, you can control encrypted traffic based on whether the CA that issued the session encryption certificate subsequently revoked the certificate.

Supported file formats for CRLs include:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

After you add the CRL, you can view the list of revoked certificates. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

You can upload only files that contain a proper CRL. There is no limit to the number of CRLs you can add to a trusted CA object. However, you must save the object each time you upload a CRL, before adding another CRL.

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

Add a certificate revocation list to a trusted CA object

Add a certificate revocation list (CRL) to a trusted certificate authority (CA) object. This step ensures that revoked certificates are recognized during certificate validation.

Add a CRL to a trusted CA object to ensure that Secure Firewall Management Center validates client certificates against a list of revoked certificates.

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

Before you begin

Ensure you have a DER or PEM-encoded CRL file available for upload.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Trusted CAs**.

Step 3 Click **Edit** ( ) next to a trusted CA object.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add CRL** and upload your DER or PEM-encoded CRL file.

Step 5 Click **OK** to save the changes.

The certificate revocation list is added to the trusted CA object, updating it with the new CRL information.

What to do next

- If an active policy references your object, deploy configuration changes.

External certificate objects

An external certificate object is a certificate management item that

- represents a server public key certificate that does not belong to your organization,
- consists of the object name and certificate, and
- can be used in SSL rules to control traffic that is encrypted with the server certificate. For example, you can upload a self-signed server certificate that you trust, but cannot verify by using a trusted CA certificate.

Supported certificate formats

You can configure an external certificate object by uploading an X.509 v3 server certificate. The supported file formats include:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

The system validates the file before saving the object, ensuring your certificate is correctly processed. If the certificate is encoded in the PEM format, you can also copy and paste the information.

Add external certificate objects

Add external certificate objects to facilitate secure certificate management and integration with external systems.

Use this task when you need to import and manage external X.509 v3 server certificates in Secure Firewall Management Center for PKI integration.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **External Certs**.

Step 3 Click **Add External Cert**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Internal certificate objects

An internal certificate object is a server public key certificate representation that

- belongs to your organization and consists of the object name, public key certificate, and paired private key
- supports SSL rule traffic decryption using the known private key, and
- enables authentication for ISE connections and captive portal configurations.

Internal certificate object usage and configuration

You can use internal certificate objects and groups in:

- your SSL rules to decrypt traffic incoming to one of your organization's servers using the known private key.
- your ISE/ISE-PIC connection. Select an internal certificate object for the **MC Server Certificate** field.
- your captive portal configuration to authenticate the identity of your captive portal device when connecting to users' web browsers. Select an internal certificate object for the **Server Certificate** field.

You can configure an internal certificate object by uploading an X.509 v3 RSA-based or elliptic curve-based server certificate and paired private key. You can upload a file in one of these supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

You can upload only files that contain proper certificate or key information, and that are paired with each other. The system validates the pair before saving the object.

After you create the internal certificate object, you can modify the name, but cannot modify other object properties.

You cannot delete an internal certificate object that is in use. Additionally, after you edit an internal certificate object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

Add internal certificate objects

Add and manage internal certificate objects for secure handling of server certificates and associated private keys within the system.

Use this task when you need to upload and manage DER or PEM-encoded X.509 v3 server certificates and their corresponding private keys for internal use. This is typically required for secure communication and authentication within your environment.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal Certs**.

Step 3 Click **Add Internal Cert**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.

Step 6 Above the **Key** field, or click **Browse** to upload a DER or PEM-encoded paired private key file.

Step 7 If the uploaded private key file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 8 Click **Save**.

Certificate enrollment objects

A certificate enrollment object is a PKI configuration item that

- contains the Certification Authority (CA) server information and enrollment parameters required for creating Certificate Signing Requests (CSRs)
- obtains identity certificates from the specified CA, and
- may include certificate revocation information.

Certificate enrollment object reference information

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

This section describes how to use and manage certificate enrollment objects in your PKI infrastructure.

- Certificate enrollment objects are used to enroll managed devices into your PKI infrastructure and create trustpoints (CA objects) on devices that support VPN connections.
- To manage certificate enrollment objects, go to **Objects** > **Object Management** > **PKI** > **Certificate Enrollment**. The following information is shown:
  - Existing certificate enrollment objects are listed in the **Name** column. Use the search field (the magnifying glass) to filter the list.
  - The enrollment type of each object is shown in the **Type** column. These enrollment methods can be used:
    - **Self Signed**—The managed device generates its own self signed root certificate.
    - **EST**—Enrollment over Secure Transport is used by the device to obtain an identity certificate from the CA.
    - **SCEP**—(Default) Simple Certificate Enrollment Protocol (SCEP) is used by the device to obtain an identity certificate from the CA.
    - **Manual**—The process of enrolling is carried out manually by the administrator.
    - **PKCS12 File**—Import a PKCS12 file on a Threat Defense managed device that supports VPN connectivity. A PKCS#12, or PFX or P12 file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. Enter the **Passphrase** value for decryption.
  - The **Override** column indicates whether the object allows overrides (a green check mark) or not (a red X). If a number is displayed, it is the number of overrides in place. Use the Override option to customize the object settings for each device that is part of the VPN configuration. Overriding makes each device's trustpoint details unique. Typically the Common Name or Subject is overridden for each device in the VPN configuration. See Object overrides, on page 2939 for details and procedures on overriding objects of any type.
  - **Edit** a previously created certificate enrollment object by clicking on the edit icon (a pencil). Editing can only be done if the enrollment object is not associated with any managed devices. Refer to the adding instructions for editing a certificate enrollment object. Failed enrollment objects can be edited.
  - **Delete** a previously created certificate enrollment object by clicking on the delete icon (a trash can). You cannot delete a certificate enrollment object if it is associated with any managed device.

1. Define parameters for CA authentication and enrollment in a certificate enrollment object. Specify shared parameters and use the override facility to specify unique object settings for different devices.
2. Associate and install this object on each managed device that requires the identity certificate. On the device, it becomes a trustpoint.

   When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed, SCEP, EST, and PKCS12 file enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.
3. Specify the created trustpoint in your VPN configuration.

Press (+)**Add Cert Enrollment** to open the **Add Cert Enrollment** dialog and configure a certificate enrollment object, see Add certificate enrollment objects, on page 2999. Then install the certificate on each managed, headend device.

For more information on PKI, digital certificates, and certificate enrollment see PKI infrastructure and digital certificates, on page 1718.

Add certificate enrollment objects

Add certificate enrollment objects to manage device trustpoints and enable secure certificate enrollment for Firewall Threat Defense devices.

- Support multiple enrollment protocols, including SCEP, EST, ACME, Manual, and PKCS12 file import.

Use these objects to enable secure certificate management and device trustpoint enrollment. You must have Admin or Network Admin privileges to do this task.

Procedure

Step 1 Open the **Add Certificate Enrollment** dialog:

- Directly from Object Management: In the **Objects** > **Object Management** > **PKI** > **Certificate Enrollment** from the navigation pane, and click **Add Certificate Enrollment**.
- While configuring a managed device: In the **Devices** > **Certificates** screen, choose **Add** > **Add New Certificate** and click (+) for the **Certificate Enrollment** field.

Step 2 Enter the **Name**. When enrollment is complete, this name is used as the trustpoint name on the managed devices with which it is associated. Click the **CA Information** tab, and then choose the **Enrollment Type**.

- **Self-Signed Certificate**—The managed device, acting as a CA, generates its own self-signed root certificate. No other information is needed in this pane.

  Note
  When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.

- **EST**—Enrollment over Secure Transport protocol. Specify the EST information. See EST enrollment configuration options in Certificate Enrollment Object , on page 3001.
- **SCEP**—(Default) Simple Certificate Enrollment Protocol. Specify the SCEP information. See Certificate Enrollment Object SCEP options , on page 3002.
- **Manual**
  - **CA Only**—Check this check box to create only the CA certificate from the selected CA. An identity certificate will not be created for this certificate.

    If you do not select this check box, a CA certificate is not mandatory. You can generate the CSR without having a CA certificate and obtain the identity certificate.
  - **CA Certificate**—Paste the CA certificate in the PEM format in the box. You can also obtain a CA certificate by copying it from another device.

    You can leave this box empty if you choose to generate a CSR without the CA certificate.

- **PKCS12 File**—Import a PKCS12 file on a Firewall Threat Defense managed device that supports VPN connectivity. A PKCS#12, or PFX, file holds a server certificate, intermediate certificates, and a private key in one encrypted file. Enter the **Passphrase** value for decryption.
- **ACME**—ACME protocol is an open and standardized protocol designed to automate the issuance, renewal, and management of SSL and TLS certificates. Management Center communicates with an ACME-enabled CA server and after domain validation, the ACME server issues an SSL or TLS certificate to the device. Refer to Certificate enrollment object options for ACME certificates, on page 3003.

Step 3 **Skip Check for CA flag in basic constraints of the CA Certificate**—Check this check box if you want to skip checking the basic constraints extension and the CA flag in a trustpoint certificate.

Step 4 **Validation Usage**—Choose from the options to validate the certificate during a VPN connection:

- **IPsec Client**—Validate an IPsec client certificate for a site-to-site VPN connection.
- **SSL Client**—Validate an SSL client certificate during a remote access VPN connection attempt.
- **SSL Server**—Select to validate an SSL server certificate, such as a Cisco Umbrella server certificate.

Step 5 (Optional) Click the **Certificate Parameters** tab and specify the certificate contents. Refer to Certificate Enrollment Object certificate parameters in certificate requests , on page 3008.

This information is placed in the certificate and is readable by any party who receives the certificate from the router.

Step 6 (Optional) Click the **Key** tab and specify the Key information. Refer to Certificate Enrollment Object key options , on page 3009.

Step 7 (Optional) Click the **Revocation** tab and specify the revocation options: Refer to Certificate Enrollment Object revocation options , on page 3011.

Step 8 **Allow Overrides** of this object if desired.

When you allow overrides in the PKCS12 certificate enrollment object, update the**Passphrase** for the certificate on the device where you override it.

See Object overrides, on page 2939 for a full description of object overrides.

Step 9 Click **Save**.

What to do next

Associate and install the enrollment object on a device to create a trustpoint on that device.

Install a certificate using self-signed enrollment, on page 3084
Install a certificate using EST enrollment, on page 3084
Install a certificate using SCEP enrollment, on page 3085
Install a certificate using manual enrollment, on page 3086
Install a certificate using a PKCS12 file, on page 3087

Add a certificate enrollment

A valid IdP certificate ensures that your system can securely authenticate users through an identity provider. This is essential for secure communications and compliance.

Procedure

Step 1 Enter the **Name**.

Step 2 Paste the certificate information in the **IdP Certificate** field in PEM format.

Note
If the certificate is dependent on a root or intermediate certificate, you must install the dependent certificates. See Certificates, on page 3079.

Step 3 Click **Save**.

EST enrollment configuration options in Certificate Enrollment Object

This topic describes the EST enrollment options and the required fields for configuring EST certificate enrollment in the Secure Firewall Management Center.

Cloud-Delivered Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**. Click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog, and select the **CA Information** tab.

Fields

Enrollment Type—set to **EST**.

Note

- EST enrollment type does not support EdDSA key.
- EST's ability to auto-enroll a device when its certificate expires is not supported.

Enrollment URL—Enter the URL of the CA server to which devices should attempt to enroll.

Use an HTTPS URL in the form of **https://CA_name:port**, where *CA_name* is the host DNS name or IP address of the CA server. The *port* number is mandatory.

Username—The username required to access the CA server.

Password / Confirm Password—The password required to access the CA server.

Fingerprint—Optionally, enter the fingerprint of the CA server certificate. Verifying the fingerprint helps ensure you are connecting to the legitimate CA server and not a substitute. Enter the fingerprint in hexadecimal format. If the fingerprint does not match, the certificate is rejected. Obtain the fingerprint directly from the CA server.

Source Interface—The interface that interacts with the CA server. By default, the diagnostic interface is displayed. To configure a data interface as the source interface, choose the respective security zone or interface group object.

Ignore EST Server Certificate Validations—By default, EST server certificate validation is enabled. Check the check box to ignore Firewall Threat Defense validating EST server certificate.

Certificate Enrollment Object SCEP options

This topic describes the SCEP enrollment options and fields available when adding a certificate enrollment object in Secure Firewall Management Center.

Cloud-Delivered Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**. Click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog, and select the **CA Information** tab.

Fields

Enrollment Type—Set to **SCEP**.

Enrollment URL—Enter the URL of the CA server to which devices should attempt to enroll.

Use an HTTP URL in the format **`http://CA_name:port,`** . The CA_name is the DNS name or IP address of the CA server, and the port number is mandatory.

Note If the SCEP Server is referred with hostname/FQDN, configure the DNS Server using FlexConfig object.

If the CA cgi-bin script location at the CA is not the default (/cgi-bin/pkiclient.exe) include the nonstandard script location in the URL, in the form of http://CA_name:port/script_location, where script_location is the full path to the CA scripts.

Challenge Password / Confirm Password—The password used by the CA server to validate the identity of the device. You can obtain the password by contacting the CA server directly or by entering the following address in a web browser: **`http://URLHostName/certsrv/mscep/mscep.dll`**. Because the password is valid for only 60 minutes, deploy it as soon as possible after creation.

Retry Period—The interval (in minutes) between certificate request attempts. Values range from 1 to 60 minutes. The default is 1 minute.

Retry Count—The number of retries that should be made if no certificate is issued on the first request. Value can be 1 to 100. The default is 10.

CA Certificate Source—Specifies how the CA certificate will be obtained.

- **Retrieve Using SCEP** (default and only supported option)—Retrieve the certificate from the CA server using the Simple Certificate Enrollment Process (SCEP). Using SCEP requires a connection between your device and the CA server. Ensure a network route exists between your device and the CA server before beginning enrollment.

Fingerprint—When retrieving the CA certificate using SCEP, you may enter the fingerprint for the CA server. Using the fingerprint to verify the authenticity of the CA server's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one. Enter the **Fingerprint** for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. Obtain the CA's fingerprint by contacting the server directly, or by opening: **`http://<URLHostName>/certsrv/mscep/mscep.dll`**.

Certificate enrollment object options for ACME certificates

This topic details the ACME options available when configuring certificate enrollment objects, including navigation steps, workflow, and field definitions for ACME certificate enrollment.

Cloud-Delivered Firewall Management Center navigation path

To access ACME certificate enrollment options:

1. Go to **Objects** > **Object Management**.
2. From the navigation pane, choose **PKI** > **Certificate Enrollment**.
3. Click **Add Certificate Enrollment** to open the Add Certificate Enrollment dialog box.
4. Select the **CA Information** tab.

How ACME certificates work

ACME certificate enrollment involves the following steps:

1. A Firewall Threat Defense device requests an ACME certificate for a specific domain or a list of domains through the source interface.
2. The ACME server validates the domain ownership through port 80 of the Firewall Threat Defense device's authentication interface. For domain validation, the Firewall Threat Defense device uses an HTTP-based challenge mechanism (HTTP-01).

Note Firewall Threat Defense briefly opens port 80 during the enrollment challenge-response process to provide only the ACME challenge data; the port closes as soon as the enrollment succeeds or fails.

3. After domain validation, the ACME server issues an SSL or TLS certificate to the device.

Note The stages are repeated for each FQDN in the certificate enrollment request.

ACME Fields and Options

Enrollment Type—Choose **ACME**.

Enrollment URL—Enter the URL of the ACME server.

The default URL is that of the Let's Encrypt service: https://acme-v02.api.letsencrypt.org/directory.

In the **Authentication Protocol** field, **HTTP-01** is the predefined protocol used to validate domain ownership.

Authentication Interface—Choose a security zone or an interface group that has the interface through which the ACME server communicates with the device to verify ownership of the domain. Click + to add a security zone or an interface group.

Source Interface—Choose a security zone or an interface group that has the interface through which the device interacts with the ACME server to request and receive the enrolled ACME certificate. Click + to add a security zone or an interface group.

ACME CA Certificate—Choose a manually installed CA-only certificate that authenticates the ACME server.

Enable Auto Enrollment—Check this check box to enable automatic enrollment of the ACME certificates based on the configured lifetime.

Certificate Lifetime—Enter the percentage of the ACME certificate lifetime after which certificate re-enrollment automatically starts (default value is 70). For example, if the certificate's lifetime is 100 days and this field is set to 80, auto-renewal is triggered on day 81.

Regenerate Key—Check this check box to generate a new key for each ACME enrollment. If you uncheck this check box, the previous key is used for enrollment.

Prerequisites for using ACME certificates

Review these prerequisites for configuring a remote access VPN policy.

General prerequisites

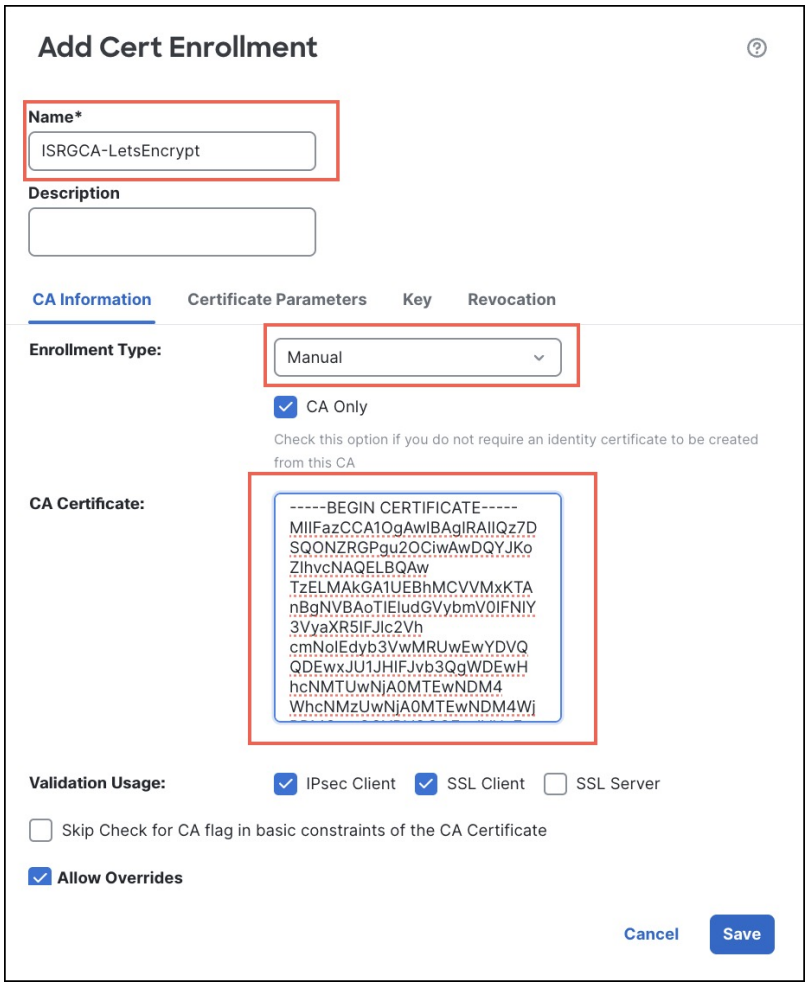
- The Firewall Threat Defense device is Version 10.0 or later.
- Configure DNS in the Firewall Threat Defense platform settings to resolve the domain name of the ACME server.
- Ensure your domain maps to a public IP address. Configure the device interface with this IP address, and set it as the authentication interface in the ACME certificate enrollment.
- Configure the same NTP server for the ACME server and the Firewall Threat Defense device.
- Ensure that you enroll an ACME CA certificate (manually installed CA-only certificate) on the device to authenticate the ACME server.

Note The ACME enrollment will fail if you do not enroll this ACME CA certificate first and add it to the device before configuring any ACME certificate.

For example, if you use Let's Encrypt as the ACME server, you must:

- Get the Internet Security Research Group (ISRG) root certificate from https://letsencrypt.org/certificates/. You can use the root certificate from https://letsencrypt.org/certs/isrgrootx1.pem.txt.

  Sample manual CA certificate for the ACME server from https://letsencrypt.org/certs/isrgrootx1.pem.txt:



```

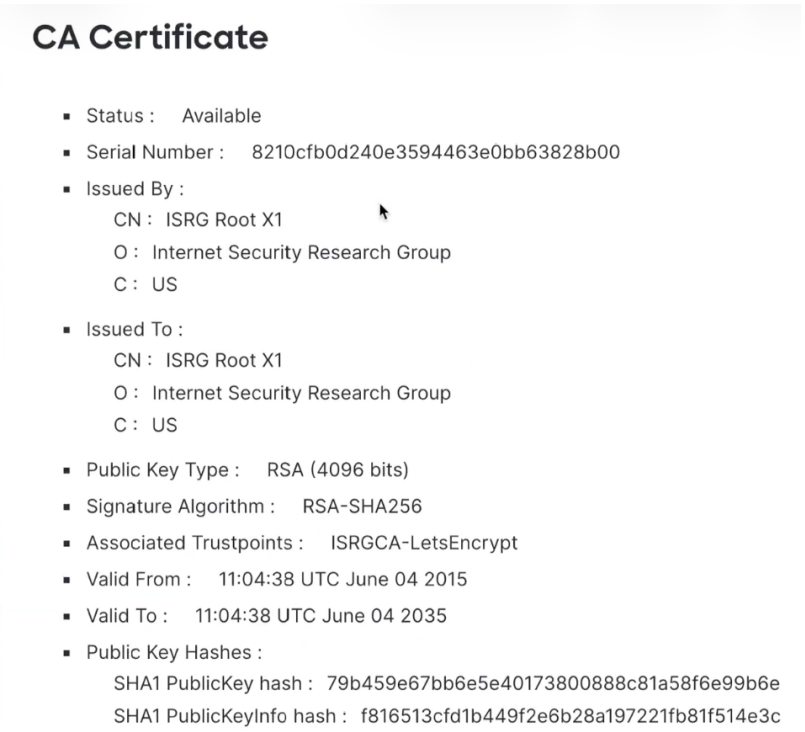
-----END CERTIFICATE-----
```

- Enroll it as a manual CA-only certificate on the device. If you configure object overrides for any device, ensure that you enroll an ACME CA certificate on that device too.

  To enroll this ACME CA certificate on the device:

  1. Choose **Objects** > **Object Management** > **PKI** > **Certificate Enrollment**.
  2. Click **Add Certificate Enrollment**.
  3. Configure the name and description for the certificate.
  4. In the **CA Information** tab, configure these parameters:
     a. From the **Enrollment Type** drop-down list, choose **Manual**.
     b. Check the **CA Only** check box.
     c. In the CA Certificate text box, paste the manual CA certificate for the ACME server. In our example, we use the root certificate from Let's Encrypt (https://letsencrypt.org/certs/isrgrootx1.pem.txt).



d. Click **Save**.

Note This ACME CA certificate is listed in the **Certificate Enrollment** page and not under **Trusted CAs**.

- Attach this ACME CA certificate to the device:
  1. Choose **Devices** > **Certificates**, and click **Add**.
  2. From the **Device** drop-down list, choose a Firewall Threat Defense device.
  3. From the **Cert Enrollment** drop-down list, choose the ACME CA certificate.
  4. Click **Add**.

Figure 398: Details of the manual CA certificate

Prerequisites for ACME server

- Access to an ACME server such as Let's Encrypt, or any other public or on-prem ACME server.
- The ACME server must be reachable from the Firewall Threat Defense device.
- The ACME server must be able to validate the domain name and the alternate FQDNs.
- If the authentication and source interfaces of the Firewall Threat Defense device differ, ensure that the ACME server is reachable from the source interface of the Firewall Threat Defense device.
    - Authentication interface of the Firewall Threat Defense device is the interface through which the ACME server communicates with the device to verify ownership of the domain.

      Source interface of the Firewall Threat Defense device is the interface through which the device interacts with the ACME server to request and receive the enrolled ACME certificate.
- Firewall Threat Defense device does not support ACME wildcard certificates.

Prerequisite for VPN load balancing

- When configuring an ACME enrollment object for a VPN load balancing group, include both director and member FQDNs in the Alternate FQDN field.

ACME certificate limitations and compatibility considerations

ACME certificates come with several limitations and compatibility requirements. Review these restrictions and supported features before deploying ACME certificates in your environment.

- ACME certificates do not support:
  - Site-to-site VPN
  - Management interface in the converged mode
  - DNS authentication (DNS-01); only HTTP-01 is supported
  - Domain override
  - Wildcard certificates (Certificates that secure a domain and multiple subdomains using a wildcard character (*) in the domain name field)
  - Clustering
- Supported key sizes:
  - RSA keys: 2048, 3072, and 4096 bits
  - ECDSA keys: 256, 384, and 521 bits
- ACME enrolment is not compatible with control plane ACLs.

  When using Let's Encrypt with control plane ACLs:

  1. Disable the ACL before the ACME enrollment to allow port 80 access.
  2. Enroll the ACME certificate.
  3. Verify the enrollment.
  4. Re-enable the ACL.

  When using ACME servers other than Let's Encrypt with control plane ACLs, include the server's FQDN in the ACL.

Certificate Enrollment Object certificate parameters in certificate requests

When sending a certificate request to a CA server, you can specify additional information that is placed into the certificate and is viewable by recipients. All information should follow the standard LDAP X.500 format.

Cloud-Delivered Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**. Click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog box, and select the **Certificate Parameters** tab.

Fields

Field	Description
Include FQDN	Whether to include the device's fully qualified domain name (FQDN) in the certificate request. You can select from these options: • **Use Device Hostname as FQDN** • **Don't use FQDN in certificate** • **Custom FQDN**—Select this and then specify it in the **Custom FQDN** field that displays.
Include Device's IP Address	Specify the interface whose IP address you want to include in the certificate request.
Common Name (CN)	Specify the X.500 common name to include in the certificate. **Note** When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.
Organization Unit (OU)	Specify the name of the organization unit (for example, a department name) to include in the certificate.
Organization (O)	Specify the organization or company name to include in the certificate.
Locality (L)	Specify the state or province to include in the certificate.
State (ST)	The state or province to include in the certificate.
County Code (C)	The country to include in the certificate. These codes conform to ISO 3166 country abbreviations, for example "US" for the United States of America.
Email (E)	Specify the email address to include in the certificate.
Include Device's Serial Number	Specify whether to include the device's serial number in the certificate. The CA uses the serial number to authenticate certificates or to later associate a certificate with a particular device. If you are unsure, include the serial number, because it is useful for debugging purposes.

Certificate Enrollment Object key options

This topic describes the available key options and their settings when adding certificate enrollment and selecting the Key tab in the Certificate Enrollment Object dialog box.

Cloud-Delivered Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**, and click **Add Certificate Enrollment** to open the **Add Certificate Enrollment** dialog box, and select the **Key** tab.

Fields

- **Key Type**: Choose RSA, ECDSA, EdDSA.

Note

- EdDSA is not supported for EST enrollment type.
- EdDSA is supported only in Site-to-Site VPN topologies.
- EdDSA is not supported as an identity certificate for Remote Access VPN.

- **Key Name**: Specifies the name of the key pair. If the key pair already exists, this field refers to the existing name. If not, it defines the name for a new key pair to be generated during enrollment. If no name is specified, the fully qualified domain name (FQDN) key pair is used instead.
- **Key Size**: When generating a new key pair, defines the desired key size (modulus) in bits. The recommended size is 2048 bits. Larger modulus sizes offer more security but require more time (a minute or more when larger than 512 bits) to generate and process.

Important

- On Cloud-Delivered Firewall Management Center and Firewall Threat Defense Versions 7.0 and higher, you cannot enroll certificates with RSA key sizes smaller than 2048 bits and keys using SHA-1 with the RSA Encryption algorithm.
- You can use the PKI Enrollment of Certificates with Weak-Crypto to allow certificates with SHA-1 and smaller key size.
- You cannot generate RSA keys with sizes smaller than 2048 bits for Firewall Threat Defense 7.0, even when you enable the weak-crypto option.

- **Advanced Settings**: Select **Ignore IPsec Key Usage** if you do not want to validate values in the key usage and extended key usage extensions of IPsec remote client certificates. You can suppress key usage checking on IPsec client certificates. By default, this option is not enabled.

Note For site-to-site VPN connection, if you use a Windows Certificate Authority (CA), the default Application Policies extension is **IP security IKE intermediate**. If you are using this default setting, you must select the **Ignore IPsec Key Usage** option for the object you select. Otherwise, the endpoints cannot complete the site-to-site VPN connection.

Enroll PKI certificates with weak-crypto

Certificates that use weak cryptography (such as SHA-1 signatures or RSA keys smaller than 2048 bits) have restricted support on Cloud-Delivered Firewall Management Center and Firewall Threat Defense devices. This reference details the conditions under which weak-crypto certificates may be enrolled and the required steps for enabling their use.

SHA-1 hashing signature algorithm, and RSA key sizes that are smaller than 2048 bits for certification are not supported on Cloud-Delivered Firewall Management Center and Firewall Threat Defense Version 7.0 and later. You cannot enroll certificates with RSA key sizes that are smaller than 2048 bits.

To override these restrictions on Cloud-Delivered Firewall Management Center 7.0 managing Firewall Threat Defenses running Versions earlier than 7.0, use the enable weak-crypto option on the Firewall Threat Defense. Do not permit weak-crypto keys, because, such keys are not as secure as the ones with larger key sizes.

Note Firewall Threat Defense 7.0 or later does not support generating RSA keys with sizes smaller than 2048 bits even when you permit weak-crypto.

To enable weak-crypto on the device, navigate to the **Devices** > **Certificates** page. Click the **Enable Weak-Crypto**() button provided against the Firewall Threat Defense device. When the weak-crypto option is enabled, the button changes to . By default, the weak-crypto option is disabled.

Note When a certificate enrollment fails due to weak cipher usage, the Cloud-Delivered Firewall Management Center displays a warning message prompting you to enable the weak-crypto option. Similarly, when you turn on the enable weak-crypto button, the Cloud-Delivered Firewall Management Center displays a warning message before enabling weak-crypto configuration on the device.

Upgrade earlier versions to Firewall Threat Defense 7.0

When you upgrade to Firewall Threat Defense 7.0, the existing certificate configurations are retained. However, if those certificates have RSA keys smaller than 2048 bits and use SHA-1 encryption algorithm, they cannot be used to establish VPN connections. You must either procure a certificate with RSA key size of at least 2048 bits or enable the permit weak-crypto option for VPN connections.

Certificate Enrollment Object revocation options

Specify whether to check the revocation status of a certificate by choosing and configuring the method. Revocation checking is off by default. The system does not check either method (CRL or OCSP).

Cloud-Delivered Firewall Management Center navigation path

Objects > **Object Management** > **PKI** > **Certificate Enrollment**, and click () **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Revocation** tab.

Fields

- **Enable Certificate Revocation Lists**—Check to enable CRL checking.
  - **Use CRL distribution point from the certificate**—Check to obtain the revocation lists distribution URL from the certificate.
  - **Use static URL configured**—Check this to add a static, predefined distribution URL for revocation lists. Then add the URLs.

    CRL Server URLs—Specify the URL of the LDAP server from which the CRL can be downloaded.

    URLs must start with **`http://`**. Include a port number in the URL. Enclose IPv6 addresses in square brackets, for example: *http://[0:0:0:0:0.18:0a01:7c16]*.

- **Enable Online Certificate Status Protocol (OCSP)**—Check to enable OCSP checking.

OCSP Server URL—The URL of the OCSP server checking for revocation if you require OCSP checks.

URLs must start with **`http://`**. Enclose IPv6 addresses in square brackets, for example: *http://**[**0:0:0:0:0.18:0a01:7c16**]***.

- **Consider the certificate valid if revocation information cannot be reached**—Checked by default. Uncheck if you do not want to allow this.

Configure a policy list

Configure a policy list to group and manage multiple match statements for use in route maps. This allows for efficient policy management and flexible routing decisions.

Use the Configure Policy List page to create, copy, and edit policy list objects. You can create policy list objects to use when you are configuring route maps. When a policy list is referenced within a route map, all of the match statements in that policy list are evaluated and processed. With a route map, you can configure two or more policy lists. A policy list can coexist with other match and set statements that are configured in the same route map but outside the policy list. When multiple policy lists perform matching within a route map entry, only the incoming attribute is matched by all policy lists.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Select **Objects** > **Object Management** > **Policy List**.

Step 2 Click **Add Policy List**. Specify these values:

a. Enter a name for the policy list object in the **Name** field. Object names are not case-sensitive.

b. Select whether to allow or block access for matching conditions from the **Action** drop-down list.

Step 3 Enter the details in each of these tabs:

Tabs	Details
Interface	Use this tab to distribute routes that have their next hop out of one of the interfaces specified. In the **Zones/Interfaces** list, add the zones that contain the interfaces through which the device communicates with the management station. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. The host will be configured on a device only if the device includes the selected interfaces or zones.
Address	Use this tab to redistribute any routes that have a destination address that is permitted by a standard access list or prefix list. Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.

Tabs	Details
Next Hop	Use this tab to redistribute any routes that have a next hop router address passed by one of the access lists or prefix lists specified. Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
Route Source	Use this tab to redistribute routes that have been advertised by routers and access servers at the address specified by the access lists or prefix list. Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
AS Path	Use this tab to match a BGP autonomous system path. If you specify more than one AS path, then the route can match either AS path.
Community Rule	Use this tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively. If you specify more than one rule, the routes are verified against the rules until a matching permit or deny is met. **a.** To specify a community list to the rule, click **Edit** ( ) given in the **Selected Community List** field. The community lists appear under **Available Community List**. Select the required list, click **Add**, and then click **Ok**. To enable matching the BGP community exactly with the specified community, check the **Match the specified community exactly** check box. **b.** To add the extended community list, click **Edit** ( ) given in the **Selected Extended Community List** field. The extended community lists appear under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**. **Note** The extended community lists are applicable only for configuring import or export of routes.
Metric & tag	Use this tab to match the metric and security group tag of a route. **a.** Enter the metric values to use for matching in the **Metric** field. You can enter multiple values, separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295. **b.** Enter the tag values to use for matching in the **Tag** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 5 Click **Save**.

Ports

A port object is a network configuration element that

- represents different protocols, such as TCP, UDP, ICMP, and others, in distinct ways
- can specify protocol numbers, port numbers or ranges, and optional type and code for certain protocols, and
- is used to define access and monitoring rules within the system's web interface.

Port object representations and usage

Port objects represent protocols differently depending on their type.

- **TCP and UDP**: Port objects represent these transport layer protocols by specifying the protocol number, and may include an associated port or port range. For example: `TCP(6)/22`.
- **ICMP and ICMPv6 (IPv6-ICMP)**: Port objects represent these Internet layer protocols by specifying the protocol number and optional type and code. For example: `ICMP(1):3:3`.

  Restrict an ICMP or IPV6-ICMP port object by type and, if needed, code. Learn more about ICMP types and codes at:

  - ICMP Types and Codes: http://www.iana.org/assignments/ICMP-parameters/ICMP-parameters.xml
  - ICMPv6 Types and Codes: http://www.iana.org/assignments/icmpv6-parameters/icmpv6-parameters.xml
- **Other protocols**: Port objects can represent protocols that do not use ports.

The system provides default port objects for well-known ports. Default objects are read-only and always available for use. You can create custom port objects or groups in addition to the default ones.

Port objects and groups can be used throughout the system's web interface in access control policies, identity rules, network discovery rules, port variables, and event searches. For example, you can configure a network discovery policy to exclude monitoring ports used by a custom client if it generates excessive or misleading events.

Guidelines for using port objects

- You cannot add any protocol other than TCP or UDP for source port conditions in access control rules.
- Set source and destination port conditions in a rule using only one transport protocol.
- Add only supported protocols to a port object group used in a source port condition so that the rule takes effect on the managed device when you deploy the configuration.
- To add a destination port, create a port object using only TCP or only UDP ports for the source port condition in a rule. Similarly, to add a source port, create a port object using only TCP or only UDP ports as the destination port condition.

Create port objects

Create port objects to specify protocol and port information for network traffic management in Secure Firewall Management Center.

Use this task to add or modify port objects in access control or other security policies within Secure Firewall Management Center. Port objects allow you to specify which network traffic is allowed or blocked based on protocol and port criteria. They are critical when you set up or update security rules.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Port** from the object types list.

Step 3 Choose **Add Object** from the **Add Port** drop-down list.

Alternatively, clone an existing port object and edit its parameters to create a new port object. Click the **Clone** icon on the existing port object that you want to clone.

Step 4 Enter a **Name**.

Step 5 Choose a **Protocol**.

Step 6 Depending on the protocol you chose, constrain by **Port**, or choose an ICMP **Type** and **Code**.

You can enter ports from `1` to `65535`. Use a hyphen to specify a port range. You must constrain the object by port if you chose to match **All** protocols, using the **Other** drop-down list.

Step 7 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2942.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Import port objects

To import port objects, refer to Import objects, on page 2932.

Prefix lists

A prefix list is a route filtering object that

- defines IPv4 and IPv6 address ranges

- is used when configuring route maps, policy maps, OSPF filtering, or BGP neighbor filtering, and
- enables control over which routes are permitted or denied.

Configure an IPv6 prefix list

Use IPv6 prefix lists in Firewall Threat Defense devices to specify which IPv6 routes are allowed or blocked during redistribution. This enhances routing policy control for protocols such as OSPF and BGP.

Procedure

Step 1 Select **Objects** > **Object Management** > **Prefix Lists** > **IPv6 Prefix List** from the table of contents.

Step 2 Click **Add Prefix List**.

a. Enter a name for the prefix list object in the **Name** field

b. Click **Add**.

Step 3 Select the appropriate action, Allow or Block, from the **Action** drop-down list to indicate the redistribution access.

Step 4 Enter a unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object, in the **Sequence No.** field. If left blank, the sequence number will default to five more than the largest sequence number currently in use.

Step 5 Specify the IPv6 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1 and 128.

Step 6 Enter the minimum prefix length in the **Minimum Prefix Length** field and the maximum prefix length in the **Maximum Prefix Length** field.

The minimum prefix length value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.

If the Minimum Prefix Length is present, the maximum prefix length value must be greater than or equal to it. If the Minimum Prefix Length is not specified, the maximum value must be greater than the mask length.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 9 Click **Save**.

Configure an IPv4 prefix list

Use the Configure IPv4 Prefix list page to manage prefix list objects. These objects can be used when configuring route maps, policy maps, OSPF filtering, or BGP neighbor filtering.

You can use this object with Firewall Threat Defense devices.

Procedure

Step 1 Select **Objects** > **Object Management** > **Prefix Lists** > **IPv4 Prefix List** from the table of contents.

Step 2 Click **Add Prefix List**.

a. Enter a name for the prefix list object in the **Name** field

b. Click **Add**.

Step 3 Select the appropriate action, Allow or Block, from the **Action** drop-down list to indicate the redistribution access.

Step 4 Enter a unique number in the **Sequence No.** field to specify the position of the new prefix list entry. If the field is left blank, the system assigns a sequence number that is five higher than the largest one currently in use.

Step 5 Specify the IPv4 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1 and 32.

Step 6 Enter the minimum prefix length in the **Minimum Prefix Length** field and the maximum prefix length in the **Maximum Prefix Length** field.

The minimum prefix length value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.

If the Minimum Prefix Length is present, the maximum prefix length value must be greater than or equal to it. If the Minimum Prefix Length is not specified, the maximum value must be greater than the mask length.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 9 Click **Save**.

Configure a route map

Route maps are used to manage route redistribution between routing protocols and to control default route generation. Route maps can specify which routes are permitted or denied and apply rules for matching route attributes.

You can use this object with Firewall Threat Defense devices.

Configure a route map to create or edit route map entries in a Route Map object.

Before you begin

A Route Map can use one or more of these objects. It is not mandatory to add all of them. Create and use any of these objects as required to configure your route map.

- Add ACLs.
- Add Prefix Lists.
- Add AS Path.

- Add Community Lists.
- Add Extended Community Lists.

Note The extended community lists apply only to configuring import or export of routes.

- Add Policy Lists.

Procedure

Step 1 Select **Objects** > **Object Management** > **Route Map**.

Step 2 Click **Add Route Map**.

Step 3 Click **Add** on the **New Route Map Object** window.

Step 4 In the **Sequence No.** field, enter a number, from 0 through 65535, that indicates the position a new route map entry has in the list of route maps entries already configured for this route map object.

Note
We recommend that you number clauses in intervals of at least 10 to reserve numbering space in case you want to insert clauses in the future.

Step 5 Select Allow or Block from the **Redistribution** drop-down list, to indicate the redistribution access.

Step 6 Click the **Match Clauses** tab to match routes or traffic based on the following criteria, which you select in the table of contents:

- **Security Zones** —Match traffic based on the (ingress/egress) interfaces. You can select zones and add them, or type in interface names and add them.
- **IPv4**— Match IPv4 (routes/traffic) based on the following criteria; select the tab to define the criteria.
  - **a.** Click the **Address** tab to match routes based on the route address. For IPv4 addresses, choose whether to use an Access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  - **b.** Click the **Next Hop** tab to match routes based on the next hop address of a route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  - **c.** Click the **Route Source** tab to match routes based on the advertising source address of the route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
- **IPv6** —Match IPv6 (routes/traffic) based on the route address, next-hop address or advertising source address of route.
- **BGP**—Match BGP (routes/traffic) based on the following criteria; select the tab to define the criteria.
  - **a.** Click the **AS Path** tab to enable matching the BGP autonomous system path access list with the specified path access list. If you specify more than one path access list, then the route can match either path access list.

b. Click the **Community List** tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively.

- To specify a community list to the rule, click **Edit** ( ) given in the **Selected Community List** field. The community lists appears under **Available Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create community list objects, see Configure a community list, on page 2959
- To add the extended community list, click **Edit** ( ) given in the **Selected Extended Community List** field. The extended community lists appears under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create extended community list objects, see Configure an extended community list, on page 2960.

To enable matching the BGP community exactly with the specified community list objects, check the **Match the specified community exactly** check box. This option is not applicable for the extended community list.

Note
If you specify more than one rule, the routes are verified against the rules until a matching permit or deny condition is met. Any route that does not match at least one Match community will not be advertised for outbound route maps.

c. Click the **Policy List** tab to configure a route map to evaluate and process a BGP policy. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.

- **Others** —Match routes or traffic based on the following criteria.

a. Enter the metric values to use for matching in the **Metric Route Value** field, to enable matching the metric of a route. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.

b. Enter the tag values to use for matching in the **Tag Values** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

c. Check the appropriate **Route Type** option to enable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. You can choose more than one route type from the list.

Step 7 Click the **Set Clauses** tab to set routes/traffic based on the following criteria, which you select in the table of contents:

- **Metric Values**—Set either Bandwidth, all of the values or none of the values.

a. Enter a metric value or bandwidth in Kbits per second in the **Bandwidth** field. Valid values are an integer value in the range from 0 to 4294967295.

b. Select to specify the type of metric for the destination routing protocol, from the **Metric Type** drop-down list. Valid values are: internal, type-1, or type-2.

- **BGP Clauses** —Set BGP routes based on the following criteria; select the tab to define the criteria.

a. Click the **AS Path** tab to modify an autonomous system path for BGP routes.

1. Enter an AS path number in the **Prepend AS Path** field to prepend an arbitrary autonomous system path string to BGP routes. Usually the local AS number is prepended multiple times, increasing the autonomous system path length. If you specify more than one AS path number then the route can prepend either AS number.
2. Enter an AS path number in the **Prepend Last AS to AS Path** field to prepend the AS path with the last AS number. Enter a value for the AS number from 1 to 10.
3. Check the **Convert route tag into AS path** check box to convert the tag of a route into an autonomous system path.

b. Click the **Community List** tab to set the community attributes:

Under **Specific Community**:

1. Click the **None** radio button, to remove the community attribute from the prefixes that pass the route map.
2. Click the **Specific Community** radio button, to enter a community number, if applicable. Valid values are from 1 to 4294967295.
3. Check the **Add to existing communities** check box, to add the community to the already existing communities.
4. Select the **Internet**, **No-Advertise**, or **No-Export** check-boxes to use one of the well-known communities.

Under **Specific Extended Community**, in the **Route Target** field, enter the route target number in *ASN:nn* format:

- You can enter values that ranges from 1:1 to 65534:65535.

  You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.

- You can have a maximum of 8 route targets in an entry.
- You cannot have redundant route target entries across route maps.

c. Click the **Others** tab to set additional attributes.

1. Check the **Set Automatic Tag** check-box to automatically compute the tag value.
2. Enter a preference value for the autonomous system path in the **Set Local Preference** field. Enter a value between 0 and 4294967295.
3. Enter a BGP weight for the routing table in the **Set Weight** field. Enter a value between 0 and 65535.
4. Select to specify the BGP origin code. Valid values are **Local IGP** and **Incomplete**.
5. In the IPv4 Settings section, specify a next hop IPv4 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv4 address then the packets can output at either IP address.

   Select to specify an IPv4 prefix list in the **Prefix List** drop-down list.

6. In the IPv6 Settings section, specify a next hop IPv6 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv6 address, then the packets can output at any of the IP addresses.

   Select to specify an IPv6 prefix in the **Prefix List** drop-down list.

Step 8 Click **Add**.

If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.

Step 9 Click **Save**.

After completing these steps, the route map is configured and ready for use in route redistribution and policy enforcement. The route map entries and associated match and set clauses are applied AS specified.

What to do next

Review the route map configuration to ensure that all required match and set clauses are correctly defined. Make any necessary adjustments to optimize routing policies.

- Monitor route redistribution and verify that routes are processed according to the configured route map.

Security intelligence

Security Intelligence is a traffic filtering mechanism that

- uses collections of IP addresses, domain names, and URLs to quickly filter traffic that matches entries
- requires the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types), and
- operates through lists and feeds that are grouped into DNS, Network, and URL categories.

Security intelligence components

Security Intelligence *lists* and *feeds* are collections of IP addresses, domain names. You can use these to quickly filter traffic that matches an entry on a list or feed.

- A list is a static collection that you manage manually.
- A feed is a dynamic collection that updates on an interval over HTTP or HTTPS.

Security Intelligence lists/feeds are grouped into:

- DNS (Domain names)
- Network (IP addresses)
- URLs

System-provided feeds:

Cisco provides these feeds as Security Intelligence objects:

- Security Intelligence feeds updated regularly with the latest threat intelligence from Talos:
  - Cisco-DNS-and-URL-Intelligence-Feed (under DNS Lists and Feeds)
  - Cisco-Intelligence-Feed (for IP addresses, under Network Lists and Feeds)

  You cannot delete the system-provided feeds, but you can change the frequency of (or disable) their updates.
- Cisco-TID-Feed (under Network Lists and Feeds)

  This feed is not used in the Security Intelligence tab of the access control policy.

  Instead, you must enable and configure Secure Firewall Threat Intelligence Director to use this feed. The feed is a collection of TID observables data.

  Use this object to configure the frequency of data publication to TID elements.

Predefined global Block and Do Not Block lists:

The system includes predefined global Block lists and Do Not Block lists for domains (DNS), IP addresses (Networks), and URLs.

These lists are empty until you populate them. To build these lists, see Global and domain security intelligence lists, on page 3023.

By default, access control and DNS policies use these lists as part of Security Intelligence.

Custom feeds:

You can use third-party feeds or use a custom internal feed to easily maintain an enterprise-wide Block list in a large deployment with multiple Cloud-Delivered Firewall Management Center appliances.

See Custom security intelligence feeds, on page 3029.

Custom lists:

Custom lists can augment and fine-tune feeds and the global lists.

See Custom Security Intelligence lists, on page 3031.

Security Intelligence lists and feeds usage locations:

- IP address and address blocks—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence.
- Domain Names—Use Block and Do Not Block lists in DNS policies, as part of Security Intelligence.
- URLs—Use Block and Do Not Block lists in access control and QoS rules, whose analysis and traffic handling phases occur after Security Intelligence.

Modify security intelligence objects

This topic explains how to add or delete entries on a Block list, Do Not Block list, feed, or sinkhole object. It also describes the edit capabilities and redeployment requirements for each object type.

The table summarizes the editing options and redeployment requirements for various security intelligence object types.

Object Type	Edit Capabilities	Requires Redeploy After Edit?
Custom Block and Do Not Block lists	Upload new and replacement lists using the object manager.	No
Default (but custom-populated) Block lists and Do Not Block lists: Global, descendant, and domain-specific	Add entries using the context menu or delete entries using the object manager.	No
System-provided Intelligence Feeds	Disable or change update frequency using the object manager.	No
Custom feeds	Fully modify using the object manager.	No
Sinkhole	Fully modify using the object manager.	Yes

Global and domain security intelligence lists

A security intelligence list helps you manage firewall policies by

- lets you manage lists of connections to block or exempt,
- applies your policies consistently across global and domain contexts, and
- enables further threat evaluation without the need to redeploy firewall policies.

Security intelligence list reference information

The Cloud-Delivered Firewall Management Center includes Global Block and Do Not Block lists, so you can use Security Intelligence to consistently block or exempt connections, allowing evaluation by other threat detection processes you configure.

Access control and DNS policies use these Global lists by default, and they apply to all security zones. If you want, you can turn these lists off for individual policies.

- Global Block list: Lets you block specified connections in all security zones.
- Do-Not-Block list: Lets you exempt specified connections from blocking so you can further evaluate threats.

Note These options apply only to Security Intelligence. Security Intelligence does not block traffic already fastpathed. Adding an item to a Security Intelligence Do Not Block list does not mean matching traffic is trusted or fastpathed. For more information, see Security intelligence, on page 2027.

Global and domain security intelligence lists example

For example, if you notice a set of routable IP addresses in intrusion events associated with exploit attempts, you can immediately block those IP addresses. Although it may take a few minutes for your changes to propagate, you do not have to redeploy.

Security intelligence lists and multitenancy

A security intelligence list is a multitenancy feature that

- enables the creation of block or do not block lists that apply to specific subdomains,
- supports descendant domain lists that aggregate the lists of a domain's descendants, and
- allows administrators at or above a domain to populate lists, while only domain-specific administrators can remove items.

Domain lists and descendant domain lists

Domain lists are block or do not block lists whose contents apply to a particular subdomain. The global lists are domain lists for the global domain. Each subdomain has its own named lists, and their contents apply only to that subdomain.

For example, a subdomain named Company A owns these lists:

- Domain Block list - Company A and Domain Do Not Block list - Company A
- Domain Block list for DNS - Company A, Domain Do Not Block list for DNS - Company A
- Domain Block list for URL - Company A, Domain Do Not Block list for URL - Company A

Any administrator at or above the current domain can populate these lists. You can use the context menu to add an item to the block or do not block list in the current and all descendant domains. However, only an administrator in the associated domain can remove an item from a domain list.

For example, a global administrator could add the same IP address to the block list in the global domain and Company A's domain, but not in Company B's domain. This action would add the same IP address to:

- Global Block list (removable only by global administrators)
- Domain Block list - Company A (removable only by Company A administrators)

A descendant domain list is a do not block list or block list that aggregates the domain lists of the current domain's descendants. Leaf domains do not have descendant domain lists.

Descendant domain lists are useful because a higher-level domain administrator can enforce general security intelligence settings, while subdomain users can add items to a block or do not block list in their own deployment.

For example, the global domain has these descendant domain lists:

- Descendant Block lists - Global, Descendant Do Not Block lists - Global
- Descendant Block lists for DNS - Global, Descendant Do Not Block lists for DNS - Global
- Descendant Block lists for URL - Global, Descendant Do Not Block lists for URL - Global

Note Descendant domain lists do not appear in the object manager because they are symbolic aggregations, not hand-populated lists. They appear where you can use them: in access control and DNS policies.

Delete entries from global security intelligence lists

Update your security intelligence lists by removing entries that should no longer be blocked or allowed. This helps you maintain accurate and effective security intelligence lists.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence**.

Step 2 Click the appropriate option:

- **Network Lists and Feeds** (for IP addresses)
- **DNS Lists and Feeds** (for domain names)
- **URL Lists and Feeds**

Step 3 Click the pencil beside the Global Block or Global Do-Not-Block list.

Step 4 Click the trash button beside the entry to delete.

List and feed updates for security intelligence feeds

A list and feed update is a security intelligence mechanism that performs the following functions:

- Replaces the existing list or feed file with the contents of the new file.
- Does not merge contents of existing and new files.
- If a corrupt or unrecognizable feed is downloaded, the system keeps using previous feed data. This is not true for the first download. If the system recognizes at least one entry in the feed, it uses only the entries it can recognize.

Feed update frequency and device polling

- Each feed updates the Cloud-Delivered Firewall Management Center every two hours by default; you can modify this frequency.
- When the Cloud-Delivered Firewall Management Center receives updates, it immediately passes them to your managed devices.
- Your managed devices poll the Cloud-Delivered Firewall Management Center every 30 minutes for changes. You cannot change this polling frequency.
- For Secure Firewall 200, updates are downloaded once a day, not every 30 minutes.

To modify feed update intervals, see Change the update frequency for security intelligence feeds, on page 3026.

Change the update frequency for security intelligence feeds

Set the intervals at which Security Intelligence feeds are updated in the system. Adjusting the update frequency ensures that threat data is refreshed according to your organization's needs.

You can specify the intervals at which the Cloud-Delivered Firewall Management Center updates Security Intelligence Feeds.

For details about feed updates, see List and feed updates for security intelligence feeds, on page 3025.

Before you begin

No explicit prerequisites are stated. Ensure you have access to the system interface where Security Intelligence feeds are managed.

Follow these steps to change the update frequency for Security Intelligence feeds:

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Security Intelligence** node, then choose the feed type whose frequency you want to change.

The system-provided URL feed is combined with the domain feed under **DNS Lists and Feeds**.

Step 3 Next to the feed you want to update, click **Edit** ( ).

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Edit the **Update Frequency**.

Step 5 Click **Save**.

The Security Intelligence feed will update at the new interval you specified. The system will retrieve threat data according to the configured frequency.

Custom security intelligence lists and feeds

This reference describes custom Security Intelligence lists and feeds.

List custom lists and feeds requirements

Each custom list or feed must be a simple text file no larger than 500 MB. List files must have the `.txt` extension. Include one entry or comment per line—for example, one IP address, one URL, or one domain name per line.

List and feed formatting

Each custom list or feed must be a simple text file no larger than 500 MB. List files must have the `.txt` extension. Include one entry or comment per line—for example, one IP address, one URL, or one domain name per line.

Tip The number of entries is limited by the maximum file size. For example, a URL list with no comments and an average URL length of 100 characters (including Unicode representations and newlines) can support more than 5.24 million entries.

- In a DNS list entry, you can use an asterisk (`*`) wildcard character for a domain label. All labels match the wildcard. Example: `www.example.*` matches `www.example.com` and `www.example.co`.
- Comment lines must start with the pound (`#`) character.
- Comments are removed during upload. Files you download contain only the entries, not the comments.

Feed requirements

- When configuring a feed, specify its location using a URL; the URL cannot be Punycode-encoded.
- For feed update intervals of 30 minutes or less, you must provide an MD5 URL to prevent frequent downloads of unchanged feeds. If your feed server does not provide an MD5 URL, use a download interval of at least 30 minutes.
- If you use an MD5 checksum, store it in a simple text file. The file should contain only the checksum. Do not add comments to the file.

List URL syntax and matching criteria for URL lists and feeds

Security Intelligence URL lists and feeds, including custom lists and feeds and entries in the global Block list and Do Not Block list, can include hostnames, URLs, slashes for exact matches, wildcards, and IP addresses, each with specific matching behavior.

- Hostnames

  For example, **`www.example.com`**.

- URLs
  - **`example.com`** matches **`example.com`** and all subdomains, including:
    - **`www.example.com`**
    - **`eu.example.com`**
    - **`example.com/abc`**
    - **`www.example.com/def`**
  - Does not match:
    - **`example.co.uk`**
    - **`examplexyz.com`**

- **example.com.malicious-site.com**

- When a feed or list includes a single entry, every URL that ends with those domains is identified and blocked
- Example feed:

  If you add `www.netflix.com, www.amazon.*, org, edu, www.hulu.*` to the feed, these are blocked:

  - `http://www.amazon.in`
  - `http://www.rajiv.org/`
  - `http://www.edu.edu/`
  - `http://www.edu.org/`
  - `http://org.org/`
  - `http://edu.edu`

- You can also include an entire URL path, such as **https://www.cisco.com/c/en/us/products/security/firewalls/index.html**

- Custom feeds with embedded credentials:

  You can create a custom URL, Network, and DNS feeds, including the username and password inside the URL (for example: **https://admin:password@server.domain.com/list.txt**).

Note If your password contains special characters (such as a colon (:) or an at sign (@)), transmission would fail. Ensure that your passwords do not contain these special characters, or use encoded passwords.

- A slash at the end of a URL to specify an exact match

  example.com/ matches only **example.com**; it does not match **www.example.com** or any other URL.

- A wildcard (*) to represent any domain in a URL
  - An asterisk can represent a complete domain string separated by dots, but not a partial domain string, and not any part of the URL following the first slash.

    Valid examples:

    - ***.example.com**
    - **www.*.com**
    - **example.***

      (This will match **example.com** and **example.org** and **example.de**, for example, but not **example.co.uk**)

    - ***.example.***

- **example.*/**

Invalid examples:

- **example*.com**
- **example.com/***

- IP addresses (IPv4)
  - For IPv6 addresses, or to use ranges or CIDR notation, use the Security Intelligence Network object.
  - You can include one or more wildcards representing an octet, for example 10.10.10.* or 10.10.*.*.

See also Custom Security Intelligence lists, on page 3031.

Custom security intelligence feeds

A custom security intelligence feed is a threat intelligence source that

- enables augmentation of system-provided intelligence feeds with regularly updated reputable block lists and do not block lists from the internet,
- supports configuration of internal feeds for updating multiple Cloud-Delivered Firewall Management Center appliances using a single source list, and
- allows use of MD5 checksums to determine if a feed requires downloading, reducing unnecessary updates for large or internal feeds.

Security intelligence feed management

Custom or third-party Security Intelligence feeds allow you to augment the system-provided intelligence feeds with other regularly updated reputable block lists and do not block lists on the internet. You can also set up an internal feed, which is useful if you want to update multiple Cloud-Delivered Firewall Management Center appliances in your deployment using one source list.

You can configure the system to use an MD5 checksum to determine whether to download an updated feed. If the checksum has not changed since the last download, the system does not need to re-download it. Using MD5 checksums is especially helpful for internal feeds that are large.

Note You cannot add address blocks to block or do not block lists using a `/0` netmask in a Security Intelligence feed. If you want to monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** rule action and specify `any` for the **Source Networks** and **Destination Networks**.

Note The system does **not** perform peer SSL certificate verification when downloading custom feeds, nor does the system support the use of certificate bundles or self-signed certificates to verify the remote peer.

If you want strict control over when the system updates a feed from the internet, you can disable automatic updates for that feed. However, automatic updates ensure that the data is always current and relevant.

When you manually update Security Intelligence feeds, the system updates all feeds, including the system-provided intelligence feeds.

See complete requirements at List custom lists and feeds requirements, on page 3026.

Create custom security intelligence feeds

Configure security intelligence feeds to enhance your device's ability to detect and respond to threats by importing external or custom threat data sources.

You must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Use this task when you need to add new threat intelligence feeds for IP, DNS, or URL data to your security device.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** node, then choose a feed type you want to add.

Step 2 Click the option appropriate to the feed type you chose:

- **Add Network Lists and Feeds** (for IP addresses)
- **Add DNS Lists and Feeds**
- **Add URL Lists and Feeds**

Step 3 Enter a **Name** for the feed.

Step 4 Choose **Feed** from the **Type** drop-down list.

Step 5 Enter a **Feed URL**.

Step 6 Enter an **MD5 URL**.

- The MD5 URL is used to check if the feed content has changed since the last update and is required for update intervals shorter than 30 minutes.
- If your feed provider does not supply an MD5 URL, set the update interval to at least 30 minutes.

Step 7 Choose an **Update Frequency**.

Step 8 Click **Save**.
Unless you disabled feed updates, the system downloads and verifies the feed.

Update custom security intelligence feeds manually

Manually updating Security Intelligence feeds allows you to ensure that your deployment uses the most current threat intelligence data for filtering network traffic.

You must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Before you begin

At least one device must already be added to the management center.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence**.

Step 2 Click **Update Feeds**, then confirm.

Step 3 Click **OK**.

After the Cloud-Delivered Firewall Management Center downloads and verifies the feed updates, it communicates any changes to its managed devices. Your deployment begins filtering traffic using the updated feeds.

Custom Security Intelligence lists

A custom Security Intelligence list is a static list that

- contains IP addresses, address blocks, URLs, or domain names that you manually upload to the system,
- enables you to augment and fine-tune feeds or global lists for the managed devices of a single Cloud-Delivered Firewall Management Center, and
- is useful when you need to override or supplement existing feed behavior without removing the entire feed from a policy.

Formatting requirements for custom Security Intelligence lists

- Netmasks for address blocks must be integers from `0` to `32` for IPv4 or from `0` to `128` for IPv6.
- Encode Unicode in domain names using Punycode format. The encoding is not case sensitive.
- Characters in domain names are not case sensitive.
- Unicode in URLs must be percent-encoded.
- Characters in URL subdirectories are case sensitive.
- List entries that start with the number sign (`#`) are treated as comments.
- For more information about formatting requirements, see the List custom lists and feeds requirements, on page 3026.

Matching requirements for custom Security Intelligence lists

- If you add a higher-level domain to a URL or DNS list, any sub-level domains also match. For example, if you add `example.com` to a DNS list, `www.example.com` and `test.example.com` also match.
- DNS lookups (forward or reverse) are not performed on DNS or URL list entries. For example, if you add `http://198.51.100.2` to a URL list, the list matches only that exact address and not any domain it resolves to.

Note You cannot add address blocks to a Block or Do Not Block list using a `/0` netmask in a Security Intelligence list. To monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** action, and set the **Source Networks** and **Destination Networks** to `any`.

Examples for customizing Security Intelligence lists

- If a global feed blocks access to a vital resource but is otherwise useful, you can upload a custom list to allow access to that resource without disabling the feed entirely.
- You can supplement an existing feed by adding URLs or domains relevant to your organization.

Upload new custom security intelligence lists to the Cloud-Delivered Firewall Management Center

To modify a Security Intelligence list, you must make your changes to the source file and upload a new copy. You cannot modify the file's contents using the web interface. If you do not have access to the source file, download a copy from the system.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** node, then choose a list type.

Step 2 Click the option appropriate to the list you chose above:

- **Add Network Lists and Feeds** (for IP addresses)
- **Add DNS Lists and Feeds**
- **Add URL Lists and Feeds**

Step 3 Enter a **Name**.

Step 4 From the **Type** drop-down list, choose **List**.

Step 5 Click **Browse** to browse to the list `.txt` file, then click **Upload**.

Step 6 Click **Save**.

What to do next

You do not need to redeploy these changes to take effect. If you want to delete an entry from the list, see Delete entries from global security intelligence lists, on page 3025.

Update custom security intelligence lists

Modify, add, or remove entries from your security intelligence lists in Secure Firewall Management Center. Update your lists when new threats emerge or when you need to refine your firewall's response to known risks. Perform this task as part of routine security maintenance or to update your firewall based on new threat intelligence.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Security Intelligence** node, then choose a list type.

Step 2 Next to the list you want to update, click **Edit** ( ).

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 To edit the list, click **Download** and save the list as a text file using your browser's prompts.

Step 4 Change the list as needed.

Step 5 On the Security Intelligence pop-up window, click **Browse** to browse to the modified list, then click **Upload**.

Step 6 Click **Save**.

What to do next

These changes take effect without redeployment. If you want to delete an entry from the list, see Delete entries from global security intelligence lists, on page 3025.

Sinkhole objects

A sinkhole object is a network security object that

- represents either a DNS server that gives non-routable addresses for all domain names within the sinkhole
- can represent an IP address that does not resolve to a server, and
- requires assignment of both an IPv4 address and an IPv6 address.

Sinkhole object usage in DNS policy rules

You can reference the sinkhole object within a DNS policy rule to redirect matching traffic to the sinkhole.

Create a sinkhole object

Create a sinkhole object to redirect or block suspicious traffic for enhanced threat detection and analysis.

Use this task when you need to configure a sinkhole object for traffic redirection or blocking to maintain security.

Before you begin

Ensure you have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management** > **Sinkhole**.

Step 2 Click **Add Sinkhole**.

Step 3 Enter a **Name**.

Step 4 Enter the **IPv4 Address** and **IPv6 Address** of your sinkhole.

Step 5 You have these options:

- To redirect traffic to a sinkhole server, choose **Log Connections to Sinkhole**.
- To redirect traffic to a non-resolving IP address, choose **Block and Log Connections to Sinkhole**.

Step 6 (Optional) From the **Type** drop-down list, assign an Indication of Compromise (IoC) type for the sinkhole object, if needed.

Step 7 Click **Save**.

Configure an SLA monitor

Configure an SLA monitor to define a connectivity policy to a monitored address and track the availability of a route. This helps ensure that the route is periodically checked and replaced with a backup route if it becomes unavailable.

An Internet Protocol Service Level Agreement (SLA) monitor defines a connectivity policy to a monitored address and tracks the availability of a route. The monitor periodically checks the route by sending ICMP echo requests. If requests time out, the route is removed from the routing table and replaced with a backup route. SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration. The SLA Monitor Object is used in the Route Tracking field of an IPv4 Static Route Policy.

Note IPv6 routes do not support SLA monitors via route tracking.

Procedure

Step 1 Select **Objects** > **Object Management** > **SLA Monitor**.

Step 2 Click **Add SLA Monitor** and enter these values:

Fields	Details
Name	Enter a name for the object.
Description	Enter a description for the object.

Fields	Details
Frequency	Enter the frequency of ICMP echo request transmissions, in seconds. Valid values range from 1 to 604800 seconds (7 days). The default is 60 seconds. **Note** The frequency cannot be less than the timeout value; you must convert frequency to milliseconds to compare the values.
SLA Monitor ID	Enter the ID number of the SLA operation. Values range from 1 to 2147483647. You can create a maximum of 2000 SLA operations on a device. Each ID number must be unique to the policy and the device configuration.
Threshold	Enter the amount of time that must pass after an ICMP echo request before a rising threshold is declared, in milliseconds. Valid values range from 0 to 2147483647 milliseconds. The default is 5000 milliseconds. The threshold value identifies events that exceed the defined value, which you can use to evaluate the proper timeout value. However, the threshold does not serve as a direct indicator of the reachability of the monitored address. **Note** The threshold value should not exceed the timeout value.
Timeout	Enter the amount of time that the SLA operation waits for a response to the ICMP echo requests, in milliseconds. Values range from 0 to 604800000 milliseconds (7 days). The default is 5000 milliseconds. If a response is not received from the monitored address within the amount of time defined in this field, the static route is removed from the routing table and replaced by the backup route. **Note** The timeout value cannot exceed the frequency value (adjust the frequency value to milliseconds to compare the numbers).
Data Size	Enter the size of the ICMP request packet payload, in bytes. Values range from 0 to 16384 bytes. The default is 28 bytes, which creates a total ICMP packet of 64 bytes. Do not set this value higher than the maximum allowed by the protocol or the Path Maximum Transmission Unit (PMTU). For purposes of reachability, you might need to increase the default data size to detect PMTU changes between the source and the target. A low PMTU can affect session performance and, if detected, might indicate that the secondary path should be used.
ToS	Enter a value for type of service (ToS) defined in the IP header of the ICMP request packet. Values range from 0 to 255. The default is 0. This field contains information such as delay, precedence, reliability, and so on. It can be used by other devices on the network for policy routing and features such as committed access rate.

Fields	Details
Number of Packets	Enter the number of packets that are sent. Values range from 1 to 100. The default is 1 packet. **Note** Increase the default number of packets if you are concerned that packet loss might falsely cause the Secure Firewall Threat Defense device to believe that the monitored address cannot be reached.
Monitored Address	Enter the IP address that is being monitored for availability by the SLA operation.

Step 3 The **Available Zones** list displays both zones and interface groups. In the **Zones/Interfaces** list, add the zones or interface groups that contain the interfaces through which the device communicates with the management station. To specify a single interface, you need to create a zone or the interface groups for the interface; see Create security zone and interface group objects, on page 1002. The host will be configured on a device only if the device includes the selected interfaces or zones.

Step 4 Click **Save**.

After completing these steps, the SLA monitor is configured and begins tracking the availability of the specified route. If the monitored address becomes unreachable, the route is removed from the routing table and replaced with a backup route.

Time ranges

A time range is a configuration object that

- defines specific time periods,
- enables use of these periods to determine when rules apply, and
- supports integration with time-based ACLs.

Time range objects allow you to specify periods for rule enforcement.

Note Time-based ACLs is supported in Snort 3 also from Cloud-Delivered Firewall Management Center 7.0 onwards.

Create a time range object

Establish a time range object so policies apply only during specified periods, enabling precise control of network traffic.

If you want a policy to apply only during a specified time range, create a time range object and specify that object in the policy. This object works on Firewall Threat Defense devices only.

You can specify time range objects only in certain policy types, which are listed in this topic.

Note The timezone represents the device's local time and is used only for applying the time ranges in rules in the policies that support the time ranges. The timezone does not change the configured time of the device. To verify the configuration, in the Firewall Threat Defense CLI, use the **show time-range timezone** and **show time** commands (see the *Cisco Secure Firewall Threat Defense Command Reference* guide). In addition, the timezone of a chassis overrides the management center timezone.

Before you begin

Time ranges operate based on the time zone associated with the device that processes the traffic. By default, this is UTC. To change the time zone associated with a device, go to **Devices** > **Platform Settings**.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Time Range** from the list of object types.

Step 2 Click **Add Time Range**.

Step 3 Enter the object name and specify the desired time periods.

- If you see a red error box around the object name you have entered, mouse over the **Name** field to see naming restrictions.
- All times are in UTC, unless you specify a time zone for the device in **Devices** > **Platform Settings**.
- Enter times using a 24-hour clock; for example, enter 13:30 for 1:30 PM.
- To specify a single continuous range, such as typical weekend hours (Fridays at 5pm through Mondays at 8am, including evenings and nights), choose Range Type **Range**.
- To specify part of multiple days, such as Monday through Friday from 8am to 5pm (excluding evenings, nights, and early mornings every day), choose Range Type **Daily Interval**.
- You may specify up to 28 periods per object.
- For multiple noncontiguous times of day or different hours for different days, create multiple recurring intervals. For example, to apply a policy at all times other than standard working hours, create a single time range object with the following two recurring intervals:
  - A Daily Interval for Monday through Friday from 5pm through 8am, and
  - A Range recurring interval for Friday at 5pm through Monday at 8am.

Step 4 Click **Save**.

What to do next

Configure time ranges in any of these:

- Access control rules
- Prefilter rules

- Tunnel rules
- VPN group policy

In a VPN group policy object, specify the time range object using the **Access Hours** field. For details, see Configure a group policy object, on page 3062 and Advanced group policy option fields and values, on page 3068.

Time zones

A time zone is a configuration object that

- specifies the local time zone for a managed device
- is used only for applying time ranges in rules in policies that support time ranges, such as access control, prefilter, and VPN group policies), and
- defaults to UTC if not assigned to a device.

Device support and usage of time zones

- Time zone objects are supported only for Firewall Threat Defense devices.
- Time-based ACLs is supported in Snort 3 also from Cloud-Delivered Firewall Management Center 7.0 onwards.

Tunnel zones

A tunnel zone is a network object that

- represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis,
- is not an interface object, and
- can be used as an interface constraint in some configurations.

For detailed information, see Using tunnel zones to apply access control at the tunnel level, on page 2534.

URLs

A URL object is a configuration element that

- defines a single URL or IP address for use within access control policies, event searches, and Security Intelligence configurations,
- can be used in multiple locations throughout the system's web interface to specify what traffic is filtered or monitored, and
- provides distinct matching behavior compared to URL group objects, which define multiple URLs or addresses.

URL object configuration guidelines

Important For best practices for using this and similar options in Security Intelligence configurations and for URL rules in access control and QoS policies, see Manual URL filtering options, on page 2102.

When creating URL objects, consider the following guidelines:

- If the URL does not include a path (no / characters), the match is based only on the server's hostname. If a path is included (one or more / characters), the entire URL string is used for a substring match.
- A URL is considered a match if:
  - the string appears at the beginning of the URL,
  - the string follows a dot,
  - the string contains a dot at the beginning,
  - or the string follows the :// characters.
- The system ignores the encryption protocol (HTTP or HTTPS). Blocking a website applies to both unless an application condition targets a specific protocol. Specify URLs without the protocol (use example.com, not http://example.com).
- To match HTTPS traffic in access control rules, use the subject common name from the public key certificate. Do not include subdomain information. The subject common name in certificates may differ from the web site's domain (for example, youtube.com uses *.google.com). Use SSL Decryption policy to decrypt HTTPS traffic for consistent URL filtering results.
- URL objects will not match HTTPS traffic if the browser resumes a TLS session, as certificate information may not be available, which can lead to inconsistent results.
- When using URL objects as aliases in remote access VPN policies, ensure the URL is 128 characters or less.
- Do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths.

URL object matching examples

For example, ign.com matches ign.com or www.ign.com, but not versign.com. Use example.com rather than http://example.com when specifying a URL object.

Create a URL object

Use this task when you need to define a new URL object in the Secure Firewall Management Center for use in access control or other security policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **URL** from the list of object types.

Step 2 Choose **Add Object** from the **Add URL** drop-down list.

Step 3 Enter a **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Enter the **URL** or IP address.

Step 6 (Optional) Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2942.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Variable sets

A variable set is a configuration group that

- collects and manages variables used in intrusion rules and policies
- allows customization of predefined and user-defined variables, and
- enables linking of variable sets to intrusion policies for flexible network security management.

Variable set management and usage

Variables represent values commonly used in intrusion rules to identify source and destination IP addresses and PORTS. You can also use variables in intrusion policies to represent IP addresses in rule suppressions, adaptive profile updates, and dynamic rule states.

Tip Preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.

You use variable sets to manage, customize, and group your variables. You can use the default variable set provided by the system or create your own custom sets. Within any set you can modify predefined default variables and add and modify user-defined variables.

Most of the shared object rules and standard text rules that the system provides use predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web SERVERS use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Rules are more effective when variables more accurately reflect your network environment. At a minimum, you should modify default variables in the default set. By ensuring that a variable such as `$HOME_NET` correctly defines your network and `$HTTP_SERVERS` includes all web SERVERS on your network, processing is optimized and all relevant systems are monitored for suspicious activity.

To use your variables, you link variable sets to intrusion policies associated with access control rules or with the default action of an access control policy. By default, the default variable set is linked to all intrusion policies used by access control policies.

Adding a variable to any set adds it to all sets; that is, each variable set is a collection of all variables currently configured on your system. Within any variable set, you can add user-defined variables and customize the value of any variable.

Initially, the system provides a single, default variable set comprised of predefined default values. Each variable in the default set is initially set to its default value, which for a predefined variable is the value set by the Talos Intelligence Group and provided in rule updates.

Although you can leave predefined default variables configured to their default values, Cisco recommends that you modify a subset of predefined variables.

You could work with variables only in the default set, but in many cases you can benefit most by adding one or more custom sets, configuring different variable values in different sets, and perhaps even adding new variables.

When using multiple sets, it is important to remember that the *current value* of any variable in the default set determines the *default value* of the variable in all other sets.

When you select **Variable Sets** on the Object Manager page, the object manager lists the default variable set and any custom sets you created.

On a freshly installed system, the default variable set is comprised only of the default variables predefined by Cisco.

Each variable set includes the default variables provided by the system and all custom variables you have added from any variable set. Note that you can edit the default set, but you cannot rename or delete the default set.

Caution Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

Variable sets in intrusion policies

A variable set is a configuration group that

- links to intrusion policies used in an access control policy,
- provides variable values for enabled intrusion rules, and
- affects deployment status when modified.

Deployment status for variable sets in intrusion policies

By default, the system links the default variable set to all intrusion policies used in an access control policy. When you deploy an access control policy that uses an intrusion policy, intrusion rules that you have enabled in the intrusion policy use the variable values in the linked variable set.

When you modify a custom variable set used by an intrusion policy in an access control policy, the system reflects the status for that policy as out-of-date on the Access Control Policy page. You must re-deploy the access control policy to implement changes in your variable set. When you modify the default set, the system reflects the status of all access control policies that use intrusion policies as out-of-date, and you must re-deploy all access control policies to implement your changes.

Variables

A variable is a configuration element that

- can be provided by the system or created by users
- is categorized as default, customized, or advanced, and
- enables flexible management of network addresses and ports in rule creation.

Variable categories

Variables are grouped into three categories: default, customized, and advanced.

- **Default variables** are provided by the system. You cannot rename or delete a default variable, and you cannot change its default value. However, you can create a customized version of a default variable.
- **Customized variables** are variables you create. These variables can include:
  - *customized default variables*

    When you edit the value for a default variable, the system moves the variable from the Default Variables area to the Customized Variables area. Variable values in the default set determine the default values of variables in custom sets. If you customize a default variable in the default set, the system changes the default value of the variable in all other sets.
  - *user-defined variables*

    You can add and delete your own variables, customize their values within different variable sets, and reset customized variables to their default values. When you reset a user-defined variable, it remains in the Customized Variables area.

    User-defined variables can be one of these types:
    - *network* variables specify the IP addresses of hosts in your network traffic.

- *port* variables specify TCP or UDP ports in network traffic, including the value `any` for either type.

- **Advanced variables** are provided by the system under specific conditions. These variables have a very limited deployment.

Variable usage examples

For example, if you create custom standard text rules, you might also want to add your own user-defined variables to more accurately reflect your traffic or as shortcuts to simplify the rule creation process. Alternatively, if you create a rule that you want to inspect traffic in the "demilitarized zone" (or DMZ) only, you can create a variable named `$DMZ` whose value lists the server IP addresses that are exposed. You can then use the `$DMZ` variable in any rule written for this zone.

List predefined default variables

By default, the system provides a single default variable set, which is comprised of predefined default variables. The Talos Intelligence Group uses rule updates to provide new and updated intrusion rules and other intrusion policy elements, including default variables. Because many intrusion rules from the system use predefined default variables, set appropriate values for these variables. You can modify the values for these default variables in any or all variable sets, depending on how you use variable sets to identify traffic on your network.

Caution Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

This table describes the variables provided by the system and indicates which variables you typically would modify. For assistance determining how to tailor variables to your network, contact Professional Services or Support.

Table 163: System-Provided variables

Variable Name	Description	Modify?
`$AIM_SERVERS`	Defines known AOL Instant Messenger (AIM) SERVERS, and is used in chat-based rules and rules that look for AIM exploits.	Not required.
`$DNS_SERVERS`	Defines Domain Name Service (DNS) SERVERS. If you create a rule that affects DNS SERVERS specifically, you can use the `$DNS_SERVERS` variable as a destination or source IP address.	Not required in curre
`$EXTERNAL_NET`	Defines the network that the system views as the unprotected network, and is used in many rules to define the EXTERNAL network.	Yes, you should adeq `$HOME_NET` and then `$HOME_NET` as the val `$EXTERNAL_NET`.
`$FILE_DATA_PORTS`	Defines non-encrypted ports used in intrusion rules that detect files in a network stream.	Not required.

Variable Name	Description	Modify?
$FTP_PORTS	Defines the ports of FTP SERVERS on your network, and is used for FTP server exploit rules.	Yes, if your FTP SERVE ports other than the defau (you can view the defaul the web interface).
$GTP_PORTS	Defines the data channel ports where the packet decoder extracts the payload inside a GTP (General Packet Radio Service [GPRS] Tunneling Protocol) PDU.	Not required.
$HOME_NET	Defines the network that the associated intrusion policy monitors, and is used in many rules to define the internal network.	Yes, to include the IP add your internal network.
$HTTP_PORTS	Defines the ports of web SERVERS on your network, and is used for web server exploit rules.	Yes, if your web SERVE ports other than the defau (you can view the defaul the web interface).
$HTTP_SERVERS	Defines the web SERVERS on your network. Used in web server exploit rules.	Yes, if you run HTTP SE
$ORACLE_PORTS	Defines Oracle database server ports on your network, and is used in rules that scan for attacks on Oracle databases.	Yes, if you run Oracle SE
$SHELLCODE_PORTS	Defines the ports you want the system to scan for shell code exploits, and is used in rules that detect exploits that use shell code.	Not required.
$SIP_PORTS	Defines the ports of SIP SERVERS on your network, and is used for SIP exploit rules.	Not required.
$SIP_SERVERS	Defines SIP SERVERS on your network, and is used in rules that address SIP-targeted exploits.	Yes, if you run SIP SERV should adequately define $HOME_NET and then inclu $HOME_NET as the value f $SIP_SERVERS.
$SMTP_SERVERS	Defines SMTP SERVERS on your network, and is used in rules that address exploits that target mail SERVERS.	Yes, if you run SMTP SE
$SNMP_SERVERS	Defines SNMP SERVERS on your network, and is used in rules that scan for attacks on SNMP SERVERS.	Yes, if you run SNMP SE
$SNORT_BPF	Identifies a legacy advanced variable that appears only when it existed on your system in a software release before Version 5.3.0 that you subsequently upgraded to Version 5.3.0 or greater.	No, you can only view or variable. You cannot edit recover it after deleting i
$SQL_SERVERS	Defines database SERVERS on your network, and is used in rules that address database-targeted exploits.	Yes, if you run SQL SER
$SSH_PORTS	Defines the ports of SSH SERVERS on your network, and is used for SSH server exploit rules.	Yes, if your SSH SERVE ports other than the defau (you can view the defaul the web interface).

Variable Name	Description	Modify?
`$SSH_SERVERS`	Defines SSH SERVERS on your network, and is used in rules that address SSH-targeted exploits.	Yes, if you run SSH S you should adequatel `$HOME_NET` and then i `$HOME_NET` as the val `$SSH_SERVERS`.
`$TELNET_SERVERS`	Defines known Telnet SERVERS on your network, and is used in rules that address Telnet server-targeted exploits.	Yes, if you run Telne
`$USER_CONF`	Provides a general tool that allows you to configure one or more features not otherwise available via the web interface. Conflicting or duplicate `$USER_CONF` configurations will halt the system.	No, only as instructe description or with th Support.

Network variables

A network variable is a configuration element that

- represents IP addresses for use in intrusion rules, intrusion policy rule suppressions, dynamic rule states, and adaptive profile updates
- differs from network objects and network object groups by being specific to intrusion policies and intrusion rules, and
- enables specification of host IP addresses in various configurations within an intrusion policy.

Network variable usage and configuration

Network variables can be used to specify the IP addresses of hosts on the network in the following configurations:

- Intrusion rules: The **Source IPs** and **Destination IPs** fields restrict packet inspection to traffic originating from or destined to specific IP addresses.
- Suppressions: The **Network** field in source or destination intrusion rule suppressions suppresses intrusion event notifications when a specific IP address or range triggers an intrusion rule or preprocessor.
- Dynamic rule states: The **Network** field in dynamic rule states identifies when too many matches for an intrusion rule or preprocessor occur within a given time period.
- adaptive profile updates: The**Networks** field identifies hosts where packet fragment and TCP stream reassembly is improved in passive deployments.

When variables are used in these fields, the variable set linked to an intrusion policy determines the variable values applied to network traffic handled by the related access control policy.

A variable can include any combination of the following network configurations:

- network variables, network objects, and network object groups selected from the available networks list,
- individual network objects added from the New or Edit Variable page, which can then be used in variables or other configurations,

- literal single IP addresses or address blocks; multiple literal IP addresses and address blocks may be included individually, supporting both IPv4 and IPv6 addresses.

  When specifying IPv6 addresses, any addressing convention defined in RFC 4291 may be used.

The default value for included networks in any variable is `any`, which indicates any IPv4 or IPv6 address. The default value for excluded networks is `none`, meaning no network. If you specify the address `::`, it means any IPv6 address when included, or no IPv6 addresses when excluded.

Adding networks to the excluded list negates those addresses and blocks; all addresses except the excluded ones can be matched.

For example, excluding `192.168.1.1` specifies any IP address other than 192.168.1.1. Excluding `2001:db8:ca2e::fa4c`specifies any IP address except 2001:db8:ca2e::fa4c.

Exclusions can be made with any combination of literal or available networks. For instance, excluding both `192.168.1.1` and `192.168.1.5` matches any IP address other than 192.168.1.1 or 192.168.1.5.

Keep these points in mind when you add or edit network variables:

- The value `any` cannot be logically excluded, as it would mean no address; for example, it is not possible to add a variable with the value `any` to the exclusion list.
- Network variables identify traffic for specific intrusion rule and intrusion policy features; preprocessor rules can trigger events regardless of the hosts defined by network variables.
- Excluded values must resolve to a subset of included values; for example, including the address block 192.168.5.0/24 and excluding 192.168.6.0/24 is not valid.

Port variables

A port variable is a network configuration element that

- represents TCP and UDP ports you can use in the **Source Port** and **Destination Port** header fields in intrusion rules,
- is specific to intrusion rules and differs from port objects and port object groups, and
- can be used to restrict packet inspection to packets originating from or destined to specific TCP or UDP ports.

Port variable configuration details

Port variables are linked to intrusion policies associated with access control rules or policies, determining the values for these variables in the network traffic where you deploy the access control policy.

When configuring a port variable, you can include:

- any combination of port variables and port objects that you select from the list of available ports (excluding port object groups, which cannot be added to variables),
- individual port objects that you add while creating or editing a variable, which can also be reused for other variables,
- and single literal port values as well as port ranges (ranges must use a dash, e.g., 80-90; colon-separated ranges are supported for backward compatibility but not for new variables).

  You can list multiple literal port values and ranges by adding each individually in any combination.

Port variable configuration has these important considerations:

- The default value for included ports in any variable is `any`, indicating all ports or port ranges. The default for excluded ports is `none`, indicating no ports.

Tip To create a variable with the value `any`, name and save the variable without adding a specific value.

- You cannot exclude the value `any` from a variable, as that would result in no ports being matched.
- Adding ports to an excluded list prevents matching on those specified ports or port ranges. The system matches any port except those excluded.
- Excluded values must be a subset of the included values. For example, if you include the port range 10-50, you cannot exclude port 60.

Advanced variables

An advanced variable is a configuration mechanism that

- enables you configure of features not available through the web interface
- includes the USER_CONF variable as your primary advanced variable, and
- allows you to enter custom instructions or lines up to the maximum character length.

User_CONF variable details

The USER_CONF variable provides a general tool that allows configuration of one or more features not otherwise available via the web interface.

Caution Do **not** use the advanced variable USER_CONF to configure an intrusion policy feature unless you are instructed to do so in the feature description or by Support. Conflicting or duplicate configurations will halt the system.

When editing USER_CONF, you can type up to 4096 characters on a single line. The line wraps automatically. You can include any number of valid instructions or lines until you reach either the 8192-character maximum length for a variable or a physical limit, such as disk space. Use the backslash (\) character as a line continuation after any complete argument in a command directive.

Resetting USER_CONF empties it.

Variable resets

A variable reset is a configuration action that

- returns a variable to its default value on the variable set new or edit variables page,
- applies different reset behaviors depending on whether the variable is in a default or custom set, and
- affects the value used in any intrusion policy where the variable set is linked.

Variable reset values

You can reset a variable to its default value on the variable set new or edit variables page. This table summarizes the basic principles of resetting variables.

Table 164: Variable reset values

Resetting this variable type...	In this set type...	Resets it to...
default	default	the rule update value
user-defined	default	`any`
default or user-defined	custom	the current default set value (modified or unmodified)

When you reset a variable in a custom set, you return it to the current value for that variable in the default set.

If you reset or change a variable in the default set, you update the default value in all custom sets. If the reset icon is unavailable, you cannot reset the variable because it has no customized value in the set. If you have not customized the variable in a custom set, changing it in the default set also updates any intrusion policy where you have linked the variable set.

Note Before you modify a variable in the default set, check how this change affects any intrusion policy that uses the variable in a linked custom set, especially if you have not customized the variable value in the custom set.

You can hover your pointer over the **Reset** icon in a variable set to see the reset value. If the customized value and the reset value match, you are in one of these situations:

- you are in the custom or default set where you added the variable with the value `any`.
- you are in the custom set where you added the variable with an explicit value and elected to use the configured value as the default value.

Variable sets

A variable set is a configuration grouping that

- allows variables to be managed collectively across multiple sets
- enables the addition of variables to all sets simultaneously, and
- provides options for using configured or default values when adding variables.

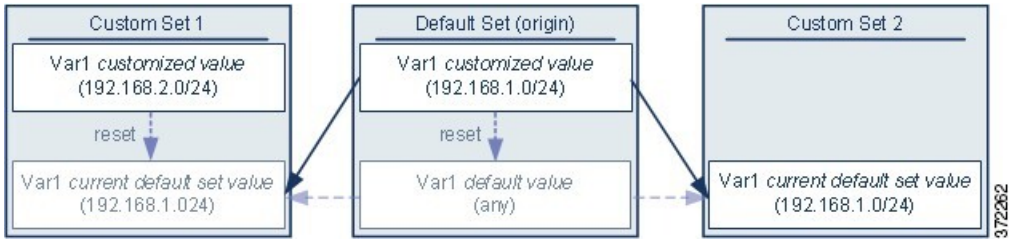
Variable set behavior

When you add a variable to a variable set, it is also added to all other sets. If you add a variable from a custom set, decide if you want to use the configured value as the customized value in the default set.

- **If you use the configured value** (for example, 192.168.0.0/16), the variable is added to the default set using the configured value as a customized value with a default value of `any`. The current value in the default set determines the default value in other sets. Therefore, the initial default value in other custom sets is the configured value (which in this example is 192.168.0.0/16).

- **If you do not use the configured value**, the variable is added to the default set using only the default value `any` and, consequently, the initial, default value in other custom sets is `any`.

Examples: Adding user-defined variables to default sets



A user-defined variable addition is a configuration action that

- enables adding a variable, such as Var1, to a default set with a specific value (like 192.168.1.0/24),
- allows customization of the variable value in any set, and
- ensures that resetting the variable in the default set resets its default value to `any` across all sets.

Set interactions and variable customization

The diagram below illustrates how adding and customizing user-defined variables affects default and custom sets.

Figure 399: Set interaction diagram

Customizing the value of `Var1` in a custom set overrides the default value. For example, if `Var1` is customized in `Custom Set 1`, it takes on a new value, while in `Custom Set 2`, if `Var1` is not customized, it retains the default value (e.g., `192.168.1.0/24`). Resetting the user-defined variable in the default set updates its default value to `any` in all sets.

Further, when `Var1` in `Custom Set 2` is not updated, customizing or resetting `Var1` in the default set updates its current value in `Custom Set 2`, affecting any intrusion policy linked to the variable set.

Note While the interactions are the same for user-defined variables and default variables, resetting a default variable in the default set resets it to the value configured by Cisco in the current rule update, not `any`.

Customizing user-defined variable values

In Custom Set 1, the customized value `192.168.2.0/24` of `Var1` overrides the default value, while in Custom Set 2, `Var1` retains the default value `192.168.1.0/24` unless customized.

Resetting default variables in default sets

Although not shown in the example, note that interactions between sets are the same for user-defined variables and default variables except that resetting a default variable in the default set resets it to the value configured by Cisco in the current rule update.

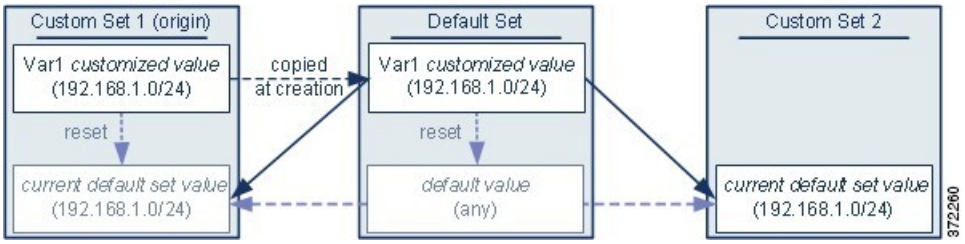
Examples: User-defined variables in custom sets

A user-defined variable in a custom set is a configuration element that:

- enables you to add variables to custom sets,
- allows you to choose whether the configured value becomes the default for other sets, and
- affects how variable values and interactions propagate across sets.

Variable set interactions and default value behavior

When you add a user-defined variable to a custom set, you are prompted to decide if the configured value should be used as the default value for other sets. The examples illustrate the outcomes of each choice.



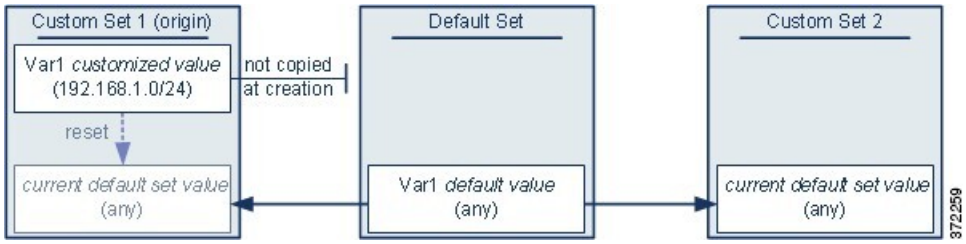
- Choosing to use the configured value as the default copies the value to the default set as a customized value, with a default value of `any`.
- Choosing not to use the configured value as the default adds the variable to all sets with a default value of `any`, allowing customization in any set.

Note Further customizing or resetting a variable in the default set updates the current, default value in other sets, which can affect any intrusion policy linked to the variable set.

Examples of adding user-defined variables to custom sets

The first example shows adding `Var1` with the value `192.168.1.0/24` to Custom Set 1 and electing **to use** the configured value as the default for other sets.

Figure 400: Variable set interaction when using the configured value as default



Except for the origin of `Var1` from Custom Set 1, this example is identical to adding `Var1` to the default set. Adding the customized value `192.168.1.0/24` for `Var1` to Custom Set 1 copies the value to the default set as a customized value with a default value of `any`. Thereafter, `Var1` values and interactions are the same as if you had added `Var1` to the default set. Further customizing or resetting `Var1` in the default set updates the current, default value of `Var1` in Custom Set 2, affecting any intrusion policy linked to the variable set.

Adding a variable and not using the configured value as default

The second example shows adding `Var1` with the value `192.168.1.0/24` to `Custom Set 1`, but electing **not to use** the configured value as the default in other sets.

Figure 401: Variable set interaction when not using the configured value as default

This approach adds `Var1` to all sets with a default value of `any`. After adding `Var1`, you can customize its value in any set. An advantage of this approach is that, by not initially customizing `Var1` in the default set, you decrease your risk of customizing the value in the default set and inadvertently changing the current value in a set such as Custom Set 2 where you have not customized `Var1`.

Nesting variables

A nesting variable is a configuration element that

- can include other variables as part of its definition
- does not support circular nesting, and
- does not support nested, negated variables.

Valid nested variables

In this example, SMTP_SERVERS, HTTP_SERVERS, and OTHER_SERVERS are valid nested variables.

Variable	Type	Included Networks	Excluded Networks
SMTP_SERVERS	customized default	10.1.1.1	—
HTTP_SERVERS	customized default	10.1.1.2	—
OTHER_SERVERS	user-defined	10.2.2.0/24	—
HOME_NET	customized default	10.1.1.0/24 OTHER_SERVERS	SMTP_SERVERS HTTP_SERVERS

Invalid nested variable

In this example, HOME_NET is an invalid nested variable because the nesting of HOME_NET is circular; that is, the definition of OTHER_SERVERS includes HOME_NET, so you would be nesting HOME_NET in itself.

Variable	Type	Included Networks	Excluded Networks
SMTP_SERVERS	customized default	10.1.1.1	—

Variable	Type	Included Networks	Excluded Networks
HTTP_SERVERS	customized default	10.1.1.2	—
OTHER_SERVERS	user-defined	10.2.2.0/24 HOME_NET	—
HOME_NET	customized default	10.1.1.0/24 OTHER_SERVERS	SMTP_SERVERS HTTP_SERVERS

Unsupported nested, negated variable

Because nested, negated variables are not supported, do not use the variable NONCORE_NET to represent IP addresses outside your protected networks.

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.0.0/16 10.2.0.0/16 10.3.0.0/16	—
EXTERNAL_NET	customized default	—	HOME_NET
DMZ_NET	user-defined	10.4.0.0/16	—
NOT_DMZ_NET	user-defined	—	DMZ_NET
NONCORE_NET	user-defined	EXTERNAL_NET NOT_DMZ_NET	—

Alternative to unsupported nested, negated variable

As an alternative to the example above, you could represent IP addresses that are outside of your protected networks by creating the variable NONCORE_NET to represent IP addresses outside your protected networks.

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.0.0/16 10.2.0.0/16 10.3.0.0/16	—
DMZ_NET	user-defined	10.4.0.0/16	—
NONCORE_NET	user-defined	—	HOME_NET DMZ_NET

Manage variable sets

Manage variable sets to organize and control the variables used by your devices. This task helps you add, edit, delete, or filter variable sets as needed for device configuration.

Variable sets are used to efficiently manage collections of variables crucial for device configuration. To use variable sets, you must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management** > **Variable Set**.

Step 2 Manage your variable sets:

- Add — If you want to add a custom variable set, click **Add Variable Set**; see Create a variable set, on page 3053.
- Delete — If you want to delete a custom variable set, click **Delete** ( ) next to the variable set, then click **Yes**. You cannot delete the default variable set or variable sets belonging to ancestor domains.

  Note
  Variables created in a variable set you delete are not deleted or otherwise affected in other sets.

- Edit — If you want to edit a variable set, click **Edit** ( ) next to the variable set you want to modify; see Edit objects, on page 2935.
- Filter — If you want to filter variable sets by name, begin entering a name; as you type, the page refreshes to display matching names. If you want to clear name filtering, click **Clear** ( ) in the filter field.
- Manage Variables — To manage the variables included in variable sets, see Manage variables, on page 3054.

Create a variable set

Variable sets allow you to define and group variables for use in Secure Firewall Management Center. Use this task when you need to create a new set of variables for policy configuration or reuse.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Variable Set**.

Step 2 Click **Add Variable Set**.

Step 3 Enter a **Name**.

Step 4 (Optional) Enter a **Description**.

Step 5 Manage the variables in the set; see Manage variables, on page 3054.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Manage variables

Configure variable sets to control device policies and manage variables for Secure Firewall Management Center.

- You can display, add, delete, edit, or reset variables as required for your environment.

To manage variables in Secure Firewall Management Center, you must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management** > **Variable Set**.

Step 2 Click **Edit** ( ) next to the variable set you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Manage your variables:

- Display — If you want to display the complete value for a variable, hover your pointer over the value in the **Value** column next to the variable.
- Add — If you want to add a variable, click **Add**; see Add variables, on page 3055.
- Delete — Click **Delete** ( ) next to the variable. If you have saved the variable set since adding the variable, click **Yes** to confirm that you want to delete the variable.

  You *cannot* delete these:

  - default variables
  - user-defined variables that are used by intrusion rules or other variables
  - variables belonging to ancestor domains

- Edit — Click **Edit** ( ) next to the variable you want to edit; see Edit variables values in a variable set, on page 3056.
- Reset — If you want to reset a modified variable to its default value, click **Reset** next to a modified variable. If reset is dimmed, one of these is true:

  - The current value is already the default value.
  - The configuration belongs to an ancestor domain.

  Tip
  Hover your pointer over an active reset to display the default value.

Step 4 Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

The current value in the default set determines the default value in all other sets. If you modify or reset a variable in the default set, the current value changes in other sets where you have not customized the default value.

What to do next

- If an active policy references your object, deploy configuration changes.

Add variables

Add variables to a variable set so you can define reusable network or port values for use in policies.

Use variables in device policies to enable flexible, reusable configurations that simplify network management.

Before you begin

Ensure you have the IPS license.

Procedure

Step 1 In the variable set editor, click **Add**.

Step 2 Enter a unique variable **Name**.

Step 3 From the **Type** drop-down list, choose either **Network** or **Port**.

Step 4 Define the values for the variable:

- To include or exclude specific networks or ports, select them and click **Include** or **Exclude**. If there is overlap, excluded addresses or ports always take precedence over included ones.
- To add literal values, enter a single IP address, address block, port, or port range. If you need to add more than one value, repeat this action.
- To remove any items from included or excluded lists, select the item and click **Delete** ( ) next to the item.
- You may use a combination of literal values, existing variables, objects, or network object groups when specifying included or excluded items for network variables.

Step 5 Save the variable.

- If adding a new variable from a custom set, choose whether to add it as a customized value in the default set or as a default value of `any` in the default and other custom sets.

Step 6 Save the variable set.

- Any access control policy linked to the variable set will display an out-of-date status until changes are deployed.

The variable is added to the variable set and is available for use in policies. Any access control policy linked to the variable set displays an out-of-date status until you deploy the changes.

What to do next

- If an active policy references your object, deploy configuration changes.

Edit variables values in a variable set

You must have the IPS license (for Firewall Threat Defense devices) or the Protection license (all other device types).

You can edit both custom and default variables.

You cannot change the **Name** or **Type** values in an existing variable.

Procedure

Step 1 In the variable set editor, click **Edit** ( ) next to the variable you want to modify.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 2 Modify the variable:

- If you want to move items from the list of available networks or ports to the list of included or excluded items, you can select one or more items and then drag and drop, or click **Include** or **Exclude**.

  Tip
  If addresses or ports overlap between the included and excluded lists for a network or port variable, the excluded addresses or ports take precedence.

- Enter a single literal value, then click **Add**. For network variables, you can enter a single IP address or address block. For port variables, you can add a single port or port range, separating the upper and lower values with a hyphen (-). Repeat this step as needed to enter multiple literal values.
- If you want to remove an item from the included or excluded lists, click **Delete** ( ) next to the item.

Note
The list of items to include or exclude can be comprised of any combination of literal strings and existing variables, objects, and network object groups in the case of network variables.

Step 3 Click **Save** to save the variable.

Step 4 Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes. Your changes are saved, and any access control policy the variable set is linked to displays an out-of-date status.

What to do next

- If an active policy references your object, deploy configuration changes.

VLAN tags

A VLAN tag is a network identifier that

- represents a single VLAN or a range of VLAN tags,
- can be grouped with other VLAN tag objects to create tag groups, and

VLAN tag usage

You can use VLAN tag objects and groups in various places in the system's web interface, such as rules and event searches. For example, you could write an access control rule that applies only to a specific VLAN.

Create a VLAN tag object

Use this task when you need to add or manage VLAN tag objects in your Secure Firewall Management Center. VLAN tag objects are referenced in access control and other policies to match specific VLAN tags or ranges.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VLAN Tag**.

Step 2 Choose **Add Object** from the **Add VLAN Tag** drop-down list.

Step 3 Enter a **Name**.

Step 4 Enter a **Description**.

Step 5 Enter a value in the **VLAN Tag** field. Use a hyphen to specify a range of VLAN tags.

Step 6 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allow object overrides, on page 2941.
- If you want to add override values to this object, expand the Override section and click **Add**; see Add object overrides, on page 2942.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

VPN

You can use the following VPN objects on Firewall Threat Defense devices. To use these objects, you must have Admin privileges, and your Smart License account must satisfy export controls. You can configure these objects in leaf domains only.

Certificate map objects

A certificate map object is a configuration element that

- contains a named set of certificate matching rules,
- associates a received certificate with a remote access VPN connection profile, and
- matches rules in priority order, ending when the first rule results in a match.

Certificate map object reference information

Remote access VPN policies use certificate map objects to map certificates to connection profiles. If a received certificate matches the rules in a certificate map, the system associates the connection with the specified profile.

Both certificate map objects and connection profiles are components of a remote access VPN policy.

- The rules are matched in the order shown in the UI.
- Matching ends when the first rule within the certificate map object results in a match.

Navigation path for certificate map objects:

- **Objects** > **Object Management** > **VPN** > **Certificate Map**

Fields in certificate map objects:

- **Name**: Identifies this object so it can be referred to from other configurations, such as remote access VPN.
- **Mapping criteria**: Specifies the contents of the certificate to evaluate. If the certificate satisfies these rules, the user is mapped to the connection profile containing this object.
  - **Field**: Select the field for the matching rule according to the subject or issuer of the client certificate.

    If you set the **Field** to *Alternative Subject* or *Extended Key Usage*, the component remains fixed as *Whole Field*.
  - **Component**: Select the component of the client certificate to use for the matching rule.

Note **SER (Serial Number) component**: Ensure you specify the serial number for the subject field. The certificate map only matches with a serial number attribute in the subject name.

  - **Operator**: Select the operator for the matching rule:
    - Equals: The certificate component must match the entered value. If they do not match exactly, the connection is denied.
    - Contains: The certificate component must contain the entered value. If the component does not contain the value, the connection is denied.

- Does not equal: The certificate component cannot equal the entered value. For example, for a selected certificate component of country and an entered value of US, if the client country value equals US, then the connection is denied.
- Does not contain: The certificate component cannot contain the entered value. For example, for a selected certificate component of country and an entered value of US, if the client country value contains US, the connection is denied.

- **Value**: The value of the matching rule. The value entered is associated with the selected component and operator.

Related Topics

Configure Certificate Maps, on page 1856

Secure Client custom attributes objects

Custom attributes objects enable Secure Client (formerly AnyConnect) to configure features such as Per App VPN, allow or defer upgrade, and dynamic split tunneling. You define the attribute type, then assign one or more named values for this type. In Secure Firewall Management Center, you create custom attributes objects, add them to a group policy, and associate the policy with a remote access VPN to enable features for VPN clients.

Supported features using custom attributes objects

Firewall Threat Defense supports these features using custom attribute objects:

- **Per App VPN**—You can specify which applications may use the VPN tunnel. The system identifies these apps and tunnels only the allowed applications.
- **Allow or defer upgrade**—You can delay downloading Secure Client updates. When a client update becomes available, you can prompt users to upgrade or defer the update.
- **Dynamic Split Tunneling**—You can configure policies to selectively include or exclude IP addresses or networks from the VPN tunnel. Create a custom attribute and add it to a group policy to achieve this.

For step-by-step instructions to configure Secure Client custom attributes, see Configure custom attributes for Secure Client, on page 3059.

For details about the specific custom attributes to configure for a feature, see the *Cisco Secure Client (including AnyConnect) Administrator Guide* for the Secure Client release you are using.

Configure custom attributes for Secure Client

Use this task when you need to configure custom attributes for Secure Client clients, such as Per App VPN, update deferment, or dynamic split tunneling, in Secure Firewall Management Center.

This is relevant for environments where device management and application-specific VPN rules are required, and when deploying secure client features that depend on custom attribute objects.

Applicable when integrating MDM-enrolled devices and advanced VPN features.

Before you begin

Ensure that you have done these steps before adding a custom attribute object for Per App VPN:

- Per App VPN must be properly configured via MDM and each device must be enrolled to the MDM server.
- Create a base64 encoded string for each app using the Cisco Secure Client Enterprise Application Selector Tool.
  1. Download the Cisco Secure Client Enterprise Application Selector Tool from here.
  2. Open the Application Selection Tool and select the mobile platform from the drop-down menu located on the upper left.
  3. Add rule by entering friendly name and App ID; the other fields are optional.
  4. On the menu bar, click **Policy**. The encoded base64 rule appears.
  5. Select and copy the policy string, and save it to use later when you create the Secure Client Custom Attributes object.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **Custom Attribute**.

Step 2 Click **Secure Client Custom Attribute**.

Step 3 Enter a **Name** and optionally a **Description** for the attribute.

Step 4 Select an attribute from the **Secure Client Attribute** drop-down list:

- **Per App VPN**—Select this option and specify the base64 encoded string in the **Attribute Value** box.
- **Allow Defer Update**—Select one of these options and specify the required information to allow or defer Secure Client update:
  - **Show the prompt until user takes action**—Display the prompt to the VPN user until the user chooses to allow or defer the VPN client update.
  - **Show the prompt until times out**—Choose this option to display the prompt for a specified duration and specify the duration in the **Timeout** box.
  - **Do not show the prompt and take automatic action**—Choose this option to automatically allow or defer the VPN update.
  - **Default Action**—Select the default action to be taken when the user does not respond, or when you want to configure an automatic action without the user's intervention. You can choose to update the Secure Client or postpone the update.
  - **Minimum Version**—Specify the minimum Secure Client version to be present on the client system to allow or defer the update.
- **Dynamic Split Tunneling**—Select this option to include or exclude IP addresses or networks from the VPN tunnel.
  - **Include domains**—Specify domain names that will be included in the remote access VPN tunnel.
  - **Exclude domains**—Specify domain names that will be excluded from the remote access VPN tunnel.

Step 5 Select the **Allow Overrides** check box to enable object overrides.

Step 6 Click **Save**.
The custom attributes object is added to the list.

What to do next

Associate the custom attributes with a group policy. See Add custom attributes to your group policy, on page 3061.

Add custom attributes to your group policy

Add custom attributes to a group policy to enable their use with remote access VPN connections. You can assign advanced VPN features to users based on their group policy membership.

To use Secure Client custom attributes with remote access VPN connections, you must associate them with the appropriate group policy. This enables you to offer advanced VPN customization to users based on their group policy membership.

Procedure

Step 1 Select **Objects** > **Object Management** > **VPN** > **Group Policy**.

Step 2 Add a new group policy or edit an existing group policy.

Step 3 Click **Secure Client** > **Custom Attributes**.

Step 4 Click **Add**.

Step 5 Select the **Secure Client Attribute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.

Step 6 Select a **Custom Attribute Object** from the list.

Note
Click Add (+) to create a new custom attribute object for the selected Secure Client attribute. You can also create a custom attribute object at **Objects** > **Object Management** > **VPN** > **Custom Attribute**. See Configure custom attributes for Secure Client, on page 3059.

Step 7 Click **Add** to save the attributes to the group policy, and then click **Save** to save the changes to the group policy.

Related Topics

Group policy options for Secure Client, on page 3065

Firewall Threat Defense group policy objects

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

Group policy object assignment and licensing

The group policy applied to a user is determined when the VPN tunnel is established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

Note There is no group policy attribute inheritance on the Firewall Threat Defense. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

To use group objects, you must have one of these Secure Client licenses associated with your Smart License account with Export-Controlled Features enabled:

- Secure Client VPN Only
- Secure Client Advantage
- Secure Client Premier

Configure a group policy object

Group policy objects are used to manage and enforce security and access policies for remote access VPN connections.

See Firewall Threat Defense group policy objects, on page 3061.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **Group Policy**.

Previously configured policies are listed including the system default. Depending on your level of access, you may edit, view, or delete a group policy.

Step 2 Click **Add Group Policy** or choose a current policy to edit.

Step 3 Enter a **Name** and optionally a **Description** for this policy.

The name can be up to 64 characters. Spaces are allowed. The description can be up to 1,024 characters.

Step 4 Specify the **General** parameters for this Group Policy as described in Group policy general options, on page 3063.

Step 5 Specify the **Secure Client** parameters for this Group Policy as described in Group policy options for Secure Client, on page 3065.

Step 6 Specify the **Advanced** parameters for this Group Policy as described in Advanced group policy option fields and values, on page 3068.

Step 7 Click **Save**.
The new Group Policy is added to the list.

What to do next

Add the group policy object to a remote access VPN connection profile.

Group policy general options

This topic describes the general options available when configuring a group policy, including navigation, VPN protocol selection, IP address pool assignment, banner configuration, DNS/WINS settings and split tunneling options.

Navigation path

Objects > **Object Management** > **VPN** > **Group Policy**, click **Add Group Policy** or choose an existing policy to edit, then select the **General** tab.

VPN protocols fields

Specify the types of Remote Access VPN tunnels (**SSL** or **IPsec IKEv2**) you want to apply for this group policy.

IP address pools

- Specifies the IPv4 address assignment based on address pools designated for user groups in Remote Access VPN.
- You can assign IP addresses from specific pools for identified user groups using RADIUS/ISE for authorization.
- You can enforce policy for users or user groups in non-identity-aware systems by configuring the Group Policy as the RADIUS Authorization attribute (GroupPolicy/Class).

Example: Select a specific address pool for contractors and enforce policy for restricted access to the internal network using those addresses.

The Firewall Threat Defense device assigns IPv4 address pools to the clients in this order:

1. RADIUS attribute for IPv4Address Pool
2. RADIUS attribute for Group Policy
3. Address Pool in Group Policy mapped to a Connection Profile
4. IPv4Address Pool in Connection Profile

Limitations:

- IPv6 address pool is not supported.
- A maximum of six IPv4 address pools can be configured in a Group Policy.
- Deployment failures may occur when address pools in use are modified. Before making any changes to the address pools, you must log off all users.
- If you rename address pools or configure overlapping address pools, deployment may fail. To address this, first remove the old address pool, then deploy the changed address pool.

  Troubleshooting commands :

- `show ip local pool <address-pool-name>`
- `show vpn-sessiondb detail anyconnect`
- `vpn-sessiondb loggoff all noconfirm`

Banner fields

Specifies the banner text to present to users at login. You can enter up to 491 characters in the banner. By default, no value is configured. The IPsec VPN client supports full HTML for the banner, however, the Secure Client supports only partial HTML. To ensure that the banner displays properly to remote users, use the /n tag for IPsec clients and the <BR> tag for SSL clients.

DNS/WINS fields

Domain Naming System (DNS) and Windows Internet Naming System (WINS) servers. Used for Secure Client name resolution.

- **Primary DNS Server** and **Secondary DNS Server**—Choose or create a Network Object which defines the IPv4 or IPv6 addresses of the DNS servers you want this group to use.
- **Primary WINS Server** and **Secondary WINS Server**—Choose or create a Network Object containing the IP addresses of the WINS servers you want this group to use.
- **DHCP Network Scope**—Choose or create a Network Object containing a routable IPv4 address on the same SUBNET as the desired pool, but not within the pool. The DHCP server determines which SUBNET this IP address belongs to and assigns an IP address from that pool. If not set properly, deployment of the VPN policy fails.

  If you configure DHCP servers for the address pool in the connection profile, the DHCP scope identifies the subnets to use for the pool for this group. The DHCP server must also have addresses in the same SUBNET identified by the scope. The scope allows you to select a subset of the address pools defined in the DHCP server for this specific group.

  If you do not define a network scope, the DHCP server assigns IP addresses in the order of the address pools configured. It goes through the pools until it identifies an unassigned address.

  We recommend using the IP address of an interface whenever possible for routing purposes. For example, if the pool is 10.100.10.2-10.100.10.254, and the interface address is 10.100.10.1/24, use 10.100.10.1 as the DHCP scope. Do not use the network number. Use DHCP only for IPv4 addressing. If the address you choose is not an interface address, you might need to create a static route for the scope address.

  LINK-SELECTION (RFC 3527) and SUBNET-SELECTION (RFC 3011) are currently not supported.
- **Default Domain**—Name of the default domain. Specify a top-level domain, for example, example.com.

Split tunneling fields

Split tunneling directs some network traffic through the VPN tunnel (encrypted) and the remaining network traffic outside the VPN tunnel (unencrypted or “in the clear”).

- **IPv4 Split Tunneling / IPv6 Split Tunneling**—By default, split tunneling is not enabled. For both IPv4 and IPv6 it is set to **Allow all traffic over tunnel**. Left as is, all traffic from the endpoint goes over the VPN connection.

To configure split tunneling, choose the **Tunnel networks specified below** or **Exclude networks specified below** policy, and then configure an access control list for that policy.

- **Split Tunnel Network List Type**—Choose the type of Access List you are using. Then choose or create a **Standard Access List** or **Extended Access List**. See Access lists, on page 2948 for details.

Note From Version 7.4, the **Standard Access List** option is disabled by default. Use the **Extended Access List** option to add an access list.

- **DNS Request Split Tunneling**—Also known as Split DNS. Configure the DNS behavior expected in your environment.

  By default, split DNS is not enabled and set to **Send DNS request as per split tunnel policy**. Choosing **Always send DNS request over tunnel** forces all DNS requests to be sent over the tunnel to the private network.

  To configure split DNS, choose **Send only specified domains over tunnel**, and enter the list of domain names in the **Domain List** field. These requests are resolved through the split tunnel to the private network. All other names are resolved using the public DNS server. Enter up to 10 entries in the list of domains, separated by commas. The entire string can be no longer than 255 characters.

Related Topics

Configure a group policy object, on page 3062

Group policy options for Secure Client

This topic lists and describes the specifications and configuration fields for group policy Secure Client VPN operation. This includes navigation steps, profile fields, management profile settings, client modules, SSL settings, connection options, and custom attributes.

These specifications apply to the operation of the Secure Client VPN.

Navigation

Objects > **Object Management** > **VPN** > **Group Policy**. Click **Add Group Policy** or choose a current policy to edit., and then select the **Secure Client** tab.

Profile fields

Profile—Choose or create a file object containing the Secure Client Profile. See File objects, on page 3075 for object creation details.

The Secure Client Profile is a group of configuration parameters stored in an XML file. The Secure Client software uses it to configure the connection entries that appear in the client's user interface. These parameters (XML tags) also configure settings to enable more Secure Client features.

Use the GUI-based Secure Client Profile Editor, an independent configuration tool, to create the Secure Client Profile. See the *Secure Client Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) Administrator Guide for details.

Management profile fields

Management VPN Tunnel—Provides always-on connectivity to the corporate network when the endpoint is powered up, regardless of the user's VPN connection status.

Management VPN Profile—The Management Profile file contains settings for enabling and establishing Management VPN Tunnel on endpoint.

The Standalone Management VPN Tunnel profile editor can be used to create a new profile file or modify an existing file. You can download the profile editor from Cisco Software Download Center.

For more information about adding a profile file, see File objects, on page 3075.

Client modules fields

Cisco Secure Client VPN Only offers enhanced security through various built-in modules. These modules provide services such as web security, network visibility into endpoint flows, and off-network roaming protection. Each module includes a custom client profile.

The following Secure Client modules are optional and you can configure these modules to be downloaded when a VPN user downloads Secure Client:

- **AMP Enabler**—Deploys advanced malware protection (AMP) for endpoints.
- **DART**—Captures a snapshot of system logs and other diagnostic information, which can be sent to the Cisco TAC for troubleshooting.
- **ISE Posture**—Uses the OPSWAT library to perform posture checks to assess an endpoint's compliance.
- **Network Access Manager**—Provides 802.1X (Layer 2) and device authentication for access to both wired and wireless networks.
- **Network Visibility**—Enhances the enterprise administrator's ability to do capacity and service planning, auditing, compliance, and security analytics.
- **Start Before Login**—Forces the user to connect to the enterprise infrastructure over a VPN connection before logging on to Windows by starting Secure Client before the Windows login dialog box appears.
- **Umbrella Roaming Security**—Provides DNS-layer security when no VPN is active.
- **Web Security**—Enforces web security policies and blocks malicious content.

Click **Add** and select the following for each client module:

- **Client Module**—Select the Secure Client module from the list.
- **Profile to download**—Choose or create a file object containing the Secure Client Profile. See File objects, on page 3075 for object creation details.
- **Enable module download**—Select to enable endpoints to download the client module along with the profile. If not selected, the endpoints can download only the client profile.

Use the GUI-based Secure Client Profile Editor, an independent configuration tool to create a client profile for each module. Download the Secure Client Profile Editor from Cisco Software Download Center. See the *Secure Client Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) for details.

SSL settings fields

- **SSL Compression**—Determines if data compression is enabled, and specifies the method to use (Deflate or LZS). SSL Compression is disabled by default.

  Data compression speeds up transmission rates, but also increases the memory requirement and CPU usage for each user session. Thereby, decreasing the overall throughput of the security appliance.

- **DTLS Compression**—Specifies whether to compress Datagram Transport Layer Security (DTLS) connections for this group using LZS. DTLS Compression is disabled by default.

- **MTU Size**—TSpecifies the maximum transmission unit (MTU) size for SSL VPN connections established by Cisco Secure Client VPN Only. The default is 1406 bytes; the valid range is 576 to 1462 bytes.

  - **Ignore DF Bit**—Whether to ignore the Don't Fragment (DF) bit in packets that need fragmentation. Allows the forced fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel.

Connection settings fields

- **Enable Keepalive Messages between Secure Client and VPN gateway** and its **Interval** setting.—Determines whether peers exchange keepalive messages to demonstrate availability for sending and receiving data in the tunnel. By default, this feature is enabled. Keepalive messages are transmitted at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending IKE keepalive packets. The default interval is 20 seconds, the valid range is 15 to 600 seconds.

- **Enable Dead Peer Detection** and its **Interval** settings.—Dead Peer Detection (DPD) ensures that the VPN secure gateway or client quickly detects when the peer is no longer responding and the connection has failed. Default is enabled for both the gateway and the client. DPD messages transmit at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending DPD messages. The default interval is 30 seconds, the valid range is 5 to 3600 seconds.

- **Enable Client Bypass Protocol**—Allows you to configure how the secure gateway manages IPv4 traffic (when it is expecting only IPv6 traffic), or how it manages IPv6 traffic (when it is expecting only IPv4 traffic).

  After the Secure Clientconnects to the headend, the headend assigns the VPN connection an IPv4 address, an IPv6 address, or both. If the headend assigns only one type of address, you can configure the Client Bypass Protocol to either drop network traffic for which an IP address was not assigned (default, disabled, not checked), or allow that traffic to bypass the headend and be sent from the client unencrypted (“in the clear”; enabled, checked).

  For example, if the secure gateway assigns only an IPv4 address to the Secure Client connection and the endpoint is dual-stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.

- **SSL rekey**—Enables the client to rekey the connection, renegotiating the crypto keys and initialization vectors, increasing the security of the connection. This is disabled by default. When enabled, the renegotiation can be done at a specified interval and rekey the existing tunnel or create a new tunnel by setting the following fields:

  - **Method**—Available when SSL rekey is enabled. Create a **New Tunnel** (default), or renegotiate, the **Existing Tunnel**'s specifications.

- **Interval**—Available when SSL rekey is enabled. Set to a default of 4 minutes with a range of 4-10080 minutes (1 week).

- **Client Firewall Rules**—Use the Client Firewall Rules to configure firewall settings for the VPN client's platform. Rules are based on criteria such as source address, destination address, and protocol. Extended Access Control List building block objects are used to define the traffic filter criteria. Choose or create an Extended ACL for this group policy. Define a **Private Network Rule** to control data flowing to the private network, a **Public Network Rule** to control data flowing "in the clear", outside of the established VPN tunnel, or both.

Note Ensure that the ACL contains only TCP/UDP/ICMP/IP ports and source network as any, any-ipv4 or any-ipv6.

Only VPN clients running Microsoft Windows can use these firewall settings.

Custom attributes fields

Custom attributes are used by the Secure Client to configure features such as Per App VPN, Allow or defer upgrade, and Dynamic split tunneling. Click **Add** to add custom attributes to the group policy.

1. Select the **Secure Client Attrinute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.
2. Select a **Custom Attribute Object** from the list.

Note Click Add (+) to create a new custom attribute object for the selected Secure Client attribute. You can also create a custom attribute object at **Objects** > **Object Management** > **VPN** > **Custom Attribute**. See Configure custom attributes for Secure Client, on page 3059.

3. Click **Add** to save the attributes to the group policy, and then click **Save** to save the changes to the group policy.

Related Topics

Configure a group policy object, on page 3062

Advanced group policy option fields and values

The advanced group policy includes options and attributes for configuring VPN access and session behavior. This reference describes where to locate advanced settings, outlines attributes related to traffic filtering, and summarizes session control fields and their allowed values.

Navigation path

Objects > **Object Management** > **VPN** > **Group Policy**. Click **Add Group Policy** or choose a current policy to edit. Then select the **Advanced** tab.

Traffic filter fields

- **Access List Filter**—Filters consist of rules that determine whether to allow or block tunneled data packets coming through the VPN connection. You set rules using criteria such as source address, destination address, and protocol.

  The VPN filter applies only to initial connections. It does not control secondary connections, such as a SIP media connection, that are opened during application inspection.

  Use Extended Access Control List building block objects to define traffic filter criteria. Choose or create an Extended ACL for this group policy.

- **Restrict VPN to VLAN**—Also called "VLAN mapping," this parameter specifies the egress VLAN interface for sessions to which this group policy applies. The ASA forwards all group traffic to the VLAN you select.

  Use this attribute to assign a VLAN to the group policy to simplify access control. You can assign a value to this attribute instead of using ACLs to filter session traffic. The drop-down list shows only the VLANs that are configured in this ASA. Allowed values range from 1 to 4094. The default value is Unrestricted.

Session settings fields

- **Access Hours**—Choose or create a time range object. This object specifies the range of time this group policy is available to be applied to a remote access user. See Time ranges, on page 3036 for details.
- **Simultaneous Logins Per User**—Specifies the maximum number of simultaneous logins allowed for a user. The default value is 3. If the minimum value is set to 0, logins are disabled and users cannot access the VPN. If you allow several simultaneous connections, security may be compromised and performance reduced.
- **Maximum Connection Time / Alert Interval**—Specifies the maximum user connection time in minutes. At the end of this time, the system disconnects the user. The minimum is 1 minute). The Alert interval lets you display a message to the user before the maximum connection time is reached.
- **Idle Timeout / Alert Interval**—Specifies this user's idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system stops the connection. The minimum time is 1 minute. The default is 30 minutes. The Alert interval lets you display a message to the user before the idle time is reached.

Configure a group policy object, on page 3062

Firewall Threat Defense IPsec proposals

IPsec Proposals (or Transform Sets) are used when configuring VPN topologies. During the IPsec security association negotiation with ISAKMP, both peers must agree on the same proposal to protect the data flow.

IPsec proposal types and negotiation

IPsec proposals are categorized based on the IKE version: IKEv1 or IKEv2.

- For an IKEv1 IPsec proposal (Transform Set), select the mode for IPsec operation and define the required encryption and authentication types. Select only one option for each algorithm. To support multiple combinations in a VPN, create multiple IKEv1 IPsec proposal objects.

- For an IKEv2 IPsec proposal, select all encryption and hash algorithms allowed in the VPN. During IKEv2 negotiations, the peers negotiate and use the most appropriate options supported by both devices.

Both IKEv1 and IKEv2 IPsec proposals use the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and antireplay services. ESP uses IP protocol type 50.

Note We recommend that you use both encryption and authentication on IPsec tunnels.

Configure an IKEv1 IPsec proposal object

Use this task when you need to create or modify IKEv1 IPsec proposal objects in Secure Firewall Management Center. Proposal objects define the cryptographic parameters for VPN connections and are required for establishing secure tunnels between firewalls or security gateways.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv1 IPsec Proposal** and then **VPN** > **IPsec IKev1 Proposal** from the table of contents.

Previously configured Proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a Proposal.

Step 2 Choose **Add IPsec IKEv1 Proposal** to create a new Proposal.

Step 3 Enter a **Name** for this proposal.

The name of the policy object can be up to 128 characters.

Step 4 Enter a **Description** for this Proposal.

Provide a description of the policy object that is up to 1024 characters.

Step 5 Choose the **ESP Encryption** method. The Encapsulating Security Protocol (ESP) encryption algorithm for this Proposal.

For IKEv1, select one of the options. When deciding which encryption and Hash Algorithms to use for the IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1715.

Step 6 Select an option for **ESP Hash**.

For a full explanation of the options, see Decide which hash algorithms to use, on page 1715.

Step 7 Click **Save**
The new Proposal is added to the list.

Configure an IKEv2 IPsec proposal object

Use this task when you need to define or update the cryptographic settings for IKEv2 IPsec VPN tunnels on your Secure Firewall Management Center. This is relevant when setting up new VPNs or adjusting security policies to meet organizational requirements.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv2 IPsec Proposal** from the table of contents.

Previously configured proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a Proposal.

Step 2 Choose **Add IKEv2 IPsec Proposal** to create a new proposal.

Step 3 Enter a **Name** for this proposal.

The policy object name can be up to 128 characters.

Step 4 Enter a **Description** for this proposal.

The policy object description can contain up to 1,024 characters.

Step 5 Click **ESP Hash**, the hash or integrity algorithm to use in the proposal for authentication.

Note
Firewall Threat Defense does not support IPSec tunnels with NULL encryption. Make sure that you do not choose NULL encryption for IPSec IKEv2 proposal.

For IKEv2, select all the options you want to support for **ESP Hash**. For a full explanation of the options, see Decide which hash algorithms to use, on page 1715.

Step 6 Click **ESP Encryption** . Select the Encapsulating Security Protocol (ESP) encryption algorithm for this proposal.

For IKEv2, click Select to open a dialog box where you can select all of the options you want to support. When deciding which encryption and hash algorithms to use for the IPsec proposal, choose only algorithms supported by the devices in the VPN. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1715.

Step 7 Click **Save**.
The new proposal is added to the list.

IKE policies

A IKE policy is a key management policy that

- defines security parameters and algorithms used to authenticate IPsec peers,
- negotiates and distributes IPsec encryption keys, and
- establishes secure communications by negotiating security associations in IPsec VPNs.

- The Internet Key Exchange (IKE) protocol manages authentication, key negotiation, and automatic establishment of IPsec security associations (SAs).
- IKE negotiation occurs in two phases:
  - Phase 1 negotiates a security association between two IKE peers, enabling secure communication in Phase 2.
  - Phase 2 establishes SAs for applications, such as IPsec.
- Both phases use proposals to negotiate connections. An IKE proposal is a set of algorithms that two peers use to secure negotiation.
- IKE negotiation starts with peers agreeing on a shared IKE policy, which defines the security parameters to protect future negotiations.
- For IKEv1, proposals include a single set of algorithms and a modulus group; multiple, prioritized policies can be created to match remote peers.
- For IKEv2, you can select multiple algorithms and modulus groups in one policy.
- Peers choose proposals during Phase 1 negotiation, enabling creation of a single IKE proposal but consideration of multiple prioritized options.
- For IKEv2, the policy object does not specify authentication; other policies must define authentication requirements.
- An IKE policy is required when you configure a site-to-site IPsec VPN. .

Configure an IKEv1 policy object

Use the IKEv1 Policy page to create, edit, or delete IKEv1 policy objects. These policy objects specify settings such as encryption, authentication, priority, and other parameters necessary for establishing secure VPN tunnels.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv1 Policy** from the table of contents.

Previously configured policies are listed including system-defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a proposal.

Step 2 (Optional) Click **Add IKEv1 Policy** to create a new policy object. Then, enter a **Name** for this policy. The policy object name can be up to 128 characters. Optionally, you can enter the description. The policy object description can contain up to 1,024 characters.

Step 3 Enter the **Priority** value of the IKE policy.

The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority. Valid values range from 1 to 65,535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

Step 4 Select the **Encryption** method.

When deciding which encryption and Hash Algorithms to use for the IKEv1 policy, your choice is limited to algorithms supported by the peer devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For IKEv1, select one of the options. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1715.

Step 5 Select the **Hash** Algorithm that creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv1 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For a full explanation of the options, see Decide which hash algorithms to use, on page 1715.

Step 6 Select the **Diffie-Hellman Group**.

The Diffie-Hellman group to use for encryption. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the group that you want to allow in the VPN. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1716.

Step 7 Enter the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

Step 8 Select the **Authentication Method** to use between the two peers.

- **Preshared Key**—Preshared keys allow for a secret key to be shared between two peers and to be used by IKE during the authentication phase. If one of the participating peers is not configured with the same preshared key, the IKE SA cannot be established.
- **Certificate**—When you use Certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

Note
In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

Step 9 Click **Save**
The new IKEv1 policy is added to the list.

Configure an IKEv2 policy object

Use the IKEv2 policy dialog box to create, delete, and edit an IKEv2 policy object. These policy objects contain the parameters required for IKEv2 policies.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **IKEv2 Policy** from the table of contents.

Previously configured policies are listed including system defined defaults. Depending on your level of access, you may **Edit** (), **View** (), or **Delete** ( ) a policy.

Step 2 Click **Add IKEv2 Policy** to create a new policy. Then, enter a **Name** for this policy. The policy object name can be up to 128 characters. Optionally, enter the description. The description can be up to 1024 characters.

Step 3 Enter the **Priority**.

The priority value of the IKE proposal. The priority value determines the order of the IKE proposals compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority policy. Valid values range from 1 to 65535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

Step 4 Enter the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

Step 5 Select algorithms for these methods:

a. Click **Integrity Algorithms** portion of the Hash Algorithm used in the IKE policy. The Hash Algorithm creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN.For a full explanation of the options, see Decide which hash algorithms to use, on page 1715.

b. Click **Encryption Algorithm** used to establish the Phase 1 SA for protecting Phase 2 negotiations.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN. For a full explanation of the options, see Decide encryption algorithms for VPN policies, on page 1715.

c. Click **PRF Algorithm**.

The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv1, the Integrity and PRF algorithms are not separated, but in IKEv2, you can specify different algorithms for these elements. Select all of the algorithms that you want to allow in the VPN. For a full explanation of the options, see Decide which hash algorithms to use, on page 1715.

d. Click **Diffie-Hellman Group** for encryption.

A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the groups that you want to allow in the VPN. For a full explanation of the options, see Decide which Diffie-Hellman modulus group to use, on page 1716.

Step 6 Click **Save**.
If a valid combination of choices has been selected the new IKEv2 policy is added to the list. If not, errors are displayed and you must make changes accordingly to successfully save this policy.

Secure client customizations

A Secure Client customization is a configuration object that

- represents files used to customize Secure Client,
- enables deployment of customizations to the VPN headend, and
- allows threat defense to distribute customizations to endpoints when users connect from Secure Client.

Supported secure client customizations

Secure Client customization objects represent files used to modify Secure Client. Secure Client supports these types of customizations:

- GUI text and messages
- Icons and images
- Scripts
- Binaries
- Custom installer transforms
- Localized installer transforms

For more information about configuring Secure Client customizations, see Customize Cisco Secure Client, on page 1868.

File objects

File objects are configuration element that

- represent files used in configurations, typically for remote access VPN policies
- can contain Secure Client Profile and Secure Client Image files, and
- are created, edited, and managed through the Add and Edit File Object dialog boxes.

File object management and usage

File objects are used to manage files for remote access VPN policies and are associated with profiles and images for deployment to endpoints.

File objects can be created and edited using the Add and Edit File Object dialog boxes. They are used in configurations for remote access VPN policies and can contain Secure Client Profile and Secure Client Image files.

Create profiles for each AnyConnect module and Secure Client Management VPN using independent profile editors. Deploy these profiles to meet administrator-defined end user requirements and authentication policies on endpoints Secure Client only. This makes preconfigured network profiles available to end users

When you create a file object, the Cloud-Delivered Firewall Management Center makes a copy of the file in its repository. When you back up the database, these files are included. If you restore the database, the files are restored as well. To use a file in a file object, upload it through the interface, not directly to the file repository.

When you deploy configurations that specify a file object, the associated file is downloaded to the device in the appropriate directory.

You can take these actions for each file object:

- **Download**: Download the Secure Client file.
- **Edit**: Modify the file object details.
- **Delete**: Delete the Secure Client file object. When you delete a file object, the associated file is not deleted from the file repository, only the object is deleted.

Navigation path

Objects > **Object Management** > **VPN** > **Secure Client File**.

Fields

- **Name**: Enter the name of the file to identify the file object; you can add up to 128 characters.
- **File Name**: Click **Browse** to select the file. The file name and full path of the file are added when you select the file.
- **File Type**: Choose the file type corresponding to the file you have selected. These file types are available:

File Types	Details
Secure Client Image	Select when you add the Secure Client image you have downloaded from the Cisco Software Download Center. You can associate any new or additional Secure Client images to the remote access VPN policy. You can also remove unsupported or end-of-life client packages that are no longer required.
Secure Client VPN Profile	Choose for the Secure Client VPN profile file. The profile file is created using the GUI-based Secure Client Profile Editor, an independent configuration tool. See the *Secure Client Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) User Guide for details.

File Types	Details
Secure Client Management VPN Profile	Select when you add a profile file for the Secure Client management VPN tunnel. Download the Secure Client **VPN Management Tunnel Standalone Profile Editor** from Cisco Software Download Center if you have not done already and create a profile with required settings for the Secure Client management VPN tunnel.
AMP Enabler Service Profile	The profile is used for the Secure Client The AMP Enabler and this profile are deployed to endpoints from Firewall Threat Defense when a user connects to the VPN using remote access.
Feedback Profile	You can add a Customer Experience Feedback profile and select this type to receive information about the features and modules customers have enabled and use.
ISE Posture Profile	Choose if you are adding a profile file for the Secure Client ISE Posture module.
NAM Service Profile	Configure and add the NAM profile file using the Network Access Manager profile editor.
Network Visibility Service Profile	Profile file for Secure Client Network Visibility module. You can create the profile using the NVM profile editor.
Umbrella Roaming Security Profile	You must select this file type if you are deploying the Umbrella Roaming Security module using the .json file created using the profile editor.
Web Security Service Profile	Select this option when you add a profile file for the Web security module.
HostScan Posture Package	Select when you add a Secure Firewall Posture Package file. This file is used while configuring a Dynamic Access Policy (DAP) to collect information about the operating system, anti-virus, anti-spyware, and firewall software installed on the endpoints.
Secure Client External Browser Package	For selecting an external browser package file for SAML single sign-on web authentication. You can add the package file when a new version of the external package file is available. For more information, see Configure AAA Settings for Remote Access VPN, on page 1835.
Description	Add an optional description.

Requirements and prerequisites for certificates

This topic outlines the domain and role-based access requirements for certificate management.

Requirement	Supported values
Supported domains	Any
User roles	• Admin • Network Admin

Secure Firewall Threat Defense VPN certificate guidelines and limitations

Certificate enrollment guidelines

When a PKI enrollment object is associated with and then installed on a device, the certificate enrollment process starts immediately. The process is automatic for self-signed and SCEP enrollment types; it does not require any additional administrator's action. Manual certificate enrollment requires administrator's action.

- When a PKI enrollment object is associated with and then installed on a device, the certificate enrollment process starts immediately. The process is automatic for self-signed and SCEP enrollment types; it does not require any additional administrator's action. Manual certificate enrollment requires administrator's action.
- When importing identity certificates into Firewall Threat Defense devices, the expiration date of the certificate must not exceed February 6, 2106. Ensure that all certificates used within devices have expiration dates earlier to February 6, 2106 to avoid issues during certificate import or renewal.
- When the certificate enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your VPN Authentication Method.
- Firewall Threat Defense devices support certificate enrollment using Microsoft Certificate Authority(CA) Service, and CA Services provided on Cisco Adaptive Security Appliances(ASA) and Cisco IOS Router.
- Firewall Threat Defense devices cannot be configured as a certificate authority (CA).

Guidelines for certificates and multitenancy

Firewall Threat Defense devices support certificate enrollment using Microsoft CA Service, as well as CA services provided by Cisco Adaptive Security Appliances and Cisco IOS Routers.

Supported certificate enrollment services:

Certificate enrollment domains

- Certificate enrollment can be done in a **child domain** or a **parent domain**.
- When enrollment is done from a **parent domain**, the certificate enrollment object must also be in the same domain.
- If the trustpoint on a device is overridden in the child domain, the overridden value will be deployed on the device.

Enrollment visibility and behavior in leaf domains

- When certificate enrollment is done on a device in a **leaf domain**, the enrollment will be visible to the parent domain or another child domain.
- Adding additional certificates in a leaf domain is possible.

Certificate enrollment restrictions and permissions

- Once a device has certificates enrolled in one domain, it will be allowed to be enrolled in any other domain. The certificates can be added in the other domain.

Device movement between domains

- When you move a device from one domain to another, the certificates also get moved accordingly. You will receive an alert to delete the enrollments on these devices.

Manage Firewall Threat Defense certificates

This task enables you to manage certificates on devices including viewing certificate status, enrolling new certificates, and performing certificate operations such as export and re-enrollment.

See PKI infrastructure and digital certificates, on page 1718 for an introduction to Digital Certificates.

See Certificate enrollment objects, on page 2997 for a description of the objects used to enroll and obtain certificates on managed devices.

Procedure

Step 1 Select **Devices** > **Certificates**.

You can see the following columns for each device listed on this screen:

- **Name**—Lists the devices that already have trustpoints associated with them. Expand the device to see the list of associated trustpoints.
- **Domain**—Displays the certificates that are enrolled in a specific domain.
- **Enrollment Type**—Displays the type of enrollment used for a trustpoint.
- **Status**—Provides the status of the **CA Certificate** and **Identity Certificate**. You can view the certificate contents, when `Available`, by clicking the magnifying glass.

  When you view the CA certificate information, you can view the hierarchy of all the certifying authorities, which issued your CA certificate. If the enrollment fails, click status to view the failure message.
- Click **Enable weak-crypto** on the right to enable weak cipher usage in certificates. When you click the toggle button, you get a warning to confirm before enabling weak ciphers. Click **Yes** to enable weak ciphers.

  Note
  When a certificate enrollment fails due to weak cipher usage, you get a prompt to enable the weak cipher. You can choose to enable weak cipher when you need to use weak encryption.

- The additional column lists icons to perform the following tasks:
  - **Export Certificate**—Click to export and download a copy of the certificate. You can choose to export the PKCS12 (Complete Certificate Chain) or the PEM (Identity Certificate Only) format.

    You must provide a pass phrase to export a PKCS12 certificate format to import the file later.
  - **Re-enroll certificate**—Re-enroll an existing certificate.
  - **Refresh certificate status**—Refresh a certificate to synchronize the device certificate status to the Cloud-Delivered Firewall Management Center.
  - **Delete certificate**—Delete all the associated certificates for a trustpoint.

Step 2 Choose **(+) Add** to associate and install an enrollment object on a device.

When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed and SCEP enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.

Note
The certificate enrollment on a device does not block the user interface and the enrollment process gets executed in the background, enabling the user to perform certificate enrollment on other devices in parallel.

The progress of these parallel operations can be monitored on the same user interface. The respective icons display the certificate enrollment status.

Automatically update CA bundles

You can set the management center to automatically update the CA certificates through CLI commands. By default, the CA certificates are automatically updated when you install or upgrade to version 7.0.5.

Note In an IPv6-only deployment, the automatic update of CA certificates may fail, because, some of the Cisco servers do not support IPv6. In such cases, force update the CA certificates using the **configure cert-update run-now force** command.

Procedure

Step 1 Log into the FMC CLI using SSH, or, if virtual, open the VM console.

Step 2 You can verify whether the CA certificates in the local system are the latest or not:

configure cert-update test

This command compares the CA bundle on the local system with the latest CA bundle (from the Cisco server). If the CA bundle is up to date, no connection check is executed and the test result is displayed as the one below:

Example:

```
> configure cert-update test
Test succeeded, certs can safely be updated or are already up to date.
```

If the CA bundle is out of date, the connection check is executed on the downloaded CA bundle and the test result is displayed.

Example:

When the connection check fails:

```
> configure cert-update test
Test failed, not able to fully connect.
```

Example:

When the connection check succeeds, or the CA bundle is already up to date:

```
> configure cert-update test
Test succeeded, certs can safely be updated or are already up to date.
```

Step 3 (Optional) To instantly update the CA bundles:

configure cert-update run-now

Example:

```
>configure cert-update run-now
Certs have been replaced or was already up to date.
```

When you execute this command, the CA certificates (from the Cisco server) are verified for SSL connectivity. If the SSL connectivity check fails for even one of the Cisco servers, the process is terminated.

Example:

```
> configure cert-update run-now
Certs failed some connection checks.
```

To proceed with the update despite connection failures, use the **force** keyword.

Example:

```
> configure cert-update run-now force
Certs failed some connection checks, but replace has been forced.
```

Step 4 If you do not want the CA bundles to be automatically updated, disable the configuration:

configure cert-update auto-update disable

Example:

```
> configure cert-update auto-update disable
Autoupdate is disabled
```

Step 5 To re-enable the automatic update of CA bundles:

configure cert-update auto-update enable

Example:

```
> configure cert-update auto-update enable
Autoupdate is enabled and set for every day at 12:18 UTC
```

When you enable the automatic update on the CA certificates, the update process is executed daily at a system-defined time.

Step 6 (Optional) View the status of automatic update of CA certificates:

show cert-update

Example:

```
> show cert-update
```

```
Autoupdate is enabled and set for every day at 09:34 UTC
CA bundle was last modified 'Thu Sep 15 16:12:35 2022'
```

Install a certificate using self-signed enrollment

Install a self-signed certificate to establish secure VPN connections by creating an identity certificate directly on the managed device.

Procedure

Step 1 On the **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type Self-Signed from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2999.

Step 4 Press **Add** to start the Self Signed, automatic, enrollment process.

For self signed enrollment type trustpoints, the **CA Certificate** status will always be displayed, since the managed device is acting as its own CA and does not need a CA certificate to generate its own Identity Certificate.

The **Identity Certificate** will go from InProgress to Available as the device creates its own self signed identity certificate.

Step 5 Click the magnifying glass to view the self-signed Identity Certificate created for this device.

What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method.

Install a certificate using EST enrollment

Use EST enrollment to automatically obtain and install identity certificates on devices from a Certificate Authority (CA).

Before you begin

Note Using EST enrollment establishes a direct connection between the managed device and the CA server. So be sure your device is connected to the CA server before beginning the enrollment process.

Note EST's ability to auto-enroll a device when its certificate expires is not supported.

Follow these steps to install a certificate using EST enrollment:

Procedure

Step 1 On the **Devices** > **Certificates** screen, click **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose the EST certificate enrollment object from the **Cert Enrollment** drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2999.

Step 4 Click **Add** to enroll the certificate on the device.

The **Identity Certificate** will go from `InProgress` to `Available` as the device obtains its identity certificate using EST from the specified CA. Sometimes, a manual refresh might be required to obtain the identity certificate.

Step 5 Click the magnifying glass to view the Identity Certificate created and installed on this device.

Install a certificate using SCEP enrollment

Install a certificate using SCEP enrollment to enable secure authentication for VPN connections and other security features on your device.

Before you begin

Note Using SCEP enrollment establishes a direct connection between the managed device and the CA server. So be sure your device is connected to the CA server before beginning the enrollment process.

Follow these steps to install a certificate using SCEP enrollment:

Procedure

Step 1 On the **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type SCEP from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2999.

Step 4 Press **Add**, to start the automatic enrollment process.

For SCEP enrollment type trustpoints, the **CA Certificate** status will transition from InProgress to Available as the CA Certificate is obtained from the CA server and installed on the device.

The **Identity Certificate** will go from `InProgress` to `Available` as the device obtains its identity certificate using SCEP from the specified CA. Sometimes, a manual refresh might be required to obtain the identity certificate.

Step 5 Click the magnifying glass to view the Identity Certificate created and installed on this device.

What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method.

Install a certificate using manual enrollment

Manual enrollment allows you to obtain and install an identity certificate on a managed device by generating a certificate signing request (CSR) and working with your PKI CA server to obtain the corresponding identity certificate.

Procedure

Step 1 On the **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a device from the **Device** drop-down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type Manual from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2999.

Step 4 Press **Add** to start the enrollment process.

Step 5 Execute the appropriate activity with your PKI CA Server to obtain an identity certificate.

a) Click **Identity Certificate** warning to view and copy the CSR.
b) Execute the appropriate activity with your PKI CA Server to obtain an identity certificate using this CSR.

   This activity is completely independent of the Cloud-Delivered Firewall Management Center or the managed device. When complete, you will have an Identity Certificate for the managed device. You can place it in a file.

c) To finish the manual process, install the obtained identity certificate onto the managed device.

   Return to the Cloud-Delivered Firewall Management Center dialog and select **Browse Identity Certificate** to choose the identity certificate file.

   Note
   Ensure not to choose a binary certificate (PKCS12, DER, and alike) file because Firewall Threat Defense does not support them.

Step 6 Select **Import** to import the Identity Certificate.

The Identity Certificate status will be `Available` when the import complete.

Step 7 Click the magnifying glass to view the **Identity Certificate** for this device.

What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method.

Install a certificate using a PKCS12 file

Install a certificate using a PKCS12 file to enable secure authentication and encrypted communications on managed devices.

Procedure

Step 1 Go to **Devices** > **Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

Step 2 Choose a pre-configured managed device from the **Device** drop down list.

Step 3 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the PKCS type from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2999.

Step 4 Press **Add**.

The CA Certificate and Identity Certificate status will go from `In Progress` to `Available` as it installs the PKCS12 file on the device.

Note

When you upload the PKCS12 file for the first time, the file is stored in Cloud-Delivered Firewall Management Center as part of the CertEnrollment object. For any failed enrollments due to a wrong passphrase or failed deployment, retry enrolling the PKCS12 certificate without uploading the file again. Also, whenever you modify the certificate enrollment object to permit overrides, you must update the **Passphrase** for the certificate for a sucessful enrollment. A PKCS12 file size should not be larger than 24K.

Step 5 Once `Available`, click the magnifying glass to view the Identity Certificate for this device.

What to do next

The certificate (trustpoint) on the managed device is named the same as the PKCS#12 file. Use this certificate in your VPN authentication configuration.

Install a certificate using ACME enrollment

Install certificates automatically using the ACME (Automatic Certificate Management Environment) protocol to eliminate manual certificate installation and renewal processes.

Procedure

Step 1 Choose **Devices** > **Certificates**.

Step 2 Click **Add** to open the **Add New Certificate** dialog.

Step 3 Choose a device from the **Device** drop-down list.

Step 4 Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type ACME from the drop-down list.
- Click **(+)**, to add a new Certificate Enrollment Object, see Add certificate enrollment objects, on page 2999.

Step 5 Click **Add**, to start the automatic enrollment process.

For ACME enrollment type trustpoints, the status shows `InProgress` until the enrollment is successful. CA is not applicable for ACME.

Step 6 Click the magnifying glass to view the Identity Certificate created and installed on this device.

What to do next

When enrollment is complete, a trustpoint is configured on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your remote access VPN authentication.

Troubleshoot Threat Defense certificates

See Secure Firewall Threat Defense VPN certificate guidelines and limitations, on page 3079 to determine if variations in your certificate enrollment environment may be causing a problem.

Certificate expiration monitoring CA server connectivity

Ensure there is a route to the CA Server from the device. If the CA Server's host name is given in the Enrollment Object, use Flex Config to configure DNS appropriately to reach the server. Alternatively, use the IP Address of the CA Server.

Microsoft 2012 CA server template configuration

If you are using a Microsoft 2012 CA Server, the default IPsec Template is not accepted by the managed device and must be changed.

To configure a working template, follow these steps as you use MS CA documentation as a reference.

1. Duplicate the IPsec (Offline Request) template.
2. In **Extensions** > **Application policies**, select *IP security end system*, instead of the *IP security IKE intermediate*.
3. Set the permissions and the template name.
4. Add the new template and change the registry settings to reflect the new template name.

Default keyring certificate regeneration

On the Cloud-Delivered Firewall Management Center, you might receive this health alert related to the Firewall Threat Defense device:

```
Code - F0853; Description - default Keyring's certificate is invalid, reason: expired
```

Solution: In such cases, use the following command to regenerate the default certificate in CLISH CLI:

```
> system support regenerate-security-keyring default
```

CA certificate configuration errors

A red cross appears in the CA certificate status with this error:

Error: `Fail to configure CA certificate`

Solution: See Troubleshoot Certificate Error on FMC.

Certificate verification in .pfx files

To check the list of the certificates in a .pfx file, use tools such as `certutil` or `openssl`. You can see the whole chain with ID certificate, SubCA certificate, and CA certificate (if any).

- `certutil -dump cert.pfx`
- `openssl pkcs12 -info -in cert.pfx`

Identity certificate import errors

Error: `Identity certificate import required`

Solution: See Troubleshoot Certificate Error "Identity certificate import required" on FMC.

Self-signed certificates hostname behavior in Threat Defense high-availability environments

In a Threat Defense HA configuration, the secondary unit adopts the primary unit's hostname. When you break the HA pair, you must perform these actions:

- Manually update the hostname on the secondary unit to its unique identifier
- Perform a certificate re-enrollment to ensure that the certificate accurately reflects the unit's identity.

Security Cloud Control Firewall Management Platform Maintenance Schedule

Security Cloud Control Firewall Management updates its platform every week with new features and quality improvements. Updates are made during a 3-hour period according to this schedule:

Day of the week	Time of day (24-hour time, UTC)
Thursday	09:00 UTC - 12:00 UTC

During the Security Cloud Control Firewall Management upgrade period, you can still access your organization and the Cloud-Delivered Firewall Management Center. Additionally, the devices that you have onboarded to Security Cloud Control Firewall Management continue to enforce their security policies.

Note

- During the maintenance period of the Security Cloud Control Firewall Management, refrain from creating or deploying configurations to the devices it manages.
- If there is any issue that stops Security Cloud Control Firewall Management from communicating, Cisco addresses that issue in all the affected tenants as quickly as possible, even if it is outside the maintenance window.

Navigate from Security Cloud Control to Cloud-Delivered Firewall Management Center

1. In the Security Cloud Control dashboard, click **Administration** > **Integrations** > **Firewall Management Center**.
2. With Cloud-Delivered Firewall Management Center selected, click **Devices** in the Management pane.

What does the default action "Analyze all tunnel traffic" for prefiltering mean?

“Analyze all tunnel traffic” means subject all network traffic to the rules in the access control policy after they have been analyzed by the prefilter policy.

How Security Cloud Control processes personal information

To learn how Security Cloud Control processes your personal identifiable information, see the Security Cloud Control Privacy Data Sheet.

Can I restore a backup from a different device?

Yes, if the devices are the same model, are running the same software version, have the same number of network modules, and the same number of physical interfaces.

Does deploying a new prefilter policy immediately affect ongoing sessions?

No. When you deploy a prefilter policy, its rules are not applied on the existing tunnel sessions. Hence, traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count.

How do I keep my security databases and feeds up to date?

If the management center has internet access, the system can often obtain updates on security databases and feeds directly from Cisco. We recommend you schedule or enable automatic content updates whenever possible. Some updates are auto-enabled by the initial setup process or when you enable the related feature. Other updates you must schedule yourself. After initial setup, we recommend you review all auto-updates and adjust them if necessary.

- There are several security databases and feeds you should update:
- Vulnerability database (VDB)
- Geolocation database (GeoDB)
- Intrusion rules (SRU/LSP)
- Security Intelligence Feeds
- URL categories and reputations

What version of Secure Firewall Threat Defense can I manage with Cloud-Delivered Firewall Management Center?

Cloud-Delivered Firewall Management Center supports these versions of Secure Firewall Threat Defense:

- Verion 7.0.3 or later 7.0.x versions.
- Version 7.2 and later versions.

Note Software Version 7.1 is _not_ supported.

All hardware and virtual deployments which can run these software versions are supported.

How do I exclude specific traffic (Webex, Zoom, etc) from the remote access VPN?

You can exclude specific traffic from the remote access VPN using dynamic split tunneling based on DNS domain names.

Excluded domains are not blocked. Instead, traffic to those domains is kept outside the VPN tunnel. For example, you could send traffic to Cisco WebEx on the public Internet, thus freeing bandwidth in your VPN tunnel for traffic that is targeted to servers within your protected network.

Procedure

Step 1 From the Security Cloud Control home page, in the navigation bar, click **Security Devices**.

Step 2 Find the Secure Firewall Threat Defense device you want to add this rule to. You can use the filter or search field to find the device.

Step 3 Select the device, and in the Device Management pane at the right, click **Device Overview**.

Step 4 Configure the group policy to use Dynamic Split Tunnel.

a) Choose **Devices** > **Remote Access**.
b) Click **Edit** on the remote access VPN policy for which you want to configure dynamic split tunneling.
c) Click **Edit** on the required connection profile.
d) Click **Edit Group Policy**.

Step 5 Configure the Secure Client custom attribute in the Add/Edit Group Policy dialog box.

a) Click the Secure Client tab.
b) Click **Custom Attributes** and click +.
c) Choose **Dynamic Split Tunneling** from the Secure Client Attribute drop-down list.
d) Click + to create a new custom attribute object.
e) Enter the name for the custom attribute object.
f) Exclude domains—Specify domain names that will be excluded from the remote access VPN.
g) Click **Save**.
h) Click **Add**.

Step 6 Verify the configured custom attribute and click **Save**.

Step 7 When you are ready to deploy this change to the device, click **Deploy** in the menu bar at the top of the page.

How do I prevent users from accessing undesirable external network resources, such as inappropriate websites?

Procedure

Step 1 From the Security Cloud Control home page, click **Security Devices** in the navigation bar.

Step 2 Find the Secure Firewall Threat Defense device you want to add these rules to. You can use the filter or search field to find the device.

Step 3 Select the device and in the Policies pane at the right, click **Access Control**.

Step 4 Click the policy you want to update.

Step 5 Click **Add Rule**.

Step 6 Give the rule a name.

Step 7 In the **Action** field, select **Block**.

Step 8 Insert the rule into either the Mandatory or into the Default policy.

Step 9 Click the **URLs** tab.

Step 10 In the Categories section, check the categories you want to block and accept the default value for "Any Reputation".

Step 11 Click **Add URL**.

Step 12 If there are specific URLs that you want to block, you can do that by entering them in the **Manually Enter URL** field and then click **Add URL**.

Step 13 Click **Apply**.

Step 14 On the policy page, click **Save**.

Step 15 When you are ready to deploy this change to the device, click **Deploy** in the menu bar at the top of the page.

Note
Note: This instruction assumes you have the URL filtering license

Security Feed Questions

Related Information

How do I update intrusion rules (SRU/LSP)?

Follow this procedure to configure recurring Intrusion Rule update downloads.

Procedure

Step 1 From the Cloud-Delivered Firewall Management Center home page, navigate **System (gear icon) > Updates > Rule Updates**.

Step 2 Under **Recurring Rule Update Imports**, check **Enable Recurring Rule Update Imports**.

Step 3 Specify the **Import Frequency** and start time.

Note
As updates are published multiple times each week, it is recommended to check on a Daily basis.

Step 4 (Optional, but recommended) Check **Reapply all policies...** to deploy after each update.

Caution
Deploying intrusion rule updates can cause a Snort restart in rare occasions. It is recommended to deploy intrusion rule updates during a maintenance window.

Step 5 Click **Save**.

Step 6 Deploy your changes when you are ready.

Caution
Deploying intrusion rule updates can cause a Snort restart. We recommend you deploy intrusion rule updates during a maintenance window.

How do I update my Cisco vulnerability database (VDB)?

The initial setup on the management center automatically downloads and installs the latest VDB from Cisco as a one-time operation. It also schedules a weekly task to download the latest available software updates, which includes the latest VDB. We recommend you review this weekly task and adjust if necessary, by navigating in the Cloud-Delivered Firewall Management Center to **System gear icon** > **Tools** > **Scheduling**.

You can choose to update the VDB either manually or automate the download and updates by creating scheduled tasks in the system. We recommend that you choose the automated method, to ensure timely downloads and updates.

Before you begin

.

You must be in the global domain to perform this task.

Procedure

Step 1 To manually update the VDB, see Manually Update the VDB and follow the steps in the procedure.

Step 2 To automate VDB updates, see Vulnerability Database Update Automation. Ensure you create tasks for both download of VDB versions and installation.

How do I update my Geolocation database?

As a part of initial configuration, the system configures a weekly automatic Geolocation (GeoDB) update. If configuring the update fails, we recommend you configure regular GeoDB updates as described in this procedure.

Procedure

Step 1 From the Cloud-Delivered Firewall Management Center home page, **System (gear icon) > Updates > Updates > Geolocation Updates**.

Step 2 Under **Recurring Geolocation Updates**, check **Enable Recurring Weekly Updates from the Support Site**.

Step 3 Specify the **Update Start Time**.

Step 4 Click **Save**.

How do I update Security Intelligence feeds?

By default, the built-in feeds on Cloud-Delivered Firewall Management Center are updated every two hours, with updates being pushed immediately to managed devices.

To change the update configuration, perform the following steps:

Procedure

Step 1 From the Cloud-Delivered Firewall Management Center home page, navigate **Objects > Object Management**.

Step 2 Expand the Security Intelligence node, then choose the feed type whose frequency you want to change.

Step 3 Next to the feed you want to update, click the pencil icon to **Edit** the update frequency.

Note
The system-provided URL feed is combined with the domain feed under DNS Lists and Feeds.

Step 4 Edit the **Update Frequency**.

Step 5 Click **Save**.

How do I update URL reputations?

If you Enable Automatic Updates, by default, automatic URL updates are enabled. The management center checks Talos updates every 30 minutes. If you need strict control over when the system contacts external

resources, disable automatic updates and instead create a recurring task using the scheduler. Although daily updates tend to be small, if it has been more than five days since your last update, new URL filtering data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

Procedure

Step 1 From the Cloud-Delivered Firewall Management Center home page, navigate **Integration > Other Integrations**.

Step 2 Click **Cloud Services**.

Step 3 In the URL Filtering pane:

a) Enable URL filtering.

b) Enable automatic updates.

Step 4 Click **Save**.

How do I setup Rate-Based Attack Prevention on the FTD using Snort 2?

Dynamic rule states are policy-specific.

A **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

Note Dynamic rule states cannot enable disabled rules or drop traffic that matches disabled rules.

Procedure:

Procedure

Step 1 On the Security Cloud Control menu bar, click **Administration** > **Integrations** > **Firewall Management Center** to view the Services page.

Step 2 Choose Cloud-Delivered FMC and click the links in the Actions, Management, or System pane to navigate to Cloud-Delivered Firewall Management Center to perform various actions. See View Services Page Information.

Step 3 Choose **Policies > Access Control > Intrusion**.

Step 4 Click Snort 2 Version next to the policy you want to edit.

If View (View button) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 5 Click **Rules** immediately under **Policy Information** in the navigation pane.

Step 6 Choose the rule or rules where you want to add a dynamic rule state.

Step 7 Choose **Dynamic State > Add Rate-Based Rule State**.

Step 8 Choose a value from the Track By drop-down list.

Step 9 If you set Track By to Source or Destination, enter the address of each host you want to track in the Network field. You can specify a single IP address, address block, variable, or a comma-separated list comprised of any combination of these.

Step 10 Next to Rate, specify the number of rule matches per time period to set the attack rate:

Step 11 From the New State drop-down list, specify the new action to be taken when the conditions are met.

Step 12 Enter a value in the Timeout field.

After the timeout occurs, the rule reverts to its original state. Specify 0 or leave the Timeout field blank to prevent the new action from timing out.

Step 13 Click OK.

Note
The system displays a Dynamic State next to the rule in the Dynamic State column. If you add multiple dynamic rule state filters to a rule, a number over the filter indicates the number of filters.

Note
To delete all dynamic rule settings for a set of rules, choose the rules on the Rules page, then choose Dynamic State > Remove Rate-Based States. You can also delete individual rate-based rule state filters from the rule details for the rule by choosing the rule, clicking Show details, then clicking Delete by the rate-based filter you want to remove.

Step 14 To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

Complete the initial configuration of a Secure Firewall Threat Defense device using the CLI

Connect to the device's CLI to perform initial setup, including setting the management IP address, gateway, and other basic networking settings using the setup wizard. Ensure all DNS and firewall ports are accessible for communication.

The dedicated management interface is a special interface with its own network settings. If you do not want to use the management interface, you can use the CLI to configure a data interface instead.

This configuration is ideal for devices that are going to be onboarded with their CLI registration key.

Note Do **not** use this configuration procedure for devices that are onboarding with zero-touch provisioning.

Procedure

Step 1 Connect to the device's CLI, either from the console port or using SSH to the management interface. If you intend to change the network settings, we recommend using the console port so you do not get disconnected.

(Firepower and Secure Firewall hardware models) The console port connects to the FXOS CLI. The SSH session connects directly to the Firewall Threat Defense CLI.

Step 2 Log in with the username **admin** and the password **Admin123** .

At the console port, you connect to the FXOS CLI. The first time you log in to FXOS, you are prompted to change the password. This password is also used for the Firewall Threat Defense login for SSH.

Note
If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default.

For Firepower and Secure Firewall hardware, see the Reimage Procedures in the Cisco FXOS Troubleshooting Guide for the Firewall Threat Defense .

For the ISA 3000, see the Cisco Secure Firewall ASA and Threat Defense Reimage Guide .

Example:

```
firepower login:
                          admin
Password:
                          Admin123
Successful login attempts for user 'admin' : 1
[...]
Hello admin. You must change your password.
Enter new password:
                          ********
Confirm new password:
                          ********
Your password was updated successfully.
[...]
firepower#
```

Step 3 If you connected to FXOS on the console port, connect to the Firewall Threat Defense CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 4 The first time you log in to the device, you are prompted to accept the End User License Agreement (EULA) and, if using an SSH connection, to change the admin password. You are then presented with the CLI setup script.

Note
You cannot repeat the CLI setup wizard unless you clear the configuration; for example, by reimaging. However, all of these settings can be changed later at the CLI using **configure network** commands. See the threat defense command reference.

Defaults or previously entered values appear in brackets. To accept previously entered values, press **Enter**.

Note
The management interface settings are used even when you enable Firewall Threat Defense access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the management interface DNS servers, and not the data interface DNS servers.

See the following guidelines:

- **Configure IPv4 via DHCP or manually?**—If you want to use a data interface for Firewall Threat Defense access instead of the management interface, choose **manual**. Although you do not plan to use the management interface, you must set an IP address, for example, a private address. You cannot configure a data interface for management if the management interface is set to DHCP, because the default route, which must be **data-interfaces** (see the next bullet), might be overwritten with one received from the DHCP server.
- **Enter the IPv4 default gateway for the management interface**—If you want to use a data interface for Firewall Threat Defense access instead of the management interface, set the gateway to be **data-interfaces**. This setting forwards management traffic over the backplane so it can be routed through the FMC access data interface.
- **If your networking information has changed, you will need to reconnect**—If you are connected with SSH but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected.
- **Manage the device locally?**—Enter **YES** to configure the device for the device to be managed by either the Cloud-Delivered Firewall Management Center or Secure Firewall Device Manager.

  Manage the device locally?—Enter **NO** to configure the device for remote management with the on-premises Firewall Management Center.
- **Configure firewall mode?**—We recommend that you set the firewall mode at initial configuration. Changing the firewall mode after initial setup erases your running configuration. Note that data interface Firewall Threat Defense access is only supported in routed firewall mode.

Step 5 (Optional) Configure a data interface for Cloud-Delivered Firewall Management Center access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

Note
You should use the console port when using this command. If you use SSH to the Management interface, you might get disconnected and have to reconnect to the console port. See below for more information about SSH usage.

See the following details for using this command. See About Data Interfaces, on page 3105 for more informatio.

- The original management interface cannot use DHCP if you want to use a data interface for management. If you did not set the IP address manually during initial setup, you can set it now using the **configure network** {**ipv4** | **ipv6**} **manual** command. If you did not already set the management interface gateway to **data-interfaces**, this command will set it now.
- When you onboard the device for Firewall Threat Defense management through Security Cloud Control, Security Cloud Control discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For more information about the DNS server configuration, see below. You can later make changes to the

access interface configuration, but make sure you don't make changes that can prevent the device or Security Cloud Control from re-establishing the management connection. If the management connection is disrupted, the device includes the **configure policy rollback** command to restore the previous deployment.

- This command sets the *data* interface DNS server. The Management DNS server that you set with the setup script (or using the **configure network dns servers** command) is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface.

  Also, local DNS servers are only retained if the DNS servers were discovered at initial registration. For example, if you registered the device using the Management interface, but then later configure a data interface using the **configure network management-data-interface** command, then you must manually configure all of these settings in Security Cloud Control, including the DNS servers, to match the device configuration.
- You can change the management interface after you onboard the Firewall Threat Defense for Firewall Threat Defense management through threat defense, to either the management interface or another data interface.
- The FQDN that you set in the setup wizard will be used for this interface.
- You can clear the entire device configuration as part of the command; you might use this option in a recovery scenario, but we do not suggest you use it for initial setup or normal operation.
- To disable data managemement, enter the **configure network management-data-interface disable** command.

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]:
IP address (manual / dhcp) [dhcp]:
DDNS server update URL [none]:
https://jcrichton:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:
```

```
Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Step 6 (Optional) Limit data interface access to Security Cloud Control on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

About Data Interfaces

You can use either the dedicated management interface or a regular data interface for communication with the device. Security Cloud Control access on a data interface is useful if you want to manage the FTD remotely from the outside interface, or you do not have a separate management network. Security Cloud Control supports high availability on the FTD managed remotely from the data interface.

FTD management access from a data interface has the following limitations:

- You can only enable manager access on one physical, data interface. You cannot use a subinterface or EtherChannel.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the FTD and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using Security Cloud Control. Because the management interface gateway will be changed to be the data interfaces, you also cannot SSH to the management interface from a remote network unless you add a static route for the management interface using the **configure network static-routes** command. For FTDv on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface.

End-of-Support for management of Secure Firewall Threat Defense devices, Version 7.0.*x*, managed by Cloud-Delivered Firewall Management Center

Which version of Secure Firewall Threat Defense devices has Cloud-Delivered Firewall Management Center stopped managing as of December 15, 2025?

Cloud-Delivered Firewall Management Center stopped managing Secure Firewall Threat Defense devices, Version 7.0.*x*, as of December 15, 2025.

Why is this necessary?

This was necessary to ensure compatibility and security for our customers' systems. As we upgrade our systems, it was essential that only the latest version of Secure Firewall Threat Defense devices were supported to maintain reliability and performance.

Can I onboard Version 7.0.*x* devices after December 15, 2025?

No, you can no longer onboard Secure Firewall Threat Defense, Version 7.0.*x*, devices after December 15, 2025.

After December 15, 2025, will I be able to use my existing Secure Firewall Threat Defense 7.0.*x* devices?

Cloud-Delivered Firewall Management Center will not support the management of Secure Firewall Threat Defense devices running Version 7.0.*x* after December 15, 2025. You will not be able to make or deploy changes to Secure Firewall Threat Defense devices running Version 7.0.*x* and earlier except to upgrade or unregister.

Note Secure Firewall Threat Defense devices running Version 7.0.*x* will still be visible in Cloud-Delivered Firewall Management Center, but in read-only mode only. Changes you make after December 15, 2025 will not be deployed to the devices.

What are the recommended upgrade options?

You are required to upgrade to at least Version 7.2.*x*. The Cisco-suggested version is 7.6.2.

How do I upgrade?

For information about upgrading Secure Firewall Threat Defense devices, refer to Threat defense upgrade guide for Cloud-Delivered Firewall Management Center.

Are there costs associated with upgrade?

There is no addtional cost, unless your hardware must also be upgraded. (The reference to hardware is limited to Cisco Secure ASA 5508-X and Cisco Secure ASA 5516-X running Secure Firewall Threat Defense Version 7.0.*x*). If you must refresh your hardware, reach out to your Cisco account team.

What will happen if I don't upgrade?

From December 15, 2025, you will not be able to make or deploy changes to Secure Firewall Threat Defense devices running Version 7.0.*x* and earlier, except to upgrade or unregister. Failing to upgrade leaves you vulnerable to compatibility issues, security issues, and possible downtime. To minimize disruption, you are required to upgrade now.

Will there be any impact to my existing systems or applications?

Upgrading is unlikely to have any significant impact on your current deployment. If you face any issues during the upgrade process, contact the Cisco Technical Assistance Center (TAC).

For assistance in upgrading, Cisco offers the LevelUp program. You can request assistance using this link.

Can I migrate my existing ASA 5508 and 5516 devices to Cloud-Delivered Firewall Management Center?

We recommend that you do *not* migrate your existing ASA 5508 and ASA 5516 devices to Cloud-Delivered Firewall Management Center because the last supported Secure Firewall Threat Defense version for these ASA devices is 7.0.

In addition, Cisco has stopped support for management of Secure Firewall Threat Defense Version 7.0.x in Cloud-Delivered Firewall Management Center as of December 31, 2025, and the ASA 5508 and 5516 devices cannot be upgraded to Version 7.2.x and later.

Can I manage my device's health in read-only mode after support ends?

After December 15, 2025, you will not be able to deploy device health policy changes, if any, to Secure Firewall Threat Defense devices running Version 7.0.x and earlier. These devices will continue to operate with the previously configured health policies.

When will Cloud-Delivered Firewall Management Center end support for management of Version 7.2.*x*?

Cloud-Delivered Firewall Management Center will support the management of Secure Firewall Threat Defense devices running Version 7.2.*x* until October 31, 2026.

What if I'm unsure about how to proceed?

Reach out to Cisco Technical Assistance Center (TAC) (or the Cisco account team) for clarifications.

CHAPTER 106

Cloud-Delivered Firewall Management Center command line reference

This reference explains the command line interface (CLI) for the Cloud-Delivered Firewall Management Center.

Note For Secure Firewall Threat Defense, see the *Cisco Secure Firewall Threat Defense Command Reference*.

- About the Cloud-Delivered Firewall Management Center CLI, on page 3109
- Cloud-Delivered Firewall Management Center CLI management commands , on page 3110
- Cloud-Delivered Firewall Management Center CLI show commands, on page 3111
- Cloud-Delivered Firewall Management Center CLI configuration commands, on page 3112
- Cloud-Delivered Firewall Management Center CLI system commands, on page 3112

About the Cloud-Delivered Firewall Management Center CLI

The Cloud-Delivered Firewall Management Center CLI provides access to view and troubleshoot your Cloud-Delivered Firewall Management Center.

When you use SSH to log into the Cloud-Delivered Firewall Management Center, you access the CLI. You can then access the Linux shell using the **expert** command, but this is strongly discouraged.

Caution We strongly recommend that you do not access the Linux shell unless directed by Cisco TAC or explicit instructions in the Secure Firewall user documentation.

Caution Users with Linux shell access can obtain root privileges, which can present a security risk. For system security reasons, we strongly recommend:

- If you establish external authentication, make sure that you restrict the list of users with Linux shell access appropriately.
- Do not establish Linux shell users in addition to the pre-defined **admin** user.

You can use the commands described in this appendix to view and troubleshoot your Cloud-Delivered Firewall Management Center. You can also perform limited configuration operations.

Cloud-Delivered Firewall Management Center CLI modes

The CLI encompasses four modes. The default mode, CLI Management, includes commands for navigating within the CLI itself. The remaining modes contain commands addressing three different areas of Cloud-Delivered Firewall Management Center functionality; the commands within these modes begin with the mode name: `system`, `show`, or `configure`.

When you enter a mode, the CLI prompt changes to reflect the current mode. For example, to display version information about system components, you can enter the full command at the standard CLI prompt:

```
> show version
```

If you have previously entered **show** mode, you can enter the command without the **show** keyword at the show mode CLI prompt:

```
show> version
```

Cloud-Delivered Firewall Management Center CLI management commands

The CLI management commands provide the ability to interact with the CLI. These commands do not affect the operation of the device.

exit command

This command moves the CLI context up to the next highest CLI context level. Issuing this command from the default mode logs the user out of the current CLI session.

Syntax: `exit`

Example:

```
system> exit
>
```

expert command

This command invokes the Linux shell.

Syntax: `expert`

Example:

```
> expert
```

? (question mark) command

This command displays context-sensitive help for CLI commands and parameters. Use the question mark (`?`) command in these ways:

- To display help for the commands that are available within the current CLI context, enter a question mark (`?`) at the command prompt.
- To display a list of the available commands that start with a particular character set, enter the abbreviated command immediately followed by a question mark (`?`).
- To display help for a command's legal arguments, enter a question mark (`?`) in place of an argument at the command prompt.

Note The question mark (`?`) is not echoed back to the console.

Syntax:

```
?
abbreviated_command ?
command [arguments] ?
```

Example: `> ?`

Cloud-Delivered Firewall Management Center CLI show commands

Show commands provide information about the state of the appliance. These commands do not change the operational mode of the appliance and running them has minimal impact on system operation.

version command

Displays the product version and build, the UUID, and other information.

Syntax:

```
show version
```

Example:

```
> show version
-------------------[ fmc-austin ]--------------------
Model                     : Cisco Secure Firewall Management Center for VMware (66) Version
```

```
 7.6.0 (Build 1385)
UUID                        : a904b8b2-ca9a-11ee-a583-5e804c16b2fd
Rules update version        : 2024-05-13-001-vrt
LSP version                 : lsp-rel-20240513-1955
VDB version                 : 380
----------------------------------------------------
```

Cloud-Delivered Firewall Management Center CLI configuration commands

The configuration commands enable the user to configure and manage the system. These commands affect system operation.

password command

Allows the current CLI user to change their password.

Caution For system security reasons, we strongly recommend that you do not establish Linux shell users in addition to the pre-defined **admin** on any appliance.

After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

Syntax:

```
configure password
```

Example:

```
> configure password
Changing password for admin.
(current) UNIX password:
New UNIX password:
Retype new UNIX password:
passwd: password updated successfully
```

Cloud-Delivered Firewall Management Center CLI system commands

The system commands enable the user to manage system-wide files and access control settings.

Following sections describes the Cloud-Delivered Firewall Management Center CLI system commands:

generate-troubleshoot command

Generates troubleshooting data for analysis by Cisco.

Syntax:

```
system generate-troubleshoot option1 optionN
```

Where options are one or more of the following, space-separated:

- `SYS`: System Configuration, Policy, and Logs
- `PER`: Hardware Performance and Logs
- `NET`: Interface and Network Related Data
- `UPG`: Upgrade Data and Logs
- `SNT`: Snort Performance and Configuration
- `DES`: Detection Configuration, Policy, and Logs
- `VDB`: Discover, Awareness, VDB Data, and Logs
- `DBO`: All Database Data
- `LOG`: All Log Data
- `NMP`: Network Map Information
- `ALL`: Run all of the following options.

Example:

```
> system generate-troubleshoot VDB NMP
starting /usr/local/sf/bin/sf_troubleshoot.pl…
Please, be patient. This may take several minutes.
The troubleshoot options codes specified are VDB,NMP.
Getting filenames from [usr/local/sf/etc/db_updates/index]
Getting filenames from [usr/local/sf/etc/db_updates/base-6.2.3]
Troubleshooting information successfully created at
/var/common/results-06-14-2018—222027.tar.gz
```

lockdown command

Removes the `expert` command and access to the Linux shell on the device.

Caution This command is irreversible without a hotfix from Support. Use with care.

Syntax: `system lockdown`

Example:

```
> system lockdown
```

reboot command

Reboots the appliance.

Syntax: `system reboot`

Example:

```
> system reboot
```

restart command

Restarts the appliance application.

Syntax: `system restart`

Example:

```
> system restart
```

show max-logins command

Displays the maximum number of parallel logins for one user.

Syntax: `show max-logins`

Command default: The default value for the number of parallel/concurrent sessions for a single user is zero.

Example:

```
> show max-logins
```

configure max-logins command

Configures the maximum number of parallel logins for one user.

Syntax: `configure max-logins`

Example:

```
> configure max-logins [0-1024]
```

shutdown command

Shuts down the appliance.

Syntax: `system shutdown`

Example:

```
> system shutdown
```

CHAPTER 107

Communication Ports and Internet Access

- Communication ports for managed devices, on page 3115
- Internet access requirements for managed devices, on page 3116
- Internet resources accessed by your browser, on page 3118

Communication ports for managed devices

Managed devices use these ports to communicate. For deployments behind a network barrier—like an edge firewall—make sure you allow traffic on the required ports. Note that ports not required for essential or default operations remain closed until needed by a configuration or feature.

Inbound ports for managed devices

Managed devices accept inbound traffic on these ports.

Table 165: Inbound ports for managed devices

Inbound port	Protocol/Feature	Details
Required for specific configurations or features		
22/tcp	SSH	Secure remote connections to the appliance.
161/udp	SNMP	Allow access to MIBs via SNMP polling.
443/tcp	Remote access VPN (SSL)	Allow secure VPN connections to your network from remote users.
443/udp	Remote access VPN (DTLS)	Allow secure VPN connections to your network from remote users.
500/udp 4500/udp	Remote access VPN (IKEv2) and site-to-site VPN	Allow secure VPN connections to your network from remote users and remote VPN peers.
885/tcp	Captive portal	Communicate with a captive portal identity source.

Outbound ports for managed devices

Managed devices initiate outbound traffic on these ports. Managed devices also use ephemeral source ports for TCP and UDP traffic that they initiate. Make sure intervening network barriers allow response traffic for these connections.

Table 166: Outbound ports for managed devices

Outbound port	Protocol/Feature	Details
Required for initial setup		
53/tcp 53/udp	DNS	DNS
123/udp	NTP	Synchronize time.
443/tcp	HTTPS	Send and receive data from the internet; see Internet access requirements for managed devices, on page 3116 for a list of resources that the device needs to access. Also accepts connections on this port.
8305/tcp	Appliance communications	Securely communicate with the Cloud-Delivered Firewall Management Center.
Required for specific configurations or features		
67/udp 68/udp	DHCP	DHCP
162/udp	SNMP	Send SNMP alerts to a remote trap server.
1812/udp 1813/udp	RADIUS	Communicate with a RADIUS server for external authentication and accounting. Configurable.
389/tcp 636/tcp	LDAP	Communicate with an LDAP server for external authentication. Configurable.
514/udp	Syslog (audit logging)	Send audit logs to a remote syslog server, when TLS is not configured.
8514/udp	Secure Network Analytics Manager	Send syslog messages to Secure Network Analytics using Security Analytics and Logging (On Premises).
8989/tcp	Cisco Support Diagnostics	Port 8989/tcp is used only for local/on-box communication between Cisco Support Diagnostics and SSEConnector. Cisco Support Diagnostics cloud/CDX communication is proxied through SSEConnector and uses HTTPS/WSS on 443/tcp externally.

Internet access requirements for managed devices

Internet access to the listed resources supports essential operations and configured features in your deployment.

For deployments behind a network barrier—like an edge firewall—make sure you allow traffic on the required ports to the listed resources.

Internet resources accessed by managed devices

This table identifies the internet resources that managed devices access.

Table 167: Internet resources for managed devices

Feature	Reason	HA/Clustering	Port	Resource
Required for initial setup				
DNS	DNS	All units communicate with the DNS server.	53/tcp 53/udp	Default OpenDNS servers: 208.67.222.222 and 208.67.220.220 2620:119:35::35
NTP	Synchronize time. Not supported with a proxy server.	All units communicate with the NTP server.	123/udp	Default NTP servers: 0.sourcefire.pool.ntp.org 1.sourcefire.pool.ntp.org 2.sourcefire.pool.ntp.org 3.sourcefire.pool.ntp.org
Required for general operations				
CA certificate bundles	Managed devices query for new CA certificates daily at a system-defined time. The local CA bundle contains certificates for accessing several Cisco services.	Each unit downloads its own certificates.	443/tcp	cisco.com/security/pki
Cisco Support Diagnostics	Cisco Support Diagnostics receives authorized CSD/CDX troubleshooting requests and uploads generated troubleshooting files through SSEConnector. External Cisco cloud connectivity utilizes HTTPS/WSS on 443/tcp.	All units communicate.	443/tcp	api-sse.cisco.com
Required for specific configurations or features				
Malware Defense	Submit files for dynamic analysis.	All units submit files.	443/tcp	fmc.api.threatgrid.com fmc.api.threatgrid.eu

Feature	Reason	HA/Clustering	Port	Resource
Upgrades	Download upgrades directly to managed devices. Tests the connection once a week.	Upgrade packages do not sync. Each unit must get its own.	443/tcp	cdo-fdm-images3-us-west-2.amazonaws.com
Umbrella DNS	Direct DNS queries to Cisco Umbrella for validation and policy enforcement.	All units communicate.	443/tcp	api.opendns.com

Security Cloud Control regional IP addresses

To onboard and manage devices using zero-touch provisioning, allow inbound access on port 443 (or whichever port you configured for device management) from the Security Cloud Control IP addresses in your region.

Table 168: Security Cloud Control IP addresses by region

Security Cloud Control region	IP addresses
Asia-Pacific-Japan (APJ)	54.199.195.111 52.199.243.0
Australia (AUS)	13.55.73.159 13.238.226.118
Europe, the Middle East, or Africa (EMEA)	35.157.12.126 35.157.12.15
India (IN)	35.154.115.175 13.201.213.99
United States (US)	52.34.234.2 52.36.70.147

Internet resources accessed by your browser

When you use the Cloud-Delivered Firewall Management Center, your browser may contact Google (google.com) or Amplitude (amplitude.com) web analytics servers to send non-personally-identifiable usage data to Cisco. For browser compatibility information, refer to the *Cisco Secure Firewall Management Center Compatibility Guide*.
