CONTENTS

PART I **Getting Started with Device Configuration** 71

CHAPTER 1 **Device Management** 1

About Device Management 1

About the FMC and Device Management 1

What Can Be Managed by a Firepower Management Center? 2

About the Management Connection 2

Beyond Policies and Events 3

About Device Management Interfaces 3

Management and Event Interfaces on the FTD 3

Using the FTD Data Interface for Management 4

Management Interface Support Per Device Model 4

Network Routes on Device Management Interfaces 5

NAT Environments 6

Management and Event Traffic Channel Examples 8

Requirements and Prerequisites for Device Management 9

Log Into the Command-Line Interface on the Device 10

Complete the FTD Initial Configuration 11

Complete the FTD Initial Configuration Using the FDM 11

Complete the FTD Initial Configuration Using the CLI 17

Configure an Event Interface 23

Manage Devices 25

Add a Device Group 26

Register With the Management Center 26

Add a Device 27

Register With a New Management Center 29

Delete (Unregister) a Device from the FMC 30
Shut Down or Restart the Device 32
Switch Managers 32
Switch from the FDM to the FMC 33
Switch from FMC to FDM 37
Hot Swap an SSD on the Secure Firewall 3100 38
History for Device Management 41

CHAPTER 2 **Device Settings** 43
Edit General Settings 43
Copy a Configuration to Another Device 44
Export and Import the Device Configuration 45
Edit License Settings 49
View System Information 50
View the Inspection Engine 51
Edit Health Settings 51
Edit Management Settings 52
Update the Hostname or IP Address in the FMC 52
Change Both Management Center and Threat Defense IP Addresses 53
Change the Manager Access Interface from Management to Data 56
Change the Manager Access Interface from Data to Management 59
View Manager Access Details for Data Interface Management 61
Modify FTD Management Interfaces at the CLI 65
Modify the FTD Data Interface Used for Management at the CLI 71
Edit the FMC IP Address/Hostname on the Device 73
Roll Back the Configuration if the FMC Loses Connectivity 74
Troubleshoot Management Connectivity on a Data Interface 76
View Inventory Details 80
Edit Applied Policies 81
Edit Advanced Settings 83
Configure Automatic Application Bypass 84
Configure Object Group Search 84
Configure Interface Object Optimization 86
History for Device Settings 87

CHAPTER 3 Users 89

About Users 89
Internal and External Users 89
CLI Access 89
CLI User Roles 90
Requirements and Prerequisites for User Accounts for Devices 90
Guidelines and Limitations for User Accounts for Devices 91
Add an Internal User at the CLI 91
Configure External Authentication for the FTD 93
About External Authentication for the FTD 93
About LDAP 94
About RADIUS 94
Add an LDAP External Authentication Object for FTD 94
Add a RADIUS External Authentication Object for FTD 100
Enable External Authentication for Users on FTD Devices 105
Troubleshooting LDAP Authentication Connections 105
History for Users 107

CHAPTER 4 Configuration Deployment 109

About Configuration Deployment 109
Configuration Changes that Require Deployment 109
Deployment Preview 110
Selective Policy Deployment 111
System Username 113
Auto-Enabling of Application Detectors 113
Asset Rediscovery with Network Discovery Policy Changes 114
Snort Restart Scenarios 114
Restart Warnings for Devices 114
Inspect Traffic During Policy Apply 115
Snort Restart Traffic Behavior 116
Configurations that Restart the Snort Process When Deployed or Activated 118
Changes that Immediately Restart the Snort Process 119
Requirements and Prerequisites for Policy Management 119

Best Practices for Deploying Configuration Changes 120
Deploy the Configuration 121
Deploy Configuration Changes 121
Redeploy Existing Configurations to a Device 127
Manage Deployments 128
View Deployment Status 128
View Deployment History 129
Roll Back a Deployment 132
Perform a Rollback 134
View the Deployment Rollback Transcript 136
Compare Policies 136
Generate Current Policy Reports 138
History for Configuration Deployment 139

PART II **Device Operations** 141

CHAPTER 5 **Transparent or Routed Firewall Mode** 143
About the Firewall Mode 143
About Routed Firewall Mode 143
About Transparent Firewall Mode 144
Using the Transparent Firewall in Your Network 144
Passing Traffic For Routed-Mode Features 144
About Bridge Groups 145
Bridge Virtual Interface (BVI) 145
Bridge Groups in Transparent Firewall Mode 145
Bridge Groups in Routed Firewall Mode 146
Allowing Layer 3 Traffic 147
Allowed MAC Addresses 147
BPDU Handling 147
MAC Address vs. Route Lookups 148
Unsupported Features for Bridge Groups in Transparent Mode 149
Unsupported Features for Bridge Groups in Routed Mode 150
Default Settings 151
Guidelines for Firewall Mode 151

Set the Firewall Mode 152

CHAPTER 6 **Logical Devices on the Firepower 4100/9300 153**

About Interfaces 153

Chassis Management Interface 153

Interface Types 154

FXOS Interfaces vs. Application Interfaces 156

Shared Interface Scalability 158

Shared Interface Best Practices 158

Shared Interface Usage Examples 160

Viewing Shared Interface Resources 166

Inline Set Link State Propagation for the FTD 167

About Logical Devices 167

Standalone and Clustered Logical Devices 168

Logical Device Application Instances: Container and Native 168

Container Instance Interfaces 168

How the Chassis Classifies Packets 169

Classification Examples 169

Cascading Container Instances 173

Typical Multi-Instance Deployment 174

Automatic MAC Addresses for Container Instance Interfaces 175

Container Instance Resource Management 176

Performance Scaling Factor for Multi-Instance Capability 176

Container Instances and High Availability 176

Container Instances and Clustering 176

Licenses for Container Instances 176

Requirements and Prerequisites for Logical Devices 177

Requirements and Prerequisites for Hardware and Software Combinations 177

Requirements and Prerequisites for Container Instances 179

Requirements and Prerequisites for High Availability 180

Requirements and Prerequisites for Clustering 181

Guidelines and Limitations for Logical Devices 184

Guidelines and Limitations for Interfaces 184

General Guidelines and Limitations 187

Configure Interfaces 188
Enable or Disable an Interface 188
Configure a Physical Interface 188
Add an EtherChannel (Port Channel) 189
Add a VLAN Subinterface for Container Instances 191
Configure Logical Devices 192
Add a Resource Profile for Container Instances 193
Add a Standalone FTD 194
Add a High Availability Pair 199
Change an Interface on a FTD Logical Device 200
Connect to the Console of the Application 202
History for Logical Devices 204

CHAPTER 7 **High Availability** 209
About Firepower Threat Defense High Availability 209
High Availability System Requirements 209
Hardware Requirements 210
Software Requirements 210
License Requirements for FTD Devices in a High Availability Pair 210
Failover and Stateful Failover Links 211
Failover Link 211
Stateful Failover Link 212
Avoiding Interrupted Failover and Data Links 213
MAC Addresses and IP Addresses in High Availability 214
Stateful Failover 215
Supported Features 215
Unsupported Features 217
Bridge Group Requirements for High Availability 217
Failover Health Monitoring 218
Unit Health Monitoring 218
Interface Monitoring 218
Failover Triggers and Detection Timing 220
About Active/Standby Failover 221
Primary/Secondary Roles and Active/Standby Status 221

Active Unit Determination at Startup 221
Failover Events 221
Requirements and Prerequisites for High Availability 222
Guidelines for High Availability 223
Add a High Availability Pair 225
Configure Optional High Availability Parameters 227
Configure Standby IP Addresses and Interface Monitoring 228
Edit High Availability Failover Criteria 228
Configure Virtual MAC Addresses 229
Manage High Availability 230
Switch the Active Peer in the FTD High Availability Pair 230
Refresh Node Status for a Single FTD High Availability Pair 230
Suspend and Resume High Availability 231
Replace a Unit in FTD High Availability Pair 232
Replace a Primary FTD HA Unit with no Backup 232
Replace a Secondary FTD HA Unit with no Backup 233
Break a High Availability Pair 233
Delete (Unregister) a High Availability Pair and Register to a New FMC 235
Monitoring High Availability 236
View Failover History 236
View Stateful Failover Statistics 236
History for High Availability 237

CHAPTER 8 **Clustering for the Secure Firewall 3100** 239
About Clustering for the Secure Firewall 3100 239
How the Cluster Fits into Your Network 239
Control and Data Node Roles 240
Cluster Interfaces 240
Cluster Control Link 240
Configuration Replication 240
Management Network 240
Licenses for Clustering 241
Requirements and Prerequisites for Clustering 241
Guidelines for Clustering 242

Configure Clustering 246
About Cluster Interfaces 246
Cluster Control Link 246
Spanned EtherChannels 248
Cable and Add Devices to the FMC 250
Create a Cluster 252
Configure Interfaces 258
Manage Cluster Nodes 261
Add a New Cluster Node 261
Break a Node 263
Break the Cluster 264
Disable Clustering 264
Rejoin the Cluster 265
Change the Control Node 266
Edit the Cluster Configuration 267
Reconcile Cluster Nodes 268
Delete (Unregister) the Cluster or Nodes and Register to a New FMC 269
Monitoring the Cluster 270
Examples for Clustering 272
Firewall on a Stick 273
Traffic Segregation 274
Reference for Clustering 274
FTD Features and Clustering 274
Unsupported Features with Clustering 274
Centralized Features for Clustering 275
Connection Settings and Clustering 276
FTP and Clustering 276
Multicast Routing in Individual Interface Mode 276
NAT and Clustering 276
Dynamic Routing 278
SIP Inspection and Clustering 278
SNMP and Clustering 279
Syslog and Clustering 279
Cisco TrustSec and Clustering 279

VPN and Clustering 279
Performance Scaling Factor 279
Control Node Election 280
High Availability Within the Cluster 280
Node Health Monitoring 280
Interface Monitoring 281
Status After Failure 281
Rejoining the Cluster 281
Data Path Connection State Replication 282
How the Cluster Manages Connections 282
Connection Roles 282
New Connection Ownership 284
Sample Data Flow for TCP 284
Sample Data Flow for ICMP and UDP 285
History for Clustering 286

CHAPTER 9 **Clustering for the Firepower 4100/9300** 287
About Clustering on the Firepower 4100/9300 Chassis 287
Bootstrap Configuration 288
Cluster Members 288
Cluster Control Link 288
Size the Cluster Control Link 289
Cluster Control Link Redundancy 289
Cluster Control Link Reliability for Inter-Chassis Clustering 290
Cluster Control Link Network 290
Management Network 290
Management Interface 290
Cluster Interfaces 290
Spanned EtherChannels 291
Connecting to a Redundant Switch System 291
Configuration Replication 292
Licenses for Clustering 292
Requirements and Prerequisites for Clustering 292
Clustering Guidelines and Limitations 296

Configure Clustering 299
FXOS: Add a FTD Cluster 299
Create a FTD Cluster 299
Add More Cluster Nodes 310
FMC: Add a Cluster 313
FMC: Configure Cluster, Data, and Diagnostic Interfaces 319
FXOS: Remove a Cluster Node 321
FMC: Manage Cluster Members 322
Add a New Cluster Member 322
Replace a Cluster Member 323
Deactivate a Member 324
Rejoin the Cluster 325
Delete (Unregister) a Data Node 326
Change the Control Unit 327
Reconcile Cluster Members 327
FMC: Monitoring the Cluster 327
Examples for Clustering 329
Firewall on a Stick 330
Traffic Segregation 331
Reference for Clustering 331
FTD Features and Clustering 331
Unsupported Features with Clustering 331
Centralized Features for Clustering 332
Connection Settings 333
Dynamic Routing and Clustering 333
FTP and Clustering 334
Multicast Routing and Clustering 334
NAT and Clustering 334
SIP Inspection and Clustering 335
SNMP and Clustering 335
Syslog and Clustering 336
TLS/SSL Connections and Clustering 336
Cisco TrustSec and Clustering 336
VPN and Clustering 336

Performance Scaling Factor 336
Control Unit Election 337
High Availability Within the Cluster 337
Chassis-Application Monitoring 337
Unit Health Monitoring 337
Interface Monitoring 338
Decorator Application Monitoring 338
Status After Failure 338
Rejoining the Cluster 339
Data Path Connection State Replication 339
How the Cluster Manages Connections 340
Connection Roles 340
New Connection Ownership 341
Sample Data Flow for TCP 341
Sample Data Flow for ICMP and UDP 342
History for Clustering 344

PART III **Interfaces and Device Settings** 349

CHAPTER 10 **Interface Overview** 351
Management/Diagnostic Interface 351
Management Interface 351
Diagnostic Interface 351
Interface Mode and Types 352
Security Zones and Interface Groups 352
Auto-MDI/MDIX Feature 354
Default Settings for Interfaces 354
Create Security Zone and Interface Group Objects 355
Enable the Physical Interface and Configure Ethernet Settings 355
Configure EtherChannel Interfaces 357
About EtherChannels 358
About EtherChannels 358
Guidelines for EtherChannels 361
Configure an EtherChannel 362

Sync Interface Changes with the FMC 366
Manage the Network Module for the Secure Firewall 3100 369
Add a Network Module 370
Hot Swap the Network Module 372
Replace the Network Module with a Different Type 374
Remove the Network Module 377
History for Interfaces 380

CHAPTER 11 **Regular Firewall Interfaces** 383
Requirements and Prerequisites for Regular Firewall Interfaces 383
Configure Firepower 1010 Switch Ports 383
About Switch Ports 384
Understanding Switch Ports and Interfaces 384
Auto-MDI/MDIX Feature 385
Guidelines and Limitations for Switch Ports 385
Configure Switch Ports and Power Over Ethernet 386
Enable or Disable Switch Port Mode 386
Configure a VLAN Interface 387
Configure Switch Ports as Access Ports 389
Configure Switch Ports as Trunk Ports 391
Configure Power Over Ethernet 393
Configure VLAN Subinterfaces and 802.1Q Trunking 394
Guidelines and Limitations for VLAN Subinterfaces 395
Maximum Number of VLAN Subinterfaces by Device Model 395
Add a Subinterface 396
Configure Geneve Interfaces 398
About Geneve Interfaces 398
Geneve Encapsulation 398
VXLAN Tunnel Endpoint 398
VTEP Source Interface 398
VNI Interfaces 399
VXLAN Packet Processing 399
Peer VTEPs 399
Geneve Single-Arm Proxy Use Case 399

Requirements and Prerequisites for Geneve Interfaces 400
Guidelines for Geneve Interfaces 400
Configure Geneve Interfaces 401
Configure the VTEP Source Interface 401
Configure the VNI 402
Allow Gateway Load Balancer Health Checks 402
Configure Routed and Transparent Mode Interfaces 403
About Routed and Transparent Mode Interfaces 403
Dual IP Stack (IPv4 and IPv6) 404
31-Bit Subnet Mask 404
Guidelines and Limitations for Routed and Transparent Mode Interfaces 404
Configure Routed Mode Interfaces 406
Configure Bridge Group Interfaces 411
Configure General Bridge Group Member Interface Parameters 411
Configure the Bridge Virtual Interface (BVI) 413
Configure IPv6 Addressing 414
About IPv6 414
Configure a Global IPv6 Address 415
Configure IPv6 Neighbor Discovery 417
Configure Advanced Interface Settings 420
About Advanced Interface Configuration 420
About MAC Addresses 420
About the MTU 421
About the TCP MSS 422
ARP Inspection for Bridge Group Traffic 423
MAC Address Table 424
Default Settings 424
Guidelines for ARP Inspection and the MAC Address Table 424
Configure the MTU 425
Configure the MAC Address 425
Add a Static ARP Entry 426
Add a Static MAC Address and Disable MAC Learning for a Bridge Group 427
Set Security Configuration Parameters 428
History for Regular Firewall Interfaces 430

CHAPTER 12 **Inline Sets and Passive Interfaces** 433

About IPS Interfaces 433

Inline Sets 433

Multiple Inline Pairs and Asynchronous Routing 434

Passive Interfaces 435

About Hardware Bypass for Inline Sets 435

Hardware Bypass Triggers 435

Hardware Bypass Switchover 436

Snort Fail Open vs. Hardware Bypass 436

Hardware Bypass Status 436

Requirements and Prerequisites for Inline Sets 436

Guidelines for Inline Sets and Passive Interfaces 437

Configure a Passive Interface 439

Configure an Inline Set 440

History for Inline Sets and Passive Interfaces 444

CHAPTER 13 **DHCP and DDNS** 447

About DHCP and DDNS Services 447

About the DHCPv4 Server 447

DHCP Options 447

About the DHCP Relay Agent 448

Requirements and Prerequisites for DHCP and DDNS 448

Guidelines for DHCP and DDNS Services 448

Configure the DHCPv4 Server 450

Configure the DHCP Relay Agent 452

Configure Dynamic DNS 453

CHAPTER 14 **SNMP for the Firepower 1000/2100** 459

About SNMP for the Firepower 1000/2100 459

Enabling SNMP and Configuring SNMP Properties for Firepower 1000/2100 459

Creating an SNMP Trap for Firepower 1000/2100 461

Creating an SNMP User for Firepower 1000/2100 462

CHAPTER 15 **Quality of Service** 465

Introduction to QoS 465

About QoS Policies 465

Requirements and Prerequisites for QoS 466

Rate Limiting with QoS Policies 466

Creating a QoS Policy 467

Setting Target Devices for a QoS Policy 468

Configuring QoS Rules 468

QoS Rule Components 469

QoS Rule Conditions 470

Interface Rule Conditions 470

Network Rule Conditions 471

User Rule Conditions 471

Application Rule Conditions 471

Port Rule Conditions 473

URL Rule Conditions 474

Custom SGT Rule Conditions 474

ISE SGT vs Custom SGT Rule Conditions 474

Autotransition from Custom SGTs to ISE SGTs 475

History for QoS 475

CHAPTER 16 **Platform Settings** 477

Introduction to Platform Settings 477

Requirements and Prerequisites for Platform Settings Policies 478

Manage Platform Settings Policies 478

ARP Inspection 479

Banner 480

DNS 481

External Authentication 483

Fragment Settings 488

HTTP 489

ICMP 490

Secure Shell 492

SMTP Server 493
SNMP 494
About SNMP 495
SNMP Terminology 496
MIBs and Traps 496
Supported Tables and Objects in MIBs 497
Add SNMPv3 Users 501
Add SNMP Hosts 504
Configure SNMP Traps 505
Configure SSL Settings 507
About SSL Settings 508
Syslog 511
About Syslog 511
Severity Levels 512
Syslog Message Filtering 513
Syslog Message Classes 513
Guidelines for Logging 516
Configure Syslog Logging for FTD Devices 517
FTD Platform Settings That Apply to Security Event Syslog Messages 518
Enable Logging and Configure Basic Settings 518
Enable Logging Destinations 520
Send Syslog Messages to an E-mail Address 521
Create a Custom Event List 522
Limit the Rate of Syslog Message Generation 523
Configure Syslog Settings 524
Configure a Syslog Server 525
Timeouts 527
Time Synchronization 529
Time Zone 530
UCAPL/CC Compliance 531
History for Platform Settings 532

CHAPTER 17 **Network Address Translation** 535
Why Use NAT? 535

NAT Basics 536
NAT Terminology 536
NAT Types 536
NAT in Routed and Transparent Mode 537
NAT in Routed Mode 537
NAT in Transparent Mode or Within a Bridge Group 538
Auto NAT and Manual NAT 539
Auto NAT 539
Manual NAT 539
Comparing Auto NAT and Manual NAT 540
NAT Rule Order 540
NAT Interfaces 542
Configuring Routing for NAT 543
Addresses on the Same Network as the Mapped Interface 543
Addresses on a Unique Network 543
The Same Address as the Real Address (Identity NAT) 543
Requirements and Prerequisites for NAT Policies 544
Guidelines for NAT 544
Firewall Mode Guidelines for NAT 544
IPv6 NAT Guidelines 545
IPv6 NAT Best Practices 545
NAT Support for Inspected Protocols 546
FQDN Destination Guidelines 547
Additional Guidelines for NAT 548
Manage NAT Policies 550
Creating NAT Policies 551
Configuring NAT Policy Targets 551
Configure NAT for Threat Defense 552
Customizing NAT Rules for Multiple Devices 554
Searching and Filtering the NAT Rule Table 556
Dynamic NAT 557
About Dynamic NAT 557
Dynamic NAT Disadvantages and Advantages 558
Configure Dynamic Auto NAT 558

Configure Dynamic Manual NAT 560
Dynamic PAT 562
About Dynamic PAT 562
Dynamic PAT Disadvantages and Advantages 563
PAT Pool Object Guidelines 563
Configure Dynamic Auto PAT 564
Configure Dynamic Manual PAT 566
Configure PAT with Port Block Allocation 569
Static NAT 572
About Static NAT 572
Configure Static Auto NAT 576
Configure Static Manual NAT 577
Identity NAT 580
Configure Identity Auto NAT 581
Configure Identity Manual NAT 582
NAT Rule Properties for FTD 584
Interface Objects NAT Properties 585
Translation Properties for Auto NAT 586
Translation Properties for Manual NAT 587
PAT Pool NAT Properties 588
Advanced NAT Properties 589
Translating IPv6 Networks 590
NAT64/46: Translating IPv6 Addresses to IPv4 591
NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet 591
NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation 593
NAT66: Translating IPv6 Addresses to Different IPv6 Addresses 597
NAT66 Example, Static Translation between Networks 597
NAT66 Example, Simple IPv6 Interface PAT 600
Monitoring NAT 603
Examples for NAT 604
Providing Access to an Inside Web Server (Static Auto NAT) 604
Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server 607
Inside Load Balancer with Multiple Mapped Addresses (Static Auto NAT, One-to-Many) 613
Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation) 616

Different Translation Depending on the Destination (Dynamic Manual PAT) 624
Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT) 631
NAT and Site-to-Site VPN 637
Rewriting DNS Queries and Responses Using NAT 642
DNS64 Reply Modification 643
DNS Reply Modification, DNS Server on Outside 650
DNS Reply Modification, DNS Server on Host Network 653
History for FTD NAT 656

CHAPTER 18 **Alarms for the Cisco ISA 3000** 659
About Alarms 659
Alarm Input Interfaces 660
Alarm Output Interface 660
Syslog Alarms 661
SNMP Alarms 661
Defaults for Alarms 661
Requirements and Prerequisites for Alarms 662
Configure the Alarms for the ISA 3000 662
Configure Alarm Input Contacts 662
Configure Power Supply Alarms 665
Configure Temperature Alarms 667
Monitoring Alarms 670
Monitoring Alarm Status 670
Monitoring Syslog Messages for Alarms 670
Turning Off the External Alarm 671
History for Alarms 671

PART IV **Routing** 673

CHAPTER 19 **Static and Default Routes** 675
About Static and Default Routes 675
Default Route 675
Static Routes 675
Route to null0 Interface to Drop Unwanted Traffic 676

Route Priorities 676
Transparent Firewall Mode and Bridge Group Routes 676
Static Route Tracking 677
Requirements and Prerequisites for Static Routes 677
Guidelines for Static and Default Routes 678
Add a Static Route 678
Reference for Routing 680
Path Determination 680
Supported Route Types 680
Static Versus Dynamic 680
Single-Path Versus Multipath 681
Flat Versus Hierarchical 681
Link-State Versus Distance Vector 681
Supported Internet Protocols for Routing 681
Routing Table 682
How the Routing Table Is Populated 682
How Forwarding Decisions Are Made 684
Dynamic Routing and High Availability 685
Dynamic Routing in Clustering 685
Routing Table for Management Traffic 686
Equal-Cost Multi-Path (ECMP) Routing 686
About Route Maps 687
Permit and Deny Clauses 688
Match and Set Clause Values 688

CHAPTER 20 **Virtual Routers** 689
About Virtual Routers and Virtual Routing and Forwarding (VRF) 689
Applications of Virtual Routers 690
Global and User-Defined Virtual Routers 690
Configuring Policies to be Virtual-Router-Aware 691
Interconnecting Virtual Routers 692
Overlapping IP Addresses 693
Configuring SNMP on User-Defined Virtual Routers 694
Maximum Number of Virtual Routers By Device Model 695

Requirements and Prerequisites for Virtual Routers 696
Guidelines and Limitations for Virtual Routers 696
Modifications to the FMC Web Interface - Routing Page 698
Manage Virtual Routers 699
Create a Virtual Router 699
Configure a Virtual Router 699
Modify a Virtual Router 701
Remove Virtual Routers 702
Monitoring Virtual Routers 702
Configuration Examples for Virtual Routers 703
How to Route to a Distant Server through Virtual Routers 703
How to Provide Internet Access with Overlapping Address Spaces 707
How to Allow RA VPN Access to Internal Networks in Virtual Routing 714
How to Secure Traffic from Networks in Multiple Virtual Routers over a Site-to-Site VPN 717
How to Route Traffic between Two Overlapping Network Host in Virtual Routing 720
How to Manage Overlapping Segments in Routed Firewall Mode with BVI Interfaces 723
How to Configure User Authentication with Overlapping Networks 727
How to Interconnect Virtual Routers using BGP 733
History for Virtual Routers 738

CHAPTER 21 ECMP 741
About ECMP 741
Guidelines and Limitations for ECMP 741
Manage ECMP Page 742
Create an ECMP Zone 743
Configure an Equal Cost Static Route 744
Modify an ECMP Zone 745
Remove an ECMP Zone 745
Configuration Example for ECMP 746
History for ECMP in Firepower Threat Defense 749

CHAPTER 22 OSPF 751
OSPF 751
About OSPF 751

OSPF Support for Fast Hello Packets 753
Prerequisites for OSPF Support for Fast Hello Packets 753
OSPF Hello Interval and Dead Interval 753
OSPF Fast Hello Packets 753
Benefits of OSPF Fast Hello Packets 753
Implementation Differences Between OSPFv2 and OSPFv3 754
Requirements and Prerequisites for OSPF 754
Guidelines for OSPF 754
Configure OSPFv2 756
Configure OSPF Areas, Ranges, and Virtual Links 757
Configure OSPF Redistribution 759
Configure OSPF Inter-Area Filtering 761
Configure OSPF Filter Rules 762
Configure OSPF Summary Addresses 763
Configure OSPF Interfaces and Neighbors 764
Configure OSPF Advanced Properties 766
Configure OSPFv3 768
Configure OSPFv3 Areas, Route Summaries, and Virtual Links 769
Configure OSPFv3 Redistribution 771
Configure OSPFv3 Summary Prefixes 772
Configure OSPFv3 Interfaces, Authentication, and Neighbors 773
Configure OSPFv3 Advanced Properties 775
History for OSPF 778

CHAPTER 23 **BGP** 779
About BGP 779
Routing Table Changes 779
When to Use BGP 780
BGP Path Selection 781
BGP Multipath 781
Requirements and Prerequisites for BGP 782
Guidelines for BGP 782
Configure BGP 783
Configure BGP Basic Settings 784

Configure BGP General Settings 786
Configure BGP Neighbor Settings 787
Configure BGP Aggregate Address Settings 791
Configure BGPv4 Filtering Settings 791
Configure BGP Network Settings 792
Configure BGP Redistribution Settings 793
Configure BGP Route Injection Settings 794
Configure BGP Route Import/Export Settings 794
History for BGP 796

CHAPTER 24 RIP 799
About RIP 799
Routing Update Process 799
RIP Routing Metric 800
RIP Stability Features 800
RIP Timers 800
Requirements and Prerequisites for RIP 801
Guidelines for RIP 801
Configure RIP 802

CHAPTER 25 Multicast 805
About Multicast Routing 805
IGMP Protocol 805
Stub Multicast Routing 806
PIM Multicast Routing 806
PIM Source Specific Multicast Support 807
Multicast Bidirectional PIM 807
PIM Bootstrap Router (BSR) 808
PIM Bootstrap Router (BSR) Terminology 808
Multicast Group Concept 809
Multicast Addresses 809
Clustering 809
Requirements and Prerequisites for Multicast Routing 809
Guidelines for Multicast Routing 809

Configure IGMP Features 810
Enable Multicast Routing 811
Configure IGMP Protocol 811
Configure IGMP Access Groups 813
Configure IGMP Static Groups 813
Configure IGMP Join Groups 814
Configure PIM Features 815
Configure PIM Protocol 815
Configure PIM Neighbor Filters 816
Configure PIM Bidirectional Neighbor Filters 817
Configure PIM Rendezvous Points 818
Configure PIM Route Trees 819
Configure PIM Request Filters 819
Configure the Firepower Threat Defense Device as a Candidate Bootstrap Router 820
Configure Multicast Routes 821
Configure Multicast Boundary Filters 822

CHAPTER 26 **Policy Based Routing** 825
About Policy Based Routing 825
Guidelines and Limitations for Policy Based Routing 827
Configure Policy-Based Routing Policy 828
Configuration Example for Policy Based Routing 830
History for Policy Based Routing 835

PART V **Objects and Certificates** 837

CHAPTER 27 **Object Management** 839
Introduction to Objects 840
The Object Manager 842
Importing Objects 842
Editing Objects 845
Viewing Objects and Their Usage 845
Filtering Objects or Object Groups 846
Object Groups 847

Grouping Reusable Objects 847
Object Overrides 848
Managing Object Overrides 849
Allowing Object Overrides 850
Adding Object Overrides 850
Editing Object Overrides 851
AAA Server 851
Add a RADIUS Server Group 851
RADIUS Server Group Options 852
RADIUS Server Options 853
Add a Single Sign-on Server 854
Access List 856
Configure Extended ACL Objects 856
Configure Standard ACL Objects 858
Address Pools 859
Application Filters 860
AS Path 860
Cipher Suite List 860
Creating Cipher Suite Lists 861
Community List 861
Extended Community 862
Distinguished Name 864
Creating Distinguished Name Objects 866
DNS Server Group 867
Creating DNS Server Group Objects 867
External Attributes 867
About API-Created Dynamic Objects 867
Add or Edit an API-Created Dynamic Object 868
Security Group Tag 869
Creating Security Group Tag Objects 869
File List 869
Source Files for File Lists 870
Adding Individual SHA-256 Values to File Lists 871
Uploading Individual Files to File Lists 871

Uploading Source Files to File Lists 872
Editing SHA-256 Values in File Lists 873
Downloading Source Files from File Lists 874
FlexConfig 874
Geolocation 875
Creating Geolocation Objects 875
Interface 875
Key Chain 876
Creating Key Chain Objects 877
Network 878
Network Wildcard Mask 879
Creating Network Objects 880
Importing Network Objects 881
PKI 881
Internal Certificate Authority Objects 882
CA Certificate and Private Key Import 882
Importing a CA Certificate and Private Key 883
Generating a New CA Certificate and Private Key 883
New Signed Certificates 884
Creating an Unsigned CA Certificate and CSR 884
Uploading a Signed Certificate Issued in Response to a CSR 884
CA Certificate and Private Key Downloads 885
Downloading a CA Certificate and Private Key 885
Trusted Certificate Authority Objects 886
Trusted CA Object 886
Adding a Trusted CA Object 886
Certificate Revocation Lists in Trusted CA Objects 887
Adding a Certificate Revocation List to a Trusted CA Object 887
External Certificate Objects 888
Adding External Certificate Objects 888
Internal Certificate Objects 889
Adding Internal Certificate Objects 889
Certificate Enrollment Objects 890
Adding Certificate Enrollment Objects 891

Certificate Enrollment Object EST Options 893
Certificate Enrollment Object SCEP Options 893
Certificate Enrollment Object Certificate Parameters 894
Certificate Enrollment Object Key Options 895
Certificate Enrollment Object Revocation Options 897
Policy List 897
Port 899
Creating Port Objects 900
Importing Port Objects 900
Prefix List 900
Configure IPv6 Prefix List 901
Configure IPv4 Prefix List 901
Route Map 902
Security Intelligence 906
How to Modify Security Intelligence Objects 907
Global and Domain Security Intelligence Lists 908
Security Intelligence Lists and Multitenancy 908
Add Entries to Global Security Intelligence Lists 909
Delete Entries from Global Security Intelligence Lists 910
List and Feed Updates for Security Intelligence 911
Changing the Update Frequency for Security Intelligence Feeds 911
Custom Security Intelligence Lists and Feeds 911
Custom Lists and Feeds: Requirements 911
URL Lists and Feeds: URL Syntax and Matching Criteria 912
Custom Security Intelligence Feeds 913
Custom Security Intelligence Lists 915
Sinkhole 917
Creating Sinkhole Objects 917
SLA Monitor 918
Time Range 919
Creating Time Range Objects 919
Time Zone 921
Tunnel Zone 921
URL 921

Creating URL Objects 922
Variable Set 923
Variable Sets in Intrusion Policies 924
Variables 924
Predefined Default Variables 925
Network Variables 927
Port Variables 928
Advanced Variables 929
Variable Reset 930
Adding Variables to Sets 930
Nesting Variables 932
Managing Variable Sets 933
Creating Variable Sets 934
Managing Variables 935
Adding Variables 936
Editing Variables 937
VLAN Tag 937
Creating VLAN Tag Objects 938
VPN 938
Certificate Map Objects 938
AnyConnect Client Custom Attributes Objects 939
Add AnyConnect Client Custom Attributes Objects 940
Add Custom Attributes to a Group Policy 941
FTD Group Policy Objects 942
Configure Group Policy Objects 942
Group Policy General Options 943
Group Policy AnyConnect Client Options 945
Group Policy Advanced Options 949
FTD IPsec Proposals 949
Configure IKEv1 IPsec Proposal Objects 950
Configure IKEv2 IPsec Proposal Objects 951
FTD IKE Policies 951
Configure IKEv1 Policy Objects 952
Configure IKEv2 Policy Objects 953

File Objects 954
History for Object Management 956

CHAPTER 28 Certificates 961
Requirements and Prerequisites for Certificates 961
Firepower Threat Defense VPN Certificate Guidelines and Limitations 961
Managing FTD Certificates 962
Automatically Update CA Bundles 963
Installing a Certificate Using Self-Signed Enrollment 965
Installing a Certificate using EST Enrollment 966
Installing a Certificate Using SCEP Enrollment 967
Installing a Certificate Using Manual Enrollment 967
Installing a Certificate Using a PKCS12 File 968
Troubleshooting FTD Certificates 969
History for Certificates 970

PART VI VPN 971

CHAPTER 29 VPN Overview 973
VPN Types 973
VPN Basics 974
Internet Key Exchange (IKE) 974
IPsec 975
VPN Packet Flow 976
VPN Licensing 976
How Secure Should a VPN Connection Be? 976
Complying with Security Certification Requirements 977
Deciding Which Encryption Algorithm to Use 977
Deciding Which Hash Algorithms to Use 978
Deciding Which Diffie-Hellman Modulus Group to Use 978
Deciding Which Authentication Method to Use 979
Pre-shared Keys 979
PKI Infrastructure and Digital Certificates 979

Removed or Deprecated Hash Algorithms, Encryption Algorithms, and Diffie-Hellman Modulus Groups 981
VPN Topology Options 981
Point-to-Point VPN Topology 982
Hub and Spoke VPN Topology 982
Full Mesh VPN Topology 983
Implicit Topologies 984

CHAPTER 30 **Site-to-Site VPNs** 985
About Site-to-Site VPN 985
Firepower Threat Defense Site-to-site VPN Guidelines and Limitations 986
Types of Site-to-Site VPN Topologies 987
Requirements and Prerequisites for Site-to-Site VPN 988
Manage Site-to-Site VPNs 988
Configure a Policy-based Site-to-Site VPN 989
FTD VPN Endpoint Options 990
FTD VPN IKE Options 994
FTD VPN IPsec Options 997
FTD Advanced Site-to-site VPN Deployment Options 999
FTD VPN Advanced IKE Options 999
FTD VPN Advanced IPsec Options 1001
FTD Advanced Site-to-site VPN Tunnel Options 1001
About Virtual Tunnel Interfaces 1002
Static VTI 1003
Guidelines and Limitations for Virtual Tunnel Interfaces 1004
Add a VTI Interface 1006
Create a Route-based Site-to-Site VPN 1007
Configure Endpoints for a Point to Point Topology 1008
Configure Endpoints for a Hub and Spoke Topology 1009
Route Traffic Through a Backup VTI Tunnel 1012
Configure Routing and AC Policies for VTI 1013
Monitoring the Site-to-Site VPNs 1015
History for Site-to-Site VPN 1017

CHAPTER 31

Remote Access VPN 1021

Remote Access VPN Overview 1021

Remote Access VPN Features 1022

AnyConnect Components 1024

Remote Access VPN Authentication 1024

Understanding Policy Enforcement of Permissions and Attributes 1026

Understanding AAA Server Connectivity 1026

License Requirements for Remote Access VPN 1028

Requirements and Prerequisites for Remote Access VPN 1028

Remote Access VPN Guidelines and Limitations 1028

Configuring a New Remote Access VPN Connection 1031

Prerequisites for Configuring Remote Access VPN 1032

Create a New Remote Access VPN Policy 1033

Update the Access Control Policy on the Firepower Threat Defense Device 1035

(Optional) Configure NAT Exemption 1036

Configure DNS 1037

Add AnyConnect Client Profile XML File 1038

(Optional) Configure Split Tunneling 1038

(Optional) Configure Dynamic Split Tunneling 1039

Verify Dynamic Split Tunneling Configuration 1040

Verify the Configuration 1041

Create a Copy of an Existing Remote Access VPN Policy 1041

Set Target Devices for a Remote Access VPN Policy 1042

Associate Local Realm with Remote Access VPN Policy 1042

Additional Remote Access VPN Configurations 1043

Configure Connection Profile Settings 1043

Configure IP Addresses for VPN Clients 1043

Configure AAA Settings for Remote Access VPN 1045

Create or Update Aliases for a Connection Profile 1060

Configure Access Interfaces for Remote Access VPN 1060

Configure Advanced Options for Remote Access VPN 1062

Cisco AnyConnect Security Mobility Client Image 1062

Remote Access VPN Address Assignment Policy 1064

Configure Certificate to Connection Profile Mapping 1065
Configure Group Policies 1066
Configuring LDAP Attribute Mapping 1067
Configuring VPN Load Balancing 1068
Configure IPsec Settings 1071
Configure AnyConnect Management VPN Tunnel 1077
Requirements and Prerequisites for AnyConnect Management VPN Tunnel 1077
Limitations of AnyConnect Management VPN Tunnel 1078
Configuring AnyConnect Management VPN Tunnel on FTD 1078
Multiple Certificate Authentication 1080
Guidelines and Limitations of Multiple Certificate Authentication 1080
Configuring Multiple Certificate Authentication 1081
Customizing Remote Access VPN AAA Settings 1082
Authenticate VPN Users via Client Certificates 1082
Configure VPN User Authentication via Client Certificate and AAA Server 1083
Manage Password Changes over VPN Sessions 1085
Send Accounting Records to the RADIUS Server 1086
Delegating Group Policy Selection to Authorization Server 1086
Override the Selection of Group Policy or Other Attributes by the Authorization Server 1087
Deny VPN Access to a User Group 1088
Restrict Connection Profile Selection for a User Group 1089
Update the AnyConnect Client Profile for Remote Access VPN Clients 1090
RADIUS Dynamic Authorization 1090
Configuring RADIUS Dynamic Authorization 1091
Two-Factor Authentication 1092
Configuring RSA Two-Factor Authentication 1092
Configuring Duo Two-Factor Authentication 1093
Secondary Authentication 1095
Configure Remote Access VPN Secondary Authentication 1096
Single Sign-On Authentication with SAML 2.0 1097
Configuring a SAML Single Sign-On Authentication 1098
Configuring SAML Authorization 1099
Advanced AnyConnect Client Configurations 1101
Configure AnyConnect Client Modules on a FTD 1101

Types of AnyConnect Client Modules 1101
Prerequisites for Configuring AnyConnect Client Modules 1102
Guidelines for Configuring AnyConnect Client Modules 1103
Install AnyConnect Client Modules using a FTD 1104
Configure a Remote Access VPN Group Policy with AnyConnect Client Modules 1104
Verify AnyConnect Client Modules Configuration 1105
Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices 1106
Prerequisites and Licensing for Configuring Per App VPN Tunnels 1106
Determine the Application IDs for Mobile Applications 1107
Configure Application-Based VPN Tunnels 1107
Verify Per App Configuration 1109
Remote Access VPN Examples 1109
How to Limit AnyConnect Bandwidth Per User 1109
How to Use VPN Identity for User-Id Based Access Control Rules 1110
Configure FTD Multiple Certificate Authentication 1110
History for Remote Access VPNs 1114

CHAPTER 32 **Dynamic Access Policies** 1117
About Firepower Threat Defense Dynamic Access Policy 1117
Hierarchy of Policy Enforcement of Permissions and Attributes in FTD 1117
Prerequisites for Dynamic Access Policy 1119
Guidelines and Limitations for Dynamic Access Policies 1119
Configure a Dynamic Access Policy (DAP) 1119
Create a Dynamic Access Policy 1119
Create a Dynamic Access Policy Record 1120
Configure AAA Criteria Settings for DAP 1120
Configure Endpoint Attribute Selection Criteria in DAP 1121
Add an Anti-Malware Endpoint Attribute to a DAP 1122
Add a Device Endpoint Attribute to a DAP 1123
Add AnyConnect Endpoint Attributes to a DAP 1123
Add NAC Endpoint Attributes to a DAP 1124
Add an Application Attribute to a DAP 1124
Add a Personal Firewall Endpoint Attribute to a DAP 1124
Add an Operating System Endpoint Attribute to a DAP 1125

Add a Process Endpoint Attribute to a DAP 1125
Add a Registry Endpoint Attribute to a DAP 1125
Add a File Endpoint Attribute to a DAP 1126
Add Certificate Authentication Attributes to a DAP 1126
Configure Advanced Settings for DAP 1127
Associate Dynamic Access Policy with Remote Access VPN 1127
History for Dynamic Access Policy 1128

CHAPTER 33 **VPN Monitoring and Troubleshooting** 1129
VPN Summary Dashboard 1129
VPN Session and User Information 1129
Viewing Remote Access VPN Active Sessions 1129
Viewing Remote Access VPN User Activity 1130
VPN Health Events 1130
Viewing VPN Health Events 1130
VPN Troubleshooting 1131
System Messages 1131
VPN System Logs 1131
Debug Commands 1131
debug aaa 1133
debug crypto 1133
debug ldap 1136
debug ssl 1137
debug webvpn 1137

PART VII **Access Control** 1141

CHAPTER 34 **Access Control Overview** 1143
Introduction to Access Control 1143
Introduction to Rules 1144
Filtering Rules by Device 1144
Rule and Other Policy Warnings 1145
Access Control Policy Default Action 1146
Deep Inspection Using File and Intrusion Policies 1148

Access Control Traffic Handling with Intrusion and File Policies 1148
File and Intrusion Inspection Order 1150
Access Control Policy Inheritance 1151
Best Practices for Application Control 1152
Recommendations for Application Control 1152
Best Practices for Configuring Application Control 1154
Application Characteristics 1156
Application-Specific Notes and Limitations 1156
Best Practices for Access Control Rules 1157
General Best Practices for Access Control 1158
Best Practices for Ordering Rules 1159
Rule Preemption 1159
Rule Actions and Rule Order 1160
Application Rule Order 1161
URL Rule Order 1161
Best Practices for Simplifying and Focusing Rules 1161
Maximum Number of Access Control Rules and Intrusion Policies 1162

CHAPTER 35 **Access Control Policies** 1163
Access Control Policy Components 1163
System-Created Access Control Policies 1165
Requirements and Prerequisites for Access Control Policies 1165
Managing Access Control Policies 1166
Creating a Basic Access Control Policy 1166
Editing an Access Control Policy 1167
Managing Access Control Policy Inheritance 1169
Choosing a Base Access Control Policy 1169
Inheriting Access Control Policy Settings from the Base Policy 1170
Locking Settings in Descendant Access Control Policies 1170
Requiring an Access Control Policy in a Domain 1171
Setting Target Devices for an Access Control Policy 1171
Logging Settings for Access Control Policies 1172
Access Control Policy Advanced Settings 1173
Associating Other Policies with Access Control 1177

Viewing Rule Hit Counts 1178
History for Access Control Policies 1180

CHAPTER 36 Access Control Rules 1181
Introduction to Access Control Rules 1181
Access Control Rule Management 1183
Access Control Rule Components 1184
Access Control Rule Order 1185
Access Control Rule Actions 1186
Access Control Rule Monitor Action 1186
Access Control Rule Trust Action 1186
Access Control Rule Blocking Actions 1187
Access Control Rule Interactive Blocking Actions 1188
Access Control Rule Allow Action 1188
Requirements and Prerequisites for Access Control Rules 1189
Guidelines and Limitations for Access Control Rules 1189
Managing Access Control Rules 1190
Adding an Access Control Rule Category 1190
Create and Edit Access Control Rules 1191
Access Control Rule Conditions 1192
Enabling and Disabling Access Control Rules 1201
Copying Access Control Rules from One Access Control Policy to Another 1202
Moving Access Control Rules to a Prefilter Policy 1203
Positioning an Access Control Rule 1205
Adding Comments to an Access Control Rule 1205
Examples for Access Control Rules 1206
How to Control Access Using Security Zones 1206
How to Block QUIC Traffic 1206
History for Access Control Rules 1209

CHAPTER 37 URL Filtering 1211
URL Filtering Overview 1211
About URL Filtering with Category and Reputation 1211
URL Category and Reputation Descriptions 1213

URL Filtering Data from the Cisco Cloud 1213
Best Practices for URL Filtering 1213
Filtering HTTPS Traffic 1216
Use Categories in URL Filtering 1217
License Requirements for URL Filtering 1218
Requirements and Prerequisites for URL Filtering 1218
How to Configure URL Filtering with Category and Reputation 1219
Enable URL Filtering Using Category and Reputation 1220
URL Filtering Options 1220
Configuring URL Conditions 1221
Rules with URL Conditions 1223
URL Rule Order 1223
DNS Filtering: Identify URL Reputation and Category During DNS Lookup 1223
Enable DNS Filtering to Identify URLs During Domain Lookup 1223
DNS Filtering Limitations 1224
DNS Filtering and Events 1224
Manual URL Filtering 1225
Manual URL Filtering Options 1225
Supplement or Selectively Override Category and Reputation-Based URL Filtering 1226
Configure HTTP Response Pages 1227
Limitations to HTTP Response Pages 1227
Requirements and Prerequisites for HTTP Response Pages 1228
Choosing HTTP Response Pages 1228
Configure Interactive Blocking with HTTP Response Pages 1229
Configuring Interactive Blocking 1229
Setting the User Bypass Timeout for a Blocked Website 1230
Configure URL Filtering Health Monitors 1230
Dispute URL Category and Reputation 1231
If the URL Category Set Changes, Take Action 1232
URL Category and Reputation Changes: Effect on Events 1233
Troubleshoot URL Filtering 1233
History for URL Filtering 1236

CHAPTER 38 **Security Intelligence** 1239

About Security Intelligence 1239
Best Practices for Security Intelligence 1240
License Requirements for Security Intelligence 1240
Requirements and Prerequisites for Security Intelligence 1241
Security Intelligence Sources 1241
Configure Security Intelligence 1242
Security Intelligence Options 1244
Security Intelligence Categories 1245
Block List Icons 1247
Configuration Example: Security Intelligence Blocking 1247
Security Intelligence Monitoring 1248
Override Security Intelligence Blocking 1249
Troubleshooting Security Intelligence 1249
Security Intelligence Categories Are Missing from the Available Options List 1250
History for Security Intelligence Block Listing 1250

CHAPTER 39 **DNS Policies** 1251
DNS Policy Overview 1251
DNS Policy Components 1252
License Requirements for DNS Policies 1253
Requirements and Prerequisites for DNS Policies 1253
Managing DNS Policies 1253
Creating Basic DNS Policies 1254
Editing DNS Policies 1254
DNS Rules 1255
Creating and Editing DNS Rules 1256
DNS Rule Management 1256
Enabling and Disabling DNS Rules 1256
DNS Rule Order Evaluation 1257
DNS Rule Actions 1257
DNS Rule Conditions 1258
Security Zone Rule Conditions 1259
Network Rule Conditions 1259
VLAN Tags Rule Conditions 1260

DNS Policy Rule Conditions 1260
How to Create DNS Rules 1260
Controlling Traffic Based on DNS and Security Zone 1260
Controlling Traffic Based on DNS and Network 1261
Controlling Traffic Based on DNS and VLAN 1262
Controlling Traffic Based on DNS List or Feed 1262
DNS Policy Deploy 1263

CHAPTER 40 **Prefiltering and Prefilter Policies** 1265
About Prefiltering 1265
About Prefilter Policies 1265
Tunnel vs Prefilter Rules 1266
Prefiltering vs Access Control 1267
Passthrough Tunnels and Access Control 1269
Best Practices for Fastpath Prefiltering 1270
Best Practices for Encapsulated Traffic Handling 1270
Requirements and Prerequisites for Prefilter Policies 1271
Configure Prefiltering 1272
Tunnel and Prefilter Rule Components 1273
Prefilter Rule Conditions 1275
Interface Rule Conditions 1275
Network Rule Conditions 1275
VLAN Tags Rule Conditions 1276
Port Rule Conditions for Prefilter Rules 1276
Time and Day Rule Conditions 1277
Tunnel Rule Conditions 1277
Encapsulation Rule Conditions 1277
Tunnel Zones and Prefiltering 1278
Using Tunnel Zones 1278
Creating Tunnel Zones 1280
Moving Prefilter Rules to an Access Control Policy 1281
Prefilter Policy Hit Counts 1283
Large Flow Offloads 1283
Flow Offload Limitations 1284

History for Prefiltering 1286

CHAPTER 41 **Service Policies** 1287

About Threat Defense Service Policies 1287

How Service Policies Relate to FlexConfig and Other Features 1288

What Are Connection Settings? 1288

Requirements and Prerequisites for Service Policies 1289

Guidelines and Limitations for Service Policies 1289

Configure Threat Defense Service Policies 1290

Configure a Service Policy Rule 1291

Bypass TCP State Checks for Asymetrical Routing (TCP State Bypass) 1293

The Asymetrical Routing Problem 1294

Guidelines and Limitations for TCP State Bypass 1295

Configure TCP State Bypass 1295

Disable TCP Sequence Randomization 1297

Examples for Service Policy Rules 1298

Protect Servers from a SYN Flood DoS Attack (TCP Intercept) 1298

Make the FTD Device Appear on Traceroutes 1301

Monitoring Service Policies 1303

History for Threat Defense Service Policy 1303

CHAPTER 42 **Intelligent Application Bypass** 1305

Introduction to IAB 1305

IAB Options 1306

Requirements and Prerequisites for Intelligent Application Bypass 1308

Configuring Intelligent Application Bypass 1308

IAB Logging and Analysis 1309

CHAPTER 43 **Content Restriction** 1313

About Content Restriction 1313

Requirements and Prerequisites for Content Restriction 1314

Guidelines and Limitations for Content Restriction 1315

Using Access Control Rules to Enforce Content Restriction 1315

Safe Search Options for Access Control Rules 1316

Using a DNS Sinkhole to Enforce Content Restriction 1316

PART VIII **Intrusion Detection and Prevention** 1319

CHAPTER 44 **Network Analysis and Intrusion Policies Overview** 1321

Network Analysis and Intrusion Policy Basics 1321

How Policies Examine Traffic For Intrusions 1322

Decoding, Normalizing, and Preprocessing: Network Analysis Policies 1323

Access Control Rules: Intrusion Policy Selection 1324

Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets 1325

Intrusion Event Generation 1326

System-Provided and Custom Network Analysis and Intrusion Policies 1327

System-Provided Network Analysis and Intrusion Policies 1327

Benefits of Custom Network Analysis and Intrusion Policies 1329

Benefits of Custom Network Analysis Policies 1329

Benefits of Custom Intrusion Policies 1330

Limitations of Custom Policies 1331

License Requirements for Network Analysis and Intrusion Policies 1333

Requirements and Prerequisites for Network Analysis and Intrusion Policies 1333

Guidelines and Limitations for Network Analysis and Intrusion Policies 1334

The Navigation Panel: Network Analysis and Intrusion Policies 1334

Conflicts and Changes: Network Analysis and Intrusion Policies 1335

Exiting a Network Analysis or Intrusion Policy 1337

CHAPTER 45 **Getting Started with Intrusion Policies** 1339

Intrusion Policy Basics 1339

License Requirements for Intrusion Policies 1340

Requirements and Prerequisites for Intrusion Policies 1341

Managing Intrusion Policies 1341

Custom Intrusion Policy Creation 1342

Creating a Custom Snort 2 Intrusion Policy 1342

Editing Snort 2 Intrusion Policies 1343

Intrusion Policy Changes 1344

Access Control Rule Configuration to Perform Intrusion Prevention 1344

Access Control Rule Configuration and Intrusion Policies 1345
Configuring an Access Control Rule to Perform Intrusion Prevention 1345
Drop Behavior in an Inline Deployment 1345
Setting Drop Behavior in an Inline Deployment 1346
Drop Behavior in a Dual System Deployment 1347
Intrusion Policy Advanced Settings 1347
Optimizing Performance for Intrusion Detection and Prevention 1348

CHAPTER 46 **Tuning Intrusion Policies Using Rules** 1349
Intrusion Rule Tuning Basics 1349
Intrusion Rule Types 1349
License Requirements for Intrusion Rules 1350
Requirements and Prerequisites for Intrusion Rules 1351
Viewing Intrusion Rules in an Intrusion Policy 1351
Intrusion Rules Page Columns 1351
Intrusion Rule Details 1352
Viewing Intrusion Rule Details 1353
Setting a Threshold for an Intrusion Rule 1354
Setting Suppression for an Intrusion Rule 1354
Setting a Dynamic Rule State from the Rule Details Page 1355
Setting an SNMP Alert for an Intrusion Rule 1356
Adding a Comment to an Intrusion Rule 1356
Intrusion Rule Filters in an Intrusion Policy 1356
Intrusion Rule Filters Notes 1357
Intrusion Policy Rule Filters Construction Guidelines 1357
Intrusion Rule Configuration Filters 1359
Intrusion Rule Content Filters 1360
Intrusion Rule Categories 1361
Intrusion Rule Filter Components 1361
Intrusion Rule Filter Usage 1362
Setting a Rule Filter in an Intrusion Policy 1362
Intrusion Rule States 1363
Intrusion Rule State Options 1363
Setting Intrusion Rule States 1364

Intrusion Event Notification Filters in an Intrusion Policy 1365
Intrusion Event Thresholds 1365
Intrusion Event Thresholds Configuration 1365
Adding and Modifying Intrusion Event Thresholds 1366
Viewing and Deleting Intrusion Event Thresholds 1367
Intrusion Policy Suppression Configuration 1368
Intrusion Policy Suppression Types 1368
Suppressing Intrusion Events for a Specific Rule 1369
Viewing and Deleting Suppression Conditions 1369
Dynamic Intrusion Rule States 1370
Dynamic Intrusion Rule State Configuration 1371
Setting a Dynamic Rule State from the Rules Page 1372
Adding Intrusion Rule Comments 1373

CHAPTER 47 **Custom Intrusion Rules** 1375
Custom Intrusion Rules Overview 1375
License Requirements for the Intrusion Rule Editor 1376
Requirements and Prerequisites for the Intrusion Rule Editor 1376
Rule Anatomy 1376
The Intrusion Rule Header 1377
Intrusion Rule Header Action 1378
Intrusion Rule Header Protocol 1378
Intrusion Rule Header Direction 1379
Intrusion Rule Header Source and Destination IP Addresses 1379
Intrusion Rule Header Source and Destination Ports 1382
Intrusion Event Details 1383
Adding a Custom Classification 1386
Defining an Event Priority 1387
Defining an Event Reference 1387
Custom Rule Creation 1388
Writing New Rules 1388
Modifying Existing Rules 1389
Viewing Rule Documentation 1390
Adding Comments to Intrusion Rules 1391

Deleting Custom Rules 1392
Searching for Rules 1393
Search Criteria for Intrusion Rules 1393
Rule Filtering on the Intrusion Rules Editor Page 1394
Filtering Guidelines 1394
Keyword Filtering 1395
Character String Filtering 1396
Combination Keyword and Character String Filtering 1396
Filtering Rules 1397
Keywords and Arguments in Intrusion Rules 1397
The content and protected_content Keywords 1398
Basic content and protected_content Keyword Arguments 1399
content and protected_content Keyword Search Locations 1400
Overview: HTTP content and protected_content Keyword Arguments 1403
Overview: content Keyword Fast Pattern Matcher 1406
The replace Keyword 1409
The byte_jump Keyword 1410
The byte_test Keyword 1413
The byte_extract Keyword 1415
The byte_math Keyword 1417
Overview: The pcre Keyword 1420
pcre Syntax 1421
pcre Modifier Options 1422
pcre Example Keyword Values 1425
The metadata Keyword 1427
Service Metadata 1429
Metadata Search Guidelines 1433
IP Header Values 1434
ICMP Header Values 1437
TCP Header Values and Stream Size 1438
The stream_reassembly Keyword 1441
SSL Keywords 1442
The appid Keyword 1443
Application Layer Protocol Values 1444

The RPC Keyword 1444
The ASN.1 Keyword 1445
The urilen Keyword 1446
DCE/RPC Keywords 1447
SIP Keywords 1450
GTP Keywords 1452
SCADA Keywords 1463
Modbus Keywords 1463
DNP3 Keywords 1465
CIP and ENIP Keywords 1467
S7Commplus Keywords 1468
Packet Characteristics 1469
Active Response Keywords 1471
The resp Keyword 1471
The react Keyword 1472
The detection_filter Keyword 1473
The tag Keyword 1474
The flowbits Keyword 1475
flowbits Keyword Options 1476
Guidelines for Using the flowbits Keyword 1477
flowbits Keyword Examples 1477
The http_encode Keyword 1482
http_encode Keyword Syntax 1483
http_encode Keyword example: Using Two http_endcode Keywords to Search for Two Encodings 1483
Overview: The file_type and file_group Keywords 1483
The file_type and file_group Keywords 1484
The file_data Keyword 1485
The pkt_data Keyword 1486
The base64_decode and base64_data Keywords 1486

CHAPTER 48 **Layers in Intrusion and Network Analysis Policies** 1489
Layer Basics 1489
License Requirements for Network Analysis and Intrusion Policy Layers 1489

Requirements and Prerequisites for Network Analysis and Intrusion Policy Layers 1490
The Layer Stack 1490
The Base Layer 1491
System-Provided Base Policies 1491
Custom Base Policies 1491
The Effect of Rule Updates on Base Policies 1492
Changing the Base Policy 1493
The Firepower Recommendations Layer 1493
Layer Management 1494
Shared Layers 1495
Managing Layers 1496
Navigating Layers 1497
Intrusion Rules in Layers 1497
Configuring Intrusion Rules in Layers 1498
Removing Rule Settings from Multiple Layers 1499
Accepting Rule Changes from a Custom Base Policy 1500
Preprocessors and Advanced Settings in Layers 1501
Configuring Preprocessors and Advanced Settings in Layers 1502

CHAPTER 49 **Tailoring Intrusion Protection to Your Network Assets** 1505
About Recommended Rules 1505
Default Settings for Firepower Recommendations 1506
Advanced Settings for Firepower Recommendations 1507
Generating and Applying Firepower Recommendations 1508
Script Detection 1509

CHAPTER 50 **Sensitive Data Detection** 1511
Sensitive Data Detection Basics 1511
Global Sensitive Data Detection Options 1512
Individual Sensitive Data Type Options 1513
System-Provided Sensitive Data Types 1514
License Requirements for Sensitive Data Detection 1514
Requirements and Prerequisites for Sensitive Data Detection 1515
Configuring Sensitive Data Detection 1515

Monitored Application Protocols and Sensitive Data 1516
Selecting Application Protocols to Monitor 1517
Special Case: Sensitive Data Detection in FTP Traffic 1518
Custom Sensitive Data Types 1518
Data Patterns in Custom Sensitive Data Types 1519
Configuring Custom Sensitive Data Types 1521
Editing Custom Sensitive Data Types 1522

CHAPTER 51 **Global Limit for Intrusion Event Logging** 1523
Global Rule Thresholding Basics 1523
Global Rule Thresholding Options 1524
License Requirements for Global Thresholds 1525
Requirements and Prerequisites for Global Thresholds 1526
Configuring Global Thresholds 1526
Disabling the Global Threshold 1527

CHAPTER 52 **Intrusion Prevention Performance Tuning** 1529
About Intrusion Prevention Performance Tuning 1529
License Requirements for Intrusion Prevention Performance Tuning 1530
Requirements and Prerequisites for Intrusion Prevention Performance Tuning 1530
Limiting Pattern Matching for Intrusions 1530
Regular Expression Limits Overrides for Intrusion Rules 1531
Overriding Regular Expression Limits for Intrusion Rules 1532
Per Packet Intrusion Event Generation Limits 1532
Limiting Intrusion Events Generated Per Packet 1533
Packet and Intrusion Rule Latency Threshold Configuration 1534
Latency-Based Performance Settings 1534
Packet Latency Thresholding 1534
Packet Latency Thresholding Notes 1535
Enabling Packet Latency Thresholding 1536
Configuring Packet Latency Thresholding 1536
Rule Latency Thresholding 1537
Rule Latency Thresholding Notes 1538
Configuring Rule Latency Thresholding 1539

Intrusion Performance Statistic Logging Configuration 1540
Configuring Intrusion Performance Statistic Logging 1540

PART IX **Network Malware Protection and File Policies 1543**

CHAPTER 53 **Network Malware Protection and File Policies 1545**

About Network Malware Protection and File Policies 1545
File Policies 1546
Requirements and Prerequisites for File Policies 1546
License Requirements for File and Malware Policies 1547
Best Practices for File Policies and Malware Detection 1547
File Rule Best Practices 1547
File Detection Best Practices 1548
File Blocking Best Practices 1548
File Policy Best Practices 1549
How to Configure Malware Protection 1550
Plan and Prepare for Malware Protection 1551
Configure File Policies 1552
Add File Policies to Your Access Control Configuration 1552
Configuring an Access Control Rule to Perform Malware Protection 1553
Set Up Maintenance and Monitoring of Malware Protection 1554
Cloud Connections for Malware Protection 1555
AMP Cloud Connection Configurations 1556
Requirements and Best Practices for AMP Cloud Connections 1556
Choose an AMP Cloud 1557
Cisco AMP Private Cloud 1557
Managing Connections to the AMP Cloud (Public or Private) 1559
Change AMP Options 1560
Dynamic Analysis Connections 1560
Requirements for Dynamic Analysis 1560
Viewing the Default Dynamic Analysis Connection 1561
Dynamic Analysis On-Premises Appliance (Cisco Secure Malware Analytics) 1561
Enabling Access to Dynamic Analysis Results in the Public Cloud 1562
Maintain Your System: Update File Types Eligible for Dynamic Analysis 1563

File Policies and File Rules 1564
Create or Edit a File Policy 1564
Advanced and Archive File Inspection Options 1564
Managing File Policies 1567
File Rules 1568
File Rule Components 1569
File Rule Actions 1570
Creating File Rules 1577
Access Control Rule Logging for Malware Protection 1578
Retrospective Disposition Changes 1578
File and Malware Inspection Performance and Storage Options 1578
Tuning File and Malware Inspection Performance and Storage 1580
(Optional) Malware Protection with AMP for Endpoints 1581
Comparison of Malware Protection: Firepower vs. AMP for Endpoints 1581
About Integrating Firepower with AMP for Endpoints 1582
Benefits of Integrating Firepower and AMP for Endpoints 1582
AMP for Endpoints and AMP Private Cloud 1583
Integrate Firepower and AMP for Endpoints 1583
History for Network Malware Protection and File Policies 1585

PART X **Encrypted Traffic Handling** 1587

CHAPTER 54 **Traffic Decryption Overview** 1589
Traffic Decryption Explained 1589
TLS/SSL Handshake Processing 1591
ClientHello Message Handling 1591
ServerHello and Server Certificate Message Handling 1594
TLS/SSL Rule and Policy Basics 1596
The Case for Decryption 1597
When to Decrypt Traffic, When Not to Decrypt 1597
Decrypt and Resign (Outgoing Traffic) 1599
Known Key Decryption (Incoming Traffic) 1599
Other TLS/SSL Rule Actions 1600
TLS/SSL Rule Components 1600

TLS/SSL Rule Order Evaluation 1601
Multi-Rule Example 1602
TLS Crypto Acceleration 1603
TLS Crypto Acceleration Guidelines and Limitations 1604
View the Status of TLS Crypto Acceleration 1605
How to Configure SSL Policies and Rules 1606
History for SSL Policy 1607

CHAPTER 55 SSL Policies 1611
SSL Policies Overview 1611
SSL Policy Default Actions 1612
Default Handling Options for Undecryptable Traffic 1613
SSL Policy Advanced Options 1614
Requirements and Prerequisites for SSL Policies 1615
Create Basic SSL Policies 1615
Set Default Handling for Undecryptable Traffic 1616
Manage SSL Policies 1616

CHAPTER 56 TLS/SSL Rules 1619
TLS/SSL Rules Overview 1619
TLS/SSL Rule Guidelines and Limitations 1619
Guidelines for Using TLS/SSL Decryption 1620
TLS/SSL Rule Unsupported Features 1621
TLS/SSL Do Not Decrypt Guidelines 1621
TLS/SSL Decrypt - Resign Guidelines 1622
TLS/SSL Decrypt - Known Key Guidelines 1625
TLS/SSL Block Guidelines 1625
TLS/SSL Certificate Pinning Guidelines 1625
TLS/SSL Heartbeat Guidelines 1626
TLS/SSL Anonymous Cipher Suite Limitation 1626
TLS/SSL Normalizer Guidelines 1626
Other TLS/SSL Rule Guidelines 1626
Requirements and Prerequisites for TLS/SSL Rules 1627
TLS/SSL Rule Traffic Handling 1627

Encrypted Traffic Inspection Configuration 1629
TLS/SSL Rule Order Evaluation 1630
TLS/SSL Rule Conditions 1631
Security Zone Rule Conditions 1632
Security Zone Conditions and Multitenancy 1633
Network Rule Conditions 1633
VLAN Tags Rule Conditions 1633
User Rule Conditions 1634
Application Rule Conditions 1634
Port Rule Conditions 1635
Category Rule Conditions 1636
Server Certificate-Based TLS/SSL Rule Conditions 1636
Certificate TLS/SSL Rule Conditions 1637
Distinguished Name (DN) Rule Conditions 1637
Trusting External Certificate Authorities 1642
Certificate Status TLS/SSL Rule Conditions 1643
Cipher Suite TLS/SSL Rule Conditions 1646
Encryption Protocol Version TLS/SSL Rule Conditions 1649
TLS/SSL Rule Actions 1649
TLS/SSL Rule Monitor Action 1649
TLS/SSL Rule Do Not Decrypt Action 1650
TLS/SSL Rule Blocking Actions 1651
TLS/SSL Rule Decrypt Actions 1651
Monitor TLS/SSL Hardware Acceleration 1652
Informational Counters 1652
Alert Counters 1652
Error Counters 1653
Fatal Counters 1653
Troubleshoot TLS/SSL Rules 1654
About TLS/SSL Oversubscription 1654
Troubleshoot TLS/SSL Oversubscription 1654
About TLS Heartbeat 1656
Troubleshoot TLS Heartbeat 1656
About TLS/SSL Pinning 1658

Troubleshoot TLS/SSL Pinning 1658
Troubleshoot Unknown or Bad Certificates or Certificate Authorities 1660
Verify TLS/SSL Cipher Suites 1662

CHAPTER 57 **TLS/SSL Rules and Policy Example** 1665
TLS/SSL Rules Best Practices 1665
Bypass Inspection with Prefilter and Flow Offload 1666
Do Not Decrypt Best Practices 1667
Decrypt - Resign and Decrypt - Known Key Best Practices 1667
TLS/SSL Rules to Put First 1668
TLS/SSL Rules to Put Last 1668
Recommended Policy and Rule Settings 1668
Recommended Policy and Rule Settings 1669
SSL Policy Settings 1669
Access Control Policy Settings 1671
SSL Policy Walkthrough 1672
Recommended Policy and Rule Settings 1673
SSL Policy Settings 1673
Access Control Policy Settings 1675
TLS/SSL Rule Examples 1676
Traffic to Prefilter 1676
1676
: Decrypt Specific Test Traffic 1677
Do Not Decrypt Low-Risk Categories, Reputations, or Applications 1677
Create a Decrypt - Resign Rule for Categories 1678
TLS/SSL Rules: Block or Monitor Certificates and Protocol Versions 1679
TLS/SSL Rule Settings 1684

PART XI **User Identity** 1685

CHAPTER 58 **User Identity Overview** 1687
About User Identity 1687
Identity Terminology 1688
About User Identity Sources 1688

Best Practices for User Identity 1690
Identity Deployments 1691
How to Set Up an Identity Policy 1692
The User Activity Database 1695
The Users Database 1695
Host and User Limits 1696
Host Limit 1696
User Limits for Microsoft Active Directory 1697
Identity Realm Limit 1699
User Limits for Microsoft Azure Active Directory Realms 1699

CHAPTER 59 **Realms** 1703
License Requirements for Realms 1703
Requirements and Prerequisites for Realms 1703
Create an LDAP Realm or an Active Directory Realm and Realm Directory 1704
About Realms and Realm Sequences 1706
Realms and Trusted Domains 1708
Supported Servers for Realms 1711
Supported Server Object Class and Attribute Names 1712
Prerequisites for Kerberos Authentication 1713
Realm Fields 1713
Realm Directory and Synchronize fields 1717
Connect Securely to Active Directory 1719
Find the Active Directory Server's Name 1719
Export the Active Directory Server's Root Certificate 1720
Synchronize Users and Groups 1722
Create a Realm Sequence 1723
Configure the FMC for Cross-Domain-Trust: The Setup 1724
Configure the Firepower Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories 1725
Configure the Firepower Management Center for Cross-Domain-Trust Step 2: Synchronize Users and Groups 1730
Configure the Firepower Management Center for Cross-Domain-Trust Step 3: Resolve Issues 1731
Manage a Realm 1732

Compare Realms 1733
Troubleshoot Realms and User Downloads 1733
Detect Realm or User Mismatches 1737
Troubleshoot Cross-Domain Trust 1738
History for Realms 1741

CHAPTER 60 User Control with ISE/ISE-PIC 1743
The ISE/ISE-PIC Identity Source 1743
Source and Destination Security Group Tag (SGT) Matching 1744
License Requirements for ISE/ISE-PIC 1745
Requirements and Prerequisites for ISE/ISE-PIC 1745
ISE/ISE-PIC Guidelines and Limitations 1745
How to Configure ISE/ISE-PIC for User Control 1747
How to Configure ISE/ISE-PIC Without a Realm 1748
How to Configure ISE/ISE-PIC for User Control Using a Realm 1749
Configure ISE/ISE-PIC 1750
Configure Security Groups and SXP Publishing in ISE 1751
Export Certificates from the ISE/ISE-PIC Server for Use in the FMC 1753
Export a System Certificate 1754
Generate a Self-Signed Certificate 1755
Import ISE/ISE-PIC Certificates 1755
Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues 1756
History for ISE/ISE-PIC 1758

CHAPTER 61 User Control with Captive Portal 1761
The Captive Portal Identity Source 1761
About Hostname Redirect 1762
License Requirements for Captive Portal 1762
Requirements and Prerequisites for Captive Portal 1762
Captive Portal Guidelines and Limitations 1762
How to Configure the Captive Portal for User Control 1765
Configure the Captive Portal Part 1: Create a Network Object 1766
Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule 1768
Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule 1770

Configure the Captive Portal Part 4: Create a User Access Control Rule 1771
Configure Captive Portal Part 5: Create an SSL Policy with a Decrypt-Resign Rule 1772
Configure Captive Portal Part 6: Associate Identity and SSL Policies with the Access Control Policy 1773
Captive Portal Fields 1774
Exclude Applications from Captive Portal 1775
Troubleshoot the Captive Portal Identity Source 1776
History for Captive Portal 1777

CHAPTER 62 **User Control with Remote Access VPN 1779**
The Remote Access VPN Identity Source 1779
Configure RA VPN for User Control 1780
Troubleshoot the Remote Access VPN Identity Source 1780
Not Observing Correct Settings for VPN Statistics 1781
History for RA VPN 1782

CHAPTER 63 **User Control with TS Agent 1783**
The Terminal Services (TS) Agent Identity Source 1783
TS Agent Guidelines 1784
User Control with TS Agent 1784
Troubleshoot the TS Agent Identity Source 1784
History for TS Agent 1785

CHAPTER 64 **User Identity Policies 1787**
About Identity Policies 1787
License Requirements for Identity Policies 1788
Requirements and Prerequisites for Identity Policies 1788
Create an Identity Policy 1789
Create an Identity Mapping Filter 1790
Identity Rule Conditions 1791
Security Zone Rule Conditions 1791
Security Zone Conditions and Multitenancy 1792
Network Rule Conditions 1792
Redirect to Host Name Network Rule Conditions 1792

VLAN Tags Rule Conditions 1793
Port Rule Conditions 1793
Port, Protocol, and ICMP Code Rule Conditions 1794
Realm & Settings Rule Conditions 1795
Create an Identity Rule 1797
Identity Rule Fields 1798
Manage an Identity Policy 1799
Manage an Identity Rule 1800
Troubleshoot User Control 1800

PART XII **Network Discovery** 1803

CHAPTER 65 **Network Discovery Overview** 1805
About Detection of Host, Application, and User Data 1805
Host and Application Detection Fundamentals 1806
Passive Detection of Operating System and Host Data 1806
Active Detection of Operating System and Host Data 1806
Current Identities for Applications and Operating Systems 1807
Current User Identities 1808
Application and Operating System Identity Conflicts 1809
NetFlow Data 1809
Requirements for Using NetFlow Data 1810
Differences between NetFlow and Managed Device Data 1810

CHAPTER 66 **Host Identity Sources** 1813
Overview: Host Data Collection 1813
Requirements and Prerequisites for Host Identity Sources 1814
Determining Which Host Operating Systems the System Can Detect 1814
Identifying Host Operating Systems 1814
Custom Fingerprinting 1815
Managing Fingerprints 1816
Activating and Deactivating Fingerprints 1816
Editing an Active Fingerprint 1817
Editing an Inactive Fingerprint 1817

Creating a Custom Fingerprint for Clients 1818
Creating a Custom Fingerprint for Servers 1820
Host Input Data 1823
Requirements for Using Third-Party Data 1823
Third-Party Product Mappings 1824
Mapping Third-Party Products 1824
Mapping Third-Party Product Fixes 1825
Mapping Third-Party Vulnerabilities 1826
Custom Product Mappings 1827
Creating Custom Product Mappings 1827
Editing Custom Product Mapping Lists 1828
Activating and Deactivating Custom Product Mappings 1829
Configuring the Host Input Client 1829
Nmap Scanning 1830
Nmap Remediation Options 1831
Nmap Scanning Guidelines 1835
Example: Using Nmap to Resolve Unknown Operating Systems 1836
Example: Using Nmap to Respond to New Hosts 1837
Managing Nmap Scanning 1838
Adding an Nmap Scan Instance 1839
Editing an Nmap Scan Instance 1840
Adding an Nmap Scan Target 1841
Editing an Nmap Scan Target 1842
Creating an Nmap Remediation 1842
Editing an Nmap Remediation 1844
Running an On-Demand Nmap Scan 1845
Nmap Scan Results 1845
Viewing Nmap Scan Results 1846
Nmap Scan Results Fields 1847
Importing Nmap Scan Results 1847
History for Host Identity Sources 1848

CHAPTER 67 **Application Detection** 1849
Overview: Application Detection 1849

Application Detector Fundamentals 1850
Identification of Application Protocols in the Web Interface 1851
Implied Application Protocol Detection from Client Detection 1852
Host Limits and Discovery Event Logging 1852
Special Considerations for Application Detection 1853
Application Detection in Snort 3 1854
Requirements and Prerequisites for Application Detection 1855
Custom Application Detectors 1855
Custom Application Detector and User-Defined Application Fields 1855
Configuring Custom Application Detectors 1858
Creating a User-Defined Application 1859
Specifying Detection Patterns in Basic Detectors 1860
Specifying Detection Criteria in Advanced Detectors 1861
Specifying EVE Process Assignments 1862
Testing a Custom Application Protocol Detector 1863
Viewing or Downloading Detector Details 1864
Sorting the Detector List 1864
Filtering the Detector List 1864
Filter Groups for the Detector List 1865
Navigating to Other Detector Pages 1866
Activating and Deactivating Detectors 1866
Editing Custom Application Detectors 1867
Deleting Detectors 1868

CHAPTER 68 **Network Discovery Policies** 1869
Overview: Network Discovery Policies 1869
Requirements and Prerequisites for Network Discovery Policies 1870
Network Discovery Customization 1870
Configuring the Network Discovery Policy 1871
Network Discovery Rules 1871
Configuring Network Discovery Rules 1872
Actions and Discovered Assets 1872
Monitored Networks 1873
Port Exclusions 1875

Zones in Network Discovery Rules 1877
The Traffic-Based Detection Identity Source 1877
Configuring Advanced Network Discovery Options 1880
Network Discovery General Settings 1881
Configuring Network Discovery General Settings 1881
Network Discovery Identity Conflict Settings 1881
Configuring Network Discovery Identity Conflict Resolution 1882
Network Discovery Vulnerability Impact Assessment Options 1882
Enabling Network Discovery Vulnerability Impact Assessment 1883
Indications of Compromise 1883
Enabling Indications of Compromise Rules 1884
Adding NetFlow Exporters to a Network Discovery Policy 1884
Network Discovery Data Storage Settings 1885
Configuring Network Discovery Data Storage 1886
Configuring Network Discovery Event Logging 1887
Adding Network Discovery OS and Server Identity Sources 1887
Troubleshooting Your Network Discovery Strategy 1888

PART XIII **FlexConfig Policies** 1891

CHAPTER 69 **FlexConfig Policies** 1893
FlexConfig Policy Overview 1893
Recommended Usage for FlexConfig Policies 1893
CLI Commands in FlexConfig Objects 1894
Determine the ASA Software Version and Current CLI Configuration 1894
Prohibited CLI Commands 1895
Template Scripts 1897
FlexConfig Variables 1897
How to Process Variables 1898
How to See What a Variable Will Return for a Device 1901
FlexConfig Policy Object Variables 1902
FlexConfig System Variables 1903
Predefined FlexConfig Objects 1904
Predefined Text Objects 1908

Requirements and Prerequisites for FlexConfig Policies 1913
Guidelines and Limitations for FlexConfig 1913
Customizing Device Configuration with FlexConfig Policies 1913
Configure FlexConfig Objects 1915
Add a Policy Object Variable to a FlexConfig Object 1918
Configure Secret Keys 1918
Configure FlexConfig Text Objects 1919
Configure the FlexConfig Policy 1921
Set Target Devices for a FlexConfig Policy 1922
Preview the FlexConfig Policy 1922
Verify the Deployed Configuration 1923
Remove Features Configured Using FlexConfig 1925
Convert from FlexConfig to Managed Feature 1927
Examples for FlexConfig 1927
How to Configure Precision Time Protocol (ISA 3000) 1927
How to Configure Automatic Hardware Bypass for Power Failure (ISA 3000) 1931
How to Configure Policy Based Routing 1933
History for FlexConfig 1942

PART XIV **Advanced Network Analysis and Preprocessing** 1945

CHAPTER 70 **Advanced Access Control Settings for Network Analysis and Intrusion Policies** 1947
About Advanced Access Control Settings for Network Analysis and Intrusion Policies 1947
Requirements and Prerequisites for Advanced Access Control Settings for Network Analysis and Intrusion Policies 1947
Inspection of Packets That Pass Before Traffic Is Identified 1948
Best Practices for Handling Packets That Pass Before Traffic Identification 1948
Specify a Policy to Handle Packets That Pass Before Traffic Identification 1948
Advanced Settings for Network Analysis Policies 1949
Setting the Default Network Analysis Policy 1950
Network Analysis Rules 1951

Getting Started with Device Configuration

- Device Management, on page 1
- Device Settings, on page 43
- Users, on page 89
- Configuration Deployment, on page 109

CHAPTER 1

Device Management

You can add and manage devices in the Firepower Management Center.

- About Device Management, on page 1
- Requirements and Prerequisites for Device Management, on page 9
- Log Into the Command-Line Interface on the Device, on page 10
- Complete the FTD Initial Configuration, on page 11
- Manage Devices, on page 25
- Switch Managers, on page 32
- Hot Swap an SSD on the Secure Firewall 3100, on page 38
- History for Device Management, on page 41

About Device Management

Use the FMC to manage your devices.

About the FMC and Device Management

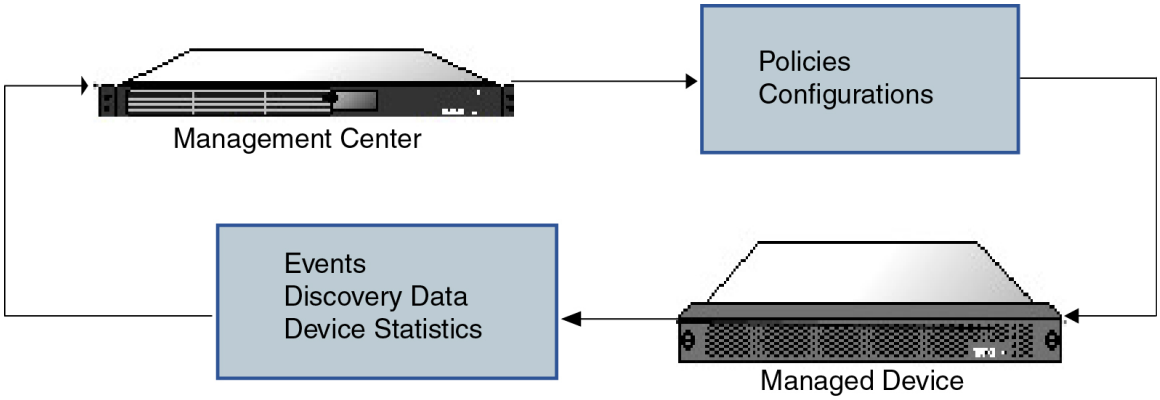
When the FMC manages a device, it sets up a two-way, SSL-encrypted communication channel between itself and the device. The FMC uses this channel to send information to the device about how you want to analyze and manage your network traffic to the device. As the device evaluates the traffic, it generates events and sends them to the FMC using the same channel.

By using the FMC to manage devices, you can:

- configure policies for all your devices from a single location, making it easier to change configurations
- install various types of software updates on devices
- push health policies to your managed devices and monitor their health status from the FMC

The FMC aggregates and correlates intrusion events, network discovery information, and device performance data, allowing you to monitor the information that your devices are reporting in relation to one another, and to assess the overall activity occurring on your network.

You can use the FMC to manage nearly every aspect of a device's behavior.



Note Although the FMC can manage devices running certain previous releases as specified in the compatibility matrix available at http://www.cisco.com/c/en/us/support/security/defense-center/products-device-support-tables-list.html, new features that require the latest version of FTD software are not available to these previous-release devices. Some FMC features may be available for earlier versions.

What Can Be Managed by a Firepower Management Center?

You can use the Firepower Management Center as a central management point to manage FTD devices.

When you manage a device, information is transmitted between the FMC and the device over a secure, TLS-1.3-encrypted communication channel. You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

The following illustration lists what is transmitted between the FMC and its managed devices. Note that the types of events and policies that are sent between the appliances are based on the device type.

About the Management Connection

After you configure the device with the FMC information and after you add the device to the FMC, either the device or the FMC can establish the management connection. Depending on initial setup:

- Either the device or the FMC can initiate.
- Only the device can initiate.
- Only the FMC can initiate.

Initiation always originates with eth0 on the FMC or with the lowest-numbered management interface on the device. Additional management interfaces are tried if the connection is not established. Multiple management interfaces on the FMC let you connect to discrete networks or to segregate management and event traffic. However, the initiator does not choose the best interface based on the routing table.

Make sure the management connection is stable, without excessive packet loss, with at least 5 Mbps throughput. By default, the management connection uses TCP port 8305 (this port is configurable). If you place another FTD between devices and the FMC, to prevent potential management disruption, be sure to exempt management traffic from deep inspection by applying a prefilter policy for it.

Note The management connection is a secure, TLS-1.3-encrypted communication channel between itself and the device. You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

Beyond Policies and Events

In addition to deploying policies to devices and receiving events from them, you can also perform other device-related tasks on the FMC.

Backing Up a Device

You cannot backup a physical managed device from the FTD CLI. To back up configuration data, and, optionally, unified files, perform a backup of the device using the FMC that is managing the device.

To back up event data, perform a backup of the FMC that is managing the device.

Updating Devices

From time to time, Cisco releases updates to the Firepower System, including:

- intrusion rule updates, which may contain new and updated intrusion rules
- vulnerability database (VDB) updates
- geolocation updates
- software patches and updates

You can use the FMC to install an update on the devices it manages.

About Device Management Interfaces

Each device includes a single dedicated Management interface for communicating with the FMC. You can optionally configure the device to use a data interface for management instead of the dedicated Management interface.

You can perform initial setup on the management interface, or on the console port.

Management interfaces are also used to communicate with the Smart Licensing server, to download updates, and to perform other management functions.

Management and Event Interfaces on the FTD

When you set up your device, you specify the FMC IP address or hostname that you want to connect to, if known. In this case, the device initiates the connection, and both management and event traffic go to this address at initial registration. If the FMC is not known, then the FMC establishes the initial connection. In this case, it might initially connect from a different FMC management interface than specified on the FTD. Subsequent connections should use the FMC management interface with the specified IP address.

If the FMC has a separate event-only interface, the managed device sends subsequent event traffic to the FMC event-only interface if the network allows. In addition, some managed-device models include an additional

management interface that you can configure for event-only traffic. Note that if you configure a data interface for management, you cannot use separate management and event interfaces. If the event network goes down, then event traffic reverts to the regular management interfaces on the FMC and/or on the managed device.

Using the FTD Data Interface for Management

You can use either the dedicated Management interface or a regular data interface for communication with the FMC. Manager access on a data interface is useful if you want to manage the FTD remotely from the outside interface, or you do not have a separate management network.

Manager Access Requirements

Manager access from a data interface has the following requirements.

- You can only enable manager access on one physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the FTD and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the FMC. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For FTDv on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- You cannot use separate management and event-only interfaces.
- Clustering is not supported. You must use the Management interface in this case.
- High availability is not supported. You must use the Management interface in this case.

Management Interface Support Per Device Model

See the hardware installation guide for your model for the management interface locations.

Note For the Firepower 4100/9300, the MGMT interface is for *chassis* management, not for FTD logical device management. You must configure a separate interface to be of type mgmt (and/or firepower-eventing), and then assign it to the FTD logical device.

Note For the FTD on any chassis, the physical management interface is shared between the Diagnostic logical interface, which is useful for SNMP or syslog, and is configured along with data interfaces in the FMC, and the Management logical interface for the FMC communication. See Management/Diagnostic Interface, on page 351 for more information.

See the following table for supported management interfaces on each managed device model.

Table 1: Management Interface Support on Managed Devices

Model	Management Interface	Optional Event Interface
Firepower 1000	management0 **Note** management0 is the internal name of the Management 1/1 interface.	No Support
Firepower 2100	management0 **Note** management0 is the internal name of the Management 1/1 interface.	No Support
Secure Firewall 3100	management0 **Note** management0 is the internal name of the Management 1/1 interface.	No Support
Firepower 4100 and 9300	management0 **Note** management0 is the internal name of this interface, regardless of the physical interface ID.	management1 **Note** management1 is the internal name of this interface, regardless of the physical interface ID.
ISA 3000	br1 **Note** br1 is the internal name of the Management 1/1 interface.	No support
Firepower Threat Defense Virtual	eth0	No support

Network Routes on Device Management Interfaces

Management interfaces (including event-only interfaces) support only static routes to reach remote networks. When you set up your managed device, the setup process creates a default route to the gateway IP address that you specify. You cannot delete this route; you can only modify the gateway address.

Note The routing for management interfaces is completely separate from routing that you configure for data interfaces. If you configure a data interface for management instead of using the dedicated Management interface, traffic is routed over the backplane to use the data routing table. The information in this section does not apply.

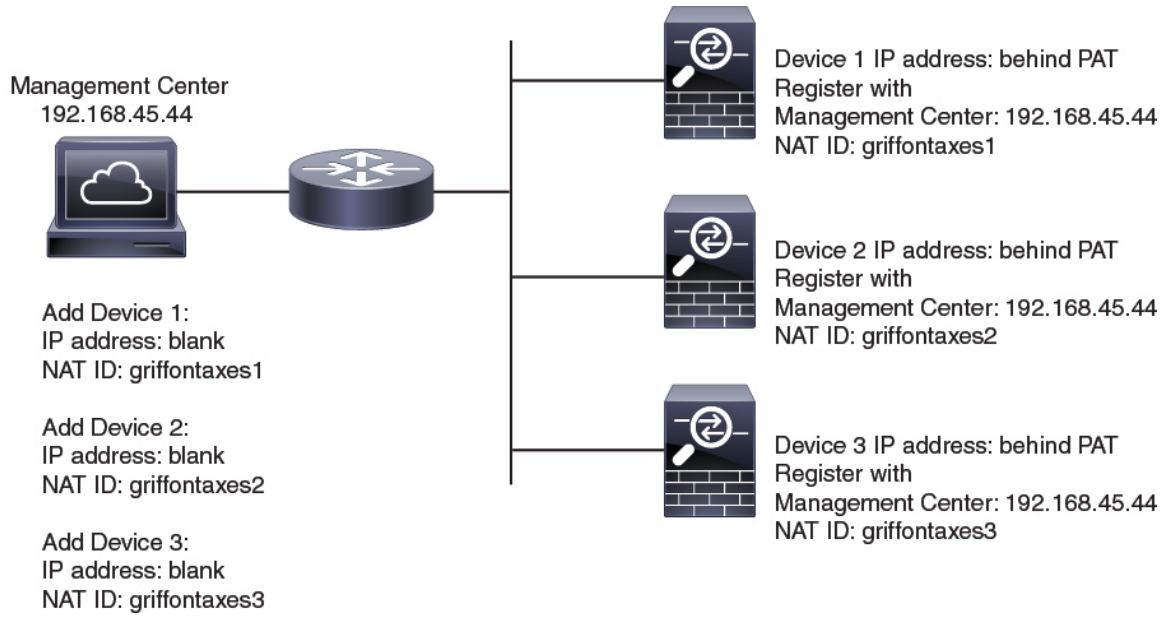
You can configure multiple management interfaces on some platforms (a management interface and an event-only interface). The default route does not include an egress interface, so the interface chosen depends on the gateway address you specify, and which interface's network the gateway belongs to. In the case of multiple interfaces on the default network, the device uses the lower-numbered interface as the egress interface.

At least one static route is recommended per management interface to access remote networks. We recommend placing each interface on a separate network to avoid potential routing problems, including routing problems from other devices to the FTD.

Note The interface used for management connections is not determined by the routing table. Connections are always tried using the lowest-numbered interface first.

NAT Environments

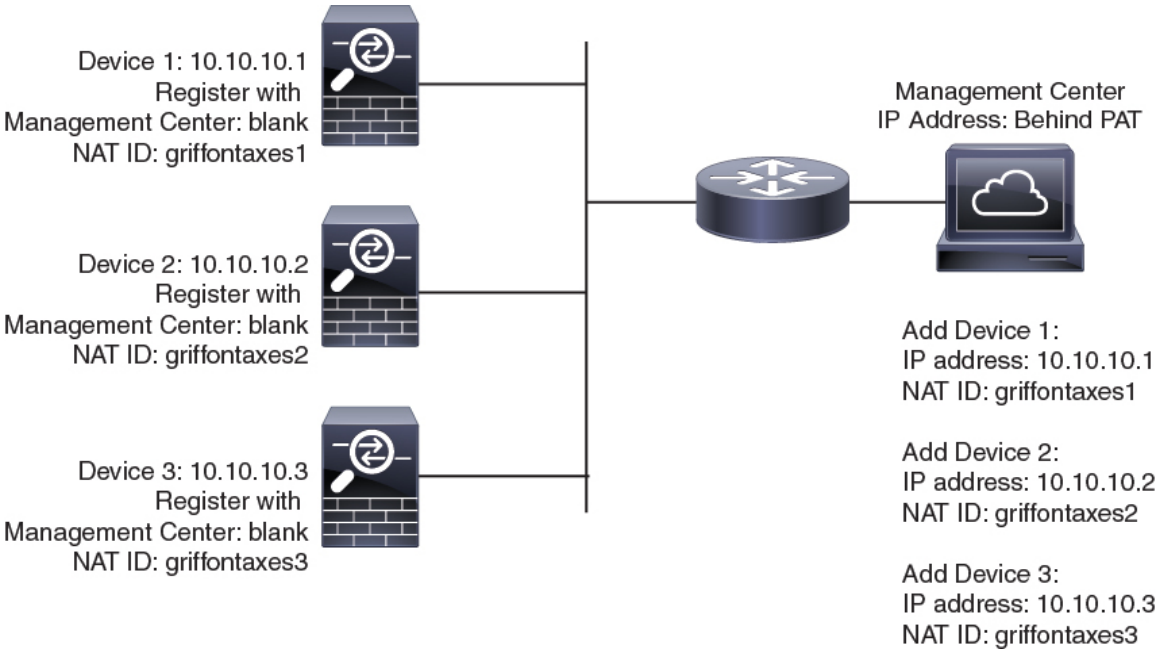
Network address translation (NAT) is a method of transmitting and receiving network traffic through a router that involves reassigning the source or destination IP address. The most common use for NAT is to allow private networks to communicate with the internet. Static NAT performs a 1:1 translation, which does not pose a problem for FMC communication with devices, but port address translation (PAT) is more common. PAT lets you use a single public IP address and unique ports to access the public network; these ports are dynamically assigned as needed, so you cannot initiate a connection to a device behind a PAT router.



Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the FMC specifies the device IP address when you add a device, and the device specifies the FMC IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. The FMC and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

For example, you add a device to the FMC, and you do not know the device IP address (for example, the device is behind a PAT router), so you specify only the NAT ID and the registration key on the FMC; leave the IP address blank. On the device, you specify the FMC IP address, the same NAT ID, and the same registration key. The device registers to the FMC's IP address. At this point, the FMC uses the NAT ID instead of IP address to authenticate the device.

Although the use of a NAT ID is most common for NAT environments, you might choose to use the NAT ID to simplify adding many devices to the FMC. On the FMC, specify a unique NAT ID for each device you want to add while leaving the IP address blank, and then on each device, specify both the FMC IP address and the NAT ID. Note: The NAT ID must be unique per device.

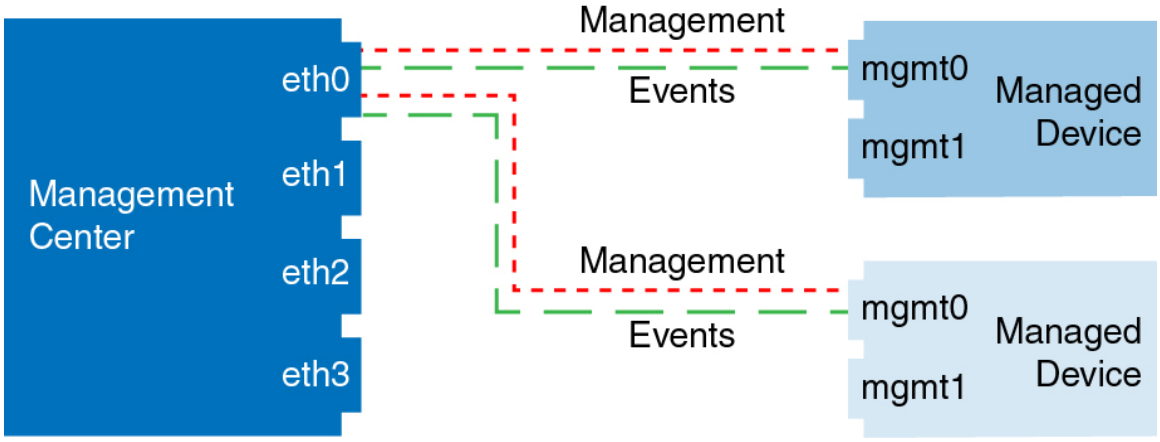


The following example shows three devices behind a PAT IP address. In this case, specify a unique NAT ID per device on both the FMC and the devices, and specify the FMC IP address on the devices.

Figure 1: NAT ID for Managed Devices Behind PAT

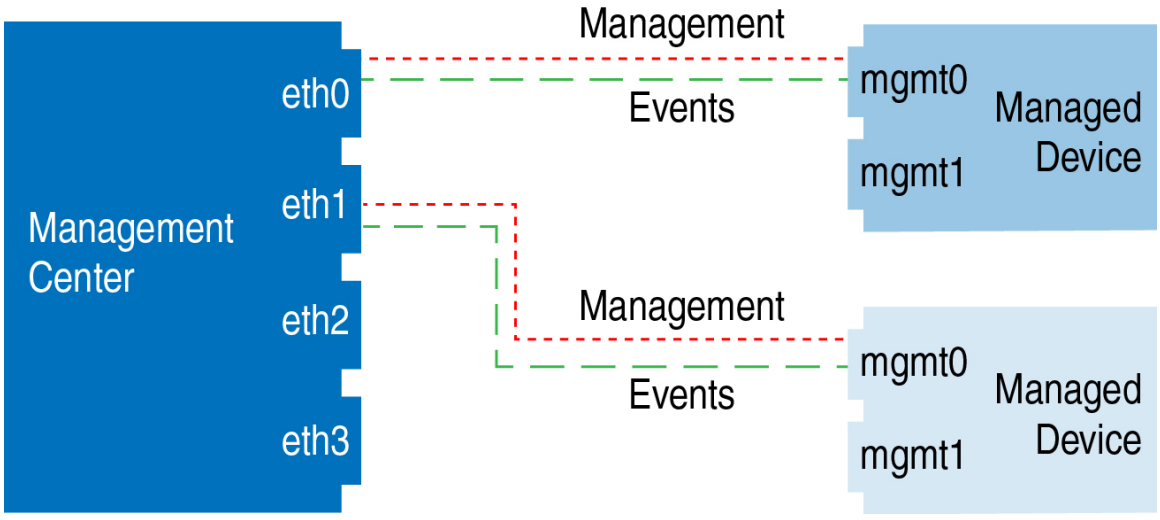
The following example shows the FMC behind a PAT IP address. In this case, specify a unique NAT ID per device on both the FMC and the devices, and specify the device IP addresses on the FMC.

Figure 2: NAT ID for FMC Behind PAT



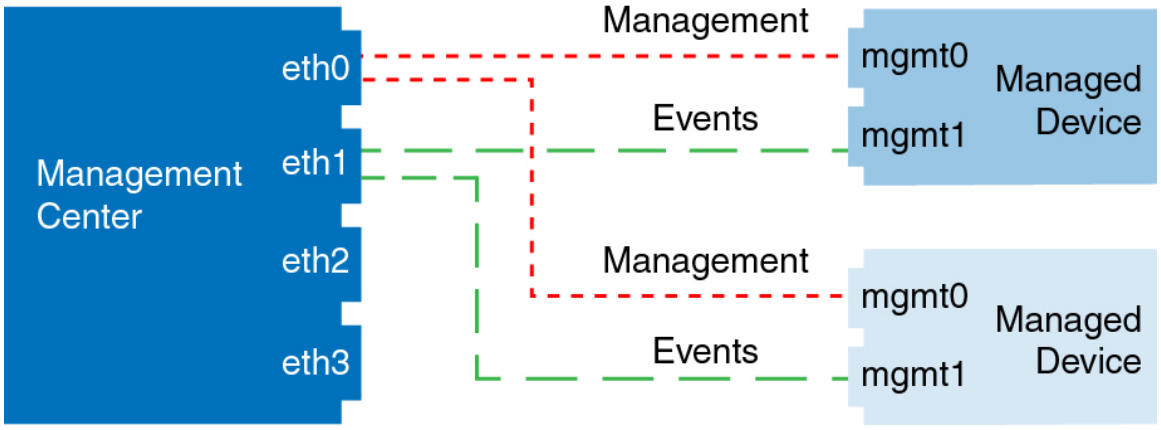
Management and Event Traffic Channel Examples

Note If you use a data interface for management on a FTD, you cannot use separate management and event interfaces for that device.



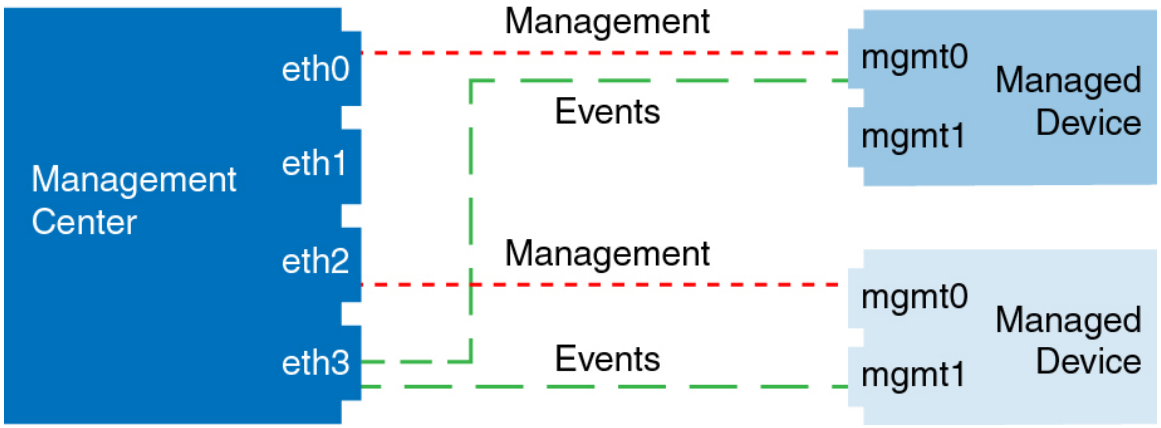
The following example shows the FMC and managed devices using only the default management interfaces.

Figure 3: Single Management Interface on the Firepower Management Center



The following example shows the FMC using separate management interfaces for devices; and each managed device using 1 management interface.

Figure 4: Multiple Management Interfaces on the Firepower Management Center



The following example shows the FMC and managed devices using a separate event interface.

Figure 5: Separate Event Interface on the Firepower Management Center and Managed Devices

The following example shows a mix of multiple management interfaces and a separate event interface on the FMC and a mix of managed devices using a separate event interface, or using a single management interface.

Figure 6: Mixed Management and Event Interface Usage

Requirements and Prerequisites for Device Management

Supported Domains

The domain in which the device resides.

User Roles

- Admin
- Network Admin

Management Connection

Make sure the management connection is stable, without excessive packet loss, with at least 5Mbps throughput.

Log Into the Command-Line Interface on the Device

You can log directly into the command-line interface on FTD devices. If this is your first time logging in, complete the initial setup process using the default **admin** user; see Complete the FTD Initial Configuration Using the CLI, on page 17.

Note If a user makes three consecutive failed attempts to log into the CLI via SSH, the system terminates the SSH connection.

Before you begin

- Create additional user accounts that can log into the CLI using the **configure user add** command.
- If you get unreadable characters when connecting to the console port, verify the port settings. If they are correct, try the cable with another device using the same settings. If the cable is good, you might need to replace the hardware for the console port. Also consider trying a different workstation to make the connection.

Procedure

Step 1 Connect to the FTD CLI, either from the console port or using SSH.

You can SSH to the management interface of the FTD device. You can also connect to the address on a data interface if you open the interface for SSH connections. SSH access to data interfaces is disabled by default. See Secure Shell, on page 492 to allow SSH connections to specific data interfaces.

For physical devices, you can directly connect to the console port on the device. See the hardware guide for your device for more information about the console cable. Use the following serial settings:

- 9600 baud
- 8 data bits
- No parity
- 1 stop bit

The CLI on the console port is FXOS (with the exception of the ISA 3000, where it is the regular FTD CLI). Use the FTD CLI for basic configuration, monitoring, and normal system troubleshooting. See the FXOS documentation for information on FXOS commands.

Step 2 Log in with the **admin** username and password.

Example:

```
firepower login: admin
Password:
Last login: Thu May 16 14:01:03 UTC 2019 on ttyS0
Successful login attempts for user 'admin' : 1
```

```
firepower#
```

Step 3 If you used the console port, access the FTD CLI.

connect ftd

Note
This step does not apply to the ISA 3000.

Example:

```
firepower# connect ftd
>
```

Step 4 At the CLI prompt (>), use any of the commands allowed by your level of command line access.

To return to FXOS on the console port, enter **exit**.

Step 5 (Optional) If you used SSH, you can connect to FXOS.

connect fxos

To return to the FTD CLI, enter **exit**.

Step 6 (Optional) Access the diagnostic CLI:

system support diagnostic-cli

Use this CLI for advanced troubleshooting. This CLI includes additional **show** and other commands.

This CLI has submodes: user EXEC mode, privileged EXEC mode. More commands are available in privileged EXEC mode than user EXEC mode. To enter privileged EXEC mode, enter the **enable** command; press enter without entering a password when prompted.

Example:

```
> system support diagnostic-cli
firepower> enable
Password:
firepower#
```

To return to the regular CLI, type **Ctrl-a**, **d**.

Complete the FTD Initial Configuration

You can complete the FTD initial configuration using the CLI or the FDM for all models except for the Firepower 4100/9300. For the Firepower 4100/9300, you complete initial configuration when you deploy the logical device. See Logical Devices on the Firepower 4100/9300, on page 153.

Complete the FTD Initial Configuration Using the FDM

When you use the FDM for initial setup, the following interfaces are preconfigured in addition to the Management interface and manager access settings:

- Ethernet 1/1—"outside", IP address from DHCP, IPv6 autoconfiguration
- Ethernet 1/2 (or for the Firepower 1010, the VLAN1 interface)— "inside", 192.168.95.1/24
- Default route—Obtained through DHCP on the outside interface

Note that other settings, such as the DHCP server on inside, access control policy, or security zones, are not configured.

If you perform additional interface-specific configuration within FDM before registering with the FMC, then that configuration is preserved.

When you use the CLI, only the Management interface and manager access settings are retained (for example, the default inside interface configuration is not retained).

- This procedure applies to all devices except for the Firepower 4100/9300 and the ISA 3000. You can use the FDM to onboard these devices to the FMC, but because they have different default configurations than other platforms, the details in this procedure may not apply to these platforms.

Procedure

Step 1 Log into the FDM.

a) Enter the following URL in your browser.

- Inside—**https://192.168.95.1**.
- Management—**https://***management_ip*. The Management interface is a DHCP client, so the IP address depends on your DHCP server. You will have to set the Management IP address to a static address as part of this procedure, so we recommend that you use the inside interface so you do not become disconnected.

b) Log in with the username **admin**, and the default password **Admin123**.

c) You are prompted to read and accept the End User License Agreement and change the admin password.

Step 2 Use the setup wizard when you first log into the FDM to complete the initial configuration. You can optionally skip the setup wizard by clicking **Skip device setup** at the bottom of the page.

After you complete the setup wizard, in addition to the default configuration for the inside interface, you will have configuration for an outside (Ethernet1/1) interface that will be maintained when you switch to the FMC management.

a) Configure the following options for the outside and management interfaces, and click **Next**.

1. **Outside Interface Address**—This interface is typically the internet gateway, and might be used as your manager access interface. You cannot select an alternative outside interface during initial device setup. The first data interface is the default outside interface.

   If you want to use a different interface from outside (or inside) for manager access, you will have to configure it manually after completing the setup wizard.

   Configure IPv4—The IPv4 address for the outside interface. You can use DHCP or manually enter a static IP address, subnet mask, and gateway. You can also select **Off** to not configure an IPv4 address. You cannot configure PPPoE using the setup wizard. PPPoE may be required if the interface is connected to a DSL modem, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address. You can configure PPPoE after you complete the wizard.

Configure IPv6—The IPv6 address for the outside interface. You can use DHCP or manually enter a static IP address, prefix, and gateway. You can also select **Off** to not configure an IPv6 address.

2. **Management Interface**

   You will not see Management Interface settings if you performed initial setup at the CLI.

   The Management interface settings are used even if you enable manager access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the Management interface DNS servers, and not the data interface DNS servers.

   DNS Servers—The DNS server for the system's management address. Enter one or more addresses of DNS servers for name resolution. The default is the OpenDNS public DNS servers. If you edit the fields and want to return to the default, click **Use OpenDNS** to reload the appropriate IP addresses into the fields.

   Firewall Hostname—The hostname for the system's management address.

b) Configure the **Time Setting (NTP)** and click **Next**.

1. **Time Zone**—Select the time zone for the system.
2. **NTP Time Server**—Select whether to use the default NTP servers or to manually enter the addresses of your NTP servers. You can add multiple servers to provide backups.

c) Select **Start 90 day evaluation period without registration**.

Do not register the FTD with the Smart Software Manager; all licensing is performed on the FMC.

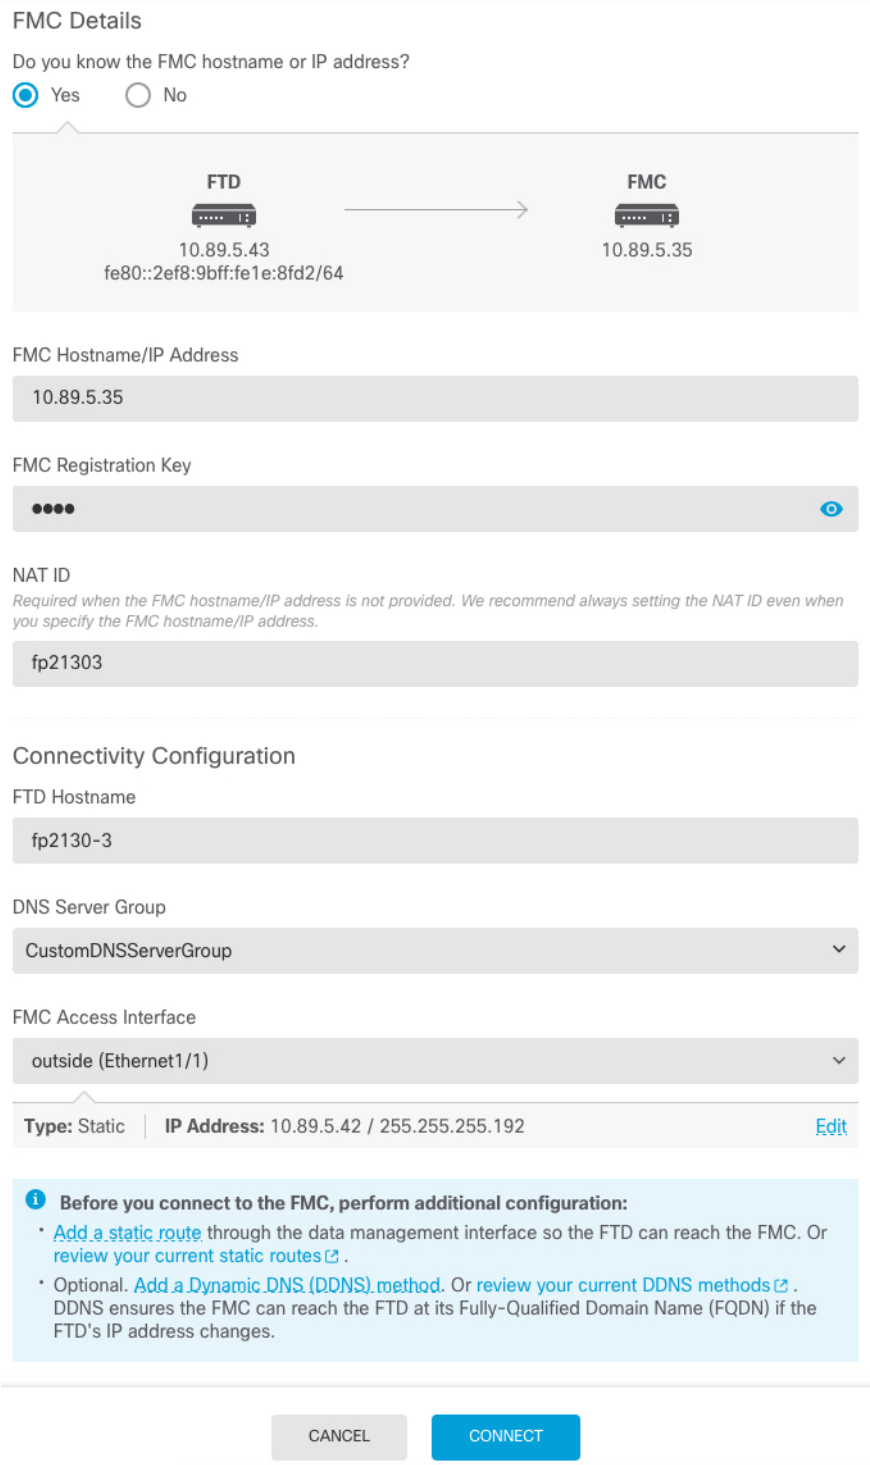
d) Click **Finish**.

e) You are prompted to choose **Cloud Management** or **Standalone**. For FMC management, choose **Standalone**, and then **Got It**.

Step 3 (Might be required) Configure the Management interface.

You may need to change the Management interface configuration, even if you intend to use a data interface for manager access. You will have to reconnect to the FDM if you were using the Management interface for the FDM connection.

- Data interface for manager access—The Management interface must have the gateway set to data interfaces. By default, the Management interface receives an IP address and gateway from DHCP. If you do not receive a gateway from DHCP (for example, you did not connect this interface to a network), then the gateway will default to data interfaces, and you do not need to configure anything. If you did receive a gateway from DHCP, then you need to instead configure this interface with a static IP address and set the gateway to data interfaces.
- Management interface for manager access—If you want to configure a static IP address, be sure to also set the default gateway to be a unique gateway instead of the data interfaces. If you use DHCP, then you do not need to configure anything assuming you successfully get the gateway from DHCP.



Step 4 If you want to configure additional interfaces, including an interface other than outside or inside that you want to use for manager access, choose **Device**, and then click the link in the **Interfaces** summary.

Other FDM configuration will not be retained when you register the device to FMC.

Step 5 Choose **Device** > **System Settings** > **Management Center**, and click **Proceed** to set up the FMC management.

Step 6 Configure the **FMC Details**.

Figure 7: FMC Details

a) For **Do you know the FMC hostname or IP address?**, click **Yes** if you can reach the FMC using an IP address or hostname, or **No** if the FMCCDO is behind NAT or does not have a public IP address or hostname.

At least one of the devices, either the FMC or the FTD device, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices.

b) If you chose **Yes**, then enter the **FMC Hostname/IP Address**.

c) Specify the **FMC Registration Key**.

This key is a one-time registration key of your choice that you will also specify on the FMC when you register the FTD device. The registration key must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID can be used for multiple devices registering to the FMC.

a) Specify a **NAT ID**.

This ID is a unique, one-time string of your choice that you will also specify on the FMC. The NAT ID must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID *cannot* be used for any other devices registering to the FMC. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked. We recommended that you always use the NAT ID even when it is optional, but it is required if:

- You set the FMC IP address to **DONTRESOLVE**.
- When adding the device on the FMC, you do not specify a reachable device IP address or hostname.
- You use the data interface for management, even if you specify IP addresses on both sides.
- The FMC uses multiple management interfaces.

Step 7 Configure the **Connectivity Configuration**.

a) Specify the **FTD Hostname**.

If you use a data interface for the **FMC Access Interface** access, then this FQDN will be used for this interface.

b) Specify the **DNS Server Group**.

Choose an existing group, or create a new one. The default DNS group is called **CiscoUmbrellaDNSServerGroup**, which includes the OpenDNS servers.

If you intend to choose a data interface for the **FMC Access Interface**, then this setting sets the *data* interface DNS server. The Management DNS server that you set with the setup wizard is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface. You are likely to choose the same DNS server group that you used for Management, because both management and data traffic reach the DNS server through the outside interface.

On the FMC, the data interface DNS servers are configured in the Platform Settings policy that you assign to this FTD device. When you add the FTD device to the FMC, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the FTD device that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the FMC and the FTD device into sync.

Also, local DNS servers are only retained by the FMC if the DNS servers were discovered at initial registration.

If you intend to choose the Management interface for the **FMC Access Interface**, then this setting configures the Management DNS server.

c) For the **FMC Access Interface**, choose any configured interface.

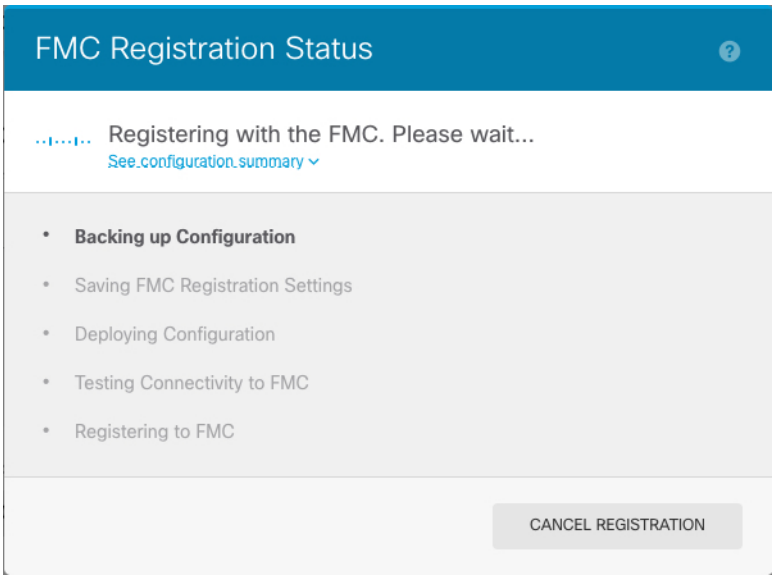
You can change the manager interface after you register the FTD device to the FMC, to either the Management interface or another data interface.

Step 8 (Optional) If you chose a data interface, and it was not the outside interface, then add a default route.

You will see a message telling you to check that you have a default route through the interface. If you chose outside, you already configured this route as part of the setup wizard. If you chose a different interface, then you need to manually configure a default route before you connect to the FMC.

If you chose the Management interface, then you need to configure the gateway to be a unique gateway before you can proceed on this screen.

Step 9 (Optional) If you chose a data interface, click **Add a Dynamic DNS (DDNS) method**.



DDNS ensures the FMC can reach the FTD device at its Fully-Qualified Domain Name (FQDN) if the IP address changes. See **Device** > **System Settings** > **DDNS Service** to configure DDNS.

If you configure DDNS before you add the FTD device to the FMC, the FTD device automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the FTD device can validate the DDNS server certificate for the HTTPS connection. FTD supports any DDNS server that uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

DDNS is not supported when using the Management interface for manager access.

Step 10 Click **Connect**. The **FMC Registration Status** dialog box shows the current status of the switch to the FMC. After the **Saving FMC Registration Settings** step, go to the FMC, and add the firewall.

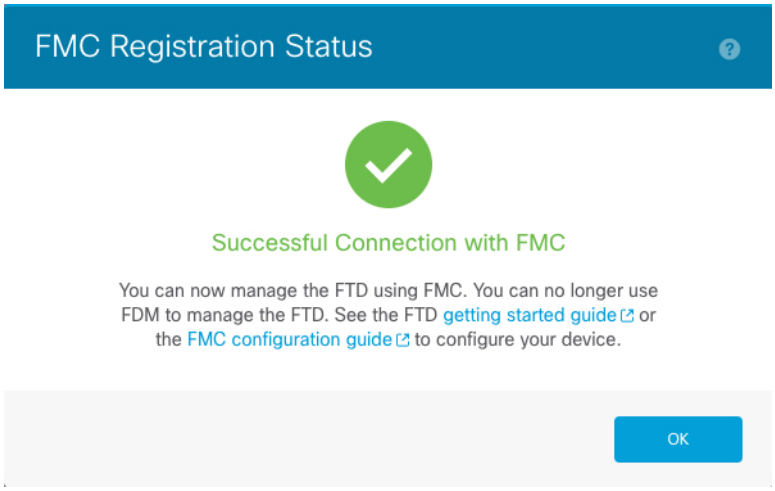


Figure 8: FMC Registration Status

If you want to cancel the switch to the FMC, click **Cancel Registration**. Otherwise, do not close the FDM browser window until after the **Saving FMC Registration Settings** step. If you do, the process will be paused, and will only resume when you reconnect to the FDM.

If you remain connected to the FDM after the **Saving FMC Registration Settings** step, you will eventually see the **Successful Connection with FMC** dialog box, after which you will be disconnected from the FDM.

Figure 9: Successful Connection with FMC

Complete the FTD Initial Configuration Using the CLI

Connect to the FTD CLI to perform initial setup, including setting the Management IP address, gateway, and other basic networking settings using the setup wizard. The dedicated Management interface is a special interface with its own network settings. If you do not want to use the Management interface for manager access, you can use the CLI to configure a data interface instead. You will also configure FMC communication settings. When you perform initial setup using the FDM, *all* interface configuration completed in the FDM is retained when you switch to the FMC for management, in addition to the Management interface and manager access interface settings. Note that other default configuration settings, such as the access control policy, are not retained.

This procedure applies to all models except for the Firepower 4100/9300. To deploy a logical device and complete initial configuration on the Firepower 4100/9300, see Logical Devices on the Firepower 4100/9300, on page 153.

Procedure

Step 1 Connect to the FTD CLI, either from the console port or using SSH to the Management interface, which obtains an IP address from a DHCP server by default. If you intend to change the network settings, we recommend using the console port so you do not get disconnected.

(Firepower and Secure Firewall hardware models) The console port connects to the FXOS CLI. The SSH session connects directly to the FTD CLI.

Step 2 Log in with the username **admin** and the password **Admin123**.

(Firepower and Secure Firewall hardware models) At the console port, you connect to the FXOS CLI. The first time you log in to FXOS, you are prompted to change the password. This password is also used for the FTD login for SSH.

Note

If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default.

For Firepower and Secure Firewall hardware, see the Reimage Procedures in the Cisco FXOS Troubleshooting Guide for the Firepower 1000/2100 and Secure Firewall 3100/4200 with Threat Defense .

For the ISA 3000, see the Cisco Secure Firewall ASA and Secure Firewall Threat Defense Reimage Guide.

Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1

[...]

Hello admin. You must change your password.
Enter new password: ********
Confirm new password: ********
Your password was updated successfully.

[...]

firepower#
```

Step 3 (Firepower and Secure Firewall hardware models) If you connected to FXOS on the console port, connect to the FTD CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 4 The first time you log in to the FTD, you are prompted to accept the End User License Agreement (EULA) and, if using an SSH connection, to change the admin password. You are then presented with the CLI setup script.

Note
You cannot repeat the CLI setup wizard unless you clear the configuration; for example, by reimaging. However, all of these settings can be changed later at the CLI using **configure network** commands. See the threat defense command reference.

Defaults or previously entered values appear in brackets. To accept previously entered values, press **Enter**.

Note
The Management interface settings are used even when you enable manager access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the Management interface DNS servers, and not the data interface DNS servers.

See the following guidelines:

- **Do you want to configure IPv4?** and/or **Do you want to configure IPv6?**—Enter **y** for at least one of these types of addresses.

- **Enter the IPv4 default gateway for the management interface** and/or **Enter the IPv6 gateway for the management interface**—If you want to use a data interface for manager access instead of the Management interface, choose **manual**. Although you do not plan to use the Management interface, you must set an IP address, for example, a private address. Make sure this interface is on a different subnet from the manager access interface to prevent routing issues. You cannot configure a data interface for management if the management interface is set to DHCP, because the default route, which must be **data-interfaces** (see the next bullet), might be overwritten with one received from the DHCP server.
- **Enter the IPv4 default gateway for the management interface** and/or **Configure IPv6 via DHCP, router, or manually?**—If you want to use a data interface for manager access instead of the management interface, set the gateway to be **data-interfaces**. This setting forwards management traffic over the backplane so it can be routed through the manager access data interface. If you want to use the Management interface for manager access, you should set a gateway IP address on the Management 1/1 network.
- **If your networking information has changed, you will need to reconnect**—If you are connected with SSH but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected.
- **Manage the device locally?**—Enter **no** to use the FMC. A **yes** answer means you will use Firepower Device Manager instead.
- **Configure firewall mode?**—We recommend that you set the firewall mode at initial configuration. Changing the firewall mode after initial setup erases your running configuration. Note that data interface manager access is only supported in routed firewall mode.

Example:

```
You must accept the EULA to continue.
Press <ENTER> to display the EULA:
Cisco General Terms
[...]

Please enter 'YES' or press <ENTER> to AGREE to the EULA:

System initialization in progress.  Please stand by.
You must configure the network to continue.
Configure at least one of IPv4 or IPv6 unless managing via data interfaces.
Do you want to configure IPv4? (y/n) [y]:
Do you want to configure IPv6? (y/n) [y]: n
Configure IPv4 via DHCP or manually? (dhcp/manual) [manual]:
Enter an IPv4 address for the management interface [192.168.45.61]: 10.89.5.17
Enter an IPv4 netmask for the management interface [255.255.255.0]: 255.255.255.192
Enter the IPv4 default gateway for the management interface [data-interfaces]: 10.89.5.1
Enter a fully qualified hostname for this system [firepower]: 1010-3
Enter a comma-separated list of DNS servers or 'none'
[208.67.222.222,208.67.220.220,2620:119:35::35]:
Enter a comma-separated list of search domains or 'none' []: cisco.com
If your networking information has changed, you will need to reconnect.
Disabling IPv6 configuration: management0
Setting DNS servers: 208.67.222.222,208.67.220.220,2620:119:35::35
Setting DNS domains:cisco.com
Setting hostname as 1010-3
Setting static IPv4: 10.89.5.17 netmask: 255.255.255.192 gateway: 10.89.5.1 on management0
Updating routing tables, please wait...
All configurations applied to the system. Took 3 Seconds.
Saving a copy of running network configuration to local disk.
For HTTP Proxy configuration, run 'configure network http-proxy'
```

```
Manage the device locally? (yes/no) [yes]: no
DHCP server is already disabled
DHCP Server Disabled
Configure firewall mode? (routed/transparent) [routed]:
Configuring firewall mode ...

Device is in OffBox mode - disabling/removing port 443 from iptables.
Update policy deployment information
    - add device configuration
    - add network discovery
    - add system policy

You can register the sensor to a Firepower Management Center and use the
Firepower Management Center to manage it. Note that registering the sensor
to a Firepower Management Center disables on-sensor Firepower Services
management capabilities.

When registering the sensor to a Firepower Management Center, a unique
alphanumeric registration key is always required.  In most cases, to register
a sensor to a Firepower Management Center, you must provide the hostname or
the IP address along with the registration key.
'configure manager add [hostname | ip address ] [registration key ]'

However, if the sensor and the Firepower Management Center are separated by a
NAT device, you must enter a unique NAT ID, along with the unique registration
key.
'configure manager add DONTRESOLVE [registration key ] [ NAT ID ]'

Later, using the web interface on the Firepower Management Center, you must
use the same registration key and, if necessary, the same NAT ID when you add
this sensor to the Firepower Management Center.
>
```

Step 5 Identify the FMC that will manage this FTD.

configure manager add {*hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE**} *reg_key* [*nat_id*]

- {*hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE**}—Specifies either the FQDN or IP address of the FMC. If the FMC is not directly addressable, use **DONTRESOLVE** and also specify the *nat_id*. At least one of the devices, either the FMC or the FTD, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you specify **DONTRESOLVE** in this command, then the FTD must have a reachable IP address or hostname.
- *reg_key*—Specifies a one-time registration key of your choice that you will also specify on the FMC when you register the FTD. The registration key must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).
- *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the FMC when you register the FTD. The NAT ID must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the FMC. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked. We recommended that you always use the NAT ID even when it is optional, but it is required if:
  - You set the FMC IP address to **DONTRESOLVE**.
  - When adding the device on the FMC, you do not specify a reachable device IP address or hostname.
  - You use the data interface for management, even if you specify IP addresses on both sides.

- The FMC uses multiple management interfaces.

Example:

```
> configure manager add MC.example.com 123456
Manager successfully configured.
```

Example:

If the FMC is behind a NAT device, enter a unique NAT ID along with the registration key, and specify DONTRESOLVE instead of the hostname, for example:

```
> configure manager add DONTRESOLVE regk3y78 natid90
Manager successfully configured.
```

Example:

If the FTD is behind a NAT device, enter a unique NAT ID along with the FMC IP address or hostname, for example:

```
> configure manager add 10.70.45.5 regk3y78 natid56
Manager successfully configured.
```

Step 6 (Optional) Configure a data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

Note
You should use the console port when using this command. If you use SSH to the Management interface, you might get disconnected and have to reconnect to the console port. See below for more information about SSH usage.

See the following details for using this command. See also Using the FTD Data Interface for Management, on page 4.

- The original Management interface cannot use DHCP if you want to use a data interface for management. If you did not set the IP address manually during initial setup, you can set it now using the **configure network** {**ipv4** | **ipv6**} **manual** command. Make sure this interface is on a different subnet from the manager access interface to prevent routing issues. If you did not already set the Management interface gateway to **data-interfaces**, this command will set it now.
- When you add the FTD to the FMC, the FMC discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For more information about the DNS server configuration, see below. In the FMC, you can later make changes to the manager access interface configuration, but make sure you don't make changes that can prevent the FTD or FMC from re-establishing the management connection. If the management connection is disrupted, the FTD includes the **configure policy rollback** command to restore the previous deployment.
- DDNS ensures the FMC can reach the FTD at its Fully-Qualified Domain Name (FQDN) if the IP address changes. If you configure a DDNS server update URL, the FTD automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the FTD can validate the DDNS server certificate for the HTTPS connection. The FTD supports any DDNS server that uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

- This command sets the *data* interface DNS server. The Management DNS server that you set with the setup script (or using the **configure network dns servers** command) is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface.

  On the FMC, the data interface DNS servers are configured in the Platform Settings policy that you assign to this FTD. When you add the FTD to the FMC, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the FTD that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the FMC and the FTD into sync.

  Also, local DNS servers are only retained by the FMC if the DNS servers were discovered at initial registration. For example, if you registered the device using the Management interface, but then later configure a data interface using the **configure network management-data-interface** command, then you must manually configure all of these settings in the FMC, including the DNS servers, to match the FTD configuration.

- You can change the management interface after you register the FTD to the FMC, to either the Management interface or another data interface.
- The FQDN that you set in the setup wizard will be used for this interface.
- You can clear the entire device configuration as part of the command; you might use this option in a recovery scenario, but we do not suggest you use it for initial setup or normal operation.
- To disable data management, enter the **configure network management-data-interface disable** command.

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]:
IP address (manual / dhcp) [dhcp]:
DDNS server update URL [none]:
https://dwinchester:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow manager access from any network,
if you wish to change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:
```

```
Configuration done with option to allow manager access from any network,
if you wish to change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Step 7 (Optional) Limit data interface access to a manager on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

What to do next

Register your device to a FMC.

Configure an Event Interface

You always need a management interface for management traffic. If your device has a second management interface, for example, the Firepower 4100/9300, you can enable it for event-only traffic.

Before you begin

To use a separate event interface, you also need to enable an event interface on the FMC. See the Firepower Management Center Administration Guide.

Procedure

Step 1 Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You can optionally disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

Example:

```
> configure network management-interface enable management1
Configuration updated successfully

> configure network management-interface disable-management-channel management1
Configuration updated successfully
```

```
>
```

Step 2 Configure the IP address of the event interface.

The event interface can be on a separate network from the management interface, or on the same network.

a) Configure the IPv4 address:

configure network ipv4 manual *ip_address netmask gateway_ip* **management1**

Note that the *gateway_ip* in this command is used to create the default route for the device, so you should enter the value you already set for the management0 interface. It does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you create a static route separately for the event-only interface.

Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.

>
```

b) Configure the IPv6 address:

- Stateless autoconfiguration:

  configure network ipv6 router management1

  Example:

  ```
  > configure network ipv6 router management1
  Setting IPv6 network configuration.
  Network settings changed.

  >
  ```

- Manual configuration:

  configure network ipv6 manual *ip6_address ip6_prefix_length* **management1**

  Example:

  ```
  > configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
  Setting IPv6 network configuration.
  Network settings changed.

  >
  ```

Step 3 Add a static route for the event-only interface if the FMC is on a remote network; otherwise, all traffic will match the default route through the management interface.

configure network static-routes {**ipv4** | **ipv6**} **add management1** *destination_ip netmask_or_prefix gateway_ip*

For the *default* route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see, Step 2, on page 24).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully

> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully

>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes
---------------[ IPv4 Static Routes ]---------------
Interface                 : management1
Destination               : 192.168.6.0
Gateway                   : 10.10.10.1
Netmask                   : 255.255.255.0
[…]
```

Manage Devices

The **Devices** > **Device Management** page provides you with range of information and options.

- **View By**—View devices based on group, licenses, model, or access control policy.
- **Device State**—View devices based on state (**Error**, **Warning**, etc.). You can click on a state icon to view the devices belonging to it. The number of devices belonging to the states are provided within brackets.
- **Search Device**—Search for a device by device name, host name, or IP address.
- **Add**—Add devices and other manageable components.
- Columns—Click the column head to sort by that column.
  - **Name**
  - **Model**
  - **Version**
  - **Chassis**—For supported models, click **Manage** to bring up the integrated Chassis Manager. For the Firepower 4100/9300, the link cross-launches the Firepower Chassis Manager.
  - **Licenses**
  - **Access Control Policy**—Click on the link in the Access Control Policy column to view the policy that is deployed to the device.
- **Edit**—For each device, use the **Edit** (✎) icon to edit the device settings.

  You can also just click on the device name or IP address.

- **More**—For each device, click the **More** ( ) icon to execute other actions:
  - **Delete**—To unregister the device.
  - **Packet Tracer**—To navigate to the packet tracer page for examining policy configuration on the device by injecting a model packet into the system.
  - **Packet Capture**—To navigate to the packet capture page, where, you can view the verdicts and actions the system takes while processing a packet.
  - **Revert Upgrade**—To revert the upgrade and configuration changes that were made after the last upgrade. This action results in restoring the device to the version that was before the upgrade.
  - **Health Monitor**—To navigate to the device's health monitoring page.
  - **Troubleshoot Files**—Generate troubleshooting files, where you can choose the type of data to be included in the report.

Add a Device Group

The FMC allows you to group devices so you can easily deploy policies and install updates on multiple devices. You can expand and collapse the list of devices in the group.

If you add the primary device in a high-availability pair to a group, both devices are added to the group. If you break the high-availability pair, both devices remain in that group.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 From the **Add** drop-down menu, choose **Add Group**.

To edit an existing group, click **Edit** ( ) for the group you want to edit.

Step 3 Enter a **Name**.

Step 4 Under **Available Devices**, choose one or more devices to add to the device group. Use Ctrl or Shift while clicking to choose multiple devices.

Step 5 Click **Add** to include the devices you chose in the device group.

Step 6 Optionally, to remove a device from the device group, click **Delete** ( ) next to the device you want to remove.

Step 7 Click **OK** to add the device group.

Register With the Management Center

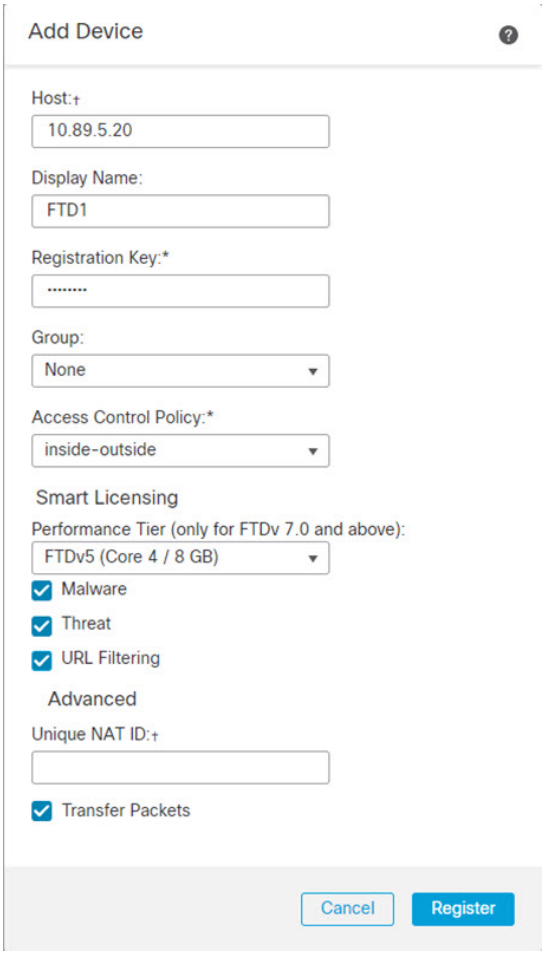
The FMC offers multiple methods to register your devices.

Add a Device

Use this procedure to add a single device to the FMC. If you plan to link devices for high availability, you must still use this procedure; see Add a High Availability Pair, on page 225. For clustering, see the clustering chapter for your model.

If you use FMC high availability, add devices *only* to the active FMC. Devices registered to the active FMC are automatically registered to the standby.

Before you begin



- Set up the device to be managed by the FMC. See:
  - Complete the FTD Initial Configuration, on page 11
  - The getting started guide for your model
- The FMC must be registered to the Smart Software Manager. A valid evaluation license is sufficient, but if it expires, you will not be able to add new devices until you successfully register.
- If you registered a device using IPv4 and want to convert it to IPv6, you must delete and reregister the device.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 From the **Add** drop-down menu, choose **Device**.

Figure 10: Add Device

Step 3 For the **Host**, enter the IP address or the hostname of the device you want to add. Leave this field blank if you don't know the device IP address (for example, it's behind NAT).

If you leave this field blank, the initial configuration on the device needs to include a reachable FMC IP address or hostname plus the NAT ID. For more information, see NAT Environments, on page 6.

Step 4 For the **Display Name**, enter a name for the device as you want it to display in the FMC. You cannot change this name later.

Step 5 For the **Registration Key**, enter the same registration key in your initial configuration. The registration key is a one-time-use shared secret. The key can be up to 37-characters in length and include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). The registration key does not need to be unique per device.

Step 6 (Optional) Add the device to a device **Group**.

Step 7 Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If the device is incompatible with the policy you choose, deploying will fail. This incompatibility could occur for multiple reasons, including licensing mismatches, model restrictions, passive vs inline issues, and other misconfigurations. After you resolve the issue that caused the failure, manually deploy configurations to the device.

Step 8 Choose licenses to apply to the device.

You can also apply licenses after you add the device, from the **System** > **Licenses** > **Smart Licenses** page.

For FTDv, you must also select the **Performance Tier**. It's important to choose the tier that matches the license you have in your account. Until you choose a tier, your device defaults to the FTDv50 selection. For more information about the performance-tiered license entitlements available for FTDv, see *FTDv Licenses* in the Firepower Management Center Administration Guide.

Note
If you are upgrading your FTDv to Version 7.0+, you can choose **FTDv - Variable** to maintain your current license compliance.

Step 9 If you specified a NAT ID during initial configuration, in the **Advanced** section enter the same NAT ID for the **Unique NAT ID**.

The **Unique NAT ID** specifies a unique, one-time string of your choice that you will also specify on the device during initial configuration. It is required when one side does not specify a reachable IP address or hostname, for example if you left the **Host** field blank. Although technically optional, we recommend always specifying the NAT ID even when you know the IP addresses of both sides because it is required in certain situations. The ID can be up to 37-characters in length and include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the FMC.

Step 10 Check **Transfer Packets** so that for each intrusion event, the device transfers the packet to the FMC for inspection.

This option is enabled by default. For each intrusion event, the device sends event information and the packet that triggered the event to the FMC for inspection. If you disable it, only event information will be sent to the FMC; the packet will not be sent.

Step 11 Click **Register**.

It may take up to two minutes for the FMC to verify the device's heartbeat and establish communication. If the registration succeeds, the device is added to the list. If it fails, you will see an error message. If the device fails to register, check the following items:

- Ping—Access the device CLI, and ping the FMC IP address using the following command:

  ping system *ip_address*

  If the ping is not successful, check your network settings using the **show network** command. If you need to change the device IP address, use the **configure network** {**ipv4** | **ipv6**} **manual** command.

- Registration key, NAT ID, and FMC IP address—Make sure you are using the same registration key, and if used, NAT ID, on both devices. You can set the registration key and NAT ID on the device using the **configure manager add** command.

For more troubleshooting information, see https://cisco.com/go/fmc-reg-error.

Register With a New Management Center

This procedure shows how to register with a new FMC. You should perform these steps even if the new FMC uses the old FMC's IP address.

Procedure

Step 1 On the old FMC, if present, delete the managed device. See Delete (Unregister) a Device from the FMC, on page 30.

You cannot change the FMC IP address if you have an active connection with the FMC.

Step 2 Connect to the device CLI, for example using SSH.

Step 3 Configure the new FMC.

configure manager add {*hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *regkey* [*nat_id*]

- {*hostname* | *IPv4_address* | *IPv6_address*}—Sets the FMC hostname, IPv4 address, or IPv6 address.
- **DONTRESOLVE**—If the FMC is not directly addressable, use **DONTRESOLVE** instead of a hostname or IP address. If you use **DONTRESOLVE** , then a *nat_id* is required. When you add this device to the FMC, make sure that you specify both the device IP address and the *nat_id*; one side of the connection needs to specify an IP address, and both sides need to specify the same, unique NAT ID.
- *regkey*—Make up a registration key to be shared between the FMC and the device during registration. You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the FMC when you add the FTD.
- *nat_id*—Make up an alphanumeric string from 1 to 37 characters used only during the registration process between the FMC and the device when one side does not specify an IP address. This NAT ID is a one-time password used only during registration. Make sure the NAT ID is unique, and not used by any other devices awaiting registration. Specify the same NAT ID on the FMC when you add the FTD.

Example:

```
> configure manager add DONTRESOLVE abc123 efg456
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.

>
```

Step 4 Add the device to the FMC.

Delete (Unregister) a Device from the FMC

If you no longer want to manage a device, you can unregister it from the FMC.

To unregister a cluster, cluster node, or high availability pair, see the chapters for those deployments.

Unregistering a device:

- Severs all communication between the FMC and the device.
- Removes the device from the **Device Management** page.
- Returns the device to local time management if the device's platform settings policy is configured to receive time from the FMC using NTP.

- Leaves the configuration intact, so the device continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

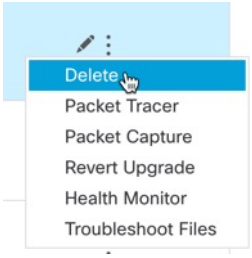
Registering the device again to the same or a different FMC causes the configuration to be removed, so the device will stop processing traffic at that point.

Before you delete the device, be sure to export the configuration so you can re-apply the device-level configuration (interfaces, routing, and so on) when you re-register it. If you do not have a saved configuration, you will have to re-configure device settings.

After you re-add the device and either import a saved configuration or re-configure your settings, you need to deploy the configuration before it starts passing traffic again.

Before you begin

To re-apply the device-level configuration if you re-add it to the FMC:



- Export the device configuration. See Export and Import the Device Configuration, on page 45.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to unregister, click **More** (⋮), and then click **Delete**.

Figure 11: Delete

Step 3 Confirm that you want to unregister the device.

Step 4 You can now change your manager.

- Re-register the device to this FMC—If you know the registration key and NAT ID, you can Add a Device, on page 27. If you need to reset them, you can reconfigure the manager as though it's new. See Register With a New Management Center, on page 29.
- Register to a new FMC—Register With a New Management Center, on page 29.
- Change to the FDM—Switch from FMC to FDM, on page 37.
- Delete the manager without specifying a new one—To sever the management connection on the FTD without identifying a new manager (no manager mode), from the FTD CLI use the **configure manager delete** command.

Shut Down or Restart the Device

It's important that you shut down your system properly. Simply unplugging the power or pressing the power switch can cause serious file system damage. Remember that there are many processes running in the background all the time, and unplugging or shutting off the power does not allow the graceful shutdown of your firewall.

Note The ISA 3000 does not support shutting down; you can only reboot the system.

See the following task to shut down or restart your system properly.

Note After restarting your device, you may see an error that the management connection could not be reestablished. In some cases, the connection is attempted before the Management interface on the device is ready. The connection will be retried automatically and should come up within 15 minutes.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device that you want to restart, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 To restart the device:

a) Click **Restart Device** ( ).
b) When prompted, confirm that you want to restart the device.

Step 5 To shut down the device:

a) Click **Shut Down Device** ( ) in the **System** section.
b) When prompted, confirm that you want to shut down the device.
c) If you have a console connection to the firewall, monitor the system prompts as the firewall shuts down. You will see the following prompt:

```
System is stopped.
It is safe to power off now.
Do you want to reboot instead? [y/N]
```

If you do not have a console connection, wait approximately 3 minutes to ensure the system has shut down.

Switch Managers

You can change between managers if needed.

Switch from the FDM to the FMC

When you switch from the FDM to the FMC, all interface configuration is retained, in addition to the Management interface and the manager access settings. Note that other configuration settings, such as the access control policy or security zones, are not retained.

After you switch to the FMC, you can no longer use the FDM to manage the FTD device.

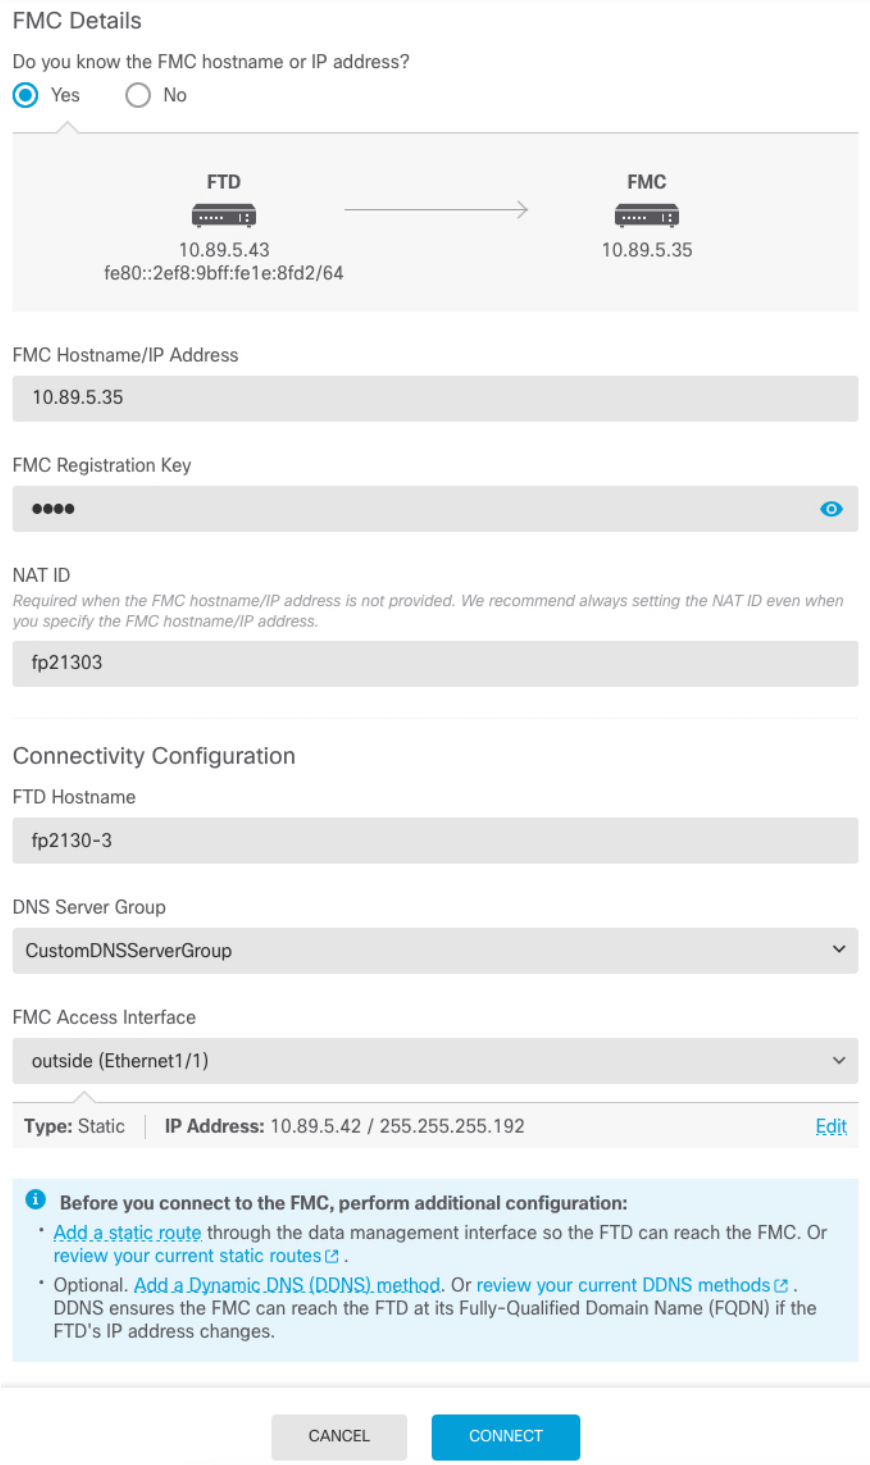
Before you begin

If the firewall is configured for high availability, you must first break the high availability configuration using the FDM (if possible) or the **configure high-availability disable** command. Ideally, break high availability from the active unit.

Procedure

Step 1 In the FDM, unregister the device from the Cisco Smart Software Manager.

Step 2 (Might be required) Configure the Management interface.



You may need to change the Management interface configuration, even if you intend to use a data interface for manager access. You will have to reconnect to the FDM if you were using the Management interface for the FDM connection.

- Data interface for manager access—The Management interface must have the gateway set to data interfaces. By default, the Management interface receives an IP address and gateway from DHCP. If you do not receive a gateway from DHCP (for example, you did not connect this interface to a network), then the gateway will default to data interfaces, and you do not need to configure anything. If you did receive a gateway from DHCP, then you need to instead configure this interface with a static IP address and set the gateway to data interfaces.
- Management interface for manager access—If you want to configure a static IP address, be sure to also set the default gateway to be a unique gateway instead of the data interfaces. If you use DHCP, then you do not need to configure anything assuming you successfully get the gateway from DHCP.

Step 3 Choose **Device** > **System Settings** > **Management Center**, and click **Proceed** to set up the FMC management.

Step 4 Configure the **FMC Details**.

Figure 12: FMC Details

a) For **Do you know the FMC hostname or IP address?**, click **Yes** if you can reach the FMC using an IP address or hostname, or **No** if the FMCCDO is behind NAT or does not have a public IP address or hostname.

At least one of the devices, either the FMC or the FTD device, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices.

b) If you chose **Yes**, then enter the **FMC Hostname/IP Address**.

c) Specify the **FMC Registration Key**.

This key is a one-time registration key of your choice that you will also specify on the FMC when you register the FTD device. The registration key must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID can be used for multiple devices registering to the FMC.

a) Specify a **NAT ID**.

This ID is a unique, one-time string of your choice that you will also specify on the FMC. The NAT ID must be between 2 and 36 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID *cannot* be used for any other devices registering to the FMC. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked. We recommended that you always use the NAT ID even when it is optional, but it is required if:

- You set the FMC IP address to **DONTRESOLVE**.
- When adding the device on the FMC, you do not specify a reachable device IP address or hostname.
- You use the data interface for management, even if you specify IP addresses on both sides.
- The FMC uses multiple management interfaces.

Step 5 Configure the **Connectivity Configuration**.

a) Specify the **FTD Hostname**.

If you use a data interface for the **FMC Access Interface** access, then this FQDN will be used for this interface.

b) Specify the **DNS Server Group**.

Choose an existing group, or create a new one. The default DNS group is called **CiscoUmbrellaDNSServerGroup**, which includes the OpenDNS servers.

If you intend to choose a data interface for the **FMC Access Interface**, then this setting sets the *data* interface DNS server. The Management DNS server that you set with the setup wizard is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface. You are likely to choose the same DNS server group that you used for Management, because both management and data traffic reach the DNS server through the outside interface.

On the FMC, the data interface DNS servers are configured in the Platform Settings policy that you assign to this FTD device. When you add the FTD device to the FMC, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the FTD device that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the FMC and the FTD device into sync.

Also, local DNS servers are only retained by the FMC if the DNS servers were discovered at initial registration.

If you intend to choose the Management interface for the **FMC Access Interface**, then this setting configures the Management DNS server.

c) For the **FMC Access Interface**, choose any configured interface.

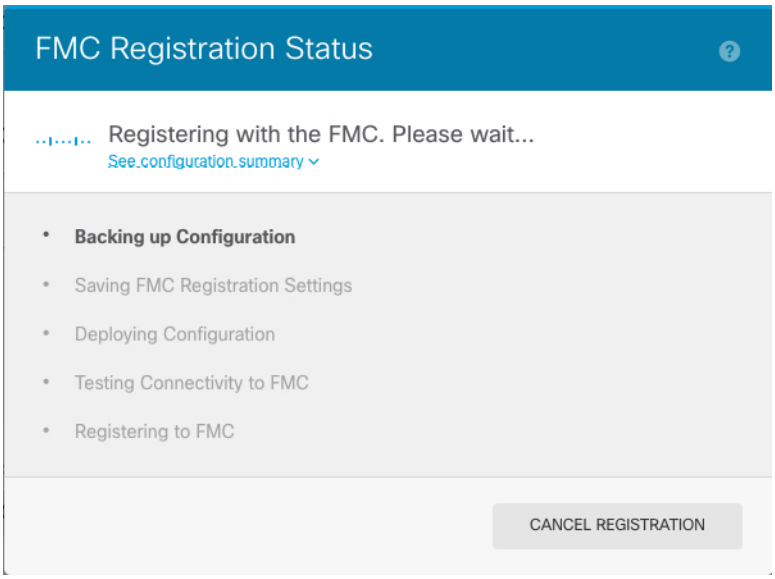
You can change the manager interface after you register the FTD device to the FMC, to either the Management interface or another data interface.

Step 6 (Optional) If you chose a data interface, and it was not the outside interface, then add a default route.

You will see a message telling you to check that you have a default route through the interface. If you chose outside, you already configured this route as part of the setup wizard. If you chose a different interface, then you need to manually configure a default route before you connect to the FMC.

If you chose the Management interface, then you need to configure the gateway to be a unique gateway before you can proceed on this screen.

Step 7 (Optional) If you chose a data interface, click **Add a Dynamic DNS (DDNS) method**.



DDNS ensures the FMC can reach the FTD device at its Fully-Qualified Domain Name (FQDN) if the IP address changes. See **Device** > **System Settings** > **DDNS Service** to configure DDNS.

If you configure DDNS before you add the FTD device to the FMC, the FTD device automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the FTD device can validate the DDNS server certificate for the HTTPS connection. FTD supports any DDNS server that uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

DDNS is not supported when using the Management interface for manager access.

Step 8 Click **Connect**. The **FMC Registration Status** dialog box shows the current status of the switch to the FMC. After the **Saving FMC Registration Settings** step, go to the FMC, and add the firewall.

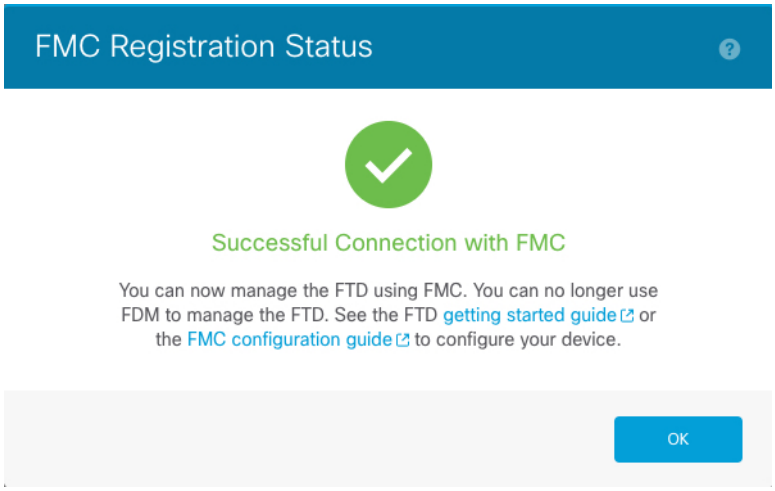


Figure 13: FMC Registration Status

If you want to cancel the switch to the FMC, click **Cancel Registration**. Otherwise, do not close the FDM browser window until after the **Saving FMC Registration Settings** step. If you do, the process will be paused, and will only resume when you reconnect to the FDM.

If you remain connected to the FDM after the **Saving FMC Registration Settings** step, you will eventually see the **Successful Connection with FMC** dialog box, after which you will be disconnected from the FDM.

Figure 14: Successful Connection with FMC

Switch from FMC to FDM

You can configure the FTD device currently being managed by the FMC to use the FDM instead.

You can switch from the FMC to the FDM without reinstalling the software. Before switching from the FMC to the FDM, verify that the FDM meets all of your configuration requirements. If you want to switch from the FDM to the FMC, see Switch from the FDM to the FMC, on page 33.

Caution Switching to the FDM erases the device configuration and returns the system to the default configuration. However, the Management IP address and hostname are preserved.

Procedure

Step 1 In the FMC, delete the firewall from the **Devices** > **Device Management** page.

Step 2 Connect to the FTD CLI using SSH or the console port. For SSH, open a connection to the **management IP address**, and log into the FTD CLI with the **admin** username (or any other user with admin privileges).

The console port defaults to the FXOS CLI. Connect to the FTD CLI using the **connect ftd** command. The SSH session connects directly to the FTD CLI.

If you cannot connect to the management IP address, do one of the following:

- Ensure that the Management physical port is wired to a functioning network.
- Ensure that the management IP address and gateway are configured for the management network. Use the **configure network ipv4/ipv6 manual** command.

Step 3 Verify you are currently in remote management mode.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.89.5.35
Registration              : Completed
```

Step 4 Delete the remote manager and go into no manager mode.

configure manager delete

You cannot go directly from remote management to local management.

Example:

```
> configure manager delete
Deleting task list
Manager successfully deleted.

>
> show managers
No managers configured.
```

Step 5 Configure the local manager.

configure manager local

You can now use a web browser to open the local manager at **https://***management-IP-address*.

Example:

```
> configure manager local
Deleting task list

> show managers
Managed locally.
```

Hot Swap an SSD on the Secure Firewall 3100

If you have two SSDs, they form a RAID when you boot up. You can perform the following tasks at the FTD CLI while the firewall is powered up:

- Hot swap one of the SSDs—If an SSD is faulty, you can replace it. Note that if you only have one SSD, you cannot remove it while the firewall is powered on.
- Remove one of the SSDs—If you have two SSDs, you can remove one.
- Add a second SSD—If you have one SSD, you can add a second SSD and form a RAID.

Caution Do not remove an SSD without first removing it from the RAID using this procedure. You can cause data loss.

Procedure

Step 1 Remove one of the SSDs.

a) Remove the SSD from the RAID.

configure raid remove-secure local-disk {**1** | **2**}

The **remove-secure** keyword removes the SSD from the RAID, disables the self-encrypting disk feature, and performs a secure erase of the SSD. If you only want to remove the SSD from the RAID and want to keep the data intact, you can use the **remove** keyword.

Example:

```
> configure raid remove-secure local-disk 2
```

b) Monitor the RAID status until the SSD no longer shows in the inventory.

show raid

After the SSD is removed from the RAID, the **Operability** and **Drive State** will show as **degraded**. The second drive will no longer be listed as a member disk.

Example:

```
> show raid
Virtual Drive
ID:                          1
Size (MB):                   858306
Operability:                 operable
Presence:                    equipped
Lifecycle:                   available
Drive State:                 optimal
Type:                        raid
Level:                       raid1
Max Disks:                   2
Meta Version:                1.0
Array State:                 active
Sync Action:                 idle
Sync Completed:              unknown
Degraded:                    0
Sync Speed:                  none

RAID member Disk:
Device Name:                 nvme0n1
Disk State:                  in-sync
Disk Slot:                   1
Read Errors:                 0
Recovery Start:              none
Bad Blocks:
Unacknowledged Bad Blocks:

Device Name:                 nvme1n1
```

```
Disk State:                 in-sync
Disk Slot:                  2
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

> show raid
Virtual Drive
ID:                         1
Size (MB):                  858306
Operability:                degraded
Presence:                   equipped
Lifecycle:                  available
Drive State:                degraded
Type:                       raid
Level:                      raid1
Max Disks:                  2
Meta Version:               1.0
Array State:                active
Sync Action:                idle
Sync Completed:             unknown
Degraded:                   1
Sync Speed:                 none

RAID member Disk:
Device Name:                nvme0n1
Disk State:                 in-sync
Disk Slot:                  1
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:
```

c) Physically remove the SSD from the chassis.

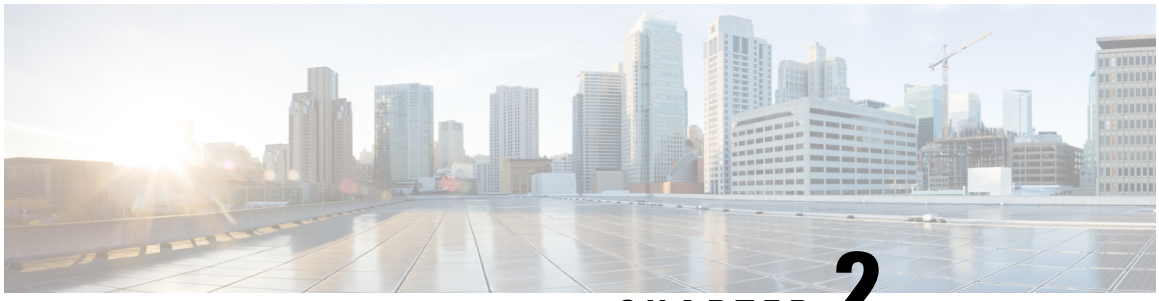
Step 2 Add an SSD.

a) Physically add the SSD to the empty slot.

b) Add the SSD to the RAID.

configure raid add local-disk {**1** | **2**}

It can take several hours to complete syncing the new SSD to the RAID, during which the firewall is completely operational. You can even reboot, and the sync will continue after it powers up. Use the **show raid** command to show the status.



If you install an SSD that was previously used on another system, and is still locked, enter the following command:

configure raid add local-disk {**1** | **2**} *psid*

The *psid* is printed on the label attached to the back of the SSD. Alternatively, you can reboot the system, and the SSD will be reformatted and added to the RAID.

History for Device Management

Feature	Minimum FMC	Minimum FTD	Details
RAID support for SSDs on the Secure Firewall 3100.	7.1.0	7.1.0	The SSDs are self-encrypting drives (SEDs), and if you have 2 SSDs, they form a software RAID. New/modified commands: **configure raid, show raid, show ssd**
Support for TLS 1.3 for the management connection.	7.1.0	7.1.0	The FMC-device management connection now uses TLS 1.3. Previously, TLS 1.2 was supported.
Use FDM to configure FTD for management by the FMC.	7.1.0	7.1.0	When you perform initial setup using FDM, all interface configuration completed in FDM is retained when you switch to FMC for management, in addition to the Management and manager access settings. Note that other default configuration settings, such as the access control policy or security zones, are not retained. When you use the FMC CLI, only the Management and manager access settings are retained (for example, the default inside interface configuration is not retained). After you switch to FMC, you can no longer use FDM to manage FTD. New/modified FDM screens: **System Settings** > **Management Center**
Filter devices by upgrade status.	6.7.0	6.7.0	The **Device Management** page now provides upgrade information about your managed devices, including whether a device is upgrading (and what its upgrade path is), and whether its last upgrade succeeded or failed. New/modified screens: **Devices** > **Device Management**
One-click access to the Firepower Chassis Manager.	6.4.0	6.4.0	For Firepower 4100/9300 series devices, the Device Management page provides a link to the Firepower Chassis Manager web interface. New/modified screens: **Devices** > **Device Management**
Filter devices by health and deployment status; view version information.	6.2.3	6.2.3	The Device Management page now provides version information for managed devices, as well as the ability to filter devices by health and deployment status. New/modified screens: **Devices** > **Device Management**

CHAPTER 2

Device Settings

After you add a device, you can edit device-related settings on the **Device** page.

1. Choose **Devices** > **Device Management**.
2. Next to the device you want to modify, click **Edit** ( ).
3. Click **Device**.

- Edit General Settings, on page 43
- Edit License Settings, on page 49
- View System Information, on page 50
- View the Inspection Engine, on page 51
- Edit Health Settings, on page 51
- Edit Management Settings, on page 52
- View Inventory Details, on page 80
- Edit Applied Policies, on page 81
- Edit Advanced Settings, on page 83
- History for Device Settings, on page 87

Edit General Settings

The **General** section of the **Device** page displays the settings described in the table below.

Table 2: General Section Table Fields

Field	Description
Name	The display name of the device on the FMC.
Transfer Packets	This displays whether or not the managed device sends packet data with the events to the FMC.
Mode	The displays the mode of the management interface for the device: **routed** or **transparent**.
Compliance Mode	This displays the security certifications compliance for a device. Valid values are CC, UCAPL and None.

Field	Description
TLS Crypto Acceleration:	Shows whether TLS crypto acceleration is enabled or disabled.
Device Configuration	Lets you copy, export, or import a configuration. See Copy a Configuration to Another Device, on page 44 and Export and Import the Device Configuration, on page 45.

You can edit some of these settings from this section.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, click **Edit** ( ).

a) Enter a **Name** for the managed device.
b) Check **Transfer Packets** to allow packet data to be stored with events on the FMC.
c) Click **Force Deploy** to force deployment of current policies and device configuration to the device.

Note
Force-deploy consumes more time than the regular deployment since it involves the complete generation of the policy rules to be deployed on the FTD.

Step 5 For **Device Configuration** actions, see Copy a Configuration to Another Device, on page 44 and Export and Import the Device Configuration, on page 45.

Step 6 Click **Deploy**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Copy a Configuration to Another Device

When a new device is deployed in the network you can easily copy configurations and policies from a pre-configured device, instead of manually reconfiguring the new device.

Before you begin

Confirm that:

- The source and destination FTD devices are the same model and are running the same version of the software.
- The source is either a standalone Firepower Threat Defense device or a Firepower Threat Defense high availability pair.

- The destination device is a standalone FTD device.
- The source and destination FTD devices have the same number of physical interfaces.
- The source and destination FTD devices are in the same firewall mode - routed or transparent.
- The source and destination FTD devices are in the same security certifications compliance mode.
- The source and destination FTD devices are in the same domain.
- Configuration deployment is not in progress on either the source or the destination FTD devices.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, do one of the following:

- Click **Get Device Configuration** ( ) to copy device configuration from another device to the new device. On the **Get Device Configuration** page, select the source device in the **Select Device** drop-down list.
- Click **Push Device Configuration** ( ) to copy device configuration from the current device to the new device. On the **Push Device Configuration** page, select the destination to which configuration is to be copied in the **Target Device** drop-down list.

Step 5 (Optional) Check **Include shared policies configuration** check box to copy policies.

Shared policies like AC policy, NAT, Platform Settings and FlexConfig policies can be shared across multiple devices.

Step 6 Click **OK**.

You can monitor the status of the copy device configuration task on **Tasks** in the Message Center.

When the copy device configuration task is initiated, it erases the configuration on the target device and copies the configuration of the source device to the destination device.

Warning When you have completed the copy device configuration task, you cannot revert the target device to its original configuration.

Export and Import the Device Configuration

You can export all of the the device-specific configuration configurable on the Device pages, including:

- Interfaces
- Inline Sets

- Routing
- DHCP
- VTEP
- Associated objects

You can then import the saved configuration for the same device in the following use cases:

- Moving the device to a different FMC—First delete the device from the original FMC, then add the device to the new FMC. Then you can import the saved configuration.
- Moving the device between domains—When you move a device between domains, some device-specific configuration is not retained because supporting objects (such as interface groups for security zones) do not exist in the new domain. By importing the configuration after the domain move, any necessary objects are created for that domain, and the device configuration is restored.
- Restore an old configuration—If you deployed changes that negatively impacted the operation of the device, you can import a backup copy of a known working configuration to restore a previous operational state.
- Reregistering a device—If you delete a device from the FMC, but then want to add it back, you can import the saved configuration.

See the following guidelines:

- You can only import the configuration to the same device (the UUID must match). You cannot import a configuration to a different device, even if it is the same model.
- Do not change the version running on the device between exporting and importing; the version must match.
- When moving the device to a different FMC, the target FMC version must be the same as the source version.
- If an object doesn't exist, it will be created. If an object exists, but the value is different, see below:

Table 3: Object Import Action

Scenario	Import Action
Object exists with the same name and value.	Reuse existing objects.
Object exists with the same name but different value.	Network and Port objects: Create object overrides for this device. See Object Overrides, on page 848. Interface objects: Create new objects. For example, if both the type (security zone or interface group) and the interface type (routed or switched, for example) do not match, then a new object is created. All other objects: Reuse existing objects even though the values are different.
Object doesn't exist.	Create new object.s

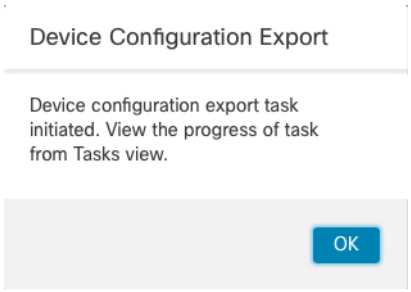
Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to edit, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 Export the configuration.



a) In the **General** area, click **Export**.

Figure 15: Export Device Configuration

You are prompted to acknowledge the export; click **OK**.

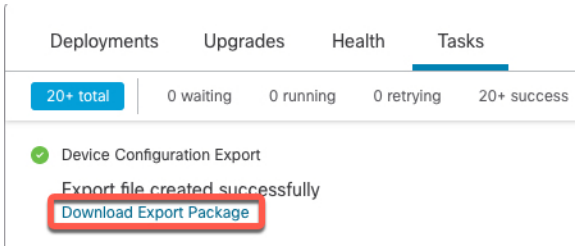


Figure 16: Acknowledge Export

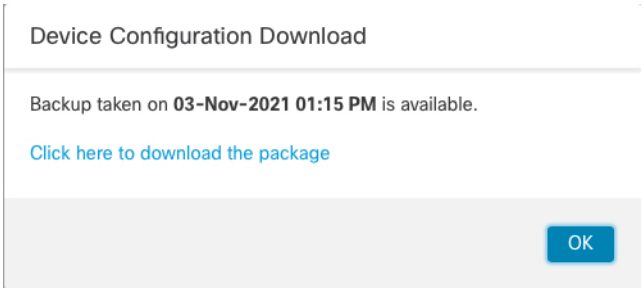
You can view the export progress in the **Tasks** page.



b) On the **Notifications** > **Tasks** page, ensure that the export has completed; click **Download Export Package**. Alternatively, you can click the **Download** button in the **General** area.

Figure 17: Export Task

You are prompted to download the package; click **Click here to download the package** to save the file locally, and then click **OK** to exit the dialog box.

Figure 18: Download Package

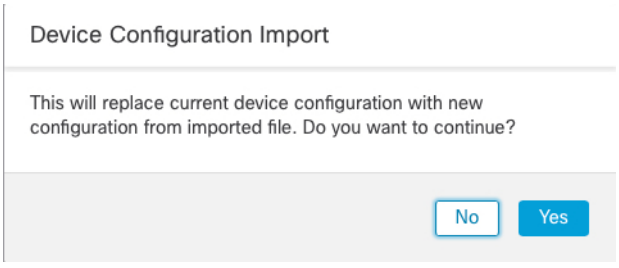
Step 5 Import the configuration.

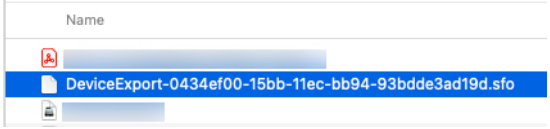
a) In the **General** area, click **Import**.

Figure 19: Import Device Configuration

You are prompted to acknowledge that the current configuration will be replace. Click **Yes**, and then navigate to the configuration package (with the suffix .sfo; note that this file is different from the Backup/Restore files).

Figure 20: Import Package





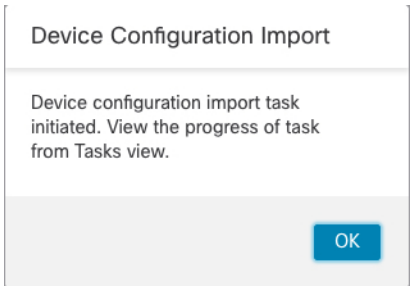


Figure 21: Navigate to Package

You are prompted to acknowledge the import; click **OK**.

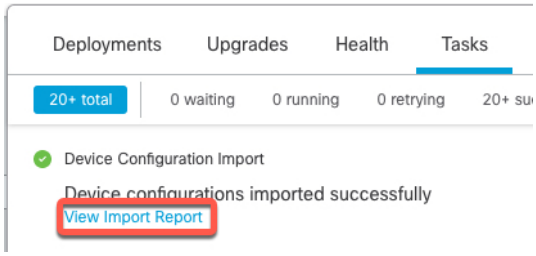

Figure 22: Acknowledge Import

You can view the import progress in the **Tasks** page.

b) View the import reports so you can see what was imported. On the **Notifications** > **Tasks** page for the import task, click **View Import Report**.

Figure 23: View Import Report

The **Device Configuration Import Reports** page provides links to available reports.

Cisco Firepower Management Center

Device Configuration Import Reports

Device	Shared Policies	Device Configurations
0434ef00-15bb-11ec-bb94-93bdde3ad19d	Report does not exist	Device configurations import report

Edit License Settings

The **License** section of the **Device** page displays the licenses enabled for the device.

You can enable licenses on your device if you have available licenses on your FMC.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to enable or disable licenses, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **License** section, click **Edit** ( ).

Step 5 Check or clear the check box next to the license you want to enable or disable for the managed device.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

View System Information

The System section of the **Device** page displays a read-only table of system information, as described in the following table.

You can also shut down or restart the device.

Figure 24: System

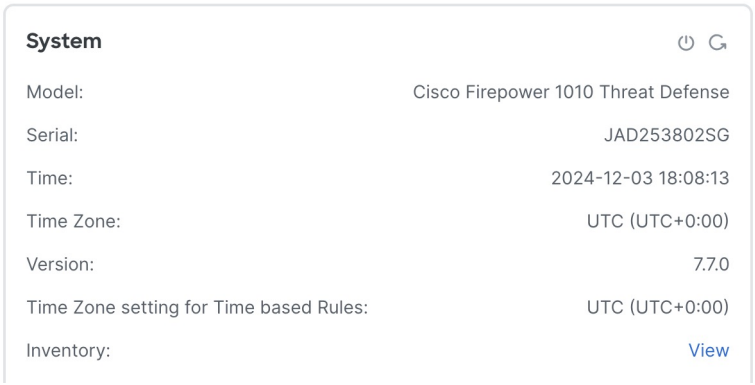

Figure 25: Inventory Details

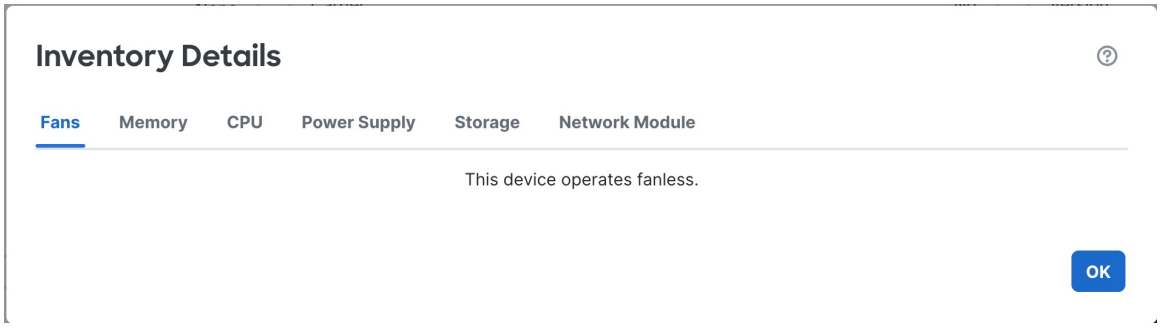

Table 4: System Section Table Fields

Field	Description
Shut Down Device ( )	Shuts down the device. See Shut Down or Restart the Device, on page 32.
Restart Device ( )	Restarts the device. See Shut Down or Restart the Device, on page 32.
Model	The model name and number for the managed device.
Serial	The serial number of the chassis of the managed device.
Time	The current system time of the device.
Time Zone	Shows the time zone.
Version	The version of the software currently installed on the managed device.
Time Zone setting for time-based rules	The current system time of the device, in the time zone specified in device platform settings.
Inventory	Link to view the device inventory: Fans, Memory, CPU, Power Supply, Storage, and Network Modules.

View the Inspection Engine

The Inspection Engine section of the **Device** page shows whether your device uses Snort 2 or Snort 3. To switch the inspection engine, see Firepower Management Center Snort 3 Configuration Guide.

Edit Health Settings

The **Health** section of the **Device** page displays the information described in the table below.

Table 5: Health Section Table Fields

Field	Description
Status	An icon that represents the current health status of the device. Clicking the icon displays the Health Monitor for the appliance.
Policy	A link to a read-only version of the health policy currently deployed at the device.
Excluded	A link to the **Health Exclude** page, where you can enable and disable health exclusion modules.

Edit Management Settings

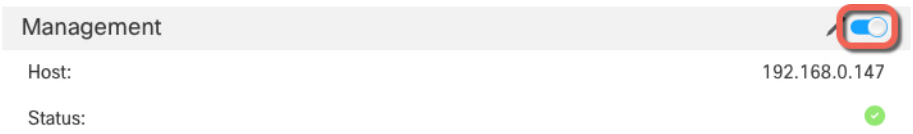
You can edit management settings in the **Management** area.

Update the Hostname or IP Address in the FMC

If you edit the hostname or IP address of a device after you added it to the FMC (using the device's CLI, for example), you need to use the procedure below to manually update the hostname or IP address on the managing FMC.

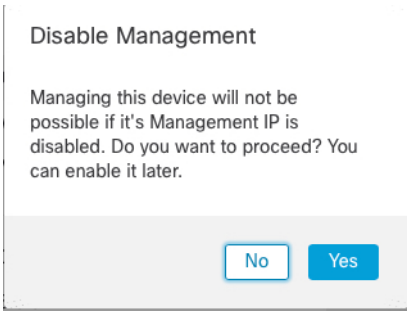
To change the device management IP address on the device, see Modify FTD Management Interfaces at the CLI, on page 65.

If you used only the NAT ID when registering the device, then the IP shows as **NO-IP** on this page, and you do not need to update the IP address/hostname.



Procedure

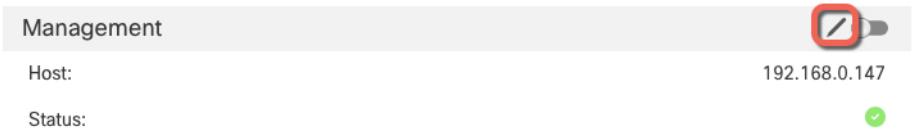
Step 1 Choose **Devices** > **Device Management**.



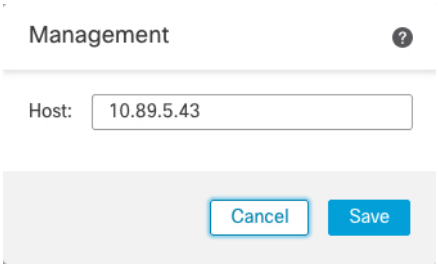
Step 2 Next to the device where you want to modify management options, click **Edit** ( ).

Step 3 Click **Device**, and view the **Management** area.

Step 4 Disable management temporarily by clicking the slider so it is disabled **Slider disabled** ( ).

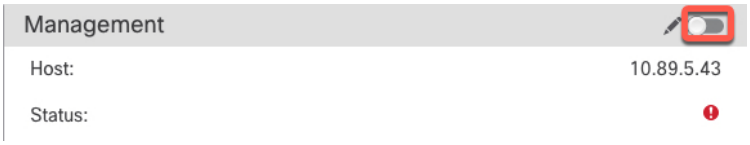


You are prompted to proceed with disabling management; click **Yes**.



Disabling management blocks the connection between the FMC and the device, but does **not** delete the device from the FMC.

Step 5 Edit the **Host** IP address or hostname by clicking **Edit** ( ).



Step 6 In the **Management** dialog box, modify the name or IP address in the **Host** field, and click **Save**.

Figure 26: Management IP Address

Step 7 Reenable management by clicking the slider so it is enabled **Slider enabled** ( ).

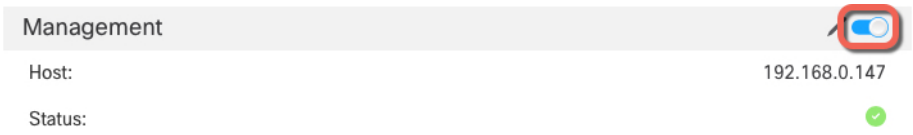
Figure 27: Enable Management Connection

Change Both Management Center and Threat Defense IP Addresses

You might want to change both FMC and FTD IP addresses if you need to move them to a new network.

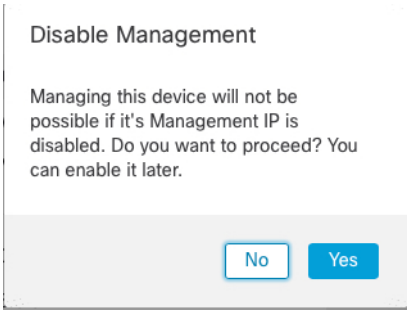
Procedure

Step 1 Disable the management connection.



For a high-availability pair or cluster, perform these steps on all units.

a) Choose **Devices** > **Device Management**.

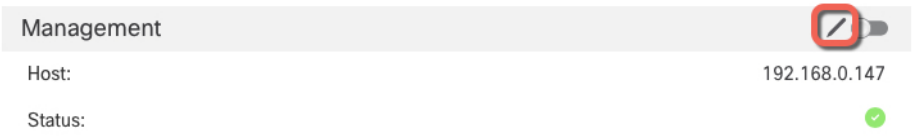


b) Next to the device, click **Edit** ( ).

c) Click **Device**, and view the **Management** area.

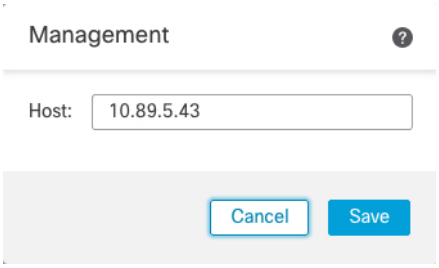
d) Disable management temporarily by clicking the slider so it is disabled ( ).

You are prompted to proceed with disabling management; click **Yes**.



Step 2 Change the device IP address in the FMC to the new device IP address.

You will change the IP address on the device later.



For a high-availability pair or cluster, perform these steps on all units.

a) Edit the **Host** IP address or hostname by clicking **Edit** ( ).

b) In the **Management** dialog box, modify the name or IP address in the **Host** field, and click **Save**.

Figure 28: Management IP Address

Step 3 Change the FMC IP address.

Caution
Be careful when making changes to the FMC interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the FMC console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** ( ) > **Configuration**, and then choose **Management Interfaces**.

b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 4 Change the manager IP address on the device.

For a high-availability pair or cluster, perform these steps on all units.

a) At the FMC CLI, view the unique UUID for the FMC so you can specify it in the FTD command. For information about the FMC CLI, see *Firepower Management Center Command Line Reference* in the Firepower Management Center Administration Guide.

show version

The FMC UUID definitively identifies the FMC; for example, in the case of FMC high availability, you need to specify the active FMC on the FTD.

Example:

```
> show version
-------------------[ firepower ]--------------------
Model                     : Cisco Firepower Management Center for VMWare (66) Version
6.7.0 (Build 1222)
UUID                      : f7ffad78-bf16-11ec-a737-baa2f76ef602
Rules update version      : 2020-05-26-001-vrt
VDB version               : 334
----------------------------------------------------
```

b) Edit the FMC IP address or hostname.

configure manager edit *identifier* {*ip_address* | *hostname*}

If the FMC was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 10.10.5.1
```

Step 5 Change the IP address of the manager access interface at the console port.

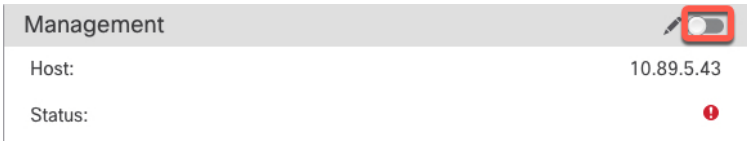
For a high-availability pair or cluster, perform these steps on all units.

If you use the dedicated Management interface:

configure network ipv4

configure network ipv6

If you use the dedicated Management interface:



configure network management-data-interface disable

configure network management-data-interface

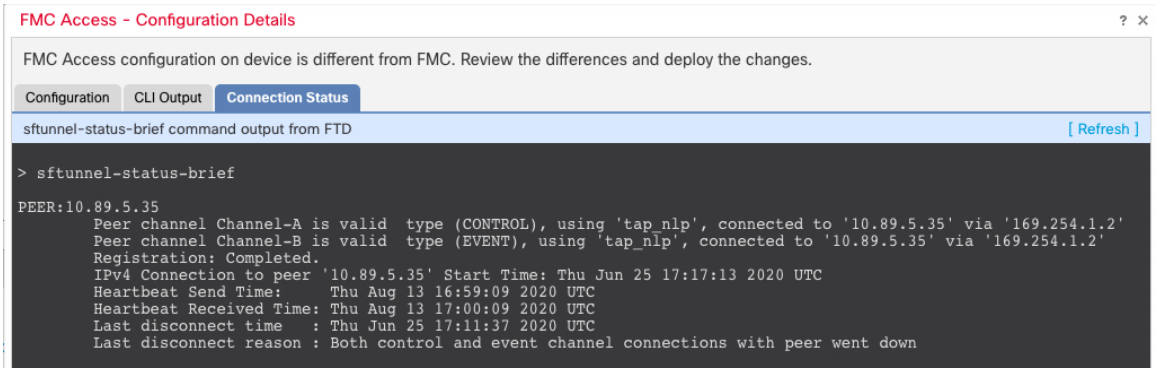
Step 6 Reenable management by clicking the slider so it is enabled ( ).

For a high-availability pair or cluster, perform these steps on all units.

Figure 29: Enable Management Connection

Step 7 (If using a data interface for manager access) Refresh the data interface settings in the FMC.

For a high-availability pair, perform this step on both units.



a) Choose **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details**, and click **Refresh**.
b) Choose **Devices** > **Device Management** > **Interfaces**, and set the IP address to match the new address.
c) Return to the **FMC Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

Step 8 Ensure the management connection is reestablished.

In the FMC, check the management connection status on the **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details** > **Connection Status** page.

At the FTD CLI, enter the **sftunnel-status-brief** command to view the management connection status.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Step 9 (For a high-availability FMC pair) Repeat configuration changes on the secondary FMC.

a) Change the secondary FMC IP address.
b) Specify the new peer addresses on both units.
c) Make the secondary unit the active unit.
d) Disable the device management connection.
e) Change the device IP address in the FMC.
f) Reenable the management connection.

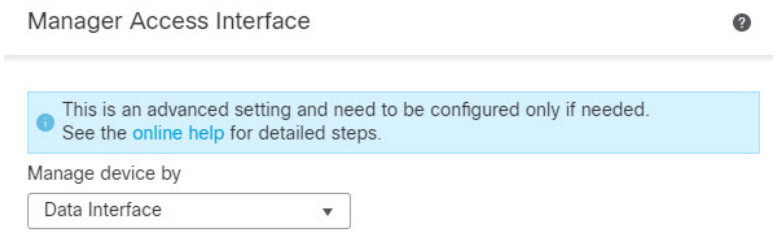
Change the Manager Access Interface from Management to Data

You can manage the FTD from either the dedicated Management interface or from a data interface. If you want to change the manager access interface after you added the device to the FMC, follow these steps to

migrate from the Management interface to a data interface. To migrate the other direction, see Change the Manager Access Interface from Data to Management, on page 59.

Initiating the manager access migration from Management to data causes the FMC to apply a block on deployment to the FTD. To remove the block, enable manager access on the data interface.

See the following steps to enable manager access on a data interface and also configure other required settings.



Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** ( ) for the device.

b) Go to the **Device** > **Management** section, and click the link for **FMC Access Interface**.

The **FMC Access Interface** field shows the current Management interface. When you click the link, choose the new interface type, **Data Interface**, in the **Manage device by** drop-down list.

c) Click **OK** and then **Close**.

You must now complete the remaining steps in this procedure to enable manager access on the data interface. The **Management** area now shows **FMC Access Interface: Data Interface**, and **FMC Access Details: Configuration**.

Figure 30: FMC Access

If you click **Configuration**, the **FMC Access - Configuration Details** dialog box opens. The **FMC Access Mode** shows a Deploy pending state.

Configuration		
Version	7.1.0	7.1.0 (Build 1760)
Configuration Cleared		No
FMC Access Mode	Data Interface (Deploy pending)	Management Interface
Connectivity Status	Connected	Connected

Step 2 Enable manager access on a data interface on the **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **FMC Access** page.

Check **Enable management access** and click **OK**. By default, all networks are allowed, but you can limit access as long as the FMC address is allowed.

If the manager access interface uses a static IP address, you are reminded to configure routing for it.

Click **Save** on the **Interfaces** page. See Configure Routed Mode Interfaces, on page 406 for more information about interface settings. You can enable manager access on one routed data interface. Make sure this interface is fully configured with a name and IP address and that it is enabled.

Step 3 (Optional) If you use DHCP for the interface, enable the web type DDNS method on the **Devices** > **Device Management** > **DHCP** > **DDNS** page.

See Configure Dynamic DNS, on page 453. DDNS ensures the FMC can reach the FTD at its Fully-Qualified Domain Name (FQDN) if the FTD's IP address changes.

Step 4 Make sure the FTD can route to the FMC through the data interface; add a static route if necessary on **Devices** > **Device Management** > **Routing** > **Static Route**.

See Add a Static Route, on page 678.

Step 5 (Optional) Configure DNS in a Platform Settings policy, and apply it to this device at **Devices** > **Platform Settings** > **DNS**.

See DNS, on page 481. DNS is required if you use DDNS. You may also use DNS for FQDNs in your security policies.

Step 6 (Optional) Enable SSH for the data interface in a Platform Settings policy, and apply it to this device at **Devices** > **Platform Settings** > **Secure Shell**.

See Secure Shell, on page 492. SSH is not enabled by default on the data interfaces, so if you want to manage the FTD using SSH, you need to explicitly allow it.

Step 7 Deploy configuration changes; see Deploy Configuration Changes, on page 121.

You will see a validation error to confirm that you are changing the manager access interface. Check **Ignore warnings** and deploy again.

The FMC will deploy the configuration changes over the current Management interface. After the deployment, the data interface is now ready for use, but the original management connection to Management is still active.

Step 8 At the FTD CLI (preferably from the console port), set the Management interface to use a static IP address and set the gateway to use the data interfaces.

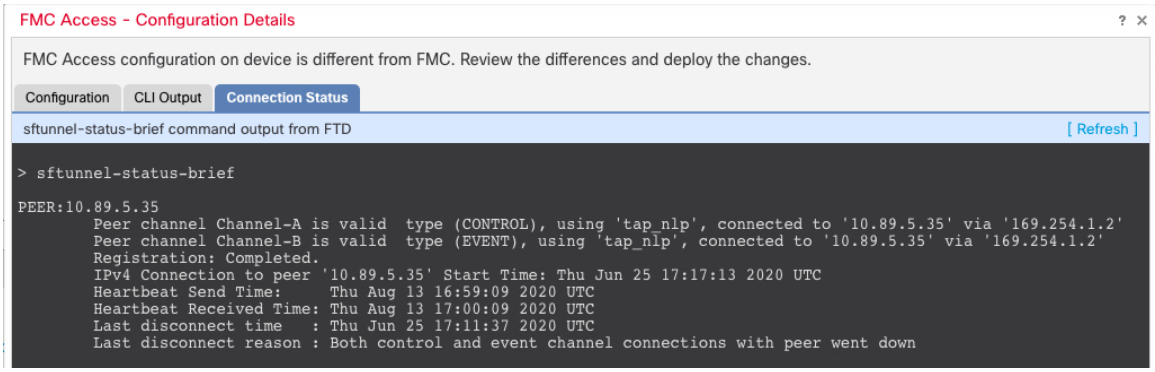
configure network {**ipv4** | **ipv6**} **manual** *ip_address netmask* **data-interfaces**

- *ip_address netmask*—Although you do not plan to use the Management interface, you must set a static IP address, for example, a private address so that you can set the gateway to **data-interfaces** (see the next bullet). You cannot use DHCP because the default route, which must be **data-interfaces**, might be overwritten with one received from the DHCP server.
- **data-interfaces**—This setting forwards management traffic over the backplane so it can be routed through the manager access data interface.

We recommend that you use the console port instead of an SSH connection because when you change the Management interface network settings, your SSH session will be disconnected.

Step 9 If necessary, re-cable the FTD so it can reach the FMC on the data interface.

Step 10 In the FMC, disable the management connection, update the **Host** IP address for the FTD in the **Devices** > **Device Management** > **Device** > **Management** section, and reenable the connection.



See Update the Hostname or IP Address in the FMC, on page 52. If you used the FTD hostname or just the NAT ID when you added the FTD to the FMC, you do not need to update the value; however, you need to disable and reenable the management connection to restart the connection.

Step 11 Ensure the management connection is reestablished.

In the FMC, check the management connection status on the **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details** > **Connection Status** page.

At the FTD CLI, enter the **sftunnel-status-brief** command to view the management connection status.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

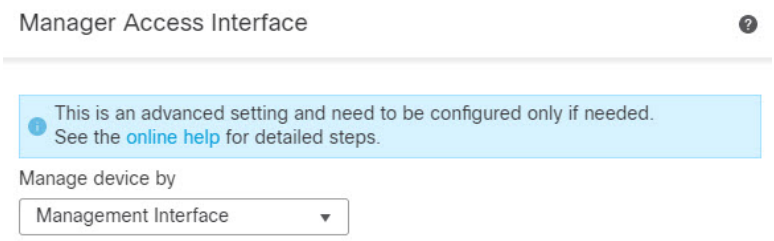
If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 76.

Change the Manager Access Interface from Data to Management

You can manage the FTD from either the dedicated Management interface or from a data interface. If you want to change the manager access interface after you added the device to the FMC, follow these steps to migrate from a data interface to the Management interface. To migrate the other direction, see Change the Manager Access Interface from Management to Data, on page 56.

Initiating the manager access migration from data to Management causes the FMC to apply a block on deployment to the FTD. You must disable manager access on the data interface to remove the block.

See the following steps to disable manager access on a data interface, and also configure other required settings.



Procedure

Step 1 Initiate the interface migration.

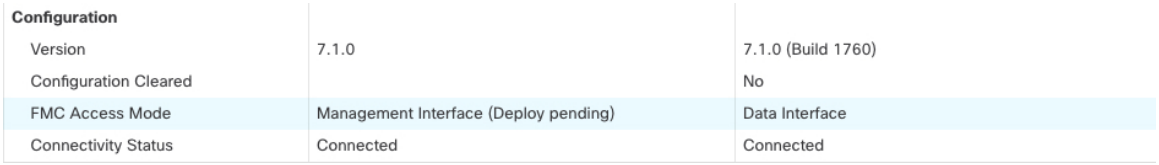
a) On the **Devices** > **Device Management** page, click **Edit** ( ) for the device.

b) Go to the **Device** > **Management** section, and click the link for **FMC Access Interface**.

The **FMC Access Interface** field shows the current management interface as data. When you click the link, choose the new interface type, **Management Interface**, in the **Manage device by** drop-down list.

c) Click **Save**.

Click **OK** and then **Close**.



You must now complete the remaining steps in this procedure to enable manager access on the Management interface. The **Management** area now shows the **FMC Access Interface: Management Interface**, and **FMC Access Details: Configuration**.

Figure 31: FMC Access

If you click **Configuration**, the **FMC Access - Configuration Details** dialog box opens. The **FMC Access Mode** shows a Deploy pending state.

Figure 32: FMC Access Mode

Step 2 Disable manager access on the data interface on the **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **FMC Access** page.

Uncheck **Enable management access** and click **OK**. Click **Save** on the **Interfaces** page. This step removes the block on deployment.

Step 3 If you have not already done so, configure DNS settings for the data interface in a Platform Setting policy, and apply it to this device at **Devices** > **Platform Settings** > **DNS**.

See DNS, on page 481. The FMC deployment that disables manager access on the data interface will remove any local DNS configuration. If that DNS server is used in any security policy, such as an FQDN in an Access Rule, then you must re-apply the DNS configuration using the FMC.

Step 4 Deploy configuration changes; see Deploy Configuration Changes, on page 121.

The FMC will deploy the configuration changes over the current data interface.

Step 5 If necessary, re-cable the FTD so it can reach the FMC on the Management interface.

Step 6 At the FTD CLI, configure the Management interface IP address and gateway using a static IP address or DHCP.

When you originally configured the data interface for manager access, the Management gateway was set to data-interfaces, which forwarded management traffic over the backplane so it could be routed through the manager access data interface. You now need to set an IP address for the gateway on the management network.

Static IP address:

configure network {**ipv4** | **ipv6**} **manual** *ip_address netmask gateway_ip*

DHCP:

configure network{**ipv4** | **ipv6**} **dhcp**

Step 7 In the FMC, disable the management connection, update the **Host** IP address for the FTD in the **Devices** > **Device Management** > **Device** > **Management** section, and reenable the connection.

See Update the Hostname or IP Address in the FMC, on page 52. If you used the FTD hostname or just the NAT ID when you added the FTD to the FMC, you do not need to update the value; however, you need to disable and reenable the management connection to restart the connection.

Step 8 Ensure the management connection is reestablished.

In the FMC, check the management connection status on the **Devices** > **Device Management** > **Device** > **Management** > **Status** field or view notifications in the FMC.

At the FTD CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 76.

View Manager Access Details for Data Interface Management

Model Support—FTD

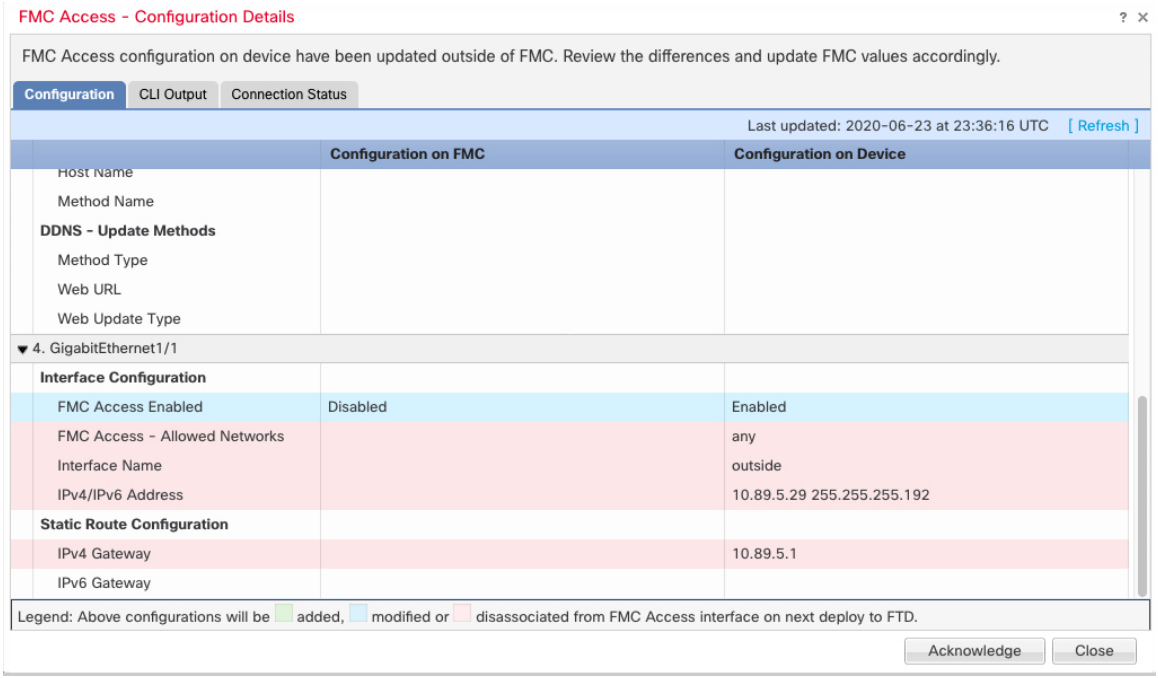
When you use a data interface for FMC management instead of using the dedicated Management interface, you must be careful about changing the interface and network settings for the device in the FMC so you do not disrupt the connection. You can also change the data interface settings locally on the device, which requires you to reconcile those changes in the FMC manually. The **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details** dialog box helps you resolve any discrepancies between the FMC and the FTD local configuration.

Normally, you configure the manager access data interface as part of initial FTD setup before you add the FTD to the FMC. When you add the FTD to the FMC, the FMC discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For the DNS server, the configuration is maintained locally if it is discovered during registration, but it is not added to the Platform Settings policy in FMC.

After you add the FTD to the FMC, if you change the data interface settings on the FTD locally using the **configure network management-data-interface** command, then the FMC detects the configuration changes,

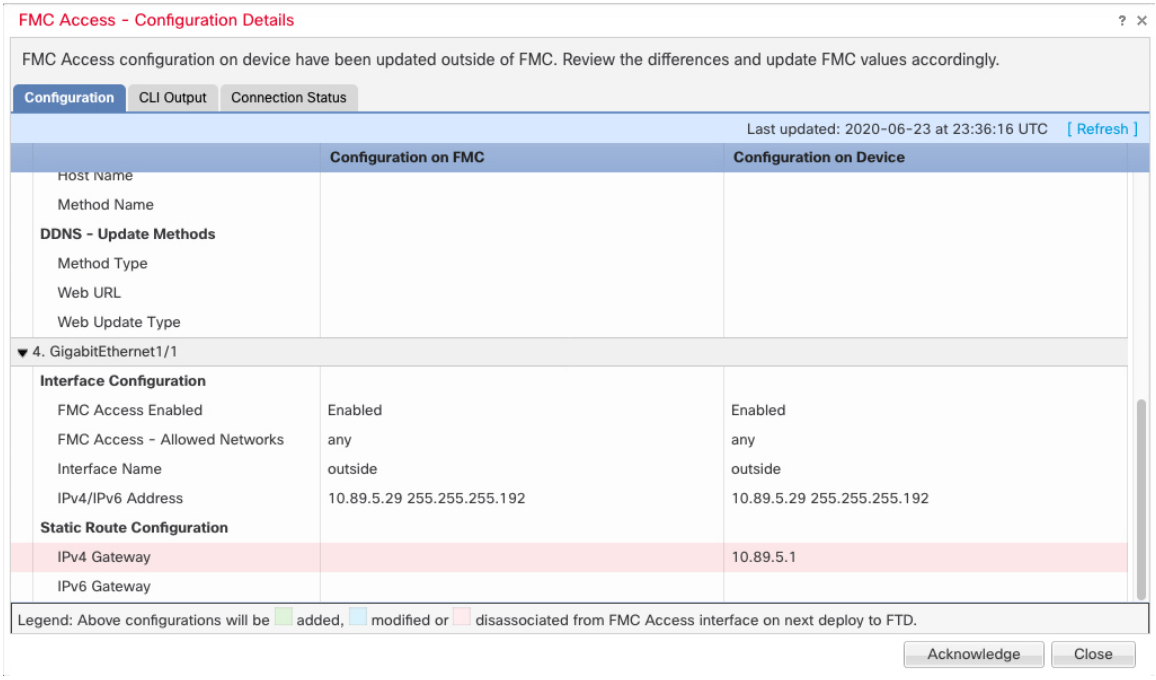
and blocks deployment to the FTD. The FMC detects the configuration changes using one of the following methods:

- Deploy to the FTD. Before the FMC deploys, it will detect the configuration differences and stop the deployment.
- The **Sync** button in the **Interfaces** page.
- The **Refresh** button on the **FMC Access - Configuration Details** dialog box.



To remove the block, you must go to the **FMC Access - Configuration Details** dialog box and click **Acknowledge**. The next time you deploy, the FMC configuration will overwrite any remaining conflicting settings on the FTD. It is your responsibility to manually fix the configuration in the FMC before you re-deploy.

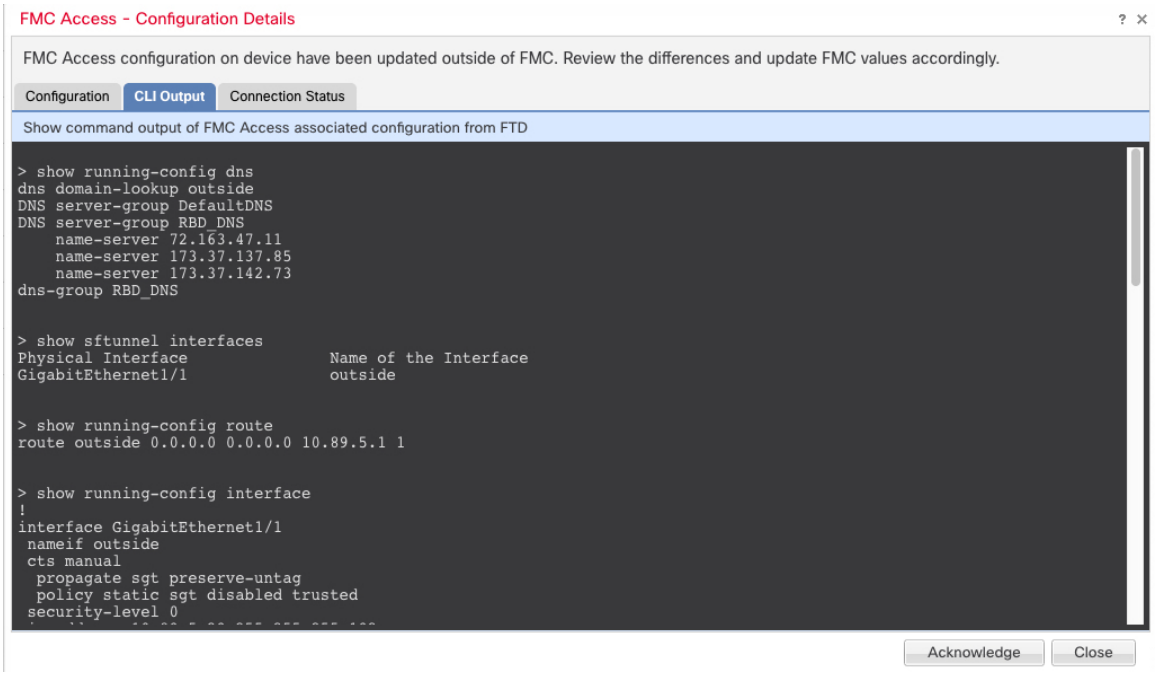
See the following pages on this dialog box.



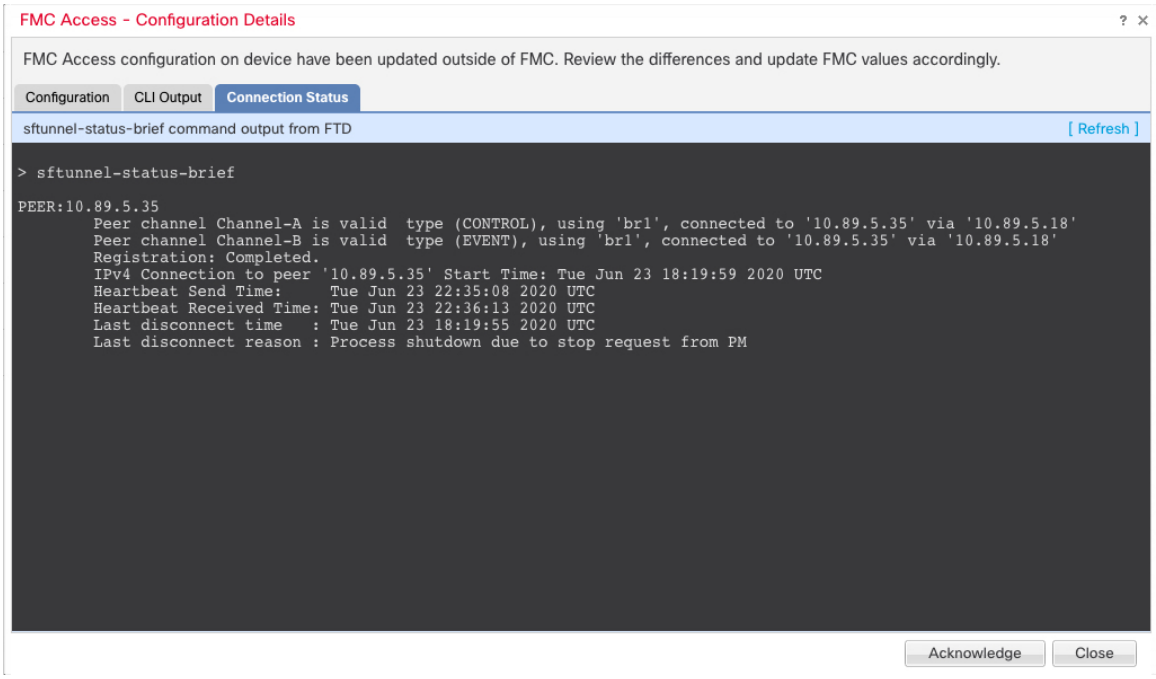
Configuration

View the configuration comparison of the manager access data interface on the FMC and the FTD.

The following example shows the configuration details of the FTD where the **configure network management-data-interface** command was entered on the FTD. The pink highlights show that if you **Acknowledge** the differences but do not match the configuration in the FMC, then the FTD configuration will be removed. The blue highlights show configurations that will be modified on the FTD. The green highlights show configurations that will be added to the FTD.

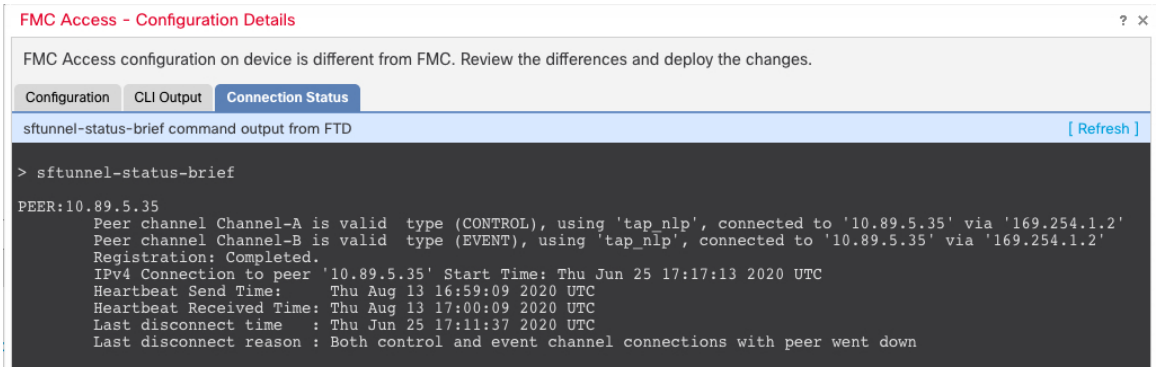


The following example shows this page after configuring the interface in the FMC; the interface settings match, and the pink highlight was removed.



CLI Output

View the CLI configuration of the manager access data interface, which is useful if you are familiar with the underlying CLI.



Connection Status

View management connection status. The following example shows that the management connection is still using the Management "br1" interface.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

See the following sample output for a connection that is down; there is no peer channel "connected to" information, nor heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went down
```

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
 '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Modify FTD Management Interfaces at the CLI

Modify the management interface settings on the managed device using the CLI. Many of these settings are ones that you set when you performed the initial setup; this procedure lets you change those settings, and set additional settings such as enabling an event interface if your model supports it, or adding static routes.

Note This topic applies to the dedicated Management interface. You can alternatively configure a data interface for management. If you want to change network settings for that interface, you should do so within FMC and not at the CLI. If you need to troubleshoot a disrupted management connection, and need to make changes directly on the FTD, see Modify the FTD Data Interface Used for Management at the CLI, on page 71.

For information about the FTD CLI, see the Cisco Secure Firewall Threat Defense Command Reference.

Note When using SSH, be careful when making changes to the management interface; if you cannot re-connect because of a configuration error, you will need to access the device console port.

Note If you change the device management IP address, then see the following tasks for FMC connectivity depending on how you identified the FMC during initial device setup using the **configure manager add** command (see Register With a New Management Center, on page 29):

- **IP address—No action.** If you identified the FMC using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in FMC to keep the information in sync; see Update the Hostname or IP Address in the FMC, on page 52. This action can help the connection reestablish faster. **Note**: If you specified an unreachable FMC IP address, then see the procedure for NAT ID below.
- **NAT ID only—Manually reestablish the connection.** If you identified the FMC using only the NAT ID, then the connection cannot be automatically reestablished. In this case, change the device management IP address in FMC according to Update the Hostname or IP Address in the FMC, on page 52.

Note In a High Availability FMC configuration, when you modify the management IP address from the device CLI or from the FMC, the secondary FMC does not reflect the changes even after an HA synchronization. To ensure that the secondary FMC is also updated, switch roles between the two FMCs, making the secondary FMC the active unit. Modify the management IP address of the registered device on the device management page of the now active FMC.

Before you begin

- You can create user accounts that can log into the CLI using the **configure user add** command; see Add an Internal User at the CLI, on page 91. You can also configure AAA users according to External Authentication, on page 483.

Procedure

Step 1 Connect to the device CLI, either from the console port or using SSH.

See Log Into the Command-Line Interface on the Device, on page 10.

Step 2 Log in with the Admin username and password.

Step 3 (Firepower 4100/9300 only) Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You always need a management interface for management traffic. If your device has a second management interface, you can enable it for event-only traffic.

You can optionally disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

To use a separate event interface, you also need to enable an event interface on the FMC. See the Firepower Management Center Administration Guide.

Example:

```
> configure network management-interface enable management1
Configuration updated successfully

> configure network management-interface disable-management-channel management1
Configuration updated successfully

>
```

Step 4 Configure the IP address of the management interface and/or event interface:

If you do not specify the *management_interface* argument, then you change the network settings for the default management interface. When configuring an event interface, be sure to specify the *management_interface*

argument. The event interface can be on a separate network from the management interface, or on the same network. If you are connected to the interface you are configuring, you will be disconnected. You can re-connect to the new IP address.

a) Configure the IPv4 address:

- Manual configuration:

  configure network ipv4 manual *ip_address netmask gateway_ip* [*management_interface*]

  Note that the *gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

  Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.

>
```

- DHCP (supported on the default management interface only):

  configure network ipv4 dhcp

b) Configure the IPv6 address:

- Stateless autoconfiguration:

  configure network ipv6 router [*management_interface*]

  Example:

```
> configure network ipv6 router management0
Setting IPv6 network configuration.
Network settings changed.

>
```

- Manual configuration:

  configure network ipv6 manual *ip6_address ip6_prefix_length* [*ip6_gateway_ip*] [*management_interface*]

  Note that the *ipv6_gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *ipv6_gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *ipv6_gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

  Example:

```
> configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
Setting IPv6 network configuration.
Network settings changed.

>
```

- DHCPv6 (supported on the default management interface only):

  configure network ipv6 dhcp

Step 5 For IPv6, enable or disable ICMPv6 Echo Replies and Destination Unreachable messages. These messages are enabled by default.

configure network ipv6 destination-unreachable {**enable** | **disable**}

configure network ipv6 echo-reply {**enable** | **disable**}

You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the device management interfaces for testing purposes.

Example:

```
> configure network ipv6 destination-unreachable disable
> configure network ipv6 echo-reply disable
```

Step 6 Enable a DHCP server on the default management interface to provide IP addresses to connected hosts:

configure network ipv4 dhcp-server-enable *start_ip_address end_ip_address*

Example:

```
> configure network ipv4 dhcp-server-enable 10.10.10.200 10.10.10.254
DHCP Server Enabled

>
```

You can only configure a DHCP server when you set the management interface IP address manually. This command is not supported on the FMCv. To display the status of the DHCP server, enter **show network-dhcp-server**:

```
> show network-dhcp-server
DHCP Server Enabled
10.10.10.200-10.10.10.254
```

Step 7 Add a static route for the event-only interface if the FMC is on a remote network; otherwise, all traffic will match the default route through the management interface.

configure network static-routes {**ipv4** | **ipv6**} **add** *management_interface destination_ip netmask_or_prefix gateway_ip*

For the *default* route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see Step 4, on page 66).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully

> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully

>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes
---------------[ IPv4 Static Routes ]---------------
Interface                : management1
Destination              : 192.168.6.0
Gateway                  : 10.10.10.1
Netmask                  : 255.255.255.0
[…]
```

Step 8 Set the hostname:

configure network hostname *name*

Example:

```
> configure network hostname farscape1.cisco.com
```

Syslog messages do not reflect a new hostname until after a reboot.

Step 9 Set the search domains:

configure network dns searchdomains *domain_list*

Example:

```
> configure network dns searchdomains example.com,cisco.com
```

Set the search domain(s) for the device, separated by commas. These domains are added to hostnames when you do not specify a fully-qualified domain name in a command, for example, **ping system**. The domains are used only on the management interface, or for commands that go through the management interface.

Step 10 Set up to 3 DNS servers, separated by commas:

configure network dns servers *dns_ip_list*

Example:

```
> configure network dns servers 10.10.6.5,10.20.89.2,10.80.54.3
```

Step 11 Set the remote management port for communication with the FMC:

configure network management-interface tcpport *number*

Example:

```
> configure network management-interface tcpport 8555
```

The FMC and managed devices communicate using a two-way, TLS-1.3-encrypted communication channel, which by default is on port 8305.

Note
Cisco **strongly** recommends that you keep the default settings for the remote management port, but if the management port conflicts with other communications on your network, you can choose a different port. If you change the management port, you must change it for **all** devices in your deployment that need to communicate with each other.

Step 12 (FTD only) Set the management or eventing interface MTU. The MTU is 1500 bytes by default.

configure network mtu [*bytes*] [*interface_id*]

- *bytes*—Sets the MTU in bytes. For the management interface, the value can be between 64 and 1500 if you enable IPv4, and 1280 to 1500 if you enable IPv6. For the eventing interface, the value can be between 64 and 9000 if you enable IPv4, and 1280 to 9000 if you enable IPv6. If you enable both IPv4 and IPv6, then the minimum is 1280. If you do not enter the *bytes*, you are prompted for a value.
- *interface_id*—Specifies the interface ID on which to set the MTU. Use the **show network** command to see available interface IDs, for example management0, management1, br1, and eth0, depending on the platform. If you do not specify an interface, then the management interface is used.

Example:

```
> configure network mtu 8192 management1
MTU set successfully to 1500 from 8192 for management1
Refreshing Network Config...
NetworkSettings::refreshNetworkConfig MTU value at start 8192

Interface management1 speed is set to '10000baseT/Full'
NetworkSettings::refreshNetworkConfig MTU value at end 8192
>
```

Step 13 Configure an HTTP proxy. The device is configured to directly-connect to the internet on ports TCP/443 (HTTPS) and TCP/80 (HTTP). You can use a proxy server, to which you can authenticate via HTTP Digest. After issuing the command, you are prompted for the HTTP proxy address and port, whether proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Note
For proxy password on FTD, you can use A-Z, a-z, and 0-9 characters only.

configure network http-proxy

Example:

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address: 10.100.10.10
Enter HTTP Proxy Port: 80
Use Proxy Authentication? (y/n) [n]: Y
Enter Proxy Username: proxyuser
Enter Proxy Password: proxypassword
Confirm Proxy Password: proxypassword
```

Step 14 If you change the device management IP address, then see the following tasks for FMC connectivity depending on how you identified the FMC during initial device setup using the **configure manager add** command (see Register With a New Management Center, on page 29):

- **IP address—No action.** If you identified the FMC using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in FMC to keep the information in sync; see Update the Hostname or IP Address in the FMC, on page 52. This action can help the connection reestablish faster. **Note**: If you specified an unreachable FMC IP address, then you must manually reestablish the connection using Update the Hostname or IP Address in the FMC, on page 52.
- **NAT ID only—Manually reestablish the connection.** If you identified the FMC using only the NAT ID, then the connection cannot be automatically reestablished. In this case, change the device management IP address in FMC according to Update the Hostname or IP Address in the FMC, on page 52.

Modify the FTD Data Interface Used for Management at the CLI

If the management connection between the FTD and the FMC was disrupted, and you want to specify a new data interface to replace the old interface, use the FTD CLI to configure the new interface. This procedure assumes you want to replace the old interface with a new interface on the same network. If the management connection is active, then you should make any changes to an existing data interface using the FMC. For initial setup of the data management interface, see the **configure network management-data-interface** command in Complete the FTD Initial Configuration Using the CLI, on page 17.

Note This topic applies to the data interface that you configured for Management, not the dedicated Management interface. If you want to change network settings for the Management interface, see Modify FTD Management Interfaces at the CLI, on page 65.

For information about the FTD CLI, see the Cisco Secure Firewall Threat Defense Command Reference.

Before you begin

You can create user accounts that can log into the CLI using the **configure user add** command; see Add an Internal User at the CLI, on page 91. You can also configure AAA users according to External Authentication, on page 483.

Procedure

Step 1 If you are changing the data management interface to a new interface, move the current interface cable to the new interface.

Step 2 Connect to the device CLI.

You should use the console port when using these commands. If you are performing initial setup, then you may be disconnected from the Management interface. If you are editing the configuration due to a disrupted management connection, and you have SSH access to the dedicated Management interface, then you can use that SSH connection.

See Log Into the Command-Line Interface on the Device, on page 10.

Step 3 Log in with the Admin username and password.

Step 4 Disable the interface so you can reconfigure its settings.

configure network management-data-interface disable

Example:

```
> configure network management-data-interface disable

 Configuration updated successfully..!!

Configuration disable was successful, please update the default route to point to a gateway
 on management interface using the command 'configure network'
```

Step 5 Configure the new data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

When you change the data management interface to a new interface on the same network, use the same settings as for the previous interface except the interface ID. In addition, for the **Do you wish to clear all the device configuration before applying ? (y/n) [n]:** option, choose **y**. This choice will clear the old data management interface configuration, so that you can successfully reuse the IP address and interface name on the new interface.

```
> configure network management-data-interface
Data interface to use for management: ethernet1/4
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]: y

Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Step 6 (Optional) Limit data interface access to the FMC on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

Step 7 The connection will be reestablished automatically, but disabling and reenabling the connection in the FMC will help the connection reestablish faster. See Update the Hostname or IP Address in the FMC, on page 52.

Step 8 Check that the management connection was reestablished.

sftunnel-status-brief

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
 '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Step 9 In the FMC, choose **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details**, and click **Refresh**.

The FMC detects the interface and default route configuration changes, and blocks deployment to the FTD. When you change the data interface settings locally on the device, you must reconcile those changes in the FMC manually. You can view the discrepancies between the FMC and the FTD on the **Configuration** tab.

Step 10 Choose **Devices** > **Device Management** > **Interfaces**, and make the following changes.

a) Remove the IP address and name from the old data management interface, and disable manager access for this interface.

b) Configure the new data management interface with the settings of the old interface (the ones you used at the CLI), and enable manager access for it.

Step 11 Choose **Devices** > **Device Management** > **Routing** > **Static Route** and change the default route from the old data management interface to the new one.

Step 12 Return to the **FMC Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

The next time you deploy, the FMC configuration will overwrite any remaining conflicting settings on the FTD. It is your responsibility to manually fix the configuration in the FMC before you re-deploy.

You will see expected messages of "Config was cleared" and "FMC access changed and acknowledged."

Edit the FMC IP Address/Hostname on the Device

If you change the FMC IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the FMC IP address or hostname on the device, in at least one case, you must perform this task for the connection to be reestablished: when you added the device to the FMC and you specified the NAT ID only. Even in other cases, we recommend keeping the FMC IP address or hostname up to date for extra network resiliency.

Procedure

Step 1 At the FMC CLI, view the unique UUID for the FMC so you can specify it in the FTD command. For information about the FMC CLI, see *Firepower Management Center Command Line Reference* in the Firepower Management Center Administration Guide.

show version

The FMC UUID definitively identifies the FMC; for example, in the case of FMC high availability, you need to specify the active FMC on the FTD.

Example:

```
> show version
------------------[ firepower ]---------------------
Model                     : Cisco Firepower Management Center for VMWare (66) Version 6.7.0
 (Build 1222)
UUID                       : f7ffad78-bf16-11ec-a737-baa2f76ef602
Rules update version       : 2020-05-26-001-vrt
VDB version                : 334
-----------------------------------------------------
```

Step 2 At the FTD CLI, edit the FMC IP address or hostname.

configure manager edit *identifier* {*ip_address* | *hostname*}

If the FMC was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

The management connection will go down, and then reestablish. You can monitor the state of the connection using the **sftunnel-status** command.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 10.10.5.1
```

Roll Back the Configuration if the FMC Loses Connectivity

If you use a data interface on the FTD for manager access, and you deploy a configuration change from the FMC that affects the network connectivity, you can roll back the configuration on the FTD to the last-deployed configuration so you can restore management connectivity. You can then adjust the configuration settings in FMC so that the network connectivity is maintained, and re-deploy. You can use the rollback feature even if you do not lose connectivity; it is not limited to this troubleshooting situation.

See the following guidelines:

- Only the previous deployment is available locally on the FTD; you cannot roll back to any earlier deployments.
- Rollback is not supported for high availability or clustering deployments.

- The rollback only affects configurations that you can set in the FMC. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the FTD CLI. Note that if you changed data interface settings after the last FMC deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed FMC settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

Step 1 At the FTD CLI, roll back to the previous configuration.

configure policy rollback

After the rollback, the FTD notifies the FMC that the rollback was completed successfully. In the FMC, the deployment screen will show a banner stating that the configuration was rolled back.

Note
If the rollback failed and the FMC management is restored, refer to https://www.cisco.com/c/en/us/support/docs/security/firepower-ngfw-virtual/215258-troubleshooting-firepower-threat-defense.html for common deployment problems. In some cases, the rollback can fail after the FMC management access is restored; in this case, you can resolve the FMC configuration issues, and redeploy from the FMC.

Example:

For the FTD that uses a data interface for manager access:

```
> configure policy rollback

The last deployment to this FTD was on June 1, 2020 and its status was Successful.
Do you want to continue [Y/N]?

Y

Rolling back complete configuration on the FTD. This will take time.
.....................
Policy rollback was successful on the FTD.
Configuration has been reverted back to transaction id:
Following is the rollback summary:
...................
.....................
>
```

Step 2 Check that the management connection was reestablished.

In FMC, check the management connection status on the **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details** > **Connection Status** page.

At the FTD CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 76.

Troubleshoot Management Connectivity on a Data Interface

When you use a data interface for manager access instead of using the dedicated Management interface, you must be careful about changing the interface and network settings for the FTD in the FMC so you do not disrupt the connection. If you change the management interface type after you add the FTD to the FMC (from data to Management, or from Management to data), if the interfaces and network settings are not configured correctly, you can lose management connectivity.

This topic helps you troubleshoot the loss of management connectivity.

View management connection status

In the FMC, check the management connection status on the **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details** > **Connection Status** page.

At the FTD CLI, enter the **sftunnel-status-brief** command to view the management connection status. You can also use **sftunnel-status** to view more complete information.

See the following sample output for a connection that is down; there is no peer channel "connected to" information, nor heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went down
```

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
 via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202'
 via '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

View the FTD network information

At the FTD CLI, view the Management and manager access data interface network settings:

show network

```
> show network
===============[ System Information ]===============
Hostname                  : FTD-4
```

```
Domains                 : cisco.com
DNS Servers             : 72.163.47.11
DNS from router         : enabled
Management port         : 8305

Gateway                 : 10.89.5.1
----------------------[ IPv6 ]----------------------
Configuration           : Disabled
```

Check that the FTD registered with the FMC

At the FTD CLI, check that the FMC registration was completed. Note that this command will not show the *current* status of the management connection.

show managers

```
> show managers
Type                    : Manager
Host                    : 10.83.57.41
Registration            : Completed
```

Ping the FMC

At the FTD CLI, use the following command to ping the FMC from the data interfaces:

ping *fmc_ip*

At the FTD CLI, use the following command to ping the FMC from the Management interface, which should route over the backplane to the data interfaces:

ping system *fmc_ip*

Capture packets on the FTD internal interface

At the FTD CLI, capture packets on the internal backplane interface (nlp_int_tap) to see if management packets are being sent:

capture *name* **interface nlp_int_tap trace detail match ip any any**

show capture*name* **trace detail**

Check the internal interface status, statistics, and packet count

At the FTD CLI, see information about the internal backplane interface, nlp_int_tap:

show interface detail

```
> show interface detail
[...]
Interface Internal-Data0/1 "nlp_int_tap", is up, line protocol is up
  Hardware is en_vtun rev00, BW Unknown Speed-Capability, DLY 1000 usec
 (Full-duplex), (1000 Mbps)
 Input flow control is unsupported, output flow control is unsupported
 MAC address 0000.0100.0001, MTU 1500
 IP address 169.254.1.1, subnet mask 255.255.255.248
 37 packets input, 2822 bytes, 0 no buffer
 Received 0 broadcasts, 0 runts, 0 giants
 0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
 0 pause input, 0 resume input

Check other settings

See the following commands to check that all other settings are present. You can also see many of these commands on the FMC's **Devices** > **Device Management** > **Device** > **Management** > **FMC Access - Configuration Details** > **CLI Output** page.

show running-config sftunnel

```
> show running-config sftunnel
sftunnel interface outside
sftunnel port 8305
```

show running-config ip-client

```
> show running-config ip-client
ip-client outside
```

show conn address *fmc_ip*

```
> show conn address 10.89.5.35
5 in use, 16 most used
```

```
Inspect Snort:
        preserve-connection: 0 enabled, 0 in effect, 0 most enabled, 0 most in effect

TCP nlp_int_tap  10.89.5.29(169.254.1.2):51231 outside  10.89.5.35:8305, idle 0:00:04,
 bytes 86684, flags UxIO
TCP nlp_int_tap  10.89.5.29(169.254.1.2):8305 outside  10.89.5.35:52019, idle 0:00:02,
 bytes 1630834, flags UIO
>
```

Check for a successful DDNS update

At the FTD CLI, check for a successful DDNS update:

debug ddns

```
> debug ddns
DDNS update request = /v3/update?hostname=domain.example.org&myip=209.165.200.225
Successfully updated the DDNS sever with current IP addresses
DDNS: Another update completed, outstanding = 0
DDNS: IDB SB total = 0
```

If the update failed, use the **debug http** and **debug ssl** commands. For certificate validation failures, check that the root certificates are installed on the device:

show crypto ca certificates *trustpoint_name*

To check the DDNS operation:

show ddns update interface *fmc_access_ifc_name*

```
> show ddns update interface outside

Dynamic DNS Update on outside:
    Update Method Name Update Destination
    RBD_DDNS not available

Last Update attempted on 04:11:58.083 UTC Thu Jun 11 2020
Status : Success
FQDN : domain.example.org
IP addresses : 209.165.200.225
```

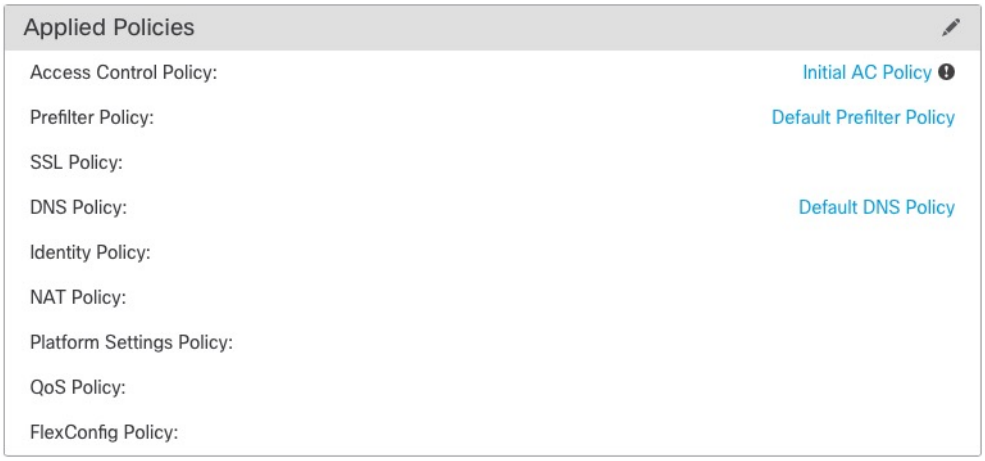
Check FMC log files

See https://cisco.com/go/fmc-reg-error.

View Inventory Details

The **Inventory Details** section of the **Device** page shows chassis details such as the CPU and memory.

Figure 33: Inventory Details



To update information, click **Refresh** ( ).

Edit Applied Policies

The **Applied Policies** section of the **Device** page displays the following policies applied to your firewall:

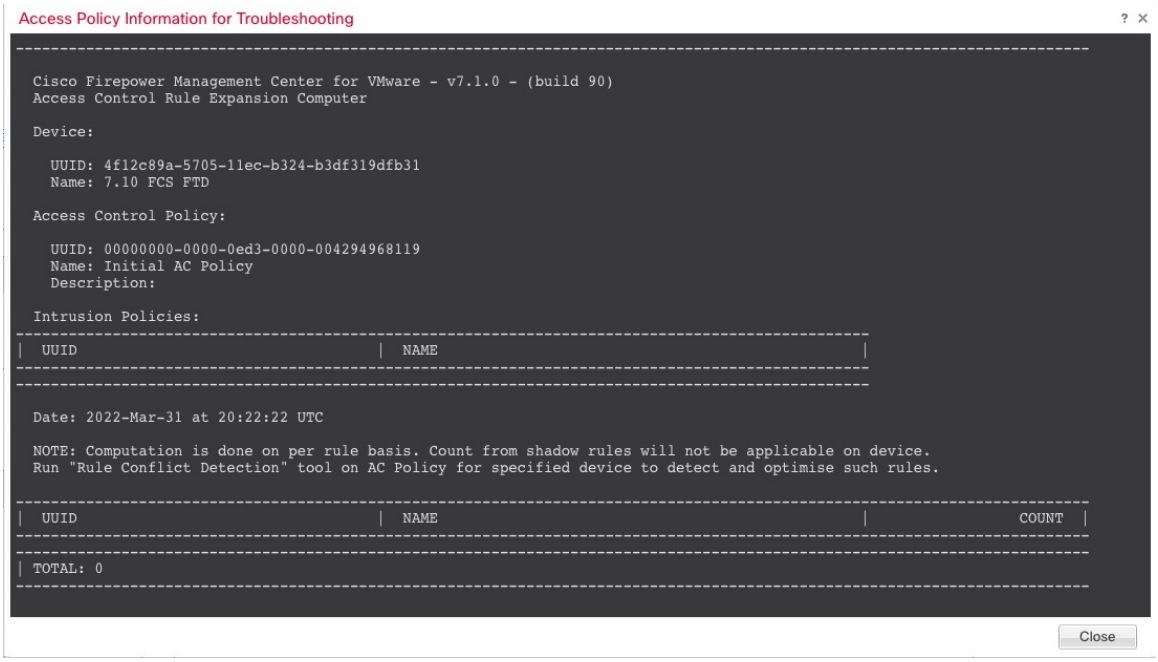


Figure 34: Applied Policies

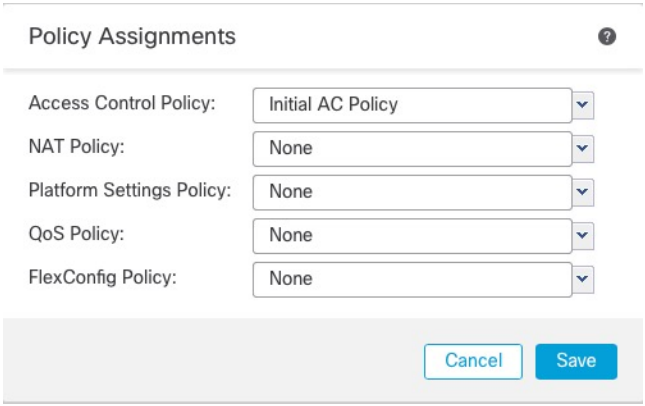
For policies with links, you can click the link to view the policy.

For the Access Control Policy, view the **Access Policy Information for Troubleshooting** dialog box by clicking the **Exclamation** ( ) icon. This dialog box shows how access rules are expanded into access control entries (ACEs).

Figure 35: Access Policy Information for Troubleshooting

You can assign policies to an individual device from the **Device Management** page.

Procedure



Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **Applied Policies** section, click **Edit** ( ).

Figure 36: Policy Assignments

Step 5 For each policy type, choose a policy from the drop-down menu. Only existing policies are listed.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Edit Advanced Settings

The **Advanced Settings** section of the **Device** page displays a table of advanced configuration settings, as described below. You can edit any of these settings.

Table 6: Advanced Section Table Fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.
Object Group Search	The state of object group search on the device. While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firepower Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules.
Interface Object Optimization	The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

The following topics explain how to edit the advanced device settings.

Note For information about the Transfer Packets setting, see Edit General Settings, on page 43.

Configure Automatic Application Bypass

Automatic Application Bypass (AAB) allows packets to bypass detection if Snort is down or, for a Classic device, if a packet takes too long to process. AAB causes Snort to restart within ten minutes of the failure, and generates troubleshooting data that can be analyzed to investigate the cause of the Snort failure.

Caution AAB activation partially restarts the Snort process, which temporarily interrupts the inspection of a few packets. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information.

See the following behavior:

FTD Behavior: If Snort is down, then AAB is triggered after the specified timer duration. If Snort is up, then AAB is never triggered, even if packet processing exceeds the configured timer.

Classic Device Behavior: AAB limits the time allowed to process packets through an interface. You balance packet processing delays with your network's tolerance for packet latency.

The feature functions with any deployment; however, it is most valuable in inline deployments.

Typically, you use Rule Latency Thresholding in the intrusion policy to fast-path packets after the latency threshold value is exceeded. Rule Latency Thresholding does not shut down the engine or generate troubleshooting data.

If detection is bypassed, the device generates a health monitoring alert.

By default the AAB is disabled; to enable AAB follow the steps described.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to edit advanced device settings, click **Edit** ( ).

Step 3 Click **Device**, then click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Automatic Application Bypass**.

Step 5 Enter a **Bypass Threshold** from 250 ms to 60,000 ms. The default setting is 3000 milliseconds (ms).

Step 6 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Configure Object Group Search

While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those

group definitions. Object group search does not impact how your access rules are defined or how they appear in FMC. It impacts only how the device interprets and processes them while matching connections to access control rules.

Enabling object group search reduces memory requirements for access control policies that include network or interface objects. However, it is important to note that object group search might also decrease rule lookup performance and thus increase CPU utilization. You should balance the CPU impact against the reduced memory requirements for your specific access control policy. In most cases, enabling object group search provides a net operational improvement.

Object group search is disabled by default. You can enable it on one device at a time; you cannot enable it globally. We recommend that you enable it on any device to which you deploy access rules that use network or interface objects.

Note If you enable object group search and then configure and operate the device for a while, be aware that subsequently disabling the feature might lead to undesirable results. When you disable object group search, your existing access control rules will be expanded in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact. If your device is operating normally, you should not disable object group search once you have enabled it.

Before you begin

- Model Support—FTD
- We recommend that you also enable transactional commit on each device. From the device CLI, enter the **asp rule-engine transactional-commit access-group** command.
- Changing this setting can be disruptive to system operation while the device recompiles the ACLs. We recommend that you change this setting during a maintenance window.
- You can use FlexConfig to configure the **object-group-search threshold** command to enable a threshold to help prevent performance degradation. When operating with a threshold, for each connection, both the source and destination IP addresses are matched against network objects. If the number of objects matched by the source address times the number matched by the destination address exceeds 10,000, the connection is dropped. Configure your rules to prevent an excessive number of matches.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the FTD device where you want to configure the rule, click the **Edit** ( ).

Step 3 Click the **Device** tab, then click the **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Object Group Search**.

Step 5 To have object group search work on interface objects in addition to network objects, check **Interface Object Optimization**.

If you do not select **Interface Object Optimization**, the system deploys separate rules for each source/interface pair, rather that use the security zones and interface groups used in the rules. This means the interface groups are not available for object group search processing.

Step 6 Click **Save**.

Configure Interface Object Optimization

During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

Interface object optimization is disabled by default. You can enable it on one device at a time; you cannot enable it globally.

Note If you disable interface object optimization, your existing access control rules will be deployed without using interface objects, which might make deployment take longer. In addition, if object group search is enabled, its benefits will not apply to interface objects, and you might see expansion in the access control rules in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact.

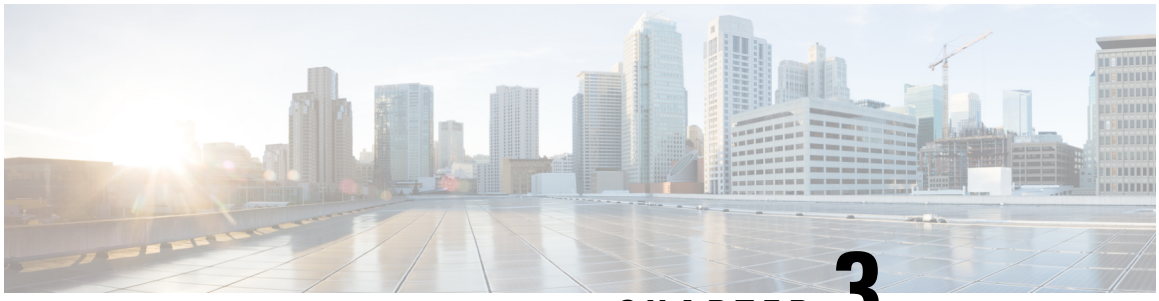
Before you begin

Model Support—FTD

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the FTD device where you want to configure the rule, click the **Edit** ( ).



Step 3 Click the **Device** tab, then click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Interface Object Optimization**.

Step 5 Click **Save**.

History for Device Settings

Feature	Minimum FMC	Minimum FTD	Details
Import and export device configurations.	7.1.0	7.1.0	You can export the device-specific configuration, and you can then import the saved configuration for the same device in the following use cases: • Moving the device to a different FMC. • Restore an old configuration. • Reregistering a device. New/modified screens: **Devices** > **Device Management** > **Device** > **General**
Update the FMC IP address on FTD.	6.7.0	6.7.0	If you change the FMC IP address, you can now use the FTD CLI to update the device. New/modified commands: **configure manager edit**

CHAPTER 3

Users

Managed devices include a default **admin** account for CLI access. This chapter discusses how to create custom user accounts.

- About Users, on page 89
- Requirements and Prerequisites for User Accounts for Devices, on page 90
- Guidelines and Limitations for User Accounts for Devices, on page 91
- Add an Internal User at the CLI, on page 91
- Configure External Authentication for the FTD, on page 93
- Troubleshooting LDAP Authentication Connections, on page 105
- History for Users, on page 107

About Users

You can add custom user accounts on managed devices, either as internal users or as external users on a LDAP or RADIUS server. Each managed device maintains separate user accounts. For example, when you add a user to the FMC, that user only has access to the FMC; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and External Users

Managed devices support two types of users:

- Internal user—The device checks a local database for user authentication.
- External user—If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

CLI Access

Firepower devices include a Firepower CLI that runs on top of Linux. You can create internal users on devices using the CLI. You can establish external users on FTD devices using the FMC.

Caution Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firepower user documentation.
- Make sure that you restrict the list of users with CLI access appropriately.
- When granting CLI access privileges, restrict the list of users with Config level access.
- Do not add users directly in the Linux shell; only use the procedures in this chapter.
- Do not access Firepower devices using CLI expert mode unless directed by Cisco TAC or by explicit instructions in the Firepower user documentation.

CLI User Roles

On managed devices, user access to commands in the CLI depends on the role you assign.

None

The user cannot log into the device on the command line.

Config

The user can access all commands, including configuration commands. Exercise caution in assigning this level of access to users.

Basic

The user can access non-configuration commands only. Only internal users and FTD external RADIUS users support the Basic role.

Requirements and Prerequisites for User Accounts for Devices

Model Support

- FTD—Internal and external users

Supported Domains

Any

User Roles

Configure external users—Admin FMC user

Configure internal users—Config CLI user

Guidelines and Limitations for User Accounts for Devices

Usernames

- You cannot add the same username for both internal and external users. If the external server uses a duplicate username, the deployment to the device fails.
- The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Defaults

All devices include an **admin** user as a local user account; you cannot delete the **admin** user. The default initial password is **Admin123**; the system forces you to change this during the initialization process. The agent stores the modified credentials in the Windows registry and uses the same encryption as the FMC, which is Cipher Block Chaining (CBC). See the getting started guide for your model for more information about system initialization.

Add an Internal User at the CLI

Use the CLI to create internal users on the FTD.

Procedure

Step 1 Log into the device CLI using an account with Config privileges.

The **admin** user account has the required privileges, but any account with Config privileges will work. You can use an SSH session or the Console port.

For certain FTD models, the Console port puts you into the FXOS CLI. Use the **connect ftd** command to get to the FTD CLI.

Step 2 Create the user account.

configure user add *username* {**basic** | **config**}

- *username*—Sets the username. The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

- **basic**—Gives the user basic access. This role does not allow the user to enter configuration commands.
- **config**—Gives the user configuration access. This role gives the user full administrator rights to all commands.

Example:

The following example adds a user account named johncrichton with Config access rights. The password is not shown as you type it.

```
> configure user add johncrichton config
Enter new password for user johncrichton: newpassword
Confirm new password for user johncrichton: newpassword
> show user
Login              UID   Auth Access  Enabled Reset    Exp Warn  Str Lock Max
admin             1000  Local Config  Enabled    No  Never  N/A  Dis   No N/A
johncrichton      1001  Local Config  Enabled    No  Never  N/A  Dis   No   5
```

Note
Tell users they can change their own passwords using the **configure password** command.

Step 3 (Optional) Adjust the characteristics of the account to meet your security requirements.

You can use the following commands to change the default account behavior.

- **configure user aging** *username max_days warn_days*

  Sets an expiration date for the user's password. Specify the maximum number of days for the password to be valid followed by the number of days before expiration the user will be warned about the upcoming expiration. Both values are 1 to 9999, but the warning days must be less than the maximum days. When you create the account, there is no expiration date for the password.

- **configure user forcereset** *username*

  Forces the user to change the password on the next login.

- **configure user maxfailedlogins** *username number*

  Sets the maximum number of consecutive failed logins you will allow before locking the account, from 1 to 9999. Use the **configure user unlock** command to unlock accounts. The default for new accounts is 5 consecutive failed logins.

- **configure user minpasswdlen** *username number*

  Sets a minimum password length, which can be from 1 to 127.

- **configure user strengthcheck** *username* {**enable** | **disable**}

  Enables or disables password strength checking, which requires a user to meet specific password criteria when changing their password. When a user's password expires or if the **configure user forcereset** command is used, this requirement is automatically enabled the next time the user logs in.

Step 4 Manage user accounts as necessary.

Users can get locked out of their accounts, or you might need to remove accounts or fix other issues. Use the following commands to manage the user accounts on the system.

- **configure user access** *username* {**basic** | **config**}

Changes the privileges for a user account.

- **configure user delete** *username*

  Deletes the specified account.

- **configure user disable** *username*

  Disables the specified account without deleting it. The user cannot log in until you enable the account.

- **configure user enable** *username*

  Enables the specified account.

- **configure user password** *username*

  Changes the password for the specified user. Users should normally change their own password using the **configure password** command.

  Caution
  Do not use the Linux **passwd** command in Expert Mode to change the admin user password. This command can cause file system corruption. Only use the regular FTD CLI **configure user password admin** command (if you are not admin) or **configure password** command (if you are admin). If you don't know the password and can't log in at all, see the password recovery procedure.

- **configure user unlock** *username*

  Unlocks a user account that was locked due to exceeding the maximum number of consecutive failed login attempts.

Configure External Authentication for the FTD

To enable external authentication for FTD devices, you need to add one or more external authentication objects.

About External Authentication for the FTD

When you enable external authentication for FTD users, the FTD verifies the user credentials with an LDAP or RADIUS server as specified in an *external authentication object*.

External authentication objects can be used by the FMC and FTD devices. You can share the same object between the different appliance/device types or create separate objects. For the FTD, you can only activate one external authentication object in the platform settings that you deploy to the devices.

Note The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the FTD external authentication configuration will not work.

Only a subset of fields in the external authentication object are used for FTD SSH access. If you fill in additional fields, they are ignored. If you also use this object for other device types, those fields will be used.

LDAP users always have Config privileges. RADIUS users can be defined as either Config or Basic users.

You can either define users on the RADIUS server (with the Service-Type attribute), or you can pre-define the user list in the external authentication object. For LDAP, you can specify a filter to match CLI users on the LDAP server.

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you:

- Restrict the list of users with Linux shell access.
- Do not create Linux shell users.

About LDAP

The Lightweight Directory Access Protocol (LDAP) allows you to set up a directory on your network that organizes objects, such as user credentials, in a centralized location. Multiple applications can then access those credentials and the information used to describe them. If you ever need to change a user's credentials, you can change them in one place.

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, see 2020 LDAP channel binding and LDAP signing requirement for Windows on the Microsoft support site.

If you have not done so already, we recommend you start using TLS/SSL encryption to authenticate with an Active Directory server.

About RADIUS

Remote Authentication Dial In User Service (RADIUS) is an authentication protocol used to authenticate, authorize, and account for user access to network resources. You can create an authentication object for any RADIUS server that conforms to RFC 2865.

Firepower devices support the use of SecurID tokens. When you configure authentication by a server using SecurID, users authenticated against that server append the SecurID token to the end of their SecurID PIN and use that as their password when they log in. You do not need to configure anything extra on the Firepower device to support SecurID.

Add an LDAP External Authentication Object for FTD

Add an LDAP server to support external users for FTD management.

In a multidomain deployment, external authentication objects are only available in the domain in which they are created.

Sharing External Authentication Objects

External LDAP objects can be used by the FMC and FTD devices. You can share the same object between the FMC and devices or create separate objects. Be sure that both the FTD and the FMC can reach the LDAP server, even if you are not sharing the object. The FMC is essential to retrieving the user list and downloading it to the device.

Note For LDAP, the timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the deployment to the FTD will fail.

FTD Supported Fields

Only a subset of fields in the LDAP object are used for FTD SSH access. If you fill in additional fields, they are ignored. If you also use this object for the FMC, those fields will be used. This procedure only covers the supported fields for the FTD. For other fields, see Add an LDAP External Authentication Object for the FMC.

Usernames

Usernames must be Linux-valid usernames and be lower-case only, using alphanumeric characters plus period (.) or hyphen (-). Other special characters such as at sign (@) and slash (/) are not supported. You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the FMC; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the FMC.

If you previously configured the same username for an internal user using the **configure user add** command, the FTD first checks the password against the internal user, and if that fails, it checks the LDAP server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported.

Privilege Level

LDAP users always have Config privileges.

Before you begin

You must specify DNS server(s) for domain name lookup on your device. Even if you specify an IP address and not a hostname for the LDAP server on this procedure, the LDAP server may return a URI for authentication that can include a hostname. A DNS lookup is required to resolve the hostname. See Modify FTD Management Interfaces at the CLI, on page 65 to add DNS servers.

Procedure

Step 1 Choose **System** (⚙) > **Users**.

Step 2 Click the **External Authentication** tab.

Step 3 Click (+) **Add External Authentication Object**.

Step 4 Set the **Authentication Method** to **LDAP**.

Step 5 Enter a **Name** and optional **Description**.

Step 6 Choose a **Server Type** from the drop-down list.

Step 7 For the **Primary Server**, enter a **Host Name/IP Address**.

If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

Step 8 (Optional) Change the **Port** from the default.

Step 9 (Optional) Enter the **Backup Server** parameters.

Step 10 Enter **LDAP-Specific Parameters**.

a) Enter the **Base DN** for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.

b) (Optional) Enter the **Base Filter**. For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.

c) Enter a **User Name** for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at your example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.

d) Enter the user password in the **Password** and the **Confirm Password** fields.

e) (Optional) Click **Show Advanced Options** to configure the following advanced options.

- **Encryption**—Click **None**, **TLS**, or **SSL**.

  If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

- **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.

  If you previously uploaded a certificate and want to replace it, upload the new certificate and redeploy the configuration to your devices to copy over the new certificate.

  Note
  TLS encryption requires a certificate on all platforms. For SSL, the FTD also requires a certificate. For other platforms, SSL does not require a certificate. However, we recommend that you *always* upload a certificate for SSL to prevent man-in-the-middle attacks.

- (Not Used) **User Name Template**—Not used by the FTD.

- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection, between 1 and 30. The default is 30.

  Note
  The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the FTD LDAP configuration will not work.

Step 11 Configure **Attribute Mapping** to retrieve users based on an attribute.

- Enter a **UI Access Attribute**. **Note**: This field is not used for device CLI access; however, it is a required field, so you need to enter a value. You can just enter the same value that you enter for the **CLI Access Attribute**.

- Set the **CLI Access Attribute** if you want to use a CLI access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` CLI access attribute to retrieve CLI access users by typing `sAMAccountName`.

  Note

Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note
Deploying an external authentication object that allows a large number of users with CLI access may cause deployments to time out and fail while waiting for the users to be created.

Step 12 Set the **CLI Access Filter**.

Choose one of the following methods:

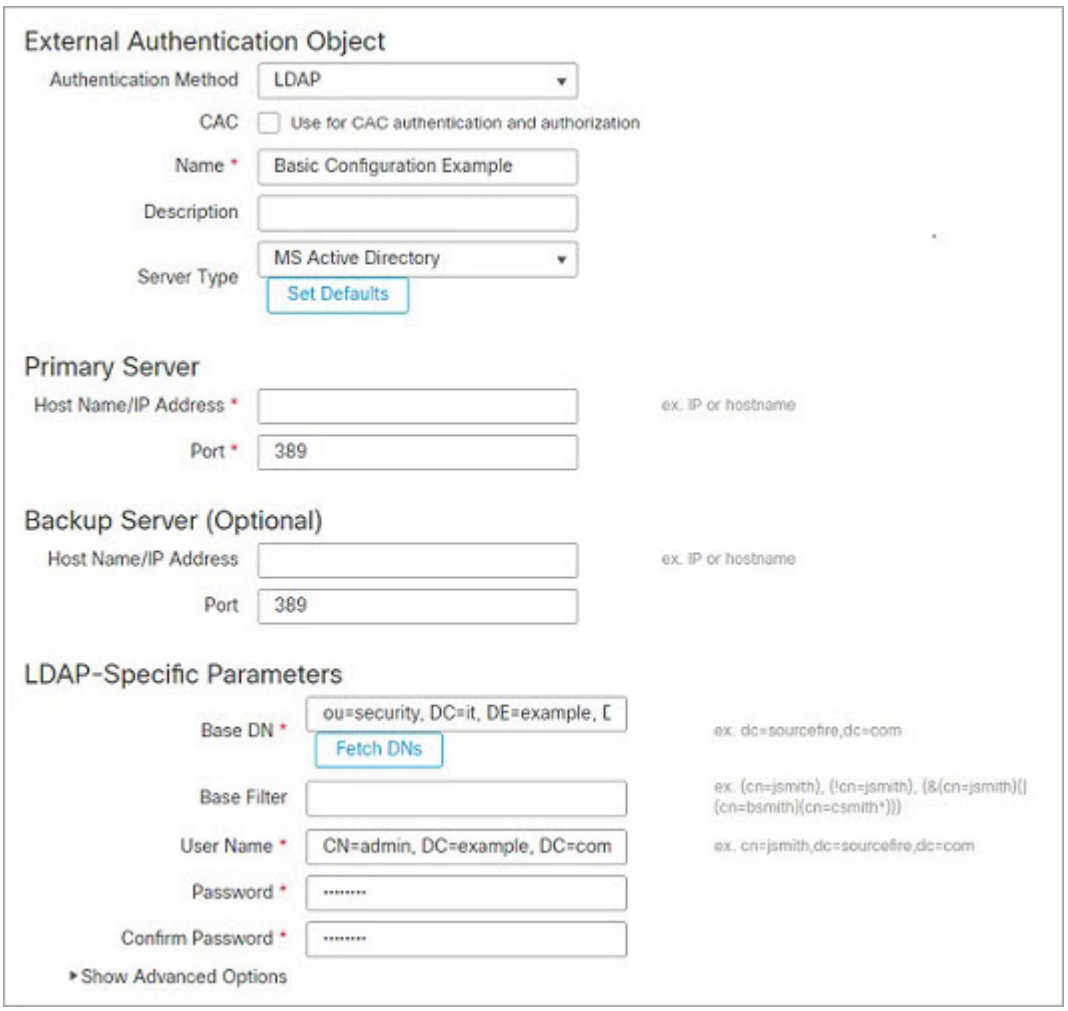
- To use the same filter you specified when configuring authentication settings, check the check box of **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The usernames must be Linux-valid:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

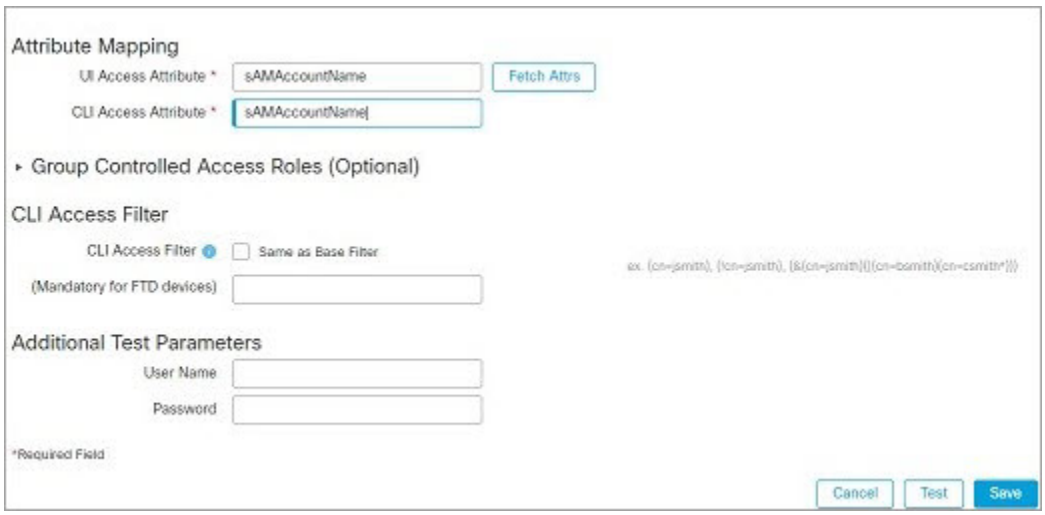
Note
If you previously configured the same username for an internal user, the FTD first checks the password against the internal user, and if that fails, it checks the LDAP server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported.

Step 13 Click **Save**.



Step 14 Enable use of this server. See External Authentication, on page 483.

Step 15 If you later add or delete users on the LDAP server, you must redeploy the Platform Settings on managed devices. The FMC redownloads the user list and deploys it to the device. See Deploy Configuration Changes, on page 121.

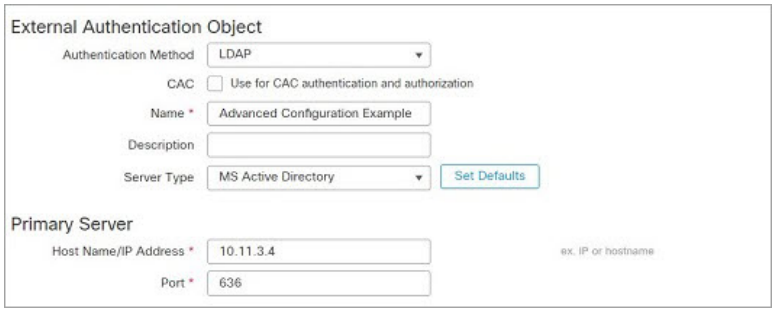


Examples

Basic Example

The following figures illustrate a basic configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 389 for access.

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company.



A **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into the FTD.

Note that because no base filter is applied to this server, the FTD checks attributes for all objects in the directory indicated by the base distinguished name. Connections to the server time out after the default time period (or the timeout period set on the LDAP server).

Advanced Example

This example illustrates an advanced configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 636 for access.

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company. However, note that this server has a base filter of `(cn=*smith)`. The filter restricts the users retrieved from the server to those with a common name ending in `smith`.

The connection to the server is encrypted using SSL and a certificate named `certificate.pem` is used for the connection. In addition, connections to the server time out after 60 seconds because of the **Timeout (Seconds)** setting.

Because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute.

The **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into the FTD.

In the following example, the CLI access filter is set to be the same as the base filter.

Add a RADIUS External Authentication Object for FTD

Add a RADIUS server to support external users for the FTD.

Sharing External Authentication Objects

You can share the same object between the FMC and devices or create separate objects. Note that the FTD supports defining users on the RADIUS server, while the FMC requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the FTD, but if you want to define users on the RADIUS server, you must create separate objects for the FTD and the FMC.

Note The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-300 seconds). If you set the timeout to a higher value, the FTD RADIUS configuration will not work.

FTD Supported Fields

Only a subset of fields in the RADIUS object are used for FTD SSH access. If you fill in additional fields, they are ignored. If you also use this object for the FMC, those fields will be used. This procedure only covers the supported fields for the FTD. For other fields, see Add a RADIUS External Authentication Object for FMC in the Firepower Management Center Administration Guide.

Usernames

You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the FMC; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the FMC.

If you previously configured the same username for an internal user using the **configure user add** command, the FTD first checks the password against the internal user, and if that fails, it checks the RADIUS server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Procedure

Step 1 Define users on the RADIUS server using the Service-Type attribute.

The following are supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a sign (@) or slash (/)

Alternatively, you can predefine users in the external authentication object (see, Step 12, on page 102). To use the same RADIUS server for the FTD and FMC while using the Service-Type attribute method for the FTD, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the FMC), and the other object leaves the **CLI Access Filter** empty (for use with FTDs).

Step 2 In the FMC, choose **System** (⚙) > **Users**.

Step 3 Click **External Authentication**.

Step 4 Click (+)**Add External Authentication Object**.

Step 5 Set the **Authentication Method** to **RADIUS**.

Step 6 Enter a **Name** and optional **Description**.

Step 7 For the **Primary Server**, enter a **Host Name/IP Address**.

Only IPv4 is supported.

Note

If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field.

Step 8 (Optional) Change the **Port** from the default.

Step 9 Enter the **RADIUS Secret Key**.

Step 10 (Optional) Enter the **Backup Server** parameters.

Step 11 (Optional) Enter **RADIUS-Specific Parameters**.

a) Enter the **Timeout (Seconds)** in seconds before retrying the primary server, between 1 and 300. The default is 30.

Note
The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-300 seconds). If you set the timeout to a higher value, the FTD RADIUS configuration will not work.

b) Enter the **Retries** before rolling over to the backup server. The default is 3.

Step 12 (Optional) Instead of using RADIUS-defined users (see, Step 1, on page 101), in the **CLI Access Filter** area **Administrator CLI Access User List** field, enter the user names that should have CLI access, separated by commas. For example, enter `jchrichton, aerynsun, rygel`.

You may want to use the **CLI Access Filter** method for FTD so you can use the same external authentication object with FTD and other platform types.

Note
If you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note
Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note
Deploying an external authentication object that allows a large number of users with CLI access may cause deployments to time out and fail while waiting for the users to be created.

Step 13 (Optional) Click **Test** to test FMC connectivity to the RADIUS server.

This function can only test FMC connectivity to the RADIUS server; there is no test function for managed device connectivity to the RADIUS server.

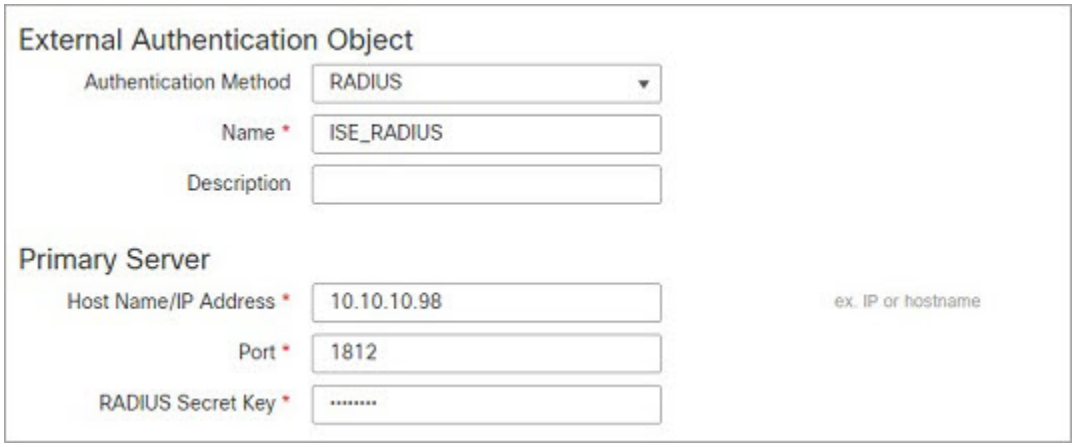
Step 14 (Optional) You can also enter **Additional Test Parameters** to test user credentials for a user who should be able to authenticate: enter a **User Name** and **Password**, and then click **Test**.

Tip

If you mistype the name or password of the test user, the test fails even if the server configuration is correct. To verify that the server configuration is correct, click **Test** without entering user information in the **Additional Test Parameters** field first. If that succeeds, supply a user name and password to test with the specific user.

Example:

To test if you can retrieve the `JSmith` user credentials at the Example company, enter `JSmith` and the correct password.



Step 15 Click **Save**.

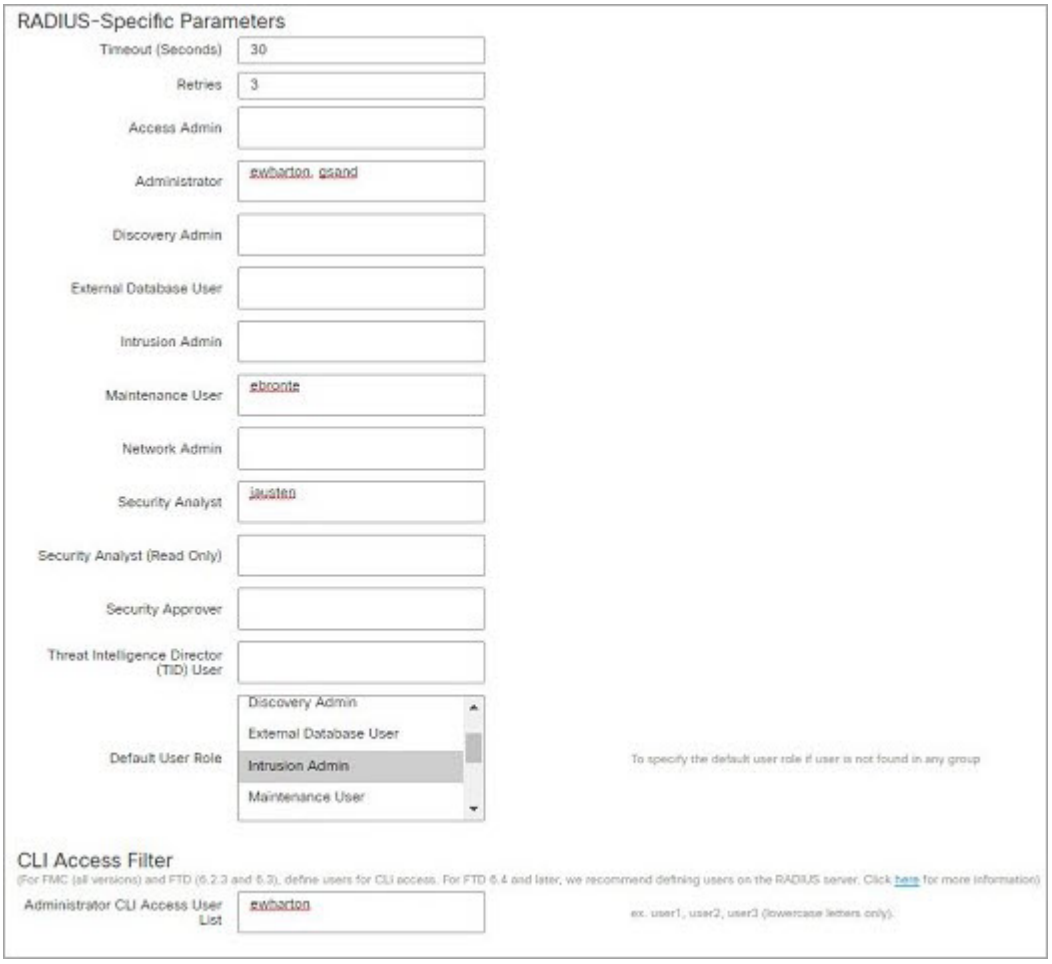
Step 16 Enable use of this server. See External Authentication, on page 483

Examples

Simple User Role Assignments

The following figure illustrates a sample RADIUS login authentication object for a server running Cisco Identity Services Engine (ISE) with an IP address of 10.10.10.98 on port 1812. No backup server is defined.

The following example shows RADIUS-specific parameters, including the timeout (30 seconds) and number of failed retries before the system attempts to contact the backup server, if any.



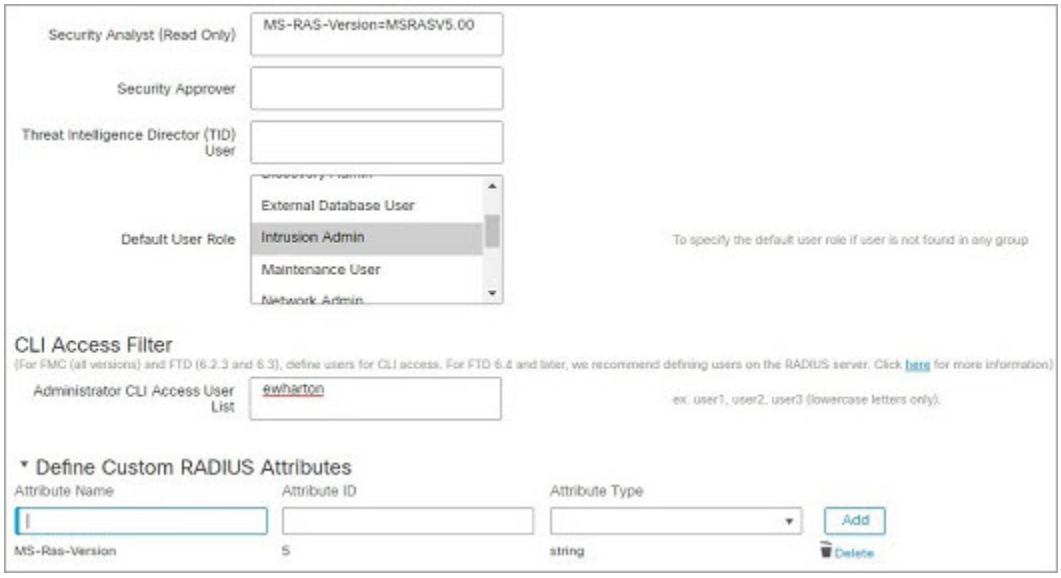
This example illustrates important aspects of RADIUS user role configuration:

Users `ewharton` and `gsand` are granted web interface Administrative access.

The user `cbronte` is granted web interface Maintenance User access.

The user `jausten` is granted web interface Security Analyst access.

The user `ewharton` can log into the device using a CLI account.



The following graphic depicts the role configuration for the example:

Roles for Users Matching an Attribute-Value Pair

You can use an attribute-value pair to identify users who should receive a particular user role. If the attribute you use is a custom attribute, you must define the custom attribute.

The following figure illustrates the role configuration and custom attribute definition in a sample RADIUS login authentication object for the same ISE server as in the previous example.

In this example, however, the `MS-RAS-Version` custom attribute is returned for one or more of the users because a Microsoft remote access server is in use. Note the `MS-RAS-Version` custom attribute is a string. In this example, all users logging in to RADIUS through a Microsoft v. 5.00 remote access server should receive the Security Analyst (Read Only) role, so you enter the attribute-value pair of `MS-RAS-Version=MSRASV5.00` in the **Security Analyst (Read Only)** field.

Enable External Authentication for Users on FTD Devices

Enable External Authentication in the Threat Defense Platform Settings, and then deploy the settings to the managed devices. See External Authentication, on page 483 for more information.

Troubleshooting LDAP Authentication Connections

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the web interface screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
  - Check that you have the rights to browse to the directory indicated in your base-distinguished name by connecting to the LDAP server using a third-party LDAP browser.
  - Check that the user name is unique to the directory information tree for the LDAP server.
  - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.
- Check that you have correctly identified the server:
  - Check that the server IP address or host name is correct.
  - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.

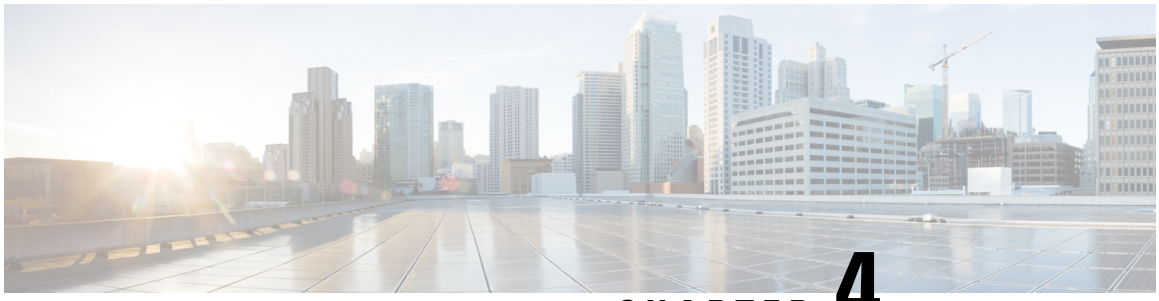
  - Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
  - If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.
  - Check that you have not used an IPv6 address for the server connection if you are authenticating CLI access.
  - If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.

- If you typed in your base-distinguished name, click **Fetch DNs** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.
- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a CLI access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator (maximum 450 characters, including the enclosing parentheses).
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.
- If you are using an encrypted connection:
  - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
  - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query that you are using by connecting to the LDAP server and using this syntax:

```
ldapsearch -x -b 'base_distinguished_name'
-h LDAPserver_ip_address -p port -v -D
'user_distinguished_name' -W 'base_filter'
```

For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of (`cn=*`), you could test the connection using this statement:

```
ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
-h myrtle.example.com -p 389 -v -D
'domainadmin@myrtle.example.com' -W '(cn=*)'
```



If you can test your connection successfully but authentication does not work after you deploy a platform settings policy, check that authentication and the object you want to use are both enabled in the platform settings policy that is applied to the device.

If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or CLI access filter or use a more restrictive or less restrictive base DN.

While authenticating a connection to Active Directory (AD) server, rarely the connection event log indicates blocked LDAP traffic although the connection to AD server is successful. This incorrect connection log occurs when the AD server sends a duplicate reset packet. The Firepower Threat Defense device identifies the second reset packet as part of a new connection request and logs the connection with Block action.

History for Users

Feature	Minimum FMC	Minimum FTD	Details
Support for the Service-Type attribute for FTD users defined on the RADIUS server.	6.4.0	Any	For RADIUS authentication of FTD CLI users, you used to have to pre-define the usernames in the RADIUS external authentication object and manually make sure that the list matched usernames defined on the RADIUS server. You can now define CLI users on the RADIUS server using the Service-Type attribute and also define both Basic and Config user roles. To use this method, be sure to leave the shell access filter blank in the external authentication object. New/modified screens: **System**(⚙) > **Users** > **External Authentication** > **Add External Authentication Object** > **Shell Access Filter**
External authentication for FTD SSH access.	6.2.3	Any	You can now configure external authentication for SSH access to the FTD using LDAP or RADIUS. New/modified screens: **Devices** > **Platform Settings** > **External Authentication**

CHAPTER 4

Configuration Deployment

This chapter describes how to download configuration changes to one or more managed devices.

- About Configuration Deployment, on page 109
- Requirements and Prerequisites for Policy Management, on page 119
- Best Practices for Deploying Configuration Changes, on page 120
- Deploy the Configuration, on page 121
- Manage Deployments, on page 128
- History for Configuration Deployment, on page 139

About Configuration Deployment

All device configuration is managed by the FMC and then deployed to the managed devices.

Configuration Changes that Require Deployment

The system marks out-of-date policies with red status text that indicates how many of its targeted devices need a policy update. To clear this status, you must re-deploy the policy to the devices.

Deployment Required

Configuration changes that require a deployment include:

- Modifying an access control policy: any changes to access control rules, the default action, policy targets, Security Intelligence filtering, advanced options including preprocessing, and so on.
- Modifying any of the policies that the access control policy invokes: the SSL policy, network analysis policies, intrusion policies, file policies, identity policies, or DNS policies.
- Changing any reusable object or configuration used in an access control policy or policies it invokes:
  - network, port, VLAN tag, URL, and geolocation objects
  - Security Intelligence lists and feeds
  - application filters or detectors
  - intrusion policy variable sets
  - file lists

- decryption-related objects and security zones

- Updating the system software, intrusion rules, or the vulnerability database (VDB).

Keep in mind that you can change some of these configurations from multiple places in the web interface. For example, you can modify security zones using the object manager (**Objects** > **Object Management**), but modifying an interface type in a device's configuration (**Devices** > **Device Management**) can also change a zone and require a deployment.

Deployment Not Required

Note that the following updates do **not** require a deployment:

- automatic updates to Security Intelligence feeds and additions to the Security Intelligence global Block or Do Not Block list using the context menu
- automatic updates to URL filtering data
- scheduled geolocation database (GeoDB) updates

Deployment Preview

Preview provides a snapshot of all the policy and object changes to be deployed on the device. The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. The unused object changes are not displayed because they are not deployed on the device.

The preview shows all the default values, even when they are not altered, along with the other configured settings when an interface or a platform settings policy is added for the first time. Similarly, the high availability-related policies and default values for settings are shown, even when they are not altered, in the first preview after a high availability pair is configured or disrupted.

Unsupported Features

- Object additions and attribute changes are displayed in the preview only if the objects are associated with any device or interface. Object deletions are not displayed.
- Preview is not supported for the following policies:
  - High availability
  - Network discovery
  - Network analysis
  - Device settings
- User information at the rule level is not available for intrusion policies.
- The preview does not show the reordering of rules across policies.

  For DNS policies, reordered rules appear in the preview list as rule additions and deletions. For example, moving a rule from position 1 to position 3 in the rule order is displayed as if the rule was deleted from position 1 and added as a new rule in position 3. Similarly, when a rule is deleted, the rules under it are

listed as edited rules as they have changed their positions. The changes are displayed in the final order in which they appear in the policy.

- Preview is not supported in the following HA scenarios:
  - If a device was in standalone mode and if a chain is made, then an auto-deployment is triggered. For that particular job, preview is not supported. On hover over the **Preview** (), a message is displayed that it is a HA bootstrap deployment, and no preview is supported.
  - **Configuration groups** - Consider a flow in which a device was initially standalone. Subsequently, three deployments took place. In the fourth deployment, the device was a HA bootstrap deployment. After these, the user deploys devices 5, 6, and 7. The deployment 7 is an HA break deployment, and the user deploys devices 8, 9, and 10.

    In this flow, the preview between 3 and 5 is not supported because 4 was a HA deployment. Similarly, the preview between 8 and 3 is also not supported. Preview is supported only from 3 to 1, 7,6, 5, 4, and 10, 9, and 8.
  - If a device is broken (HA is broken) then the new device is considered as a fresh device.

Selective Policy Deployment

The FMC allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy. Selective deployment is available only for the following policies:

- Access control policies
- Intrusion policies
- Malware and file policies
- DNS policies
- Identity policies
- SSL policies
- QoS policies
- Prefilter policies
- Network discovery
- NAT policies
- Routing policies
- VPN policies

There are certain limitations to selectively deploying policies. Follow the contents in the table below to understand when selective policy deployment can be used.

Table 7: Limitations for Selective Deployment

Type	Description	Scenarios
Full deployment	Full deployment is necessary for specific deploy scenarios, and the FMC does not support selective deployment in such scenarios. If you encounter an error in such scenarios, you may choose to proceed by selecting all the changes for deployment on the device.	Scenarios wherein a full deployment is required are: • The first deployment after you have upgraded the FTD or the FMC. • The first deployment after you have restored the FTD. • The first deployment after modifications in the FTD interface settings. • The first deployment after modifications in the virtual router settings. • When the FTD device is moved to a new domain (global to sub-domain or sub-domain to global).
Associated policy deployment	The FMC identifies interdependent policies which are interlinked. When one of the interlinked policies is selected, the remaining interlinked policies are automatically selected.	Scenarios wherein an associated policy is automatically selected: • When a new object is associated with an existing policy. • When an existing policy's object is modified. Scenarios wherein multiple policies are automatically selected: • When a new object is associated with an existing policy, and the same object is already associated with other policies, all the associated policies are automatically selected. • When a shared object is modified, all the associated policies are automatically selected.
Interdependent policy changes (shown using color-coded tags)	The FMC dynamically detects dependencies in-between policies, and between the shared objects and the policies. The interdependency of the objects or policies is shown using color-coded tags.	Scenarios wherein color-coded interdependent policies or objects are automatically selected: • When all the out-of-date policies have interdependent changes. For example, when an access control policy, an intrusion policy, and a NAT policy are out-of-date. Since access control policy and NAT policy share an object, all policies are selected together for deployment. • When all out-of-date policies share an object, and the object is modified.

Type	Description	Scenarios
Access Policy Group specifications	Access Policy Group policies are listed together in the preview window under **Access Policy Group** when you click **View** ().	The scenarios and the expected behavior for Access Policy Group policies are: • If the access control policy is out-of-date, all other out-of-date policies under this group, except file policy and intrusion policy, are selected when the access control policy is selected for deployment. However, if the access control policy is out-of-date, intrusion and file policies can be individually selected or deselected irrespective of whether the access control policy is selected or not, unless there are any dependent changes. For example, if a new intrusion policy is assigned to an access control rule, it indicates that there are dependent changes, then both the access control policy and the intrusion policy will be automatically selected when either of them is selected. • If no access control policy is out-of-date, other out-of-date policies in this group can be selected and deployed individually.

System Username

The FMC displays the username as **system** for the following operations:

- Rollback
- Upgrade
- FTD backup and restore
- SRU update
- LSP update
- VDB update

Auto-Enabling of Application Detectors

If you are performing application control but disable required detectors, the system automatically enables the appropriate system-provided detectors upon policy deploy. If none exist, the system enables the most recently modified user-defined detector for the application.

Asset Rediscovery with Network Discovery Policy Changes

When you deploy changes to a network discovery policy, the system deletes and then rediscovers MAC address, TTL, and hops information from the network map for the hosts in your monitored networks. Also, the affected managed devices discard any discovery data that has not yet been sent to the FMC.

Snort Restart Scenarios

When the traffic inspection engine referred to as *the Snort process* on a managed device restarts, inspection is interrupted until the process resumes. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information. Additionally, resource demands may result in a small number of packets dropping without inspection when you deploy, regardless of whether the Snort process restarts.

Any of the scenarios in the following table cause the Snort process to restart.

Table 8: Snort Restart Scenarios

Restart Scenario	More Information
Deploying a specific configuration that requires the Snort process to restart.	Configurations that Restart the Snort Process When Deployed or Activated, on page 118
Modifying a configuration that immediately restarts the Snort process.	Changes that Immediately Restart the Snort Process, on page 119
Traffic-activation of the currently deployed Automatic Application Bypass (AAB) configuration.	Configure Automatic Application Bypass, on page 84
Enabling or disabling "Logging connection events to RAM disk" feature.	See the section **Log to Ramdisk** in Troubleshoot Drain of FMC Unprocessed Events.

Related Topics

Access Control Policy Advanced Settings, on page 1173
Configurations that Restart the Snort Process When Deployed or Activated, on page 118

Restart Warnings for Devices

When you deploy, the **Inspect Interruption** column in the deploy page specifies whether a deployed configuration restarts the Snort process on the FTD device. When the traffic inspection engine referred to as *the Snort process* restarts, inspection is interrupted until the process resumes. Whether traffic is interrupted or passes without inspection during the interruption depends on how the device handles traffic. Note that you can proceed with the deployment, cancel the deployment and modify the configuration, or delay the deployment until a time when deploying would have the least impact on your network.

When the **Inspect Interruption** column indicates **Yes** and you expand the device configuration listing, the system indicates any specific configuration type that would restart the Snort process with an **Inspect Interruption** ( ). When you hover your mouse over the icon, a message informs you that deploying the configuration may interrupt traffic.

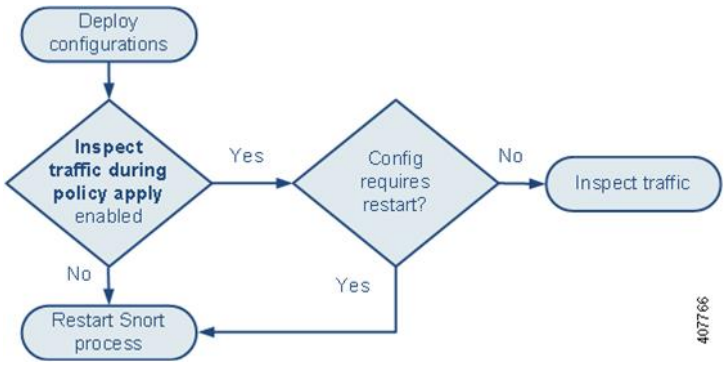
The following table summarizes how the deploy page displays inspection interruption warnings.

Table 9: Inspection Interruption Indicators

Type	Inspect Interruption	Description
FTD	**Inspect Interruption** ()Yes	At least one configuration would interrupt inspection on the device if deployed, and might interrupt traffic depending on how the device handles traffic. You can expand the device configuration listing for more information.
	--	Deployed configurations will not interrupt traffic on the device.
	Undetermined	The system cannot determine if a deployed configuration may interrupt traffic on the device. Undetermined status is displayed before the first deployment after a software upgrade, or in some cases during a Support call.
	Errors ()	The system cannot determine the status due to an internal error. Cancel the operation and click **Deploy** again to allow the system to redetermine the **Inspect Interruption** status. If the problem persists, contact Support.
sensor	--	The device identified as *sensor* is not the FTD device; the system does not determine if a deployed configuration may interrupt traffic on this device.

For information on all configurations that restart the Snort process for all device types, see Configurations that Restart the Snort Process When Deployed or Activated, on page 118.

Inspect Traffic During Policy Apply



Inspect traffic during policy apply is an advanced access control policy general setting that allows managed devices to inspect traffic while deploying configuration changes; this is the case unless a configuration that you deploy requires the Snort process to restart. You can configure this option as follows:

- Enabled — Traffic is inspected during the deployment unless certain configurations require the Snort process to restart.

  When the configurations you deploy do not require a Snort restart, the system initially uses the currently deployed access control policy to inspect traffic, and switches during deployment to the access control policy you are deploying.

- Disabled — Traffic is not inspected during the deployment. The Snort process always restarts when you deploy.

The following graphic illustrates how Snort restarts can occur when you enable or disable **Inspect traffic during policy apply**.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 and Configurations that Restart the Snort Process When Deployed or Activated, on page 118.

Snort Restart Traffic Behavior

The following tables explain how different devices handle traffic when the Snort process restarts.

Table 10: The FTD and the FTDv Restart Traffic Effects

Interface Configuration	Restart Traffic Behavior
inline: **Snort Fail Open: Down**: disabled	dropped
inline: **Snort Fail Open: Down**: enabled	passed without inspection Some packets can be delayed in buffer for several seconds before the system recognizes that Snort is down. This delay can vary depending upon the load distribution. However, the buffered packets are eventually passed.

Interface Configuration	Restart Traffic Behavior
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** enabled (**configure snort preserve-connection enable**; default) For more information, see Cisco Secure Firewall Threat Defense Command Reference.	existing TCP/UDP flows: passed without inspection so long as at least one packet arrives while Snort is down new TCP/UDP flows and all non-TCP/UDP flows: dropped Note that the following traffic drops even when **preserve-connection** is enabled: • plaintext, passthrough prefilter tunnel traffic that matches an **Analyze** rule action or an **Analyze all tunnel traffic** default policy action • connections that do not match an access control rule and are instead handled by the default action. • decrypted TLS/SSL traffic • a safe search flow • a captive portal flow
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** disabled (**configure snort preserve-connection disable**)	dropped
inline: tap mode	egress packet immediately, copy bypasses Snort
passive	uninterrupted, not inspected

Note In addition to traffic handling when the Snort process is down while it restarts, traffic can also pass without inspection or drop when the Snort process is busy, depending on the configuration of the Snort Fail Open **Busy** option (see Configure an Inline Set, on page 440). A device supports either the Failsafe option or the Snort Fail Open option, but not both.

Note When the Snort process is busy but not down during configuration deployment, some packets may drop on routed, switched, or transparent interfaces if the total CPU load exceeds 60 percent.

Warning Do not reboot the system while the Snort Rule Update is in progress.

Snort-busy drops happen when snort is not able to process the packets fast enough. Lina does not know whether Snort is busy due to processing delay, or if is stuck or due to call blocking. When transmission queue is full, snort-busy drops occur. Based on Transmission queue utilization, Lina will try to access if the queue is being serviced smoothly.

Configurations that Restart the Snort Process When Deployed or Activated

Deploying any of the following configurations except AAB restarts the Snort process as described. Deploying AAB does not cause a restart, but excessive packet latency activates the currently deployed AAB configuration, causing a partial restart of the Snort process.

Access Control Policy Advanced Settings

- Deploy when **Inspect Traffic During Policy Apply** is disabled.
- Add or remove an SSL policy.

File Policy

Deploy the first or last of any one of the following configurations; note that while otherwise deploying these file policy configurations does not cause a restart, deploying non-file-policy configurations can cause restarts.

- Take either of the following actions:
  - Enable or disable **Inspect Archives** when the deployed access control policy includes at least one file policy.
  - Add the first or remove the last file policy rule when **Inspect Archives** is enabled (note that at least one rule is required for **Inspect Archives** to be meaningful).
- Enable or disable **Store files** in a **Detect Files** or **Block Files** rule.
- Add the first or remove the last active file rule that combines the **Malware Cloud Lookup** or **Block Malware** rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**).

Note that access control rules that deploy these file policy configurations to security zones or tunnel zones cause a restart only when your configuration meets the following conditions:

- Source or destination security zones in your access control rule must match the security zones associated with interfaces on the target devices.
- Unless the destination zone in you access control rule is *any*, a source tunnel zone in the rule must match a tunnel zone assigned to a tunnel rule in the prefilter policy.

Identity Policy

- When SSL decryption is disabled (that is, when the access control policy does not include an SSL policy), add the first or remove the last active authentication rule.

  An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Network Discovery

- Enable or disable non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy.

Device Management

- MTU: Change the highest MTU value among all non-management interfaces on a device.
- Automatic Application Bypass (AAB): The currently deployed AAB configuration activates when a malfunction of the Snort process or a device misconfiguration causes a single packet to use an excessive amount of processing time. The result is a partial restart of the Snort process to alleviate extremely high latency or prevent a complete traffic stall. This partial restart causes a few packets to pass without inspection, or drop, depending on how the device handles traffic.

Updates

- System update: Deploy configurations the first time after a software update that includes a new version of the Snort binary or data acquisition library (DAQ).
- For managed devices running Snort 3, deploying configurations the first time after installing a vulnerability database (VDB) update may temporarily interrupt application detection, but there will be no traffic interruptions.

Changes that Immediately Restart the Snort Process

The following changes immediately restart the Snort process without going through the deploy process. How the restart affects traffic depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information.

- Take any of the following actions involving applications or application detectors:
  - Activate or deactivate a system or custom application detector.
  - Delete an activated custom detector.
  - **Save and Reactivate** an activated custom detector.
  - Create a user-defined application.

  A message warns you that continuing restarts the Snort process, and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains.
- Create or break a FTD high availability pair.

  A message warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Best Practices for Deploying Configuration Changes

The following are guidelines for deploying configuration changes.

Reliable Management Connection

The management connection between the FMC and the device is a secure, TLS-1.3-encrypted communication channel between itself and the device.

You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

Caution We recommend against a device's management connection going through a VPN tunnel that terminates on the device itself. If you deploy a configuration change that causes the VPN to go down, the management connection will be disconnected and you will not have any way to recover the configuration without connecting directly to the device.

If management traffic exits a VPN-terminating interface, be sure to exclude the management traffic from the VPN tunnel.

Maximum Concurrent Deployments

You should not deploy to more than 25% of the maximum devices allowed for a FMC in the same job. For example, for the FMCv300, the maximum job size should be 75 devices (25% of 300). Concurrent deployment to more devices can cause performance issues.

Deployment of Shared Policies

For best performance, deploy to devices that use the same policies. Create separate deployment jobs for each group of devices that share policies.

Time to Deploy and Memory Limitations

The time it takes to deploy depends on multiple factors, including (but not limited to):

- The configurations you send to the device. For example, if you dramatically increase the number of Security Intelligence entries you block, deployment can take longer.
- Device model and memory. On lower-memory devices, deploying can take longer.

Do not exceed the capability of your devices. If you exceed the maximum number of rules or policies supported by a target device, the system displays a warning. The maximum depends on a number of factors—not only memory and the number of processors on the device, but also on policy and rule complexity. For information on optimizing policies and rules, see Best Practices for Access Control Rules, on page 1157.

Use a Maintenance Window to Lessen the Impact of Traffic Interruptions

We *strongly* recommend you deploy in a maintenance window or at a time when interruptions will have the least impact.

When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 and Configurations that Restart the Snort Process When Deployed or Activated, on page 118.

For the FTD devices, the **Inspect Interruption** column in the Deploy dialog warns you when deploying might interrupt traffic flow or inspection. You can either proceed with, cancel, or delay deployment; see Restart Warnings for Devices, on page 114 for more information.

Snort Restart Scenarios, on page 114

Deploy the Configuration

After you configure your deployment, and any time you change that configuration, you must deploy the changes to affected devices. You can view deployment status in the Message Center.

Deploying updates the following components:

- Device and interface configurations
- Device-related policies: NAT, VPN, QoS, platform settings
- Access control and related policies: DNS, file, identity, intrusion, network analysis, prefilter, SSL
- Network discovery policy
- Intrusion rule updates
- Configurations and objects associated with any of these elements

You can configure the system to deploy automatically by scheduling a deploy task or by setting the system to deploy when importing intrusion rule updates. Automating policy deployment is especially useful if you allow intrusion rule updates to modify system-provided base policies for intrusion and network analysis. Intrusion rule updates can also modify default values for the advanced preprocessing and performance options in your access control policies.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices. We *strongly* recommend that you deploy in a maintenance window or at a time when any interruptions to traffic flow and inspection will have the least impact.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 and Configurations that Restart the Snort Process When Deployed or Activated, on page 118.

Before you begin

- Be sure all managed devices use the same revision of the Security Zones object. If you have edited security zone objects: Do not deploy configuration changes to any device until you edit the zone setting for interfaces on *all* devices you want to sync. You must deploy to all managed devices at the same time.
- To preview the deployment changes, enable REST API access. To enable the REST API access, follow the steps in *Enabling REST API Access* in the Firepower Management Center Administration Guide.

Note The deployment process fails if the device configuration is being read at the device CLI during deployment. Do not execute commands such as **show running-config** during the deployment.

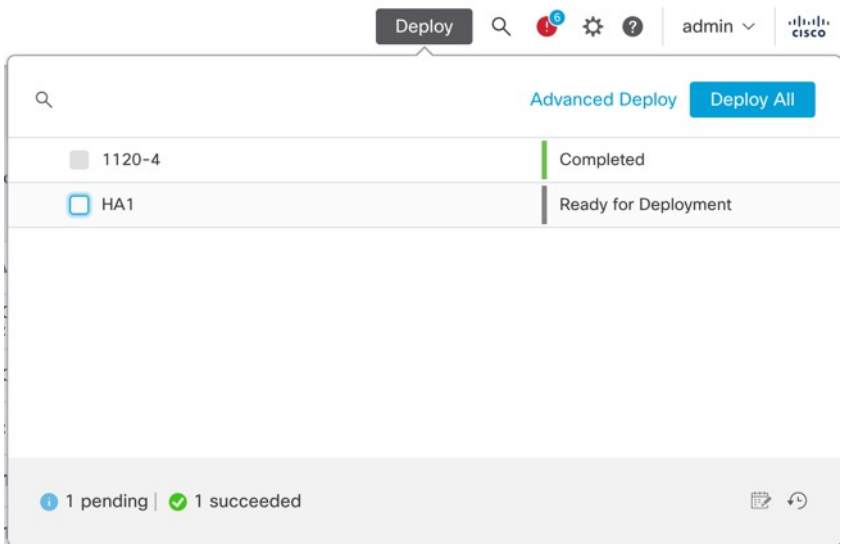
Procedure

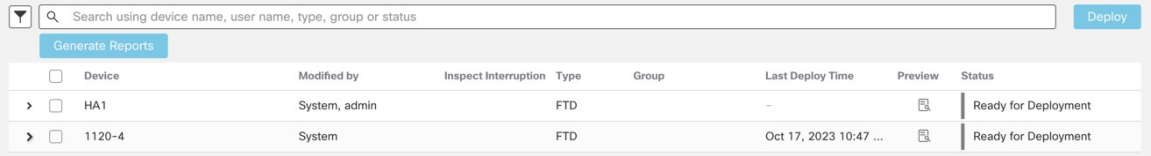
Step 1 On the FMC menu bar, click **Deploy**.

Step 2 For a quick deployment, check specific devices and then click **Deploy**, or click **Deploy All** to deploy to all devices. Otherwise, for additional deployment options, click **Advanced Deploy**.

The rest of this procedure applies to the **Advanced Deploy** screen.

Figure 37: Quick Deploy





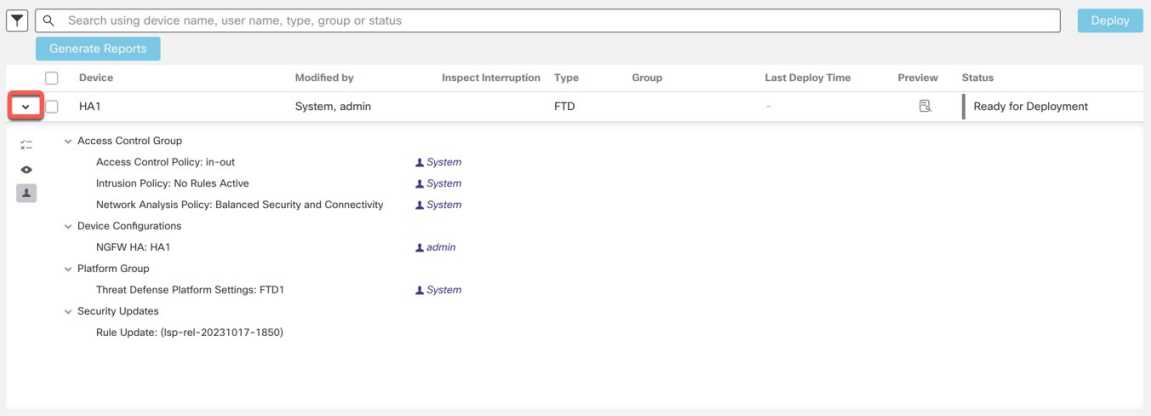


Figure 38: Advanced Deploy

Step 3 Click **Expand Arrow** ( ) to view device-specific configuration changes to be deployed.

Figure 39: Expand

- The **Modified By** column lists the users who have modified the policies or objects. On expanding the device listing, you can view the users who have modified the policies against each policy listing. For information about when the **System** user is shown (instead of the logged-in user), see System Username, on page 113.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption may be caused in the device during deployment.

  When the status indicates (Yes) that deploying will interrupt inspection, and perhaps traffic, on the FTD device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).

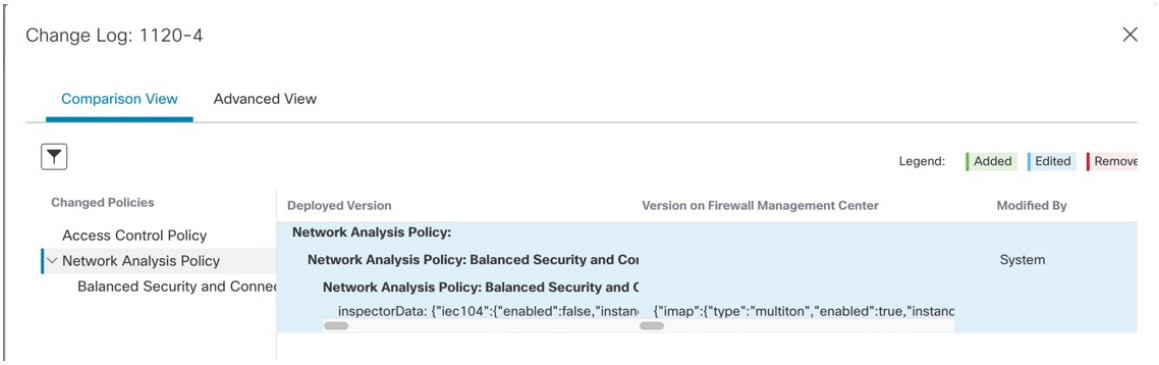
  If the entry is blank in this column for a device, then it indicates that there will be no traffic inspection interruptions on that device during deployment.

  See Restart Warnings for Devices, on page 114 for information to help you identify configurations that interrupt traffic inspection and might interrupt traffic when deployed to the FTD devices.

- The **Last Modified Time** column specifies when you last made the configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment. For more information, see View Deployment Status, on page 128.

Step 4 In the **Preview** column, click **Preview** ( ) to see the configuration changes that you can deploy.

Figure 40: Preview



Note

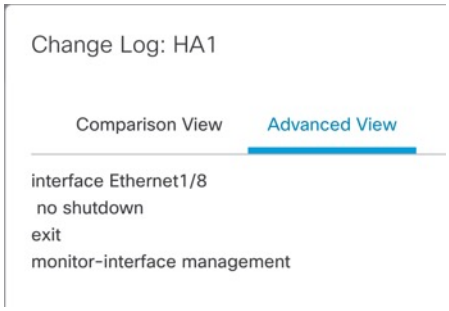
If you change the FMC name in **System** ( ) > **Configuration** > **Information**, the deployment preview does not specify this change, yet it requires a deployment.

For unsupported features for Preview, see Deployment Preview, on page 110.

The **Comparison View** tab lists all the policy and object changes. The left pane lists all the different policy types that have changed on the device, organized in a tree structure.

Figure 41: Comparison View

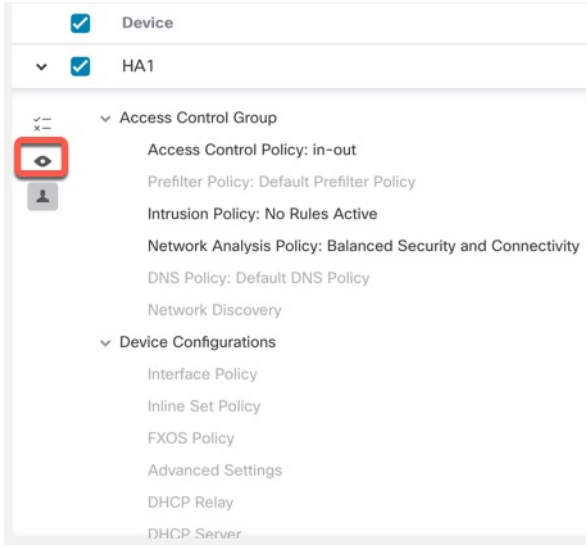
The **Filter**(lets you filter the policies at the user level and policy level.



The right pane lists all the additions, changes, or deletions in the policy, or the object selected in the left pane. The two columns on the right pane provide the last deployed configuration settings (in the **Deployed Version** column) versus the changes that are due for deployment (in the **Version on Firewall Management Center** column). The last-deployed configuration settings are derived from a snapshot of the last saved deployment in the FMC and not from the device. The background colors of the settings are color-coded as per the legend available on the top-right of the page.

The **Modified By** column lists the users who have modified, or added the configuration settings. At the policy level, the FMC displays all the users who have modified the policy, and at the rule level, the FMC displays only the last user who has modified the rule.

You can download a copy of the change log by clicking the **Download Report** button.



The **Advanced View** tab shows the CLI commands that will be applied. This view is useful if you are familiar with ASA CLI, which is used on the back end of the FTD.

Figure 42: Advanced View

Step 5 Use **Show or Hide Policy** ( ) to selectively view or hide the associated unmodified policies.

Figure 43: Show or Hide Policy

Step 6 Check the box next to the device name to deploy all configuration changes, or click **Policy selection** ( ) to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.

You can also view the interdependent changes for a certain policy or configuration using this option. The FMC dynamically detects dependencies between policies (for example, between an access control policy and an intrusion policy), and between the shared objects and the policies. Interdependent changes are indicated using color-coded tags to identify a set of interdependent deployment changes. When one of the deployment changes is selected, the interdependent changes are automatically selected.

For more details, see Selective Policy Deployment, on page 111.

Note

- When the changes in shared objects are deployed, the impacted policies should also be deployed along with them. When you select a shared object during deployment, the impacted policies are automatically selected.
- Selective deployment is not supported for scheduled deployments and deployments using REST APIs. You can only opt for complete deployment of all the changes in these cases.

- The pre-deployment checks for warnings and errors are performed not only on the selected policies, but on all the policies that are out-of-date. Therefore, the warnings or errors list shows the deselected policies as well.
- Similarly, the **Inspect Interruption** column indication on the Deployment page considers all out-of-date policies and not just the selected policies. For information on the **Inspect Interruption** column, see Restart Warnings for Devices, on page 114.

Step 7 After you select the devices or policies to deploy, click **Estimate** to get a rough estimate of the deployment duration.

Figure 44: Estimate

Figure 45: Deploy Time

The time duration is a rough estimate (having around 70% accuracy), and the actual time taken for deployment may vary for a few scenarios. The estimate is dependable for deployments of up to 20 devices.

When an estimate is not available, it indicates that the data is not available, since the first successful deployment on the selected device is pending. This situation could occur after the FMC reimage, version upgrade, or after a high availability failover.

Note
The estimate is incorrect and unreliable for bulk policy changes (in case of bulk policy migrations), and selective deployments because the estimate is based on the heuristic technique.

Step 8 Click **Deploy**.

Step 9 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. Check the **Ignore warnings** checkbox, to ignore warnings and deploy the changes. You cannot proceed if the system identifies errors.
- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the Firepower Management Center Administration Guide.
- If the deployment fails, see Best Practices for Deploying Configuration Changes, on page 120.
- During deployment, if there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For example, in a cluster environment, an erroneous configuration of an IP address that is not in the same subnet as the Site IPs is configured on the interface. Due to this

error, deployment fails and the device attempts to clear the configuration while the rollback operation is being processed. These events collectively lead to a deployment failure that interrupts the traffic.

See the following table to know what configuration changes may cause traffic interruption when deployment fails.

Configuration Changes	Exists?	Traffic Impacted?
Threat Defense Service changes in an access control policy	Yes	Yes
VRF	Yes	Yes
Interface	Yes	Yes
QoS	Yes	Yes

Note The configuration changes interrupting traffic during deployment is valid only if both the FMC and the FTD are of version 6.2.3 or higher.

Snort Restart Scenarios, on page 114

Redeploy Existing Configurations to a Device

You can force-deploy existing (unchanged) configurations to a single managed device. We *strongly* recommend you deploy in a maintenance window or at a time when any interruptions to traffic flow and inspection will have the least impact.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 and Configurations that Restart the Snort Process When Deployed or Activated, on page 118.

Before you begin

Review the guidelines described in Best Practices for Deploying Configuration Changes, on page 120.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device where you want to force deployment.

Step 3 Click **Device**.

Step 4 Click **Edit** ( ) next to the **General** section heading.

Step 5 Click **Force Deploy** ( ).

Note
Force-deploy takes more time than the regular deployment because it involves the complete generation of the policy rules to be deployed on the FTD.

Step 6 Click **Deploy**.

The system identifies any errors or warnings with the configurations you are deploying. You can click **Proceed** to continue without resolving warning conditions. However, you cannot proceed if the system identifies an error.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the Firepower Management Center Administration Guide.
- If deploy fails, see Best Practices for Deploying Configuration Changes, on page 120.

Related Topics

Snort Restart Scenarios, on page 114

Manage Deployments

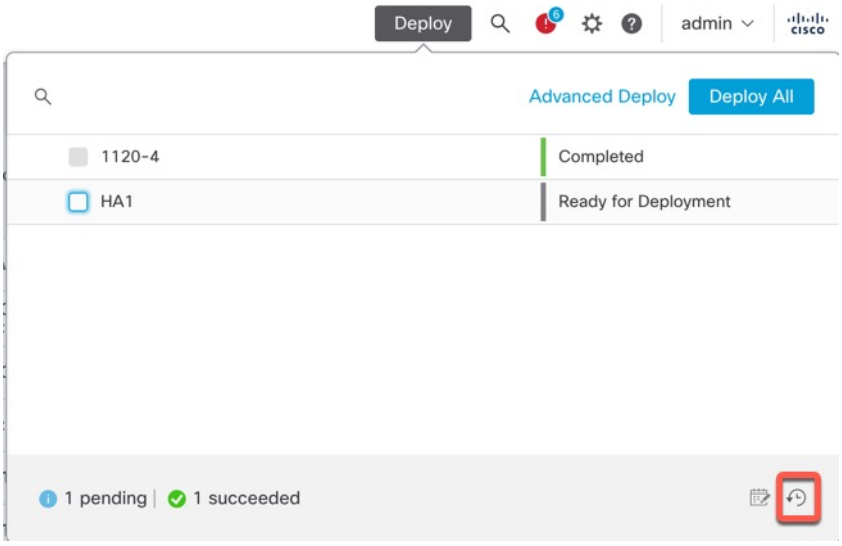
View Deployment Status

On the Deployment page, the **Status** column provides the deployment status for each device. If a deployment is in progress, then the live status of the deployment progress is displayed, else one of the following statuses is displayed:

- Pending—Indicates that there are changes in the device that are to be deployed.
- Warnings or errors—Indicates that the pre-deployment checks have identified warnings or errors for the deployment, and you have not proceeded with the deployment. You can continue with the deployment if there are any warnings, but not if there are any errors.

Note The status column provides the warning or error status only for a single user session on the deployment page. If you navigate away from the page or refresh the page, the status changes to pending.

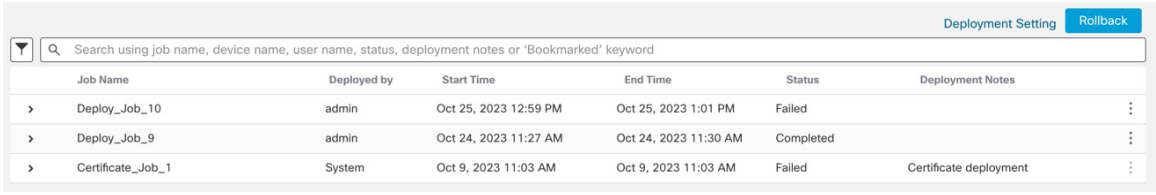
- Failed—Indicates that the previous deployment attempt failed. Click on the status to view the details.
- In queue—Indicates that deployment is initiated, and the system is yet to start the deployment process.
- Completed—Indicates that deployment has completed successfully.



View Deployment History

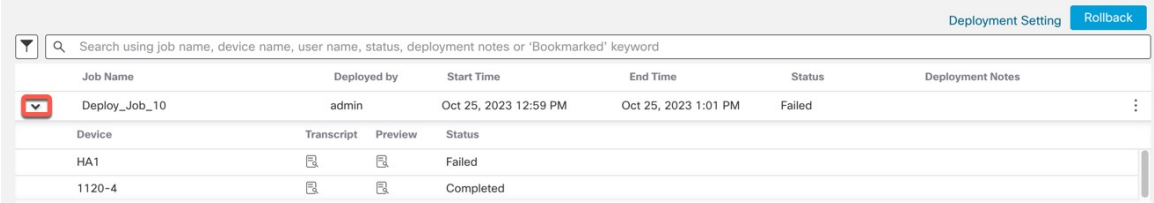
In the deployment history, the last 10 successful deployments, the last 5 failed deployments, and last 5 rollback deployments are captured.

Procedure



Step 1 On the FMC menu bar, click **Deploy** and then click **Deployment History** ( ).

Figure 46: Deployment History Icon



A list of all the previous deployment and rollback jobs is displayed in reverse chronological order.

Figure 47: Deployment History Page

Step 2 Click **Expand Arrow** ( ) next to the required deployment job to view the devices included in the job and their deployment statuses.

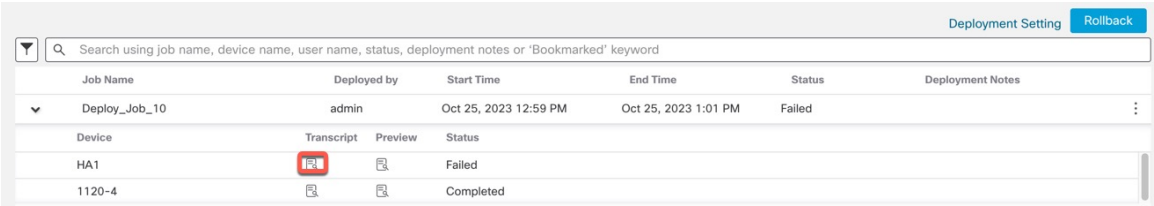
Figure 48: Expand

- View notes in the **Deployment Notes** column.

  Deployment notes are custom notes that a user can add as part of the deployment, and these notes are optional.

Step 3 (Optional) Click **Transcript Details** ( ) to view the commands sent to the device, and the responses received.

Figure 49: Transcript Details Icon



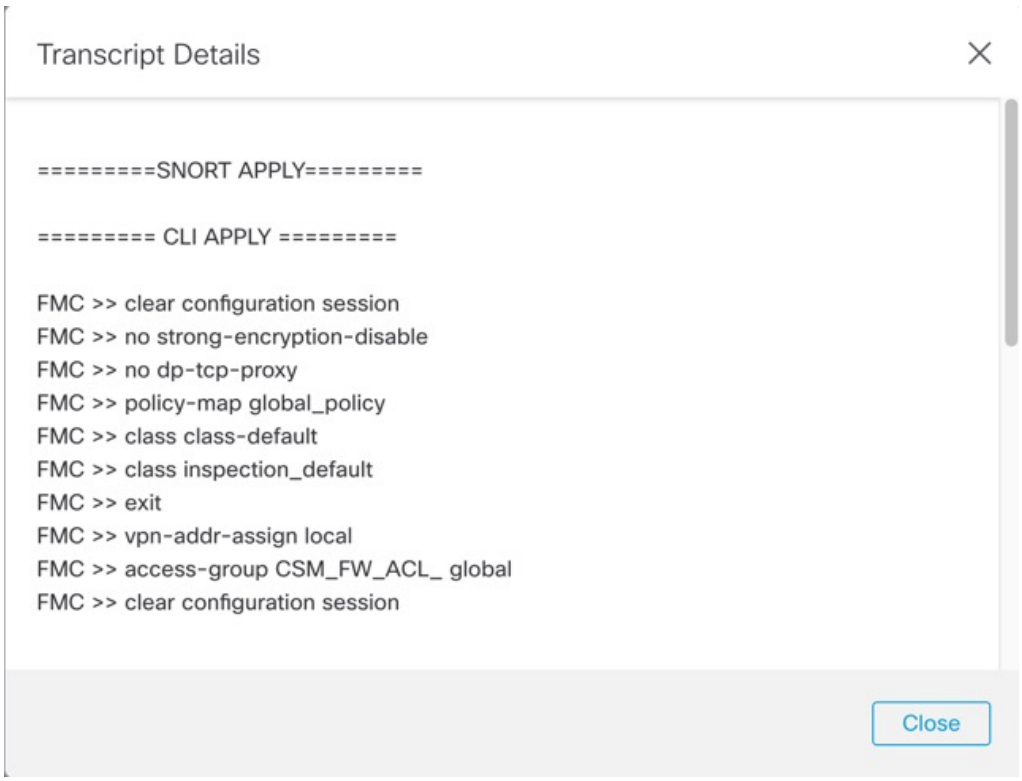


Figure 50: Transcript Details

The transcript includes the following sections:

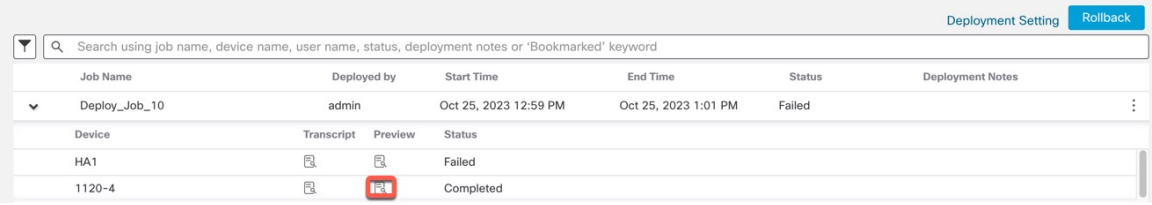
- **Snort Apply**—If there are any failures or responses from Snort-related policies, then the messages are displayed in this section. Normally, the section is empty.
- **CLI Apply**—This section covers features that are configured using commands that are sent to the device.

  Note
  The transcript for the rollback operation does not provide the CLI commands information. To view the rollback commands, see View the Deployment Rollback Transcript, on page 136.

- **Infrastructure Messages**—This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript includes commands that are sent to the device, and any responses returned from the device. These responses can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands. Examining these errors can be particularly helpful if you are using FlexConfig policies to configure customized features. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

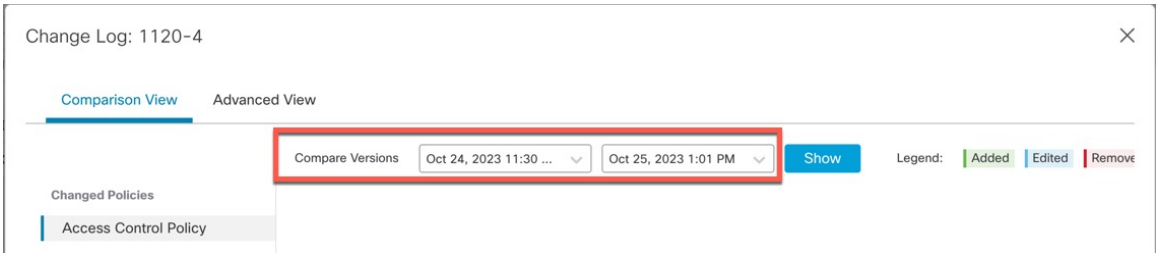
Note
There is no distinction that is made in the transcript between commands that are sent for managed features and those generated from FlexConfig policies.



For example, the following sequence shows that FMC sent commands to configure GigabitEthernet0/0 with the logical name **outside**. The device responded that it automatically set the security level to 0. FTD does not use the security level for anything.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```



Step 4 (Optional) Click **Preview** ( ) to view the policy and object changes deployed on the device versus the previously deployed version.

Figure 51: Preview Icon

a. To compare any two versions and view the change log, choose the required versions in the drop-down boxes and click the **Show** button. The drop-down boxes show the deployment job name and the end time of the deployment.

Figure 52: Compare Versions

Note
The drop-down boxes also show failed deployments.

b. The **Modified By** column lists the users who have modified the policies or objects.

1. At the policy level, FMC displays all the user names who have modified the policy.
2. At the rule level, FMC displays the last user who has modified the rule.

c. You can also download a copy of the change log by clicking **Download Report**.

Note
- Deployment history preview is not supported for certificate enrollments, HA operations, and failed deployments.
- When a device is registered, preview is not supported for the job history record that is created.

Step 5 (Optional) Against each deployment job, click the **More** (⋮) icon and execute other actions:

- **Bookmark**—To bookmark the deployment job.
- **Edit Deployment Notes**—To edit your custom deployment notes that you added for a deployment job.

Roll Back a Deployment

You can roll back a device to a previously deployed configuration. After a policy deployment, if the traffic through the device is affected in an unintended way, rollback provides an option to revert the device to the earlier state, which existed before the faulty deployment.

Rollback is a disruptive operation: all the existing connections and routes are dropped, and the traffic is disrupted.

Identifying the Disruptive Configuration

When a deployment has gone awry and caused traffic interruption in an unintended way, you should identify the change in the deployment that caused the condition and fix it so your next deployment will be successful.

See the following ways to compare configurations.

Before a Rollback

1. Choose **Deploy** > **Deployment History**, expand the last deployed job (that caused the traffic disruption), and click the **Preview** ( ).

   The preview page provides an option to compare deployments, which can be useful to identify specific changes for a deployment compared to a previous deployment.

2. After identifying the change causing the problem, rectify the configuration, and redeploy it on the device.

After a Rollback

1. After a successful rollback operation, choose **Deploy** > **Deployment**, and click the **Preview** icon next to the rolled back device.
2. View the changes between the rolled back configuration and the current changes in the FMC that are pending deployment.
3. After identifying the change causing the problem, rectify the configuration, and redeploy it on the device.

Rollback Guidelines and Limitations

- You can roll back to any one of the last 10 versions before the currently deployed version. Rollback to versions prior to these are not supported. The rollback icon is greyed out for unsupported versions.
- You have to perform a deployment before you can roll back again.
- After you perform a rollback, the rolled back devices are marked as out-of-date on the FMC. The changes you made to the configuration are still pending for the next deployment. To see the pending changes, choose **Deploy** > **Deployment**, and click the **Preview** icon next to the rolled back device.
- For devices with very large access lists, if the **Object Group Search** setting is disabled, then the rollback operation may take a longer duration to complete. To verify the **Object Group Search** setting, choose **Devices** > **Device Management**, and then select the device and click **Edit Advanced Settings**.
- For the Firepower 4100/9300, make sure your current Firepower Chassis Manager interface configuration is the same for any rollback versions. Otherwise, the rollback interface configuration may not match your actual interfaces.
- Rollback is not supported if the manager access interface (Manager or data interface) is different between the rollback version and the current version.
- Independent certificate enrollments are also listed as deployment jobs in the Deployment History page. However, you cannot roll back to these versions. A rollback from a deployment version created after certificate enrollments reverts the certificate associations as well. In the next deployment after a rollback, manually associate the certificates before proceeding with the deployment.
- If you upgrade the FMC, all rollback versions from the previous software release will no longer be available for devices, even if you did not upgrade the devices.
- If you upgrade the device, you can only roll back to versions on the current software release.
- If a deployment for a device with a FlexConfig object configured with a deployment frequency set to **Once** is rolled back, then you will not be able to redeploy the object even though it is displayed as out-of-date on the Preview page. After a rollback, you will have to manually unassign and then reassign the FlexConfig object to the device before the next deployment.
- For High Availability, rollback is not supported in the following scenarios:

- When the version you want to roll back to contains the high-availability bootstrap configuration. In other words, the deployment when you first formed high availability for the standalone devices.
- When a device that is currently in standalone mode was part of a high availability pair in the previous deployment version.

- For clustering, see the following guidelines:
  - Rollback is not supported when a device that is currently in standalone mode was part of a cluster in the previous deployment version.
  - (Secure Firewall 3100) If you change the clustering bootstrap configuration or add or delete nodes, you cannot roll back to a version prior to those changes.

Configurations Not Reverted After a Rollback

Rollback reverts all the configurations on the device except a few. See the table below for details.

Configurations that are reverted during a rollback	Configurations that are not reverted during a rollback
• All policy configurations • Interface configurations • SRU configurations • VDB configurations • LSP configurations • VPN configurations • FXOS configurations	• Snort binaries • Geo DB

Perform a Rollback

You can roll back a device to a previously deployed configuration. After a policy deployment, if the traffic through the device is affected in an unintended way, rollback provides an option to revert the device to the earlier state, which existed before the faulty deployment.

Rollback reverts the configuration only on the selected devices.

Procedure

Step 1 Choose **Deploy >Deployment History** ( ).

A list of all the previous deployment jobs is displayed in reverse chronological order.

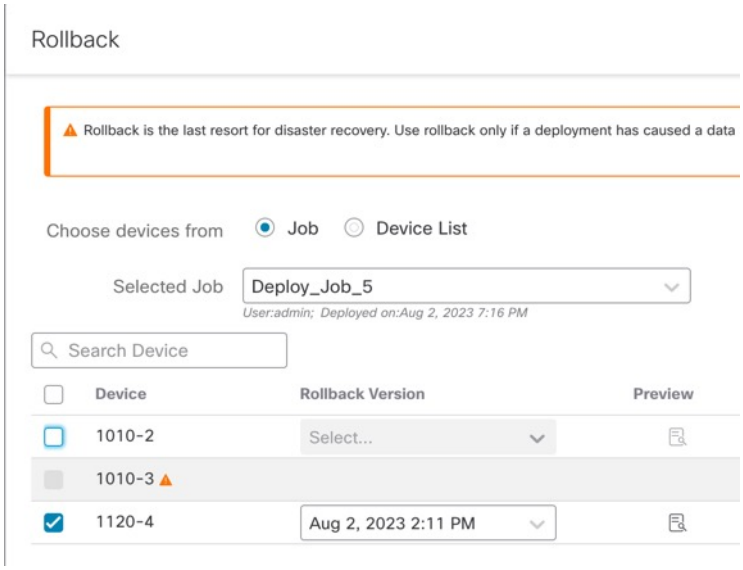
Step 2 Click **Rollback**.

Step 3 Filter the list of devices displayed by either clicking **Job** and choosing a job from the **Selected Job** drop-down list, or by clicking **Device List**.

Step 4 (Optional) Enter the device name in the **Search Device** search box to filter the device list.

Step 5 Check the box next to the devices you want to roll back and choose the version for each device from the **Rollback Version** drop-down list.

Figure 53: Selected Job List



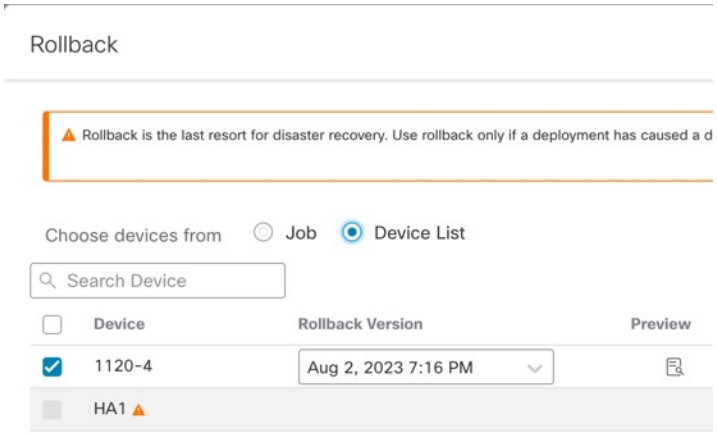


Figure 54: Device List

The job names and associated deployment notes are also listed for a particular rollback version.

Step 6 (Optional) Click the **Preview** ( ) to view the changes deployed in the selected version.

Step 7 Click **Rollback**.

What to do next

To know the status of the rollback, choose **Deploy** > **Deployment**. You can view the rollback status next to the device name.

View the Deployment Rollback Transcript

Rollback transcript is a written version of the commands that are sent to the device, along with the responses returned from the device. If a rollback operation has failed, the transcript in the **Deploy > Deployment History** page provides the reason for the failure. However, to know the CLI commands executed for a successful rollback operation, follow the steps given below after a rollback operation has completed. Note that this information is available only until the next deployment.

Note The CLI command information is available after a rollback is complete and is available only until the next deployment. The first deployment after a rollback operation erases all the rollback-related information.

Note For any rollback deployment, the Deployment Notes are updated automatically as Rollback Job. In the **Deployment History** page, the user can filter the Rollback Jobs easily using the Search option.

Procedure

Step 1 On the Firepower Management Center menu bar, choose **System** > **Health** > **Monitor**.

Step 2 Select the device, which was rolled back, from the left pane.

Step 3 Click **View System & Troubleshooting Details** link.

Step 4 Click **Advanced Troubleshooting**.

Step 5 Click **Threat Defense CLI**.

Step 6 Select **show** from the **Command** drop-down box.

Step 7 Enter `running` in the **Parameter** field.

Step 8 Click **Execute**.

Compare Policies

To review policy changes for compliance with your organization's standards or to optimize system performance, you can examine the differences between two policies or between a saved policy and the running configuration.

You can compare the following policy types:

- DNS
- File
- Health
- Identity
- Network Analysis
- SSL

The comparison view displays both policies in a side-by-side format. Differences between the two policies are highlighted:

- Blue indicates that the highlighted setting is different in the two policies, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy but not the other.

Before you begin

You can compare policies only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy you want to compare:

- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, then click **Network Analysis Policies**

  Note
  If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **SSL**

Step 2 Click **Compare Policies**.

Step 3 From the **Compare Against** drop-down list, choose the type of comparison you want to make:

- To compare two different policies, choose **Other Policy**.
- To compare two revisions of the same policy, choose **Other Revision**.
- To compare another policy to the currently active policy, choose **Running Configuration**.

Step 4 Depending on the comparison type you choose, you have the following choices:

- If you are comparing two different policies, choose the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
- If you are comparing the running configuration to another policy, choose the second policy from the **Policy B** drop-down list.

Step 5 Click **OK**.

Step 6 Review the comparison results:

- Comparison Viewer—To use the comparison viewer to navigate individually through policy differences, click **Previous** or **Next** above the title bar.

- Comparison Report—To generate a PDF report that lists the differences between the two policies, click **Comparison Report**.

Generate Current Policy Reports

For most policies, you can generate two kinds of reports. A report on a single policy provides details on the policy's current saved configuration, while a comparison report lists only the differences between two policies. You can generate a single-policy report for all policy types except health.

Note Intrusion policy reports combine the settings in the base policy with the settings of the policy layers, and make no distinction between which settings originated in the base policy or policy layer.

Before you begin

You can generate policy reports only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy for which you want to generate a report:

- Access Control—**Policies** > **Access Control heading** > **Access Control**
- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Intrusion—**Policies** > **Access Control heading** > **Intrusion**
- NAT—**Devices** > **NAT**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, then click **Network Analysis Policies**

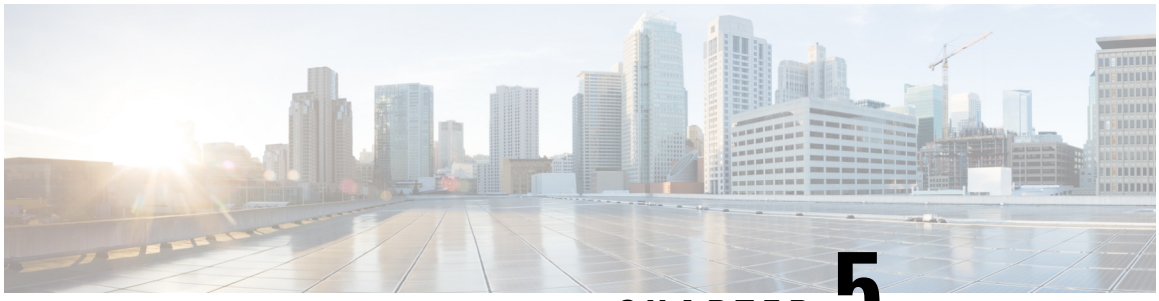
  Note
  If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **SSL**

Step 2 Click **Report** (📄) next to the policy for which you want to generate a report.

History for Configuration Deployment

Feature	Minimum FMC	Minimum FTD	Details
Deployment preview and user information in preview.	7.0	Any	The Deployment page has the following newly added features: • On the **Deployment** page, the **Modified By** column lists the users who have modified the policies against each policy listing. • Filter support for deployment – The Filter icon provided on the **Deployment** page provides an option to filter the device listings that are pending deployment. The Filter icon provides options to filter the listings based on selected devices and user names. • Deployment History Preview – Click **Preview** to view the policy and object changes deployed on the device versus the previously deployed version. In the deployment history, the last 10 successful deployments, the last five failed deployments, and last five rollback deployments are captured. • Deployment Notes – The **Deployment Notes** are custom and optional notes that a user can add as part of deployment. You can view the **Deployment Notes** column in the **Deployment History** page. • Deployment rollback is available for Snort 3 policies as well.
Roll back deployment on FTD devices.	6.7	6.7	Rollback is a deployment functionality provided to remove the existing deployment on FTD devices and to reconfigure the device with the previously deployed configuration. New/modified pages: The **Deploy** > **Deployment History** page provides a new Rollback column with the rollback icons. Similar rollback icons can also be found when the jobs are expanded, to initiate rollback at the device level.



Feature	Minimum FMC	Minimum FTD	Details
New deployment web interface.	6.6	Any	The **Deploy** button on the FMC menu bar is changed to **Deploy** menu. There are two new sub-menu options under it. These are **Deployment** and **Deployment History**. The Deployment page has undergone an improvement along with newly added features, and the new Deployment History page provides a legend of all the previous deployments. The Deployment page has the following newly added features: • Deployment status - On the Deployment page, the Status column provides the deployment status for each device. • Deployment estimate - The **Estimate** link is available on the Deployment page after you select a device, a policy, or a configuration. The **Estimate** link provides an estimate of the deployment duration once clicked. • Deployment preview - Preview provides a snapshot of all the policy and object changes to be deployed on the device. The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. • Selective policy deployment - FMC allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy.

CHAPTER 5

Transparent or Routed Firewall Mode

This chapter describes how to set the firewall mode to routed or transparent, as well as how the firewall works in each firewall mode.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes. See Inline Sets and Passive Interfaces, on page 433 for more information about IPS-only interfaces. Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode described in this chapter or the firewall-type interfaces.

Caution

- Use FTD CLI commands to set "Firewall Mode."

- About the Firewall Mode, on page 143
- Default Settings, on page 151
- Guidelines for Firewall Mode, on page 151
- Set the Firewall Mode, on page 152

About the Firewall Mode

The FTD supports two firewall modes for regular firewall interfaces: Routed Firewall mode and Transparent Firewall mode.

About Routed Firewall Mode

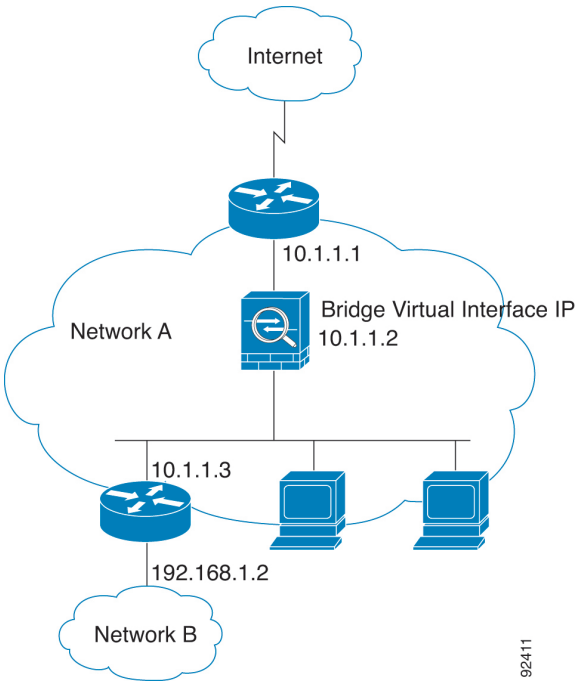
In routed mode, the FTD device is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet.

With Integrated Routing and Bridging, you can use a "bridge group" where you group together multiple interfaces on a network, and the FTD device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. The FTD device routes between BVIs and regular routed interfaces. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead of transparent mode. In

routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

About Transparent Firewall Mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. However, like any other firewall, access control between interfaces is controlled, and all of the usual firewall checks are in place.



Layer 2 connectivity is achieved by using a "bridge group" where you group together the inside and outside interfaces for a network, and the FTD device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. You can have multiple bridge groups for multiple networks. In transparent mode, these bridge groups cannot communicate with each other.

Using the Transparent Firewall in Your Network

The FTD device connects the same network between its interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

The following figure shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

Figure 55: Transparent Firewall Network

Passing Traffic For Routed-Mode Features

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality. For example, by using an access rule,

you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or multicast traffic such as that created by IP/TV. You can also establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an access rule. Likewise, protocols like HSRP or VRRP can pass through the FTD device.

About Bridge Groups

A bridge group is a group of interfaces that the FTD device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. Like any other firewall interfaces, access control between interfaces is controlled, and all of the usual firewall checks are in place.

Bridge Virtual Interface (BVI)

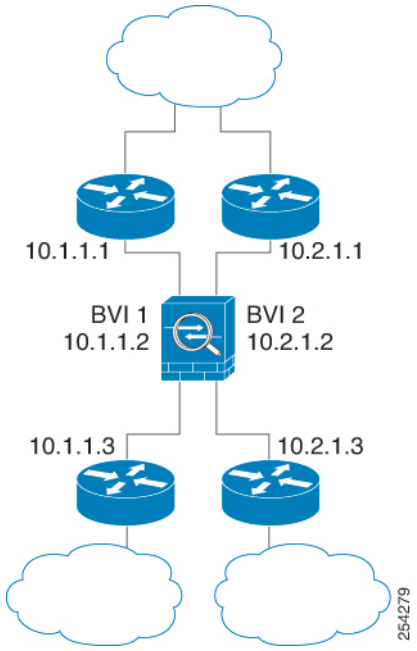
Each bridge group includes a Bridge Virtual Interface (BVI). The FTD device uses the BVI IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the bridge group member interfaces. The BVI does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

In transparent mode: Only bridge group member interfaces are named and can be used with interface-based features.

In routed mode: The BVI acts as the gateway between the bridge group and other routed interfaces. To route between bridge groups/routed interfaces, you must name the BVI. For some interface-based features, you can use the BVI itself:

- DHCPv4 server—Only the BVI supports the DHCPv4 server configuration.
- Static routes—You can configure static routes for the BVI; you cannot configure static routes for the member interfaces.
- Syslog server and other traffic sourced from the FTD device—When specifying a syslog server (or SNMP server, or other service where the traffic is sourced from the FTD device), you can specify either the BVI or a member interface.

If you do not name the BVI in routed mode, then the FTD device does not route bridge group traffic. This configuration replicates transparent firewall mode for the bridge group. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.



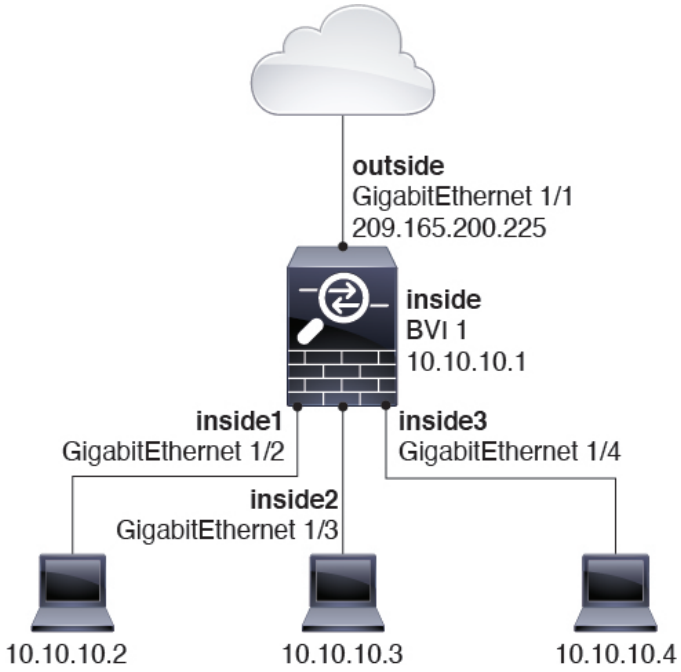
Bridge Groups in Transparent Firewall Mode

Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the FTD device, and traffic must exit the FTD device before it is routed by an external router back to another bridge group in the FTD device. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration.

You can include multiple interfaces per bridge group. See Guidelines for Firewall Mode, on page 151 for the exact number of bridge groups and interfaces supported. If you use more than 2 interfaces per bridge group, you can control communication between multiple segments on the same network, and not just between inside and outside. For example, if you have three inside segments that you do not want to communicate with each other, you can put each segment on a separate interface, and only allow them to communicate with the outside interface. Or you can customize the access rules between interfaces to allow only as much access as desired.

The following figure shows two networks connected to the FTD device, which has two bridge groups.

Figure 56: Transparent Firewall Network with Two Bridge Groups



Bridge Groups in Routed Firewall Mode

Bridge group traffic can be routed to other bridge groups or routed interfaces. You can choose to isolate bridge group traffic by not assigning a name to the BVI interface for the bridge group. If you name the BVI, then the BVI participates in routing like any other regular interface.

One use for a bridge group in routed mode is to use extra interfaces on the FTD instead of an external switch. For example, the default configuration for some devices include an outside interface as a regular interface, and then all other interfaces assigned to the inside bridge group. Because the purpose of this bridge group is to replace an external switch, you need to configure an access policy so all bridge group interfaces can freely communicate.

Figure 57: Routed Firewall Network with an Inside Bridge Group and an Outside Routed Interface

Allowing Layer 3 Traffic

- Unicast IPv4 and IPv6 traffic requires an access rule to be allowed through the bridge group.
- ARPs are allowed through the bridge group in both directions without an access rule. ARP traffic can be controlled by ARP inspection.
- IPv6 neighbor discovery and router solicitation packets can be passed using access rules.
- Broadcast and multicast traffic can be passed using access rules.

Allowed MAC Addresses

The following destination MAC addresses are allowed through the bridge group if allowed by your access policy (see Allowing Layer 3 Traffic, on page 147). Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD

BPDU Handling

To prevent loops using the Spanning Tree Protocol, BPDUs are passed by default.

By default BPDUs are also forwarded for advanced inspection, which is unnecessary for this type of packet, and which can cause problems if they are blocked due to an inspection restart, for example. We recommend

that you always exempt BPDUs from advanced inspection. To do so, use FlexConfig to configure an EtherType ACL that trusts BPDUs and exempts them from advanced inspection on each member interface. See FlexConfig Policies, on page 1893.

The FlexConfig object should deploy the following commands, where you replace <if-name> with an interface name. Add as many access-group commands as needed to cover each bridge group member interface on the device. You can also choose a different name for the ACL.

```
access-list permit-bpdu ethertype trust bpdu
access-group permit-bpdu in interface <if-name>
```

MAC Address vs. Route Lookups

For traffic within a bridge group, the outgoing interface of a packet is determined by performing a destination MAC address lookup instead of a route lookup.

Route lookups, however, are necessary for the following situations:

- Traffic originating on the FTD device—Add a default/static route on the FTD device for traffic destined for a remote network where a syslog server, for example, is located.
- Voice over IP (VoIP) and TFTP traffic, and the endpoint is at least one hop away—Add a static route on the FTD device for traffic destined for the remote endpoint so that secondary connections are successful. The FTD device creates a temporary "pinhole" in the access control policy to allow the secondary connection; and because the connection might use a different set of IP addresses than the primary connection, the FTD device needs to perform a route lookup to install the pinhole on the correct interface.

  Affected applications include:

  - H.323
  - RTSP
  - SIP
  - Skinny (SCCP)
  - SQL*Net
  - SunRPC
  - TFTP

- Traffic at least one hop away for which the FTD device performs NAT—Configure a static route on the FTD device for traffic destined for the remote network. You also need a static route on the upstream router for traffic destined for the mapped addresses to be sent to the FTD device.

  This routing requirement is also true for embedded IP addresses for VoIP and DNS with NAT enabled, and the embedded IP addresses are at least one hop away. The FTD device needs to identify the correct egress interface so it can perform the translation.

Figure 58: NAT Example: NAT within a Bridge Group

Unsupported Features for Bridge Groups in Transparent Mode

The following table lists the features are not supported in bridge groups in transparent mode.

Table 11: Unsupported Features in Transparent Mode

Feature	Description
Dynamic DNS	—
DHCP relay	The transparent firewall can act as a DHCPv4 server, but it does not support DHCP relay. DHCP relay is not required because you can allow DHCP traffic to pass through using two access rules: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.
Dynamic routing protocols	You can, however, add static routes for traffic originating on the FTD device for bridge group member interfaces. You can also allow dynamic routing protocols through the FTD device using an access rule.

Feature	Description
Multicast IP routing	You can allow multicast traffic through the FTD device by allowing it in an access rule.
QoS	—
VPN termination for through traffic	The transparent firewall supports site-to-site VPN tunnels for management connections only on bridge group member interfaces. It does not terminate VPN connections for traffic through the FTD device. You can pass VPN traffic through the ASA using an access rule, but it does not terminate non-management connections.

Unsupported Features for Bridge Groups in Routed Mode

The following table lists the features are not supported in bridge groups in routed mode.

Table 12: Unsupported Features in Routed Mode

Feature	Description
EtherChannel member interfaces	Only physical interfaces, redundant interfaces, and subinterfaces are supported as bridge group member interfaces. Diagnostic interfaces are also not supported.
Clustering	Bridge groups are not supported in clustering.
Dynamic DNS	—
DHCP relay	The routed firewall can act as a DHCPv4 server, but it does not support DHCP relay on BVIs or bridge group member interfaces.
Dynamic routing protocols	You can, however, add static routes for BVIs. You can also allow dynamic routing protocols through the FTD device using an access rule. Non-bridge group interfaces support dynamic routing.
Multicast IP routing	You can allow multicast traffic through the FTD device by allowing it in an access rule. Non-bridge group interfaces support multicast routing.
QoS	Non-bridge group interfaces support QoS.
VPN termination for through traffic	You cannot terminate a VPN connection on the BVI. Non-bridge group interfaces support VPN. Bridge group member interfaces support site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the FTD device. You can pass VPN traffic through the bridge group using an access rule, but it does not terminate non-management connections.

Default Settings

Bridge Group Defaults

By default, all ARP packets are passed within the bridge group.

Guidelines for Firewall Mode

Bridge Group Guidelines (Transparent and Routed Mode)

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The FTD device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the FTD device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the FTDv on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.
- For the Firepower 1010, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the FTD as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.

- In transparent mode, PPPoE is not supported for the Diagnostic interface.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, FTD-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the FTD when using bridge group members. If there are two neighbors on either side of the FTD running BFD, then the FTD will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Set the Firewall Mode

You can set the firewall mode when you perform the initial system setup at the CLI. We recommend setting the firewall mode during setup because changing the firewall mode erases your configuration to ensure you do not have incompatible settings. If you need to change the firewall mode later, you must do so from the CLI.

Procedure

Step 1 Unregister the FTD device from the FMC.

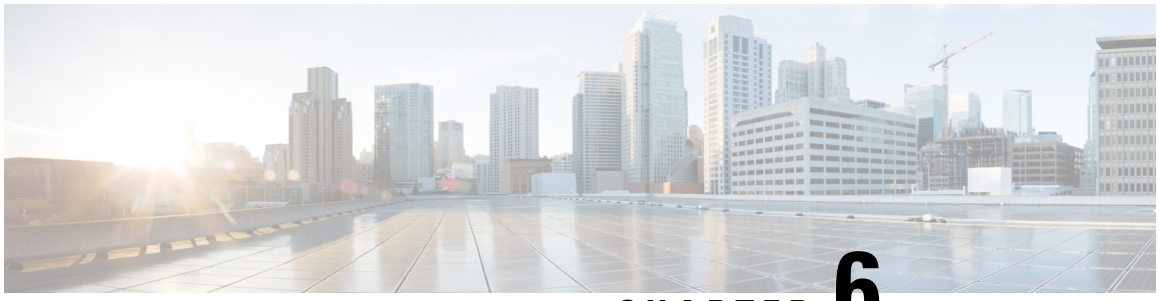
You cannot change the mode until you deregister the device.

a) Choose **Devices** > **Device Management**.

b) Next to the device you want to unregister, click **More** (⋮), and then click **Delete**.

Step 2 Access the FTD device CLI, preferably from the console port.

If you use SSH to the diagnostic interface, then changing the mode erases your interface configuration and you will be disconnected. You should instead connect to the management interface.



Step 3 Change the firewall mode:

configure firewall [**routed** | **transparent**]

Example:

```
> configure firewall transparent
This will destroy the current interface configurations, are you sure that you want to
proceed? [y/N] y
The firewall mode was changed successfully.
```

Step 4 Re-register with the FMC. See Complete the FTD Initial Configuration Using the CLI, on page 17 and Add a Device, on page 27.

CHAPTER 6

Logical Devices on the Firepower 4100/9300

The Firepower 4100/9300 is a flexible security platform on which you can install one or more *logical devices*. Before you can add the FTD to the FMC, you must configure chassis interfaces, add a logical device, and assign interfaces to the device on the Firepower 4100/9300 chassis using the Firepower Chassis Manager or the FXOS CLI. This chapter describes basic interface configuration and how to add a standalone or High Availability logical device using the Firepower Chassis Manager. To add a clustered logical device, see Clustering for the Firepower 4100/9300, on page 287. To use the FXOS CLI, see the FXOS CLI configuration guide. For more advanced FXOS procedures and troubleshooting, see the FXOS configuration guide.

- About Interfaces, on page 153
- About Logical Devices, on page 167
- Licenses for Container Instances, on page 176
- Requirements and Prerequisites for Logical Devices, on page 177
- Guidelines and Limitations for Logical Devices, on page 184
- Configure Interfaces, on page 188
- Configure Logical Devices, on page 192
- History for Logical Devices, on page 204

About Interfaces

The Firepower 4100/9300 chassis supports physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. EtherChannel interfaces can include up to 16 member interfaces of the same type.

Chassis Management Interface

The chassis management interface is used for management of the FXOS Chassis by SSH or Firepower Chassis Manager. This interface appears at the top of the **Interfaces** tab as **MGMT**, and you can only enable or disable this interface on the **Interfaces** tab. This interface is separate from the mgmt-type interface that you assign to the logical devices for application management.

To configure parameters for this interface, you must configure them from the CLI. To view information about this interface in the FXOS CLI, connect to local management and show the management port:

Firepower # **connect local-mgmt**

Firepower(local-mgmt) # **show mgmt-port**

Note that the chassis management interface remains up even if the physical cable or SFP module are unplugged, or if the **mgmt-port shut** command is performed, or if the logical device is offline.

Note The chassis management interface does not support jumbo frames.

Interface Types

Physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces can be one of the following types:

- Data—Use for regular data. Data interfaces cannot be shared between logical devices, and logical devices cannot communicate over the backplane to other logical devices. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another logical device.
- Data-sharing—Use for regular data. Only supported with container instances, these data interfaces can be shared by one or more logical devices/container instances (Firepower Threat Defense-using-FMC only). Each container instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of container instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, clusters, or failover links.
- Mgmt—Use to manage application instances. These interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. You can only assign one management interface per logical device. Depending on your application and manager, you can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. For information about the separate chassis management interface, see Chassis Management Interface, on page 153.

Note Mgmt interface change will cause reboot of the logical device, for example one change mgmt from e1/1 to e1/2 will cause the logical device to reboot to apply the new management.

- Eventing—Use as a secondary management interface for Firepower Threat Defense-using-FMC devices. To use this interface, you must configure its IP address and other parameters at the Firepower Threat Defense CLI. For example, you can separate management traffic from events (such as web events). See the management center configuration guide for more information. Eventing interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. If you later configure a data interface for management, you cannot use a separate eventing interface.

Note A virtual Ethernet interface is allocated when each application instance is installed. If the application does not use an eventing interface, then the virtual interface will be in an admin down state.

```
Firepower # show interface Vethernet775
Firepower # Vethernet775 is down (Administratively down)
Bound Interface is Ethernet1/10
Port description is server 1/1, VNIC ext-mgmt-nic5
```

- Cluster—Use as the cluster control link for a clustered logical device. By default, the cluster control link is automatically created on Port-channel 48. The Cluster type is only supported on EtherChannel interfaces. For multi-instance clustering, you cannot share a Cluster-type interface across devices. You can add VLAN subinterfaces to the Cluster EtherChannel to provide separate cluster control links per cluster. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster. The FDM and CDO does not support clustering.

Note This chapter discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the FTD application. See FXOS Interfaces vs. Application Interfaces, on page 156 for more information.

See the following table for interface type support for the FTD and ASA applications in standalone and cluster deployments.

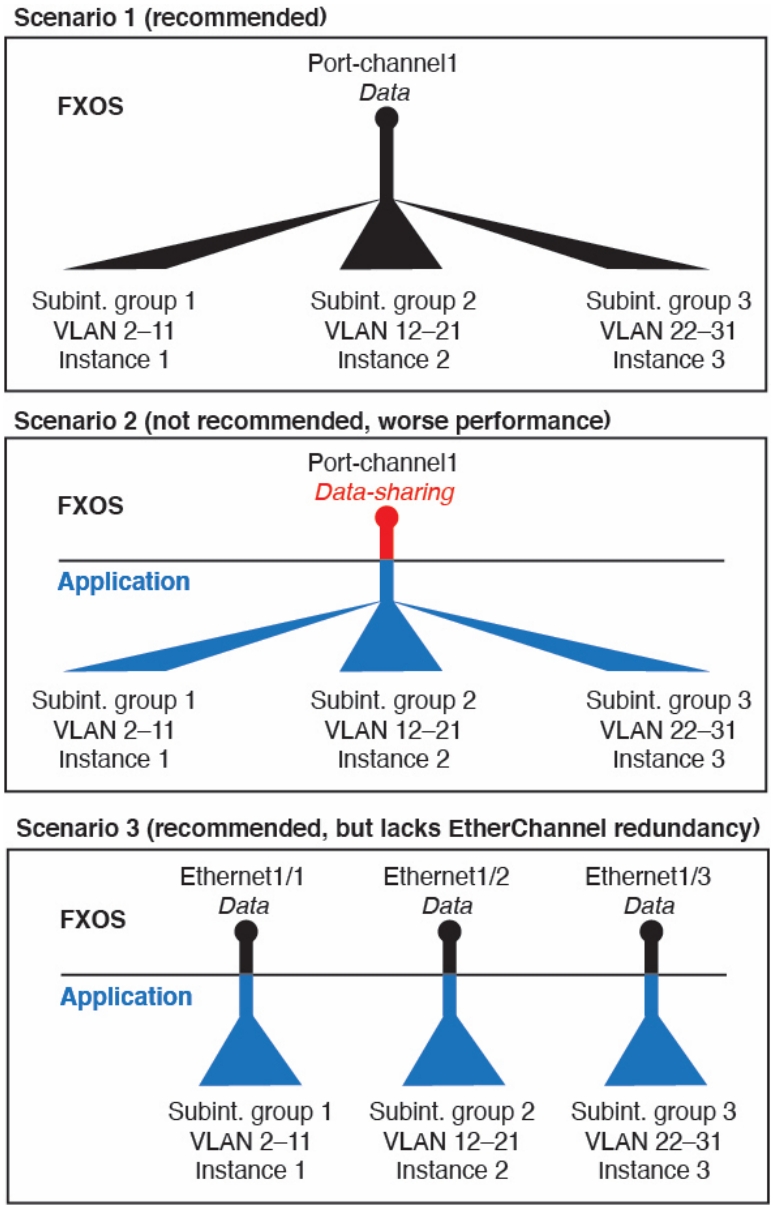
Table 13: Interface Type Support

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
FTD	Standalone Native Instance	**Yes**	—	—	—	**Yes**	**Yes**	—	—
	Standalone Container Instance	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	—	—
	Cluster Native Instance	**Yes** (EtherChannel only for inter-chassis cluster)	—	—	—	**Yes**	**Yes**	**Yes**	—
	Cluster Container Instance	**Yes** (EtherChannel only for inter-chassis cluster)	—	—	—	**Yes**	**Yes**	**Yes**	**Yes**

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
ASA	Standalone Native Instance	Yes	—	—	—	Yes	—	Yes	—
	Cluster Native Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	—	Yes	—

FXOS Interfaces vs. Application Interfaces

The Firepower 4100/9300 manages the basic Ethernet settings of physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. Within the application, you configure higher level settings. For example, you can only create EtherChannels in FXOS; but you can assign an IP address to the EtherChannel within the application.



The following sections describe the interaction between FXOS and the application for interfaces.

VLAN Subinterfaces

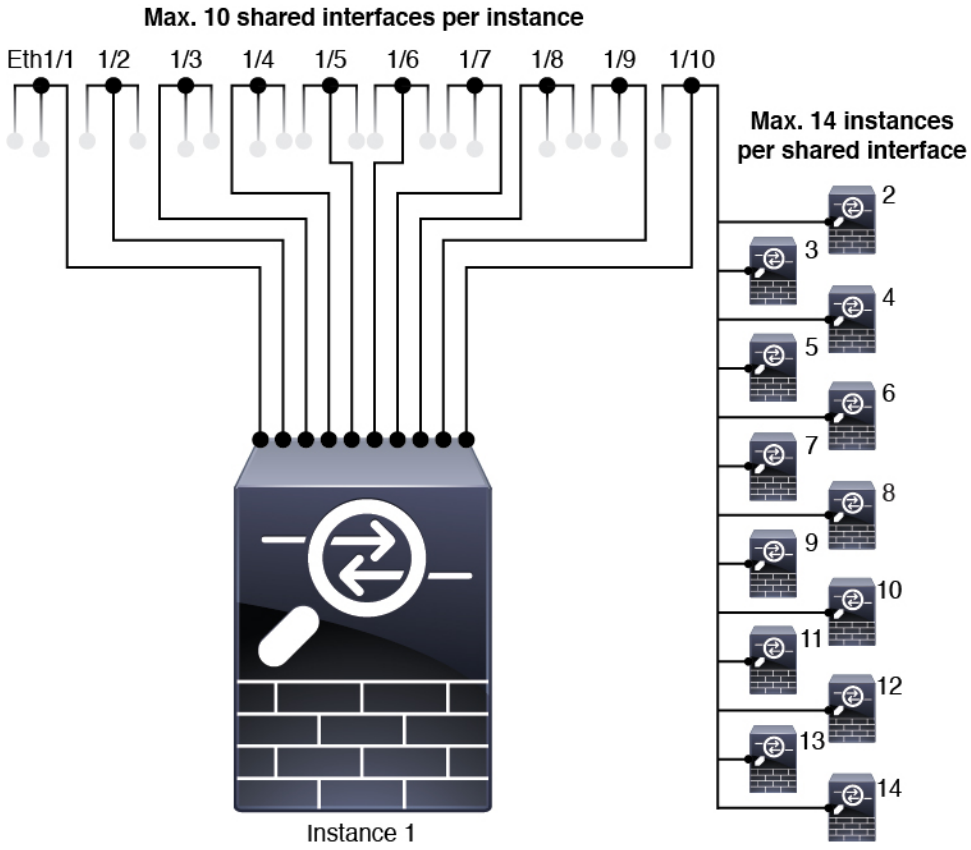
For all logical devices, you can create VLAN subinterfaces within the application.

For container instances in standalone mode only, you can *also* create VLAN subinterfaces in FXOS. Multi-instance clusters do not support subinterfaces in FXOS except on the Cluster-type interface. Application-defined subinterfaces are not subject to the FXOS limit. Choosing in which operating system to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface in FXOS. Another scenario that favors FXOS subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces within the application, then you would have to share the parent interface in FXOS, which may not be desirable. See the following illustration that shows the three ways you can accomplish this scenario:

Figure 59: VLANs in FXOS vs. the Application for Container Instances

Independent Interface States in the Chassis and in the Application

You can administratively enable and disable interfaces in both the chassis and in the application. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and application.



The default state of an interface within the application depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the application, but a subinterface is enabled by default.

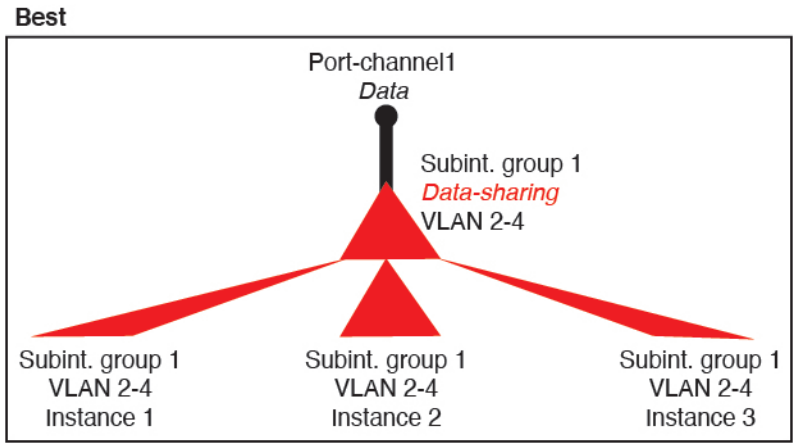
Shared Interface Scalability

Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:

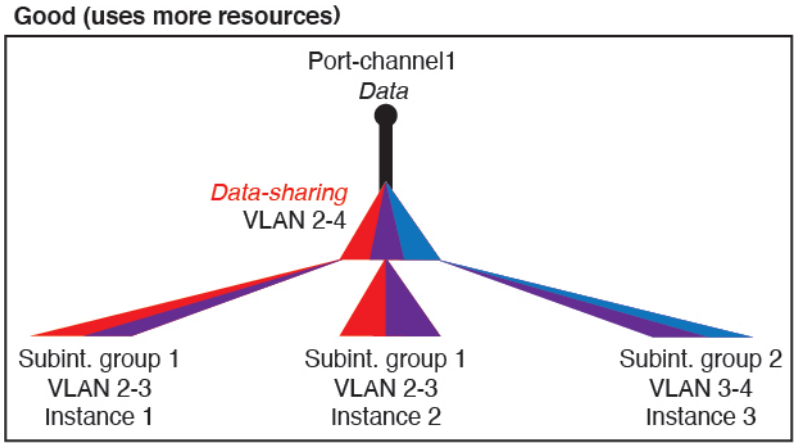
Shared Interface Best Practices



For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best—Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.



For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2, Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 60: Best: Shared Subinterface Group on One Parent

If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

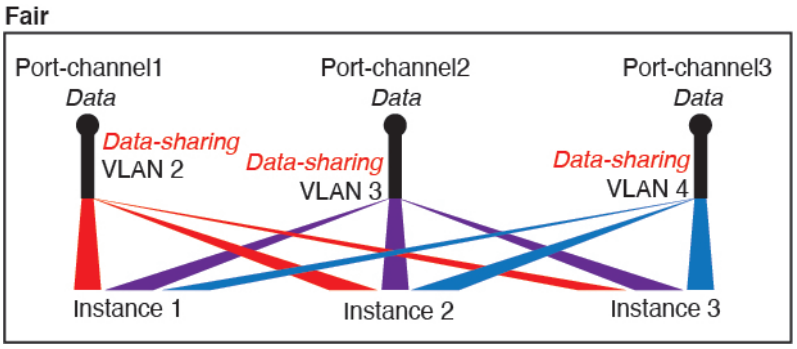


Figure 61: Good: Sharing Multiple Subinterface Groups on One Parent

2. Fair—Share subinterfaces across parents.

   For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

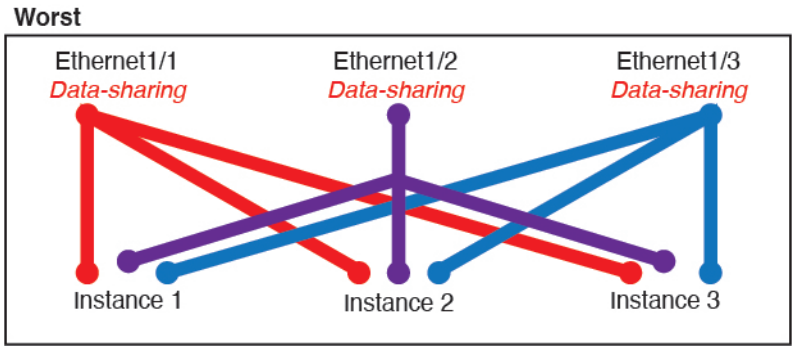

Figure 62: Fair: Shared Subinterfaces on Separate Parents

3. Worst—Share individual parent interfaces (physical or EtherChannel).

   This method uses the most forwarding table entries.

Figure 63: Worst: Shared Parent Interfaces

Shared Interface Usage Examples

See the following tables for examples of interface sharing and scalability. The below scenarios assume use of one physical/EtherChannel interface for management shared across all instances, and another physical or EtherChannel interface with dedicated subinterfaces for use with High Availability.

- Table 14: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s, on page 161
- Table 15: Subinterfaces on One Parent and Instances on a Firepower 9300 with Three SM-44s, on page 162
- Table 16: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with One SM-44, on page 164
- Table 17: Subinterfaces on One Parent and Instances on a Firepower 9300 with One SM-44, on page 165

Firepower 9300 with Three SM-44s

The following table applies to three SM-44 security modules on a 9300 using only physical interfaces or EtherChannels. Without subinterfaces, the maximum number of interfaces are limited. Moreover, sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

Each SM-44 module can support up to 14 instances. Instances are split between modules as necessary to stay within limits.

Table 14: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s

Dedicated Interfaces	Shared Interfaces	Number of Instances	% Forwarding Table Used

24: • 6 • 6 • 6 • 6	**7**	**4:** • Instance 1 • Instance 2 • Instance 3 • Instance 4	44%
24: • 12 (6 ea.) • 12 (6 ea.)	**14:** • 7 • 7	**4:** • Instance 1-Instance2 • Instance 2-Instance 4	41%

The following table applies to three SM-44 security modules on a 9300 using subinterfaces on a single parent physical interface. For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel. Sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

Each SM-44 module can support up to 14 instances. Instances are split between modules as necessary to stay within limits.

Table 15: Subinterfaces on One Parent and Instances on a Firepower 9300 with Three SM-44s

Dedicated Subinterfaces	Shared Subinterfaces	Number of Instances	% Forwarding Table Used
168: • 168 (4 ea.)	**0**	**42:** • Instance 1-Instance 42	33%
224: • 224 (16 ea.)	**0**	**14:** • Instance 1-Instance 14	27%
14: • 14 (1 ea.)	**1**	**14:** • Instance 1-Instance 14	46%

Firepower 9300 with One SM-44

The following table applies to the Firepower 9300 with one SM-44 using only physical interfaces or EtherChannels. Without subinterfaces, the maximum number of interfaces are limited. Moreover, sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

The Firepower 9300 with one SM-44 can support up to 14 instances.

Table 16: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with One SM-44

Dedicated Interfaces	Shared Interfaces	Number of Instances	% Forwarding Table Used
32: • 8 • 8 • 8 • 8	**0**	**4:** • Instance 1 • Instance 2 • Instance 3 • Instance 4	16%

Viewing Shared Interface Resources

To view forwarding table and VLAN group usage, see the **Devices & Network** > **Interface Forwarding Utilization** area. For example:

Inline Set Link State Propagation for the FTD

An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the system to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

When you configure an inline set in the Firepower Threat Defense application and enable link state propagation, the Firepower Threat Defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the chassis senses the change and updates the link state of the other interface to match it. Note that the chassis requires up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

Note Do not enable Hardware Bypass and link state propagation for the same inline set.

About Logical Devices

A logical device lets you run one application instance (either ASA or Firepower Threat Defense) and also one optional decorator application (Radware DefensePro) to form a service chain.

When you add a logical device, you also define the application instance type and version, assign interfaces, and configure bootstrap settings that are pushed to the application configuration.

Note For the Firepower 9300, you can install different application types (ASA and Firepower Threat Defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

Standalone and Clustered Logical Devices

You can add the following logical device types:

- Standalone—A standalone logical device operates as a standalone unit or as a unit in a High Availability pair.
- Cluster—A clustered logical device lets you group multiple units together, providing all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. Multiple module devices, like the Firepower 9300, support intra-chassis clustering. For the Firepower 9300, all three modules must participate in the cluster, for both native and container instances. The FDM does not support clustering.

Logical Device Application Instances: Container and Native

Application instances run in the following deployment types:

- Native instance—A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance.
- Container instance—A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances. Multi-instance capability is only supported for the Firepower Threat Defense using FMC; it is not supported for the ASA or the Firepower Threat Defense using FDM.

Note Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode partitions a single application instance, while multi-instance capability allows independent container instances. Container instances allow hard resource separation, separate configuration management, separate reloads, separate software updates, and full Firepower Threat Defense feature support. Multiple context mode, due to shared resources, supports more contexts on a given platform. Multiple context mode is not available on the Firepower Threat Defense.

For the Firepower 9300, you can use a native instance on some modules, and container instances on the other module(s).

Container Instance Interfaces

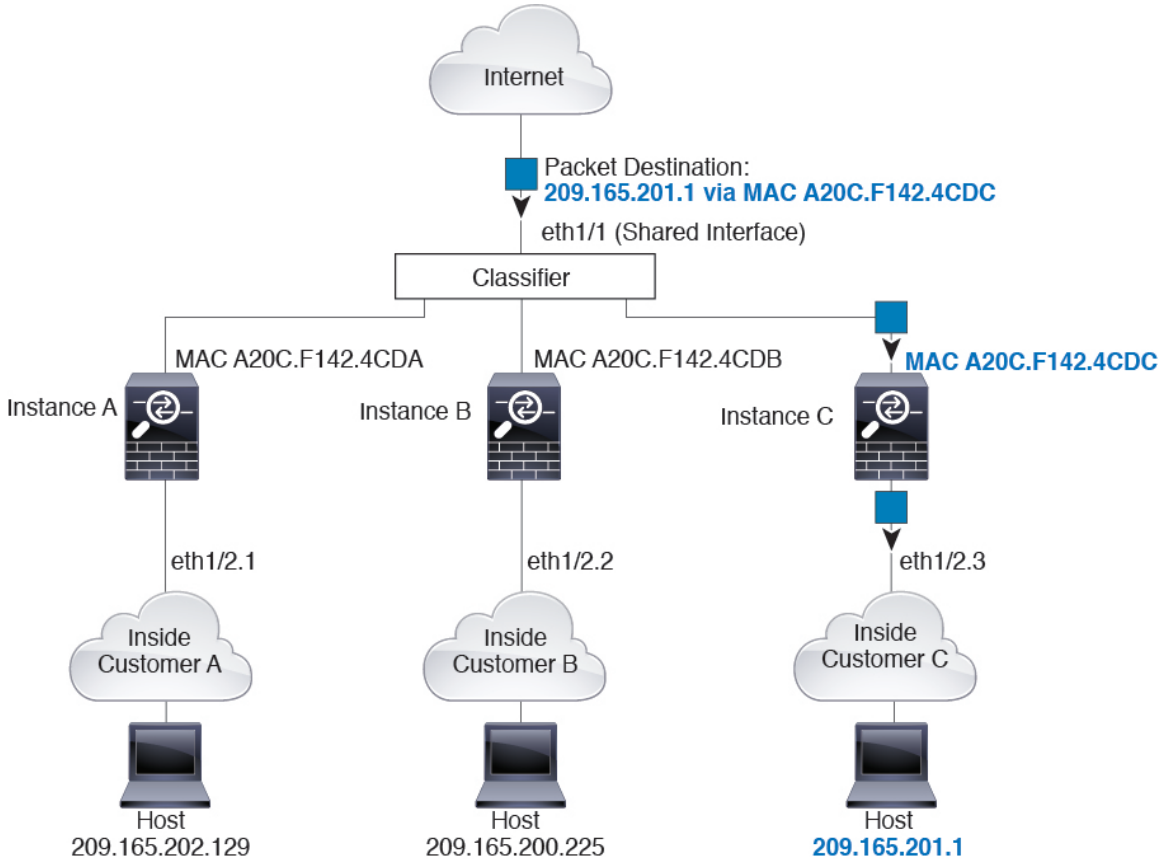
To provide flexible physical interface use for container instances, you can create VLAN subinterfaces in FXOS and also share interfaces (VLAN or physical) between multiple instances. Native instances cannot use VLAN subinterfaces or shared interfaces. A multi-instance cluster cannot use VLAN subinterfaces or shared interfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel. See Shared Interface Scalability, on page 158 and Add a VLAN Subinterface for Container Instances, on page 191.

Note This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the FTD application. See FXOS Interfaces vs. Application Interfaces, on page 156 for more information.

How the Chassis Classifies Packets

Each packet that enters the chassis must be classified, so that the chassis can determine to which instance to send a packet.

- Unique Interfaces—If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- Unique MAC Addresses—The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.



Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification Examples

Packet Classification with a Shared Interface Using MAC Addresses

The following figure shows multiple instances sharing an outside interface. The classifier assigns the packet to Instance C because Instance C includes the MAC address to which the router sends the packet.

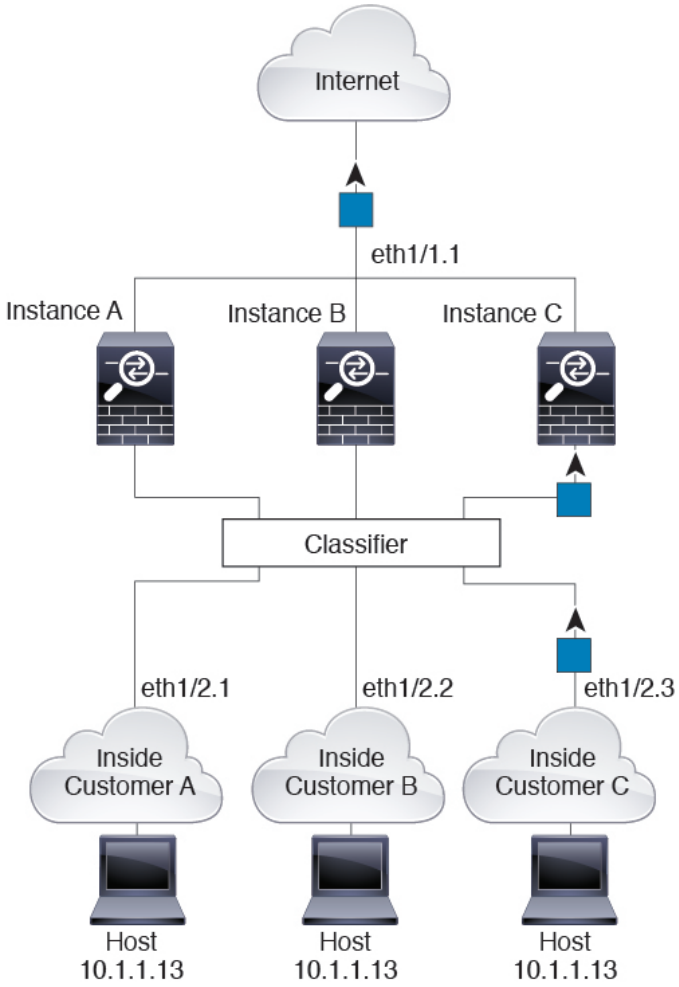


Figure 64: Packet Classification with a Shared Interface Using MAC Addresses

Incoming Traffic from Inside Networks

Note that all new incoming traffic must be classified, even from inside networks. The following figure shows a host on the Instance C inside network accessing the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

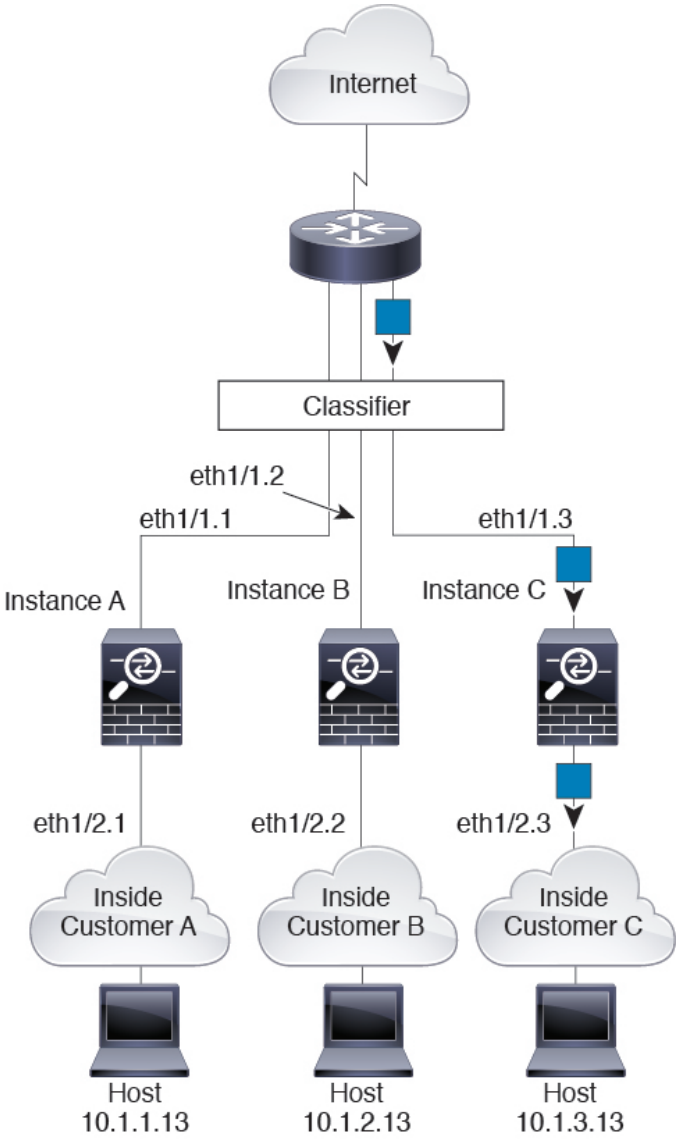

Figure 65: Incoming Traffic from Inside Networks

Transparent Firewall Instances

For transparent firewalls, you must use unique interfaces. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

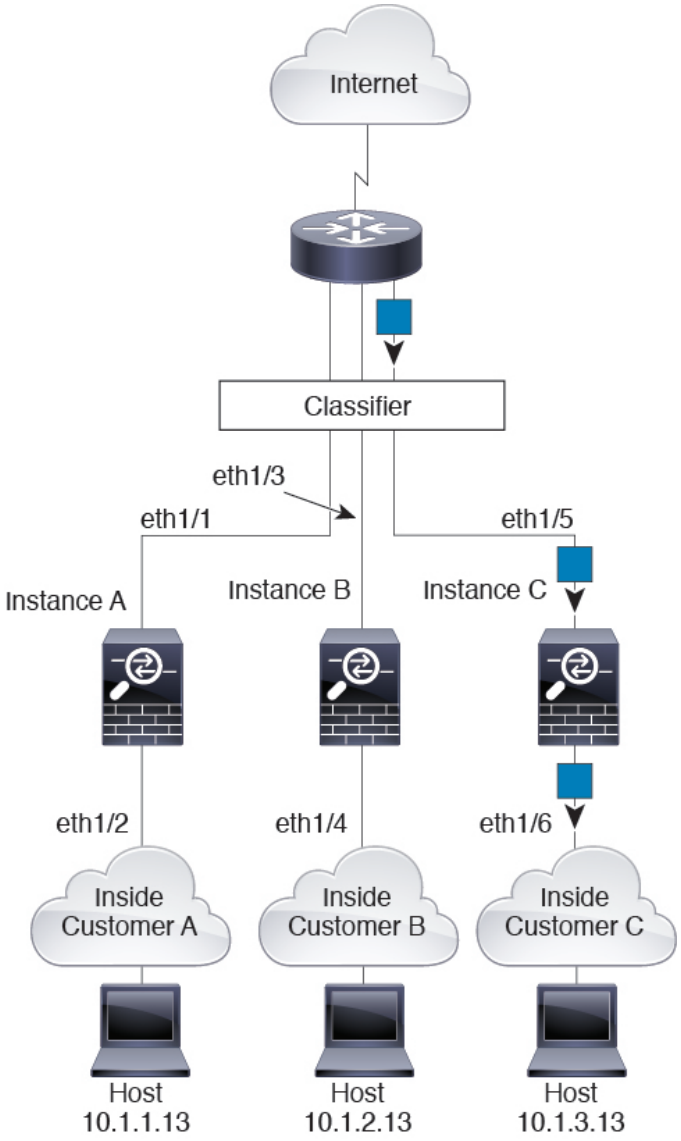

Figure 66: Transparent Firewall Instances

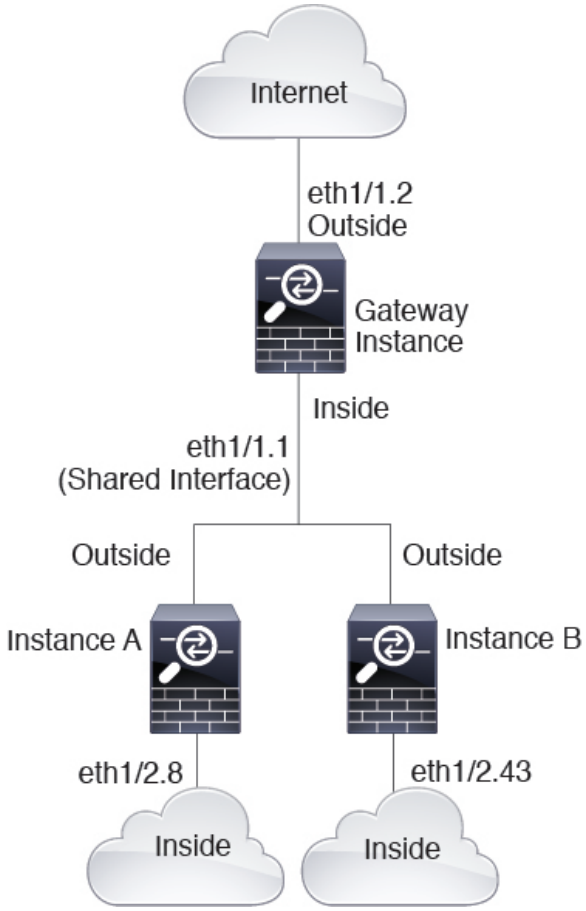
Inline Sets

For inline sets, you must use unique interfaces and they must be physical interfaces or EtherChannels. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/5, which is assigned to Instance C.

Figure 67: Inline Sets

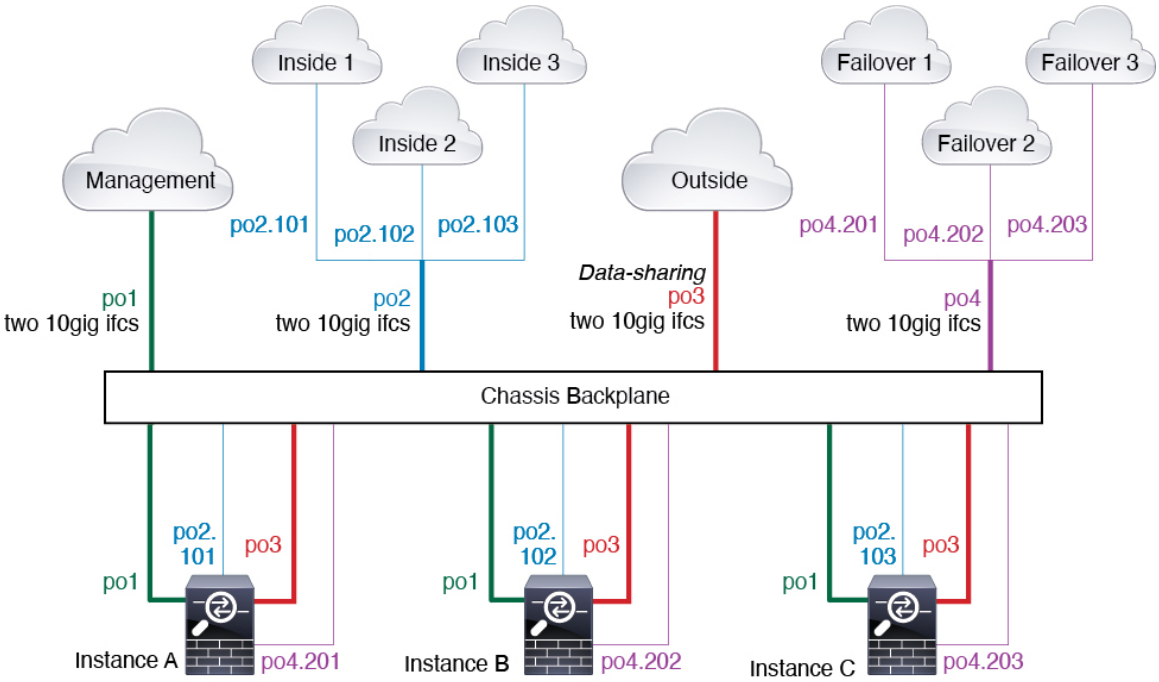


Cascading Container Instances

Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 68: Cascading Instances



Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

Typical Multi-Instance Deployment

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- Management—All instances use the Port-Channel1 interface (management type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same management network.
- Inside—Each instance uses a subinterface on Port-Channel2 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

- Outside—All instances use the Port-Channel3 interface (data-sharing type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover—Each instance uses a subinterface on Port-Channel4 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

Automatic MAC Addresses for Container Instance Interfaces

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or a system-defined prefix, and *zz.zzzz* is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the chassis native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

Container Instance Resource Management

To specify resource usage per container instance, create one or more resource profiles in FXOS. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. To view the available resources per model, see Requirements and Prerequisites for Container Instances, on page 179. To add a resource profile, see Add a Resource Profile for Container Instances, on page 193.

Performance Scaling Factor for Multi-Instance Capability

The maximum throughput (connections, VPN sessions, and TLS proxy sessions) for a platform is calculated for a native instance's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use a container instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to a container instance may be less than that available to a native instance.

For detailed instructions on calculating the throughput for instances, see https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html.

Container Instances and High Availability

You can use High Availability using a container instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. Note that High Availability is not configured in FXOS; configure each High Availability pair in the application manager.

For detailed requirements, see Requirements and Prerequisites for High Availability, on page 180 and Add a High Availability Pair, on page 199.

Container Instances and Clustering

You can create a cluster of container instances using one container instance per security module/engine. See Requirements and Prerequisites for Clustering, on page 181 for detailed requirements.

Licenses for Container Instances

All licenses are consumed per security engine/chassis (for the Firepower 4100) or per security module (for the Firepower 9300), and not per container instance. See the following details:

- Base licenses are automatically assigned: one per security module/engine.
- Feature licenses are manually assigned to each instance; but you only consume one license per feature per security module/engine. For example, for the Firepower 9300 with 3 security modules, you only need

one URL Filtering license per module for a total of 3 licenses, regardless of the number of instances in use.

For example:

Table 18: Sample License Usage for Container Instances on a Firepower 9300

Firepower 9300	Instance	Licenses
Security Module 1	Instance 1	Base, URL Filtering, Malware
	Instance 2	Base, URL Filtering
	Instance 3	Base, URL Filtering
Security Module 2	Instance 4	Base, Threat
	Instance 5	Base, URL Filtering, Malware, Threat
Security Module 3	Instance 6	Base, Malware, Threat
	Instance 7	Base, Threat

Table 19: Total Number of Licenses

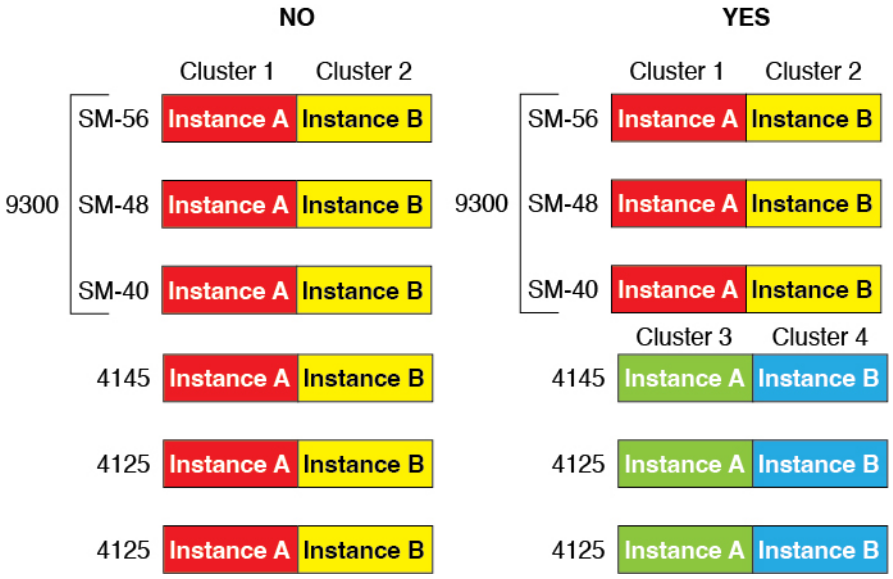
Base	URL Filtering	Malware	Threat
3	2	3	2

Requirements and Prerequisites for Logical Devices

See the following sections for requirements and prerequisites.

Requirements and Prerequisites for Hardware and Software Combinations

The Firepower 4100/9300 supports multiple models, security modules, application types, and high availability and scalability features. See the following requirements for allowed combinations.



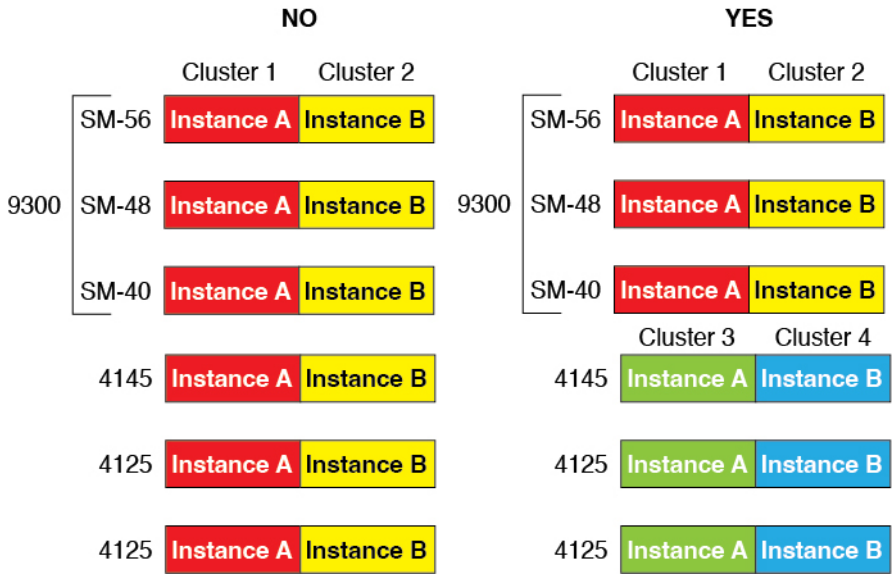
Firepower 9300 Requirements

The Firepower 9300 includes 3 security module slots and multiple types of security modules. See the following requirements:

- Security Module Types—You can install modules of different types in the Firepower 9300. For example, you can install the SM-48 as module 1, SM-40 as module 2, and SM-56 as module 3.
- Native instance Clustering—All security modules in the cluster, whether it is intra-chassis or inter-chassis, must be the same type. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots. For

example, you can install 2 SM-40s in chassis 1, and 3 SM-40s in chassis 2. You cannot use clustering if you install 1 SM-48 and 2 SM-40s in the same chassis.

- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.



- High Availability—High Availability is only supported between same-type modules on the Firepower 9300. However, the two chassis can include mixed modules. For example, each chassis has an SM-40, SM-48, and SM-56. You can create High Availability pairs between the SM-40 modules, between the SM-48 modules, and between the SM-56 modules.
- ASA and FTD application types—You can install different application types on separate modules in the chassis. For example, you can install ASA on module 1 and module 2, and FTD on module 3.
- ASA or FTD versions—You can run different versions of an application instance type on separate modules, or as separate container instances on the same module. For example, you can install the FTD 6.3 on module 1, FTD 6.4 on module 2, and FTD 6.5 on module 3.

Firepower 4100 Requirements

The Firepower 4100 comes in multiple models. See the following requirements:

- Native and Container instances—When you install a container instance on a Firepower 4100, that device can only support other container instances. A native instance uses all of the resources for a device, so you can only install a single native instance on the device.
- Native instance Clustering—All chassis in the cluster must be the same model.
- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 4145 and a 4125. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.

- High Availability—High Availability is only supported between same-type models.
- ASA and FTD application types—The Firepower 4100 can only run a single application type.
- The FTD container instance versions—You can run different versions of Firepower Threat Defense as separate container instances on the same module.

Requirements and Prerequisites for Container Instances

For information about high-availability or clustering requirements with multi-instance, see Requirements and Prerequisites for High Availability, on page 180 and see Requirements and Prerequisites for Clustering, on page 181.

Supported Application Types

- The FTD using FMC

Maximum Container Instances and Resources per Model

For each container instance, you can specify the number of CPU cores to assign to the instance. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 20: Maximum Container Instances and Resources per Model

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4110	3	22	53 GB	125.6 GB
Firepower 4112	3	22	78 GB	308 GB
Firepower 4115	7	46	162 GB	308 GB
Firepower 4120	3	46	101 GB	125.6 GB

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4125	10	62	162 GB	644 GB
Firepower 4140	7	70	222 GB	311.8 GB
Firepower 4145	14	86	344 GB	608 GB
Firepower 4150	7	86	222 GB	311.8 GB
Firepower 9300 SM-24 security module	7	46	226 GB	656.4 GB
Firepower 9300 SM-36 security module	11	70	222 GB	640.4 GB
Firepower 9300 SM-40 security module	13	78	334 GB	1359 GB
Firepower 9300 SM-44 security module	14	86	218 GB	628.4 GB
Firepower 9300 SM-48 security module	15	94	334 GB	1341 GB
Firepower 9300 SM-56 security module	18	110	334 GB	1314 GB

FMC Requirements

For all instances on a Firepower 4100 chassis or Firepower 9300 module, you must use the same FMC due to the licensing implementation.

Requirements and Prerequisites for High Availability

- The two units in a High Availability Failover configuration must:
  - Be on a separate chassis; intra-chassis High Availability for the Firepower 9300 is not supported.
  - Be the same model.
  - Have the same interfaces assigned to the High Availability logical devices.
  - Have the same number and types of interfaces. All interfaces must be preconfigured in FXOS identically before you enable High Availability.
- High Availability is only supported between same-type modules on the Firepower 9300; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.
- For container instances, each unit must use the same resource profile attributes.

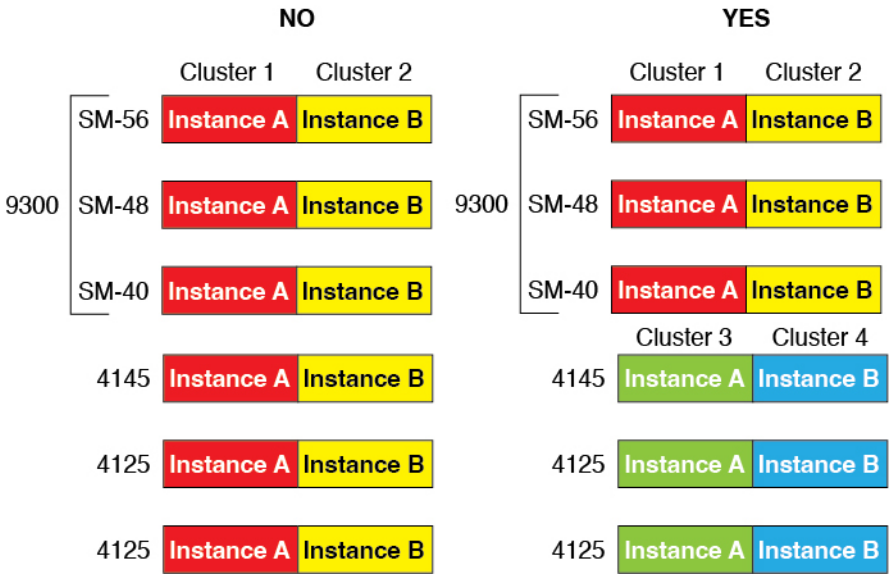
- For container instances: Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.
- For other High Availability system requirements, see High Availability System Requirements, on page 209.

Requirements and Prerequisites for Clustering

Cluster Model Support

The FTD supports clustering on the following models:

- Firepower 9300— You can include up to 6 nodes in the cluster. For example, you can use 1 module in 6 chassis, or 2 modules in 3 chassis, or any combination that provides a maximum of 6 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 6 nodes using clustering with multiple chassis.



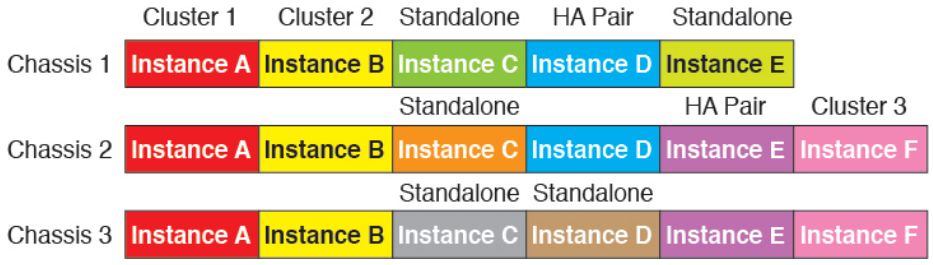
User Roles

- Admin
- Access Admin
- Network Admin

Clustering Hardware and Software Requirements

All chassis in a cluster:

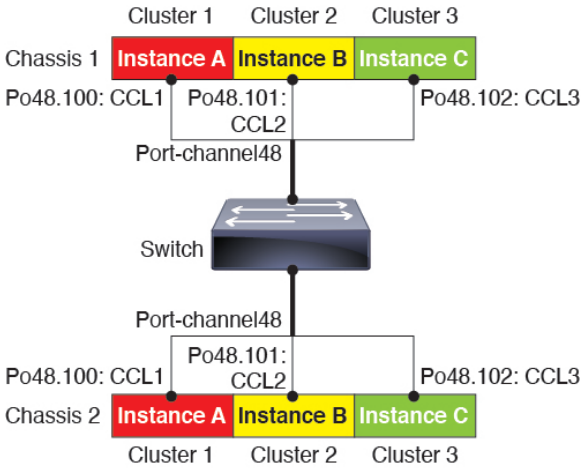
- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firepower Threat Defense, the FMC must also use the same NTP server. Do not set the time manually.

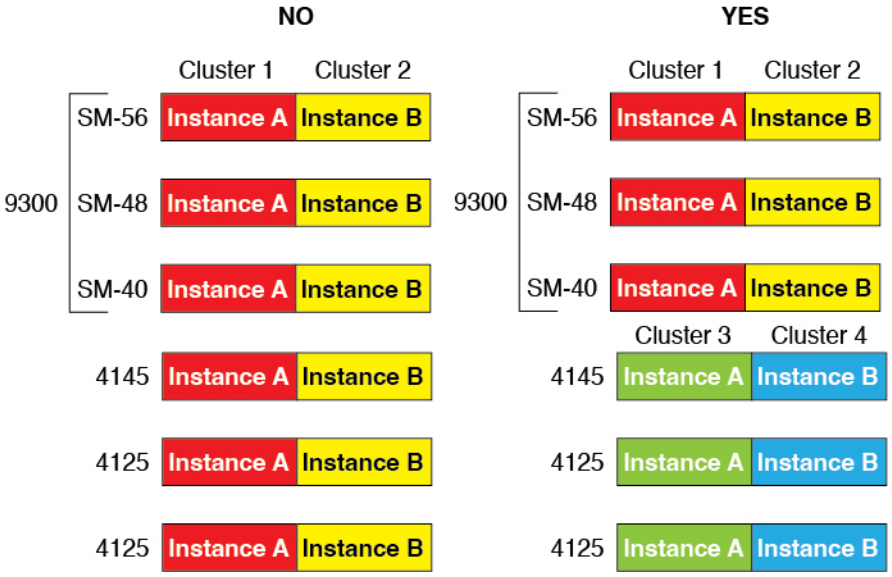
Multi-Instance Clustering Requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.



- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.

- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.



- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300

security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch Requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.
- For supported switch characteristics, see Cisco FXOS Compatibility.

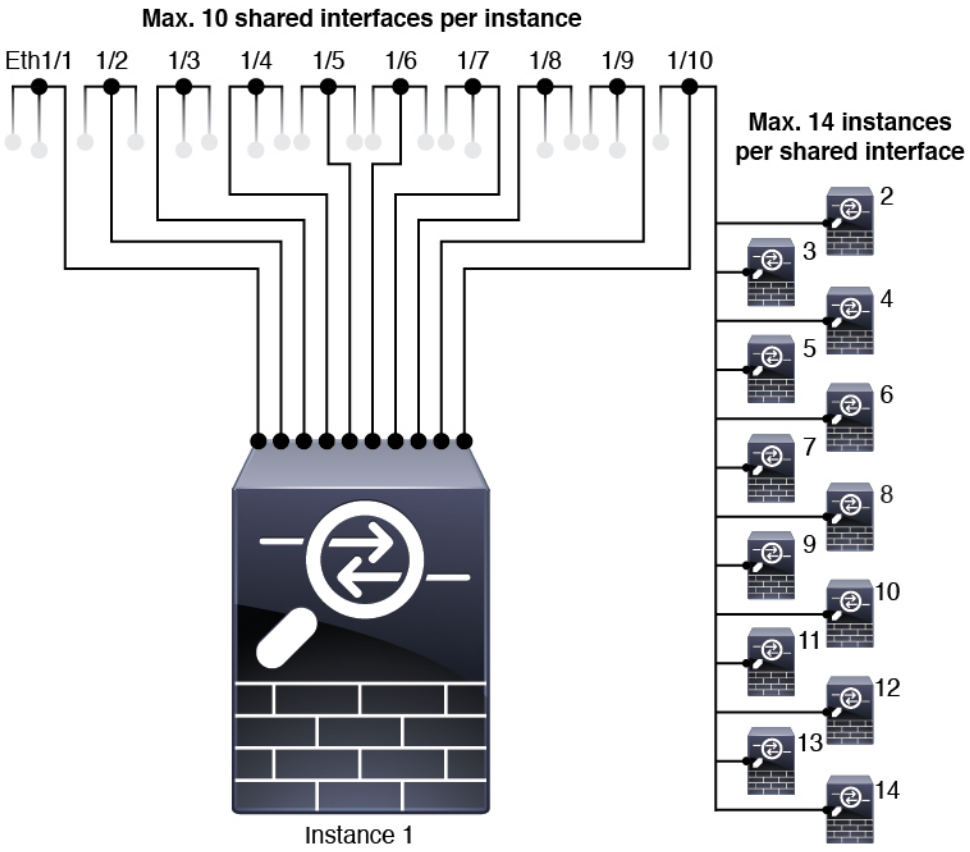
Guidelines and Limitations for Logical Devices

See the following sections for guidelines and limitations.

Guidelines and Limitations for Interfaces

VLAN Subinterfaces

- This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the FTD application. See FXOS Interfaces vs. Application Interfaces, on page 156 for more information.
- Subinterfaces (and the parent interfaces) can only be assigned to container instances.



Note If you assign a parent interface to a container instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic. For Cluster type interfaces, the parent interface cannot be used.

- Subinterfaces are supported on Data or Data-sharing type interfaces, as well as Cluster type interfaces. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.
- For multi-instance clustering, FXOS subinterfaces are not supported on Data interfaces. However, subinterfaces are supported for the cluster control link, so you can use either a dedicated EtherChannel or a subinterface of an EtherChannel for the cluster control link. Note that *application*-defined subinterfaces are supported for Data interfaces.
- You can create up to 500 VLAN IDs.
- See the following limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
  - You cannot use subinterfaces for an Firepower Threat Defense inline set or as a passive interface.
  - If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

Data-sharing Interfaces

- You cannot use a data-sharing interface with a native instance.
- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

  Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.

- You cannot use a data-sharing interface in a cluster.
- See the following limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
  - You cannot use a data-sharing interface with a transparent firewall mode device.
  - You cannot use a data-sharing interface with Firepower Threat Defense inline sets or passive interfaces.
  - You cannot use a data-sharing interface for the failover link.

Inline Sets for FTD

- Supported for physical interfaces (both regular and breakout ports) and EtherChannels. Subinterfaces are not supported.
- Link state propagation is supported.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Hardware Bypass

- Supported for the Firepower Threat Defense; you can use them as regular interfaces for the ASA.
- The Firepower Threat Defense only supports Hardware Bypass with inline sets.

- Hardware Bypass-capable interfaces cannot be configured for breakout ports.
- You cannot include Hardware Bypass interfaces in an EtherChannel and use them for Hardware Bypass; you can use them as regular interfaces in an EtherChannel.
- Hardware Bypass is not supported with High Availability.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Default MAC Addresses

For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- EtherChannels—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces, on page 175.

General Guidelines and Limitations

Firewall Mode

You can set the firewall mode to routed or transparent in the bootstrap configuration for the Firepower Threat Defense.

High Availability

- Configure high availability within the application configuration.
- You can use any data interfaces as the failover and state links. Data-sharing interfaces are not supported.

Multi-Instance

- Multi-instance capability with container instances is only available for the Firepower Threat Defense using FMC.
- For Firepower Threat Defense container instances, a single FMC must manage all instances on a security module/engine.
- For Firepower Threat Defense container instances, the following features are not supported:
  - Radware DefensePro link decorator

- FMC UCAPL/CC mode
- Flow offload to hardware

Configure Interfaces

By default, physical interfaces are disabled. You can enable interfaces, add EtherChannels, add VLAN subinterfaces, and edit interface properties.

Enable or Disable an Interface

You can change the **Admin State** of each interface to be enabled or disabled. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The Interfaces page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 To enable the interface, click the disabled **Slider disabled** () so that it changes to the enabled **Slider enabled** ().

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from gray to green.

Step 3 To disable the interface, click the enabled **Slider enabled** () so that it changes to the disabled **Slider disabled** ().

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from green to gray.

Configure a Physical Interface

You can physically enable and disable interfaces, as well as set the interface speed and duplex. To use an interface, it must be physically enabled in FXOS and logically enabled in the application.

Note

- For QSFPH40G-CUxM, auto-negotiation is always enabled by default and you cannot disable it.
- If you replace an SFP on a port with a different SFP module, the speed, duplex, and auto-negotiation of the interface is not updated automatically. You must manually re-configure the interface.

Before you begin

- Interfaces that are already a member of an EtherChannel cannot be modified individually. Be sure to configure settings before you add it to the EtherChannel.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Edit** in the row for the interface you want to edit to open the **Edit Interface** dialog box.

Step 3 To enable the interface, check the **Enable** check box. To disable the interface, uncheck the **Enable** check box.

Step 4 Choose the interface **Type**:

See Interface Types, on page 154 for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For Firepower Threat Defense only.
- **Cluster**—Do not choose the **Cluster** type; by default, the cluster control link is automatically created on Port-channel 48.

Step 5 (Optional) Choose the speed of the interface from the **Speed** drop-down list.

Step 6 (Optional) If your interface supports **Auto Negotiation**, click the **Yes** or **No** radio button.

Step 7 (Optional) Choose the duplex of the interface from the **Duplex** drop-down list.

Step 8 (Optional) Explicitly configure **Debounce Time (ms)**. Enter a value between 0-15000 milli-seconds.

Note
Configuring Debounce Time is not supported on 1G interfaces.

Step 9 Click **OK**.

Add an EtherChannel (Port Channel)

An EtherChannel (also known as a port channel) can include up to 16 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface. The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical Data or Data-sharing interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

Note It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

Non-data interfaces only support active mode.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the Firepower 4100/9300 chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state in the following situations:

- The EtherChannel is added as a data or management interface for a standalone logical device
- The EtherChannel is added as a management interface or cluster control link for a logical device that is part of a cluster
- The EtherChannel is added as a data interface for a logical device that is part of a cluster and at least one unit has joined the cluster

Note that the EtherChannel does not come up until you assign it to a logical device. If the EtherChannel is removed from the logical device or the logical device is deleted, the EtherChannel will revert to a **Suspended** or **Down** state.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Add Port Channel** above the interfaces table to open the **Add Port Channel** dialog box.

Step 3 Enter an ID for the port channel in the **Port Channel ID** field. Valid values are between 1 and 47.

Port-channel 48 is reserved for the cluster control link when you deploy a clustered logical device. If you do not want to use Port-channel 48 for the cluster control link, you can delete it and configure a Cluster type EtherChannel with a different ID.You can add multiple Cluster type EtherChannels and add VLAN subinterfaces for use with multi-instance clustering. For intra-chassis clustering, do not assign any interfaces to the Cluster EtherChannel.

Step 4 To enable the port channel, check the **Enable** check box. To disable the port channel, uncheck the **Enable** check box.

Step 5 Choose the interface **Type**:

See Interface Types, on page 154 for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For Firepower Threat Defense only.
- **Cluster**

Step 6 Set the required **Admin Speed** for the member interfaces from the drop-down list.

If you add a member interface that is not at the specified speed, it will not successfully join the port channel.

Step 7 For Data or Data-sharing interfaces, choose the LACP port-channel **Mode**, **Active** or **On**.

For non-Data or non-Data-sharing interfaces, the mode is always active.

Step 8 Set the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.

If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.

Step 9 To add an interface to the port channel, select the interface in the **Available Interface** list and click **Add Interface** to move the interface to the Member ID list.

You can add up to 16 member interfaces of the same media type and capacity. The member interfaces must be set to the same speed and duplex, and must match the speed and duplex that you configured for this port channel. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface.

Tip
You can add multiple interfaces at one time. To select multiple individual interfaces, click on the desired interfaces while holding down the **Ctrl** key. To select a range of interfaces, select the first interface in the range, and then, while holding down the **Shift** key, click to select the last interface in the range.

Step 10 To remove an interface from the port channel, click the **Delete** button to the right of the interface in the Member ID list.

Step 11 Click **OK**.

Add a VLAN Subinterface for Container Instances

You can add between 250 and 500 VLAN subinterfaces to the chassis, depending on your network deployment. You can add up to 500 subinterfaces to your chassis.

For multi-instance clustering, you can only add subinterfaces to the Cluster-type interface; subinterfaces on data interfaces are not supported.

VLAN IDs per interface must be unique, and within a container instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different container instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the FTD application. For more information on when to use FXOS subinterfaces vs. application subinterfaces, see FXOS Interfaces vs. Application Interfaces, on page 156.

Procedure

Step 1 Choose **Interfaces** to open the **All Interfaces** tab.

The **All Interfaces** tab shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Add New** > **Subinterface** to open the **Add Subinterface** dialog box.

Step 3 Choose the interface **Type**:

See Interface Types, on page 154 for details about interface type usage.

- **Data**
- **Data-sharing**
- **Cluster**—If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

For Data and Data-sharing interfaces: The type is independent of the parent interface type; you can have a Data-sharing parent and a Data subinterface, for example.

Step 4 Choose the parent **Interface** from the drop-down list.

You cannot add a subinterface to a physical interface that is currently allocated to a logical device. If other subinterfaces of the parent are allocated, you can add a new subinterface as long as the parent interface itself is not allocated.

Step 5 Enter a **Subinterface ID**, between 1 and 4294967295.

This ID will be appended to the parent interface ID as *interface_id.subinterface_id*. For example, if you add a subinterface to Ethernet1/1 with the ID of 100, then the subinterface ID will be: Ethernet1/1.100. This ID is not the same as the VLAN ID, although you can set them to match for convenience.

Step 6 Set the **VLAN ID** between 1 and 4095.

Step 7 Click **OK**.

Expand the parent interface to view all subinterfaces under it.

Configure Logical Devices

Add a standalone logical device or a High Availability pair on the Firepower 4100/9300.

For clustering, see Clustering for the Firepower 4100/9300, on page 287.

Add a Resource Profile for Container Instances

To specify resource usage per container instance, create one or more resource profiles. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

- The minimum number of cores is 6.

Note Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.

- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the security module/chassis model; see Requirements and Prerequisites for Container Instances, on page 179.

The chassis includes a default resource profile called "Default-Small," which includes the minimum number of cores. You can change the definition of this profile, and even delete it if it is not in use. Note that this profile is created when the chassis reloads and no other profile exists on the system.

Changing the resource profile after you assign it is disruptive. See the following guidelines:

- You cannot change the resource profile settings if it is currently in use. You must disable any instances that use it, then change the resource profile, and finally reenable the instance.
- If you change the resource profile settings after you add the Firepower Threat Defense instance to the FMC, then update the inventory for each unit on the FMC **Devices** > **Device Management** > **Device** > **System** > **Inventory** dialog box.
- If you assign a different profile to an instance, it reboots.
- If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:
  1. Break high availability.
  2. Assign the new profile to both units.
  3. Re-establish high availability.
- If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they all come back up, you can apply the new profile to the control node.

Procedure

Step 1 Choose **Platform Settings** > **Resource Profiles** , and click **Add**.

The **Add Resource Profile** dialog box appears.

Step 2 Set the following paramters.

- **Name**—Sets the name of the profile between 1 and 64 characters. Note that you cannot change the name of this profile after you add it.
- **Description**—Sets the description of the profile up to 510 characters.
- **Number of Cores**—Sets the number of cores for the profile, between 6 and the maximum, depending on your chassis, as an even number.

Step 3 Click **OK**.

Add a Standalone FTD

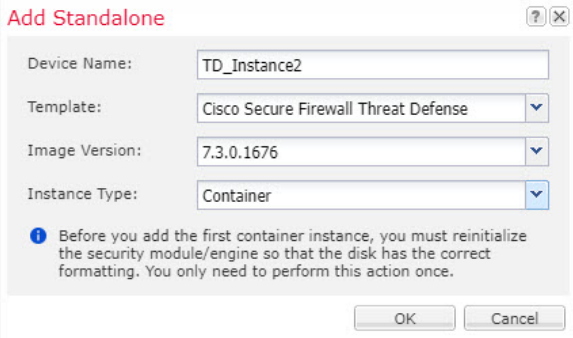
Standalone logical devices work either alone or in a High Availability pair. On the Firepower 9300 with multiple security modules, you can deploy either a cluster or standalone devices. The cluster must use all modules, so you cannot mix and match a 2-module cluster plus a single standalone device, for example.

You can use native instances on some modules, and container instances on the other module(s).

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.

Note For the Firepower 9300, you can install different application types (ASA and FTD) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.



- Configure a management interface to use with the logical device. The management interface is required. Note that this management interface is not the same as the chassis management port that is used only for chassis management (and that appears at the top of the **Interfaces** tab as **MGMT**).
- You can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. See the **configure network management-data-interface** command in the FTD command reference for more information.
- You must also configure at least one Data type interface. Optionally, you can also create a firepower-eventing interface to carry all event traffic (such as web events). See Interface Types, on page 154 for more information.

- For container instances, if you do not want to use the default profile, add a resource profile according to Add a Resource Profile for Container Instances, on page 193.
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the **Reinitialize icon**. An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Interface IDs for this device
  - Management interface IP address and network mask
  - Gateway IP address
  - FMC IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Firepower Threat Defense hostname and domain name

Procedure

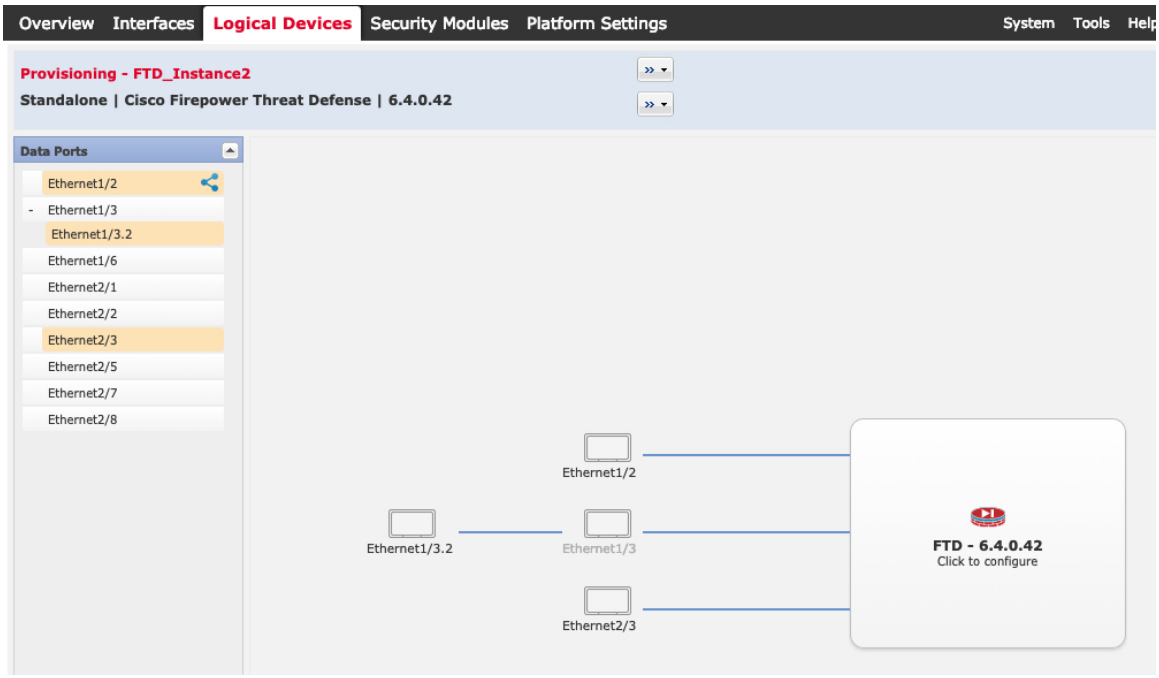
Step 1 Choose **Logical Devices**.

Step 2 Click **Add** > **Standalone**, and set the following parameters:

a) Provide a **Device Name**.

This name is used by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

Note
You cannot change this name after you add the logical device.



b) For the **Template**, choose **Cisco Firepower Threat Defense**.
c) Choose the **Image Version**.
d) Choose the **Instance Type**: **Container** or **Native**.

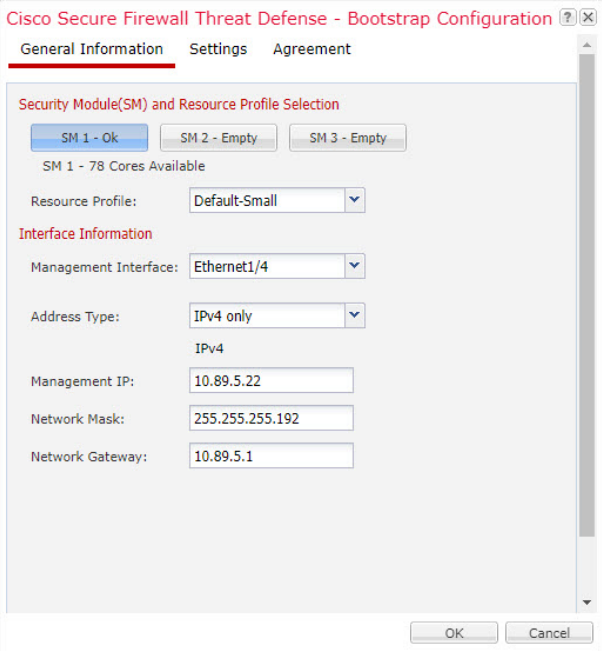
A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

e) Click **OK**.

You see the Provisioning - *device name* window.

Step 3 Expand the **Data Ports** area, and click each interface that you want to assign to the device.

You can only assign data and data-sharing interfaces that you previously enabled on the **Interfaces** page. You will later enable and configure these interfaces in FMC, including setting the IP addresses.



You can only assign up to 10 data-sharing interfaces to a container instance. Also, each data-sharing interface can be assigned to at most 14 container instances. A data-sharing interface is indicated by the sharing icon ( ).

Hardware Bypass-capable ports are shown with the following icon: . For certain interface modules, you can enable the Hardware Bypass feature for Inline Set interfaces only (see the FMC configuration guide). Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. If you do not assign both interfaces in a Hardware Bypass pair, you see a warning message to make sure your assignment is intentional. You do not need to use the Hardware Bypass feature, so you can assign single interfaces if you prefer.

Step 4 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 5 On the **General Information** page, complete the following:

a) (For the Firepower 9300) Under **Security Module Selection** click the security module that you want to use for this logical device.

b) For a container instance, specify the **Resource Profile**.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes.

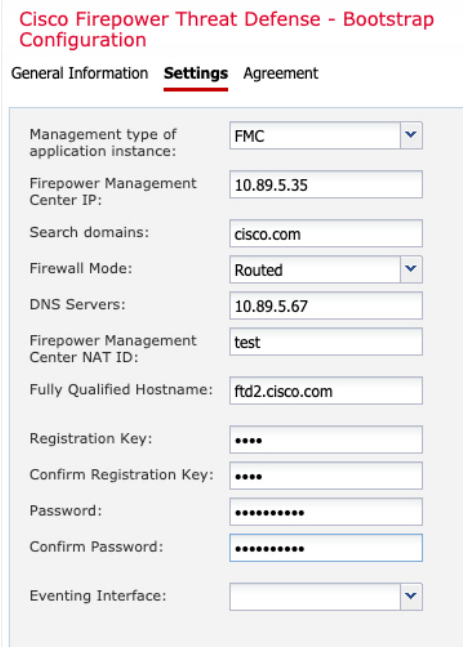
Note
If you later assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

c) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

d) Choose the management interface **Address Type**: **IPv4 only**, **IPv6 only**, or **IPv4 and IPv6**.



e) Configure the **Management IP** address.

Set a unique IP address for this interface.

f) Enter a **Network Mask** or **Prefix Length**.

g) Enter a **Network Gateway** address.

Step 6 On the **Settings** tab, complete the following:

a) For a native instance, in the **Management type of application instance** drop-down list, choose **FMC**.

   Native instances also support FDM as a manager. After you deploy the logical device, you cannot change the manager type.

b) Enter the **Firepower Management Center IP** of the managing FMC. If you do not know the FMC IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

c) For a container instance, **Permit Expert mode from FTD SSH sessions**: **Yes** or **No**. Expert Mode provides Firepower Threat Defense shell access for advanced troubleshooting.

   If you choose **Yes** for this option, then users who access the container instance directly from an SSH sesssion can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

   Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firepower Threat Defense CLI.

d) Enter the **Search Domains** as a comma-separated list.

e) Choose the **Firewall Mode**: **Transparent** or **Routed**.

   In routed mode, the Firepower Threat Defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices.

   The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

f) Enter the **DNS Servers** as a comma-separated list.

   The Firepower Threat Defense uses DNS if you specify a hostname for the FMC, for example.

g) Enter the **Fully Qualified Hostname** for the Firepower Threat Defense.

h) Enter a **Registration Key** to be shared between the FMC and the device during registration.

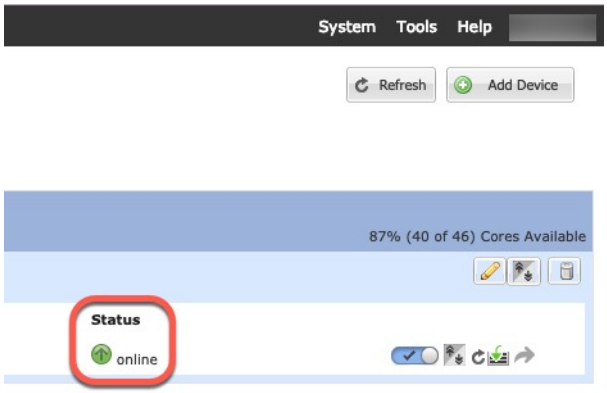
You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the FMC when you add the Firepower Threat Defense.

i) Enter a **Password** for the Firepower Threat Defense admin user for CLI access.

j) Choose the **Eventing Interface** on which events should be sent. If not specified, the management interface will be used.

This interface must be defined as a Firepower-eventing interface.

k) For a container instance, set the **Hardware Crypto** as **Enabled** or **Disabled**.



This setting enables TLS crypto acceleration in hardware, and improves performance for certain types of traffic. This feature is enabled by default. You can enable TLS crypto acceleration for up to 16 instances per security module. This feature is always enabled for native instances. To view the percentage of hardware crypto resources allocated to this instance, enter the **show hw-crypto** command.

Step 7 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 8 Click **OK** to close the configuration dialog box.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can start configuring the security policy in the application.

Step 10 See the FMC configuration guide to add the Firepower Threat Defense as a managed device and start configuring your security policy.

Add a High Availability Pair

FTD High Availability (also known as failover) is configured within the application, not in FXOS. However, to prepare your chassis for high availability, see the following steps.

Before you begin

See Requirements and Prerequisites for High Availability, on page 180.

Procedure

Step 1 Allocate the same interfaces to each logical device.

Step 2 Allocate 1 or 2 data interfaces for the failover and state link(s).

These interfaces exchange high availability traffic between the 2 chassis. We recommend that you use a 10 GB data interface for a combined failover and state link. If you have available interfaces, you can use separate failover and state links; the state link requires the most bandwidth. You cannot use the management-type interface for the failover or state link. We recommend that you use a switch between the chassis, with no other device on the same network segment as the failover interfaces.

For container instances, data-sharing interfaces are not supported for the failover link. We recommend that you create subinterfaces on a parent interface or EtherChannel, and assign a subinterface for each instance to use as a failover link. Note that you must use all subinterfaces on the same parent as failover links. You cannot use one subinterface as a failover link and then use other subinterfaces (or the parent interface) as regular data interfaces.

Step 3 Enable High Availability on the logical devices. See High Availability, on page 209.

Step 4 If you need to make interface changes after you enable High Availability, perform the changes on the standby unit first, and then perform the changes on the active unit.

Change an Interface on a FTD Logical Device

You can allocate or unallocate an interface, or replace a management interface on the Firepower Threat Defense logical device. You can then sync the interface configuration in the FMCthe .

Adding a new interface, or deleting an unused interface has minimal impact on the Firepower Threat Defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the Firepower Threat Defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the FMCthe .

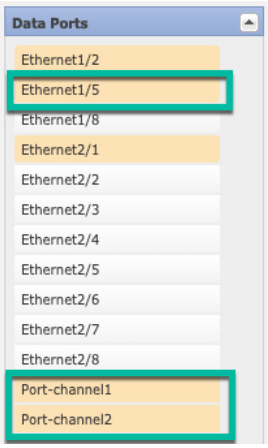
Deleting an interface will delete any configuration associated with that interface.

Before you begin

- Configure your interfaces, and add any EtherChannels according to Configure a Physical Interface, on page 188 and Add an EtherChannel (Port Channel), on page 189.
- If you want to add an already-allocated interface to an EtherChannel (for example, all interfaces are allocated by default to a cluster), you need to unallocate the interface from the logical device first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the device.
- If you want to replace the management or eventing interface with a management EtherChannel, then you need to create the EtherChannel with at least 1 unallocated data member interface, and then replace the current management interface with the EtherChannel. After the FTD device reboots (management interface

changes cause a reboot), and you sync the configuration in the FMCthe , you can add the (now unallocated) management interface to the EtherChannel as well.

- For clustering or High Availability, make sure you add or remove the interface on all units before you sync the configuration in the FMCthe . We recommend that you make the interface changes on the data/standby unit(s) first, and then on the control/active unit. Note that new interfaces are added in an administratively down state, so they do not affect interface monitoring.
- In mult-instance mode, for changing a sub-interface with an another sub-interface with the same vlan tag, you must first remove all the configuration (including nameif config) of the interface and then unalloacte the interface from Firepower Chassis Manager. Once unallocated, add the new interface and then use sync interfaces from the FMC.



Procedure

Step 1 In the Firepower Chassis Manager, choose **Logical Devices**.

Step 2 Click the **Edit** icon at the top right to edit the logical device.

Step 3 Allocate a new data interface by selecting the interface in the **Data Ports** area.

Do not delete any interfaces yet.

Step 4 Replace the management or eventing interface:

For these types of interfaces, the device reboots after you save your changes.

a) Click the device icon in the center of the page.
b) On the **General** or **Cluster Information** tab, choose the new **Management Interface** from the drop-down list.
c) On the **Settings** tab, choose the new **Eventing Interface** from the drop-down list.
d) Click **OK**.

If you change the IP address of the Management interface, then you must also change the IP address for the device in the FMC: go to **Devices** > **Device Management** > **Device/Cluster**. In the **Management** area, set the IP address to match the bootstrap configuration address.

Step 5 Click **Save**.

Step 6 Sync the interfaces in the FMC.

a) Log into the FMC.
b) Select **Devices** > **Device Management** and click **Edit** (✎) for your Firepower Threat Defense device. The **Interfaces** page is selected by default.
c) Click the **Sync Device** button on the top left of the **Interfaces** page.
d) After the changes are detected, you will see a red banner on the **Interfaces** page indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.
e) If you plan to delete an interface, manually transfer any interface configuration from the old interface to the new interface.

   Because you have not yet deleted any interfaces, you can refer to the existing configuration. You will have additional opportunity to fix the configuration after you delete the old interface and re-run the validation. The validation will show you all locations in which the old interface is still used.

f) Click **Validate Changes** to make sure your policy will still work with the interface changes.

   If there are any errors, you need to change your policy and rerun the validation.

g) Click **Save**.
h) Click **Deploy** > **Deployment**.
i) Select the devices and click **Deploy** to deploy the policy to the assigned devices. The changes are not active until you deploy them.

Step 7 In the Firepower Chassis Manager, unallocate a data interface by de-selecting the interface in the **Data Ports** area.

Step 8 Click **Save**.

Step 9 Sync the interfaces again in the FMCthe .

Connect to the Console of the Application

Use the following procedure to connect to the console of the application.

Procedure

Step 1 Connect to the module CLI using a console connection or a Telnet connection.

connect module *slot_number* {**console** | **telnet**}

To connect to the security engine of a device that does not support multiple security modules, always use **1** as the *slot_number*.

The benefits of using a Telnet connection is that you can have multiple sessions to the module at the same time, and the connection speed is faster.

Example:

```
Firepower# connect module 1 console
Telnet escape character is '~'.
Trying 127.5.1.1...
Connected to 127.5.1.1.
Escape character is '~'.

CISCO Serial Over LAN:
Close Network Connection to Exit

Firepower-module1>
```

Step 2 Connect to the application console.

connect ftd *name*

To view the instance names, enter the command without a name.

Example:

```
Firepower-module1> connect ftd ftd1
Connecting to ftd(ftd-native) console... enter exit to return to bootCLI
[...]
>
```

Step 3 Exit the application console to the FXOS module CLI.

- FTD—Enter **exit**

Step 4 Return to the supervisor level of the FXOS CLI.

Exit the console:

a) Enter **~**

You exit to the Telnet application.

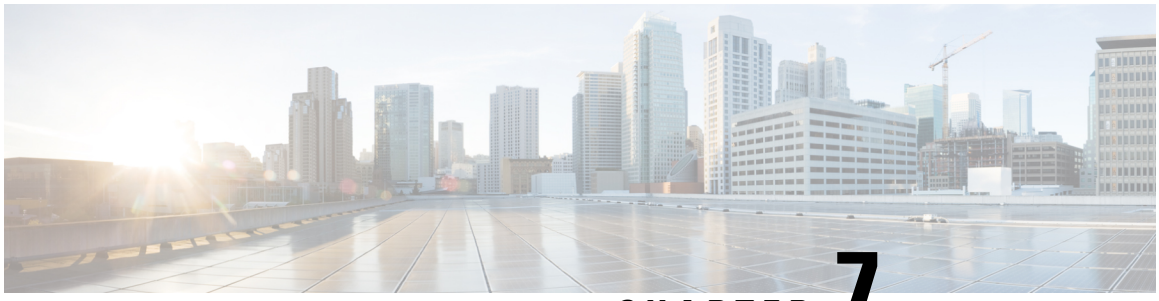
b) To exit the Telnet application, enter:

telnet>**quit**

Exit the Telnet session:

a) Enter **Ctrl-], .**

History for Logical Devices



Feature	Minimum FMC	Minimum FTD	Details
Synchronization between the FTD operational link state and the physical link state	6.7	Any	The chassis can now synchronize the FTD operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The FTD application interface admin state is not considered. Without synchronization from FTD, data interfaces can be in an Up state physically before the FTD application has completely come online, for example, or can stay Up for a period of time after you initiate FTD shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the FTD before the FTD can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS. **Note** This feature is not supported for clustering, container instances, or FTD with a Radware vDP decorator. It is also not supported for the ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices > Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled**, **show interface expand detail**
FTD configuration backup and restore using FMC for container instances	6.7	Any	You can now use the FMC backup/restore tool on FTD container instances. New/Modified FMC screens: **System > Tools > Backup/Restore > Managed Device Backup** New/Modified FTD CLI commands: **restore** Supported platforms: Firepower 4100/9300 **Note** Requires FXOS 2.9.
Support for VLAN subinterfaces on a Cluster type interface (multi-instance use only)	6.6	Any	For use with multi-instance clusters, you can now create VLAN subinterfaces on cluster type interfaces. Because each cluster requires a unique cluster control link, VLAN subinterfaces provide a simple method to fulfill this requirement. You can alternatively assign a dedicated EtherChannel per cluster. Multiple cluster interfaces are now allowed. New/Modified Firepower Chassis Manager screens: **Interfaces** > **All Interfaces** > **Add New** drop-down menu **> Subinterface > Type** field New/Modified FXOS commands: **set port-type cluster** **Note** Requires FXOS 2.8.1.

Feature	Minimum FMC	Minimum FTD	Details
FTD on the Firepower 4112	6.6	Any	We introduced the Firepower 4112. **Note** Requires FXOS 2.8.1.
TLS crypto acceleration for multiple container instances	6.5	Any	TLS crypto acceleration is now supported on multiple container instances (up to 16) on a Firepower 4100/9300 chassis. Previously, you could enable TLS crypto acceleration for only *one* container instance per module/security engine. New instances have this feature enabled by default. However, the upgrade does *not* enable acceleration on existing instances. Instead, use the **enter hw-crypto** and then the **set admin-state enabled** FXOS commands. New/Modified Firepower Chassis Manager screens: **Logical Devices** > **Add Device** > **Settings** > **Hardware Crypto** drop-down menu **Note** Requires FXOS 2.7.1.
FTD on the Firepower 4115, 4125, and 4145	6.4	Any	We introduced the Firepower 4115, 4125, and 4145. **Note** Requires FXOS 2.6.1.157.
Firepower 9300 SM-40, SM-48, and SM-56 support	6.4	Any	We introduced the following three security modules: SM-40, SM-48, and SM-56. **Note** Requires FXOS 2.6.1.157.
Support for ASA and FTD on separate modules of the same Firepower 9300	6.4	Any	You can now deploy ASA and FTD logical devices on the same Firepower 9300. **Note** Requires FXOS 2.6.1.157.
Support for SSL hardware acceleration on one FTD container instance on a module/security engine	6.4	Any	You can now enable SSL hardware acceleration for one container instance on a module/security engine. SSL hardware acceleration is disabled for other container instances, but enabled for native instances. New/Modified FXOS commands: **config hwCrypto enable** No modified screens. **Note** Requires FXOS 2.6.1.157.

Feature	Minimum FMC	Minimum FTD	Details
Multi-instance capability for FTD on the Firepower 4100/9300	6.3	Any	You can now deploy multiple logical devices, each with a FTD container instance, on a single security engine/module. Formerly, you could only deploy a single native application instance. To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances. Resource management lets you customize performance capabilities for each instance. You can use High Availability using a container instance on 2 separate chassis. Clustering is not supported. **Note** Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode is not available on the FTD. New/Modified FMC screens: • **Devices** > **Device Management** > **Edit** icon **> Interfaces** tab New/Modified Firepower Chassis Manager screens: • **Overview** > **Devices** • **Interfaces** > **All Interfaces** > **Add New** drop-down menu **> Subinterface** • **Interfaces** > **All Interfaces** > **Type** • **Logical Devices** > **Add Device** • **Platform Settings** > **Mac Pool** • **Platform Settings** > **Resource Profiles** New/Modified FXOS commands: **connect ftd** *name*, **connect module telnet, create bootstrap-key PERMIT_EXPERT_MODE, create resource-profile, create subinterface, scope auto-macpool, set cpu-core-count, set deploy-type, set port-type data-sharing, set prefix, set resource-profile-name, set vlan, scope app-instance ftd** *name***, show cgroups container, show interface, show mac-address, show subinterface, show tech-support module app-instance, show version** Supported platforms: Firepower 4100/9300

Feature	Minimum FMC	Minimum FTD	Details
Cluster control link customizable IP Address for the Firepower 4100/9300	6.3	Any	By default, the cluster control link uses the 127.2.0.0/16 network. You can now set the network when you deploy the cluster in FXOS. The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2.*chassis_id*.*slot_id*. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. Therefore, you can now set a custom /16 subnet for the cluster control link in FXOS except for loopback (127.0.0.0/8) and multicast (224.0.0.0/4) addresses. New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Add Device** > **Cluster Information** > **CCL Subnet IP** field New/Modified FXOS commands: **set cluster-control-link network** Supported platforms: Firepower 4100/9300
Support for data EtherChannels in On mode	6.3	Any	You can now set data and data-sharing EtherChannels to either Active LACP mode or to On mode. Other types of EtherChannels only support Active mode. New/Modified Firepower Chassis Manager screens: • **Interfaces** > **All Interfaces** > **Edit Port Channel** > **Mode** New/Modified FXOS commands: **set port-channel-mode** Supported platforms: Firepower 4100/9300
Support for EtherChannels in FTD inline sets	6.2	Any	You can now use EtherChannels in a FTD inline set. Supported platforms: Firepower 4100/9300
Inter-chassis clustering for 6 FTD modules	6.2	Any	You can now enable inter-chassis clustering for the FTD. You can include up to 6 modules in up to 6 chassis. New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Configuration** Supported platforms: Firepower 4100/9300
Hardware bypass support on the Firepower 4100/9300 for supported network modules	6.1	Any	Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Firepower 4100/9300

Feature	Minimum FMC	Minimum FTD	Details
Inline set link state propagation support for the FTD	6.1	Any	When you configure an inline set in the FTD application and enable link state propagation, the FTD sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. New/Modified FXOS commands: **show fault |grep link-down**, **show interface detail** Supported platforms: Firepower 4100/9300
Support for intra-chassis clustering on the FTD on the Firepower 9300	6.0.1	Any	The Firepower 9300 supports intra-chassis clustering with the FTD application. New/Modified Firepower Chassis Manager screens: • **Logical Devices** > **Configuration** New/Modified FXOS commands: **enter mgmt-bootstrap ftd, enter bootstrap-key FIREPOWER_MANAGER_IP, enter bootstrap-key FIREWALL_MODE, enter bootstrap-key-secret REGISTRATION_KEY, enter bootstrap-key-secret PASSWORD, enter bootstrap-key FQDN, enter bootstrap-key DNS_SERVERS, enter bootstrap-key SEARCH_DOMAINS, enter ipv4 firepower, enter ipv6 firepower, set value, set gateway, set ip, accept-license-agreement** Supported platforms: Firepower 4100/9300

CHAPTER 7

High Availability

The following topics describe how to configure Active/Standby failover to accomplish high availability of the Firepower Threat Defense.

- About Firepower Threat Defense High Availability, on page 209
- Requirements and Prerequisites for High Availability, on page 222
- Guidelines for High Availability, on page 223
- Add a High Availability Pair, on page 225
- Configure Optional High Availability Parameters, on page 227
- Manage High Availability, on page 230
- Monitoring High Availability, on page 236
- History for High Availability, on page 237

About Firepower Threat Defense High Availability

Configuring high availability, also called failover, requires two identical FTD devices connected to each other through a dedicated failover link and, optionally, a state link. FTD supports Active/Standby failover, where one unit is the active unit and passes traffic. The standby unit does not actively pass traffic, but synchronizes configuration and other state information from the active unit. When a failover occurs, the active unit fails over to the standby unit, which then becomes active.

The health of the active unit (hardware, interfaces, software, and environmental status) is monitored to determine if specific failover conditions are met. If those conditions are met, failover occurs.

Note High availability is not supported on FTDv running in the public cloud. See the Cisco Secure Firewall Threat Defense Virtual Getting Started Guide for more information about configuring the FTDv device for high availability.

High Availability System Requirements

This section describes the hardware, software, and license requirements for Firepower Threat Defense devices in a High Availability configuration.

Hardware Requirements

The two units in a High Availability configuration must:

- Be the same model. In addition, for container instances, they must use the same resource profile attributes.

  For the Firepower 9300, High Availability is only supported between same-type modules; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.

  If you change the resource profile after you add the High Availability pair to the FMC, update the inventory for each unit on the **Devices** > **Device Management** > **Device** > **System** > **Inventory** dialog box.

  If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

  1. Break high availability.
  2. Assign the new profile to both units.
  3. Re-establish high availability.

- Have the same number and types of interfaces.

  For the Firepower 4100/9300 chassis, all interfaces must be preconfigured in FXOS identically before you enable High Availability. If you change the interfaces after you enable High Availability, make the interface changes in FXOS on the Standby unit, and then make the same changes on the Active unit.

If you are using units with different flash memory sizes in your High Availability configuration, make sure the unit with the smaller flash memory has enough space to accommodate the software image files and the configuration files. If it does not, configuration synchronization from the unit with the larger flash memory to the unit with the smaller flash memory will fail.

Software Requirements

The two units in a High Availability configuration must:

- Be in the same firewall mode (routed or transparent).
- Have the same software version.
- Be in the same domain or group on the FMC.
- Have the same NTP configuration. See Configure NTP Time Synchronization for Threat Defense.
- Be fully deployed on the FMC with no uncommitted changes.
- Not have DHCP or PPPoE configured in any of their interfaces.
- (Firepower 4100/9300) Have the same flow offload mode, either both enabled or both disabled.

License Requirements for FTD Devices in a High Availability Pair

Both FTD units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the FMC releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit. For example, if the active unit has a Base license and a Threat license, and the standby unit has only a Base license, the FMC communicates with the Smart Software Manager to obtain an available Threat license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

Failover and Stateful Failover Links

The failover link and the optional stateful failover link are dedicated connections between the two units. Cisco recommends to use the same interface between two devices in a failover link or a stateful failover link. For example, in a failover link, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.

Failover Link

The two units in a failover pair constantly communicate over a failover link to determine the operating status of each unit.

Failover Link Data

The following information is communicated over the failover link:

- The unit state (active or standby)
- Hello messages (keep-alives)
- Network link status
- MAC address exchange
- Configuration replication and synchronization

Interface for the Failover Link

You can use an unused data interface (physical, or EtherChannel) as the failover link; however, you cannot specify an interface that is currently configured with a name. You also cannot use a subinterface with the exception of a subinterface defined on the chassis for multi-instance mode. The failover link interface is not configured as a normal networking interface; it exists for failover communication only. This interface can only be used for the failover link (and also for the state link).

The FTD does not support sharing interfaces between user data and the failover link. You also cannot use separate subinterfaces on the same parent for the failover link and for data (multi-instance chassis subinterfaces only). If you use a chassis subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links.

Note When using an EtherChannel as the failover or state link, you must confirm that the same EtherChannel with the same member interfaces exists on both devices before establishing high availability.

See the following guidelines for the failover link:

- Firepower 4100/9300—You cannot use the management-type interface for the failover link.

- See the following guidelines for sizing the link.

Table 21: Failover Link Size

Model	Interface Size for Combined Failover and State Link
Firepower 1010	1 Gbps
Firepower 1100	1 Gbps
Firepower 2100	1 Gbps
Secure Firewall 3100	Secure Firewall 3110—1 Gbps Secure Firewall 3120—1 Gbps Secure Firewall 3130—10 Gbps Secure Firewall 3140—10 Gbps
Firepower 4100	10 Gbps
Firepower 9300	10 Gbps

The alternation frequency is equal to the unit hold time.

Note If you have a large configuration and a low unit hold time, alternating between the member interfaces can prevent the secondary unit from joining/re-joining. In this case, disable one of the member interfaces until after the secondary unit joins.

For an EtherChannel used as the failover link, to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a failover link.

Connecting the Failover Link

Connect the failover link in one of the following two ways:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the Firepower Threat Defense device.
- Using an Ethernet cable to connect the units directly, without the need for an external switch.

If you do not use a switch between the units, if the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which unit has the failed interface and caused the link to come down.

Stateful Failover Link

To use Stateful Failover, you must configure a Stateful Failover link (also known as the state link) to pass connection state information.

Shared with the Failover Link

Sharing a failover link is the best way to conserve interfaces. However, you must consider a dedicated interface for the state link and failover link, if you have a large configuration and a high traffic network.

Dedicated Interface for the Stateful Failover Link

You can use a dedicated data interface (physical or EtherChannel) for the state link. See Interface for the Failover Link, on page 211 for requirements for a dedicated state link, and Connecting the Failover Link, on page 212 for information about connecting the state link as well.

For optimum performance when using long distance failover, the latency for the state link should be less than 10 milliseconds and no more than 250 milliseconds. If latency is more than 10 milliseconds, some performance degradation occurs due to retransmission of failover messages.

Avoiding Interrupted Failover and Data Links

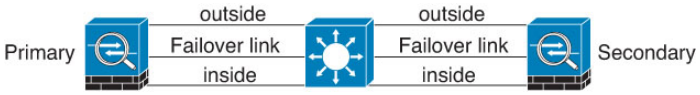
We recommend that failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time. If the failover link is down, the failover operation is suspended until the health of the failover link is restored.

See the following connection scenarios to design a resilient failover network.

Scenario 1—Not Recommended

If a single switch or a set of switches are used to connect both failover and data interfaces between two FTD devices, then when a switch or inter-switch-link is down, both FTD devices become active. Therefore, the two connection methods shown in the following figures are **not** recommended.

Figure 69: Connecting with a Single Switch Not Recommended



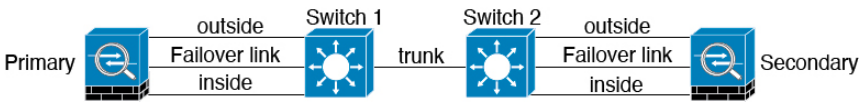


Figure 70: Connecting with a Double-Switch—Not Recommended

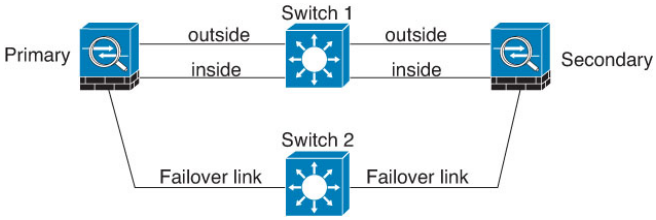
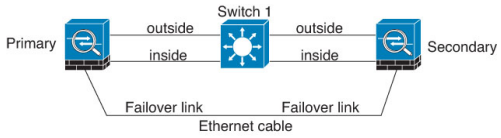
Scenario 2—Recommended

We recommend that failover links not use the same switch as the data interfaces. Instead, use a different switch or use a direct cable to connect the failover link, as shown in the following figures.

Figure 71: Connecting with a Different Switch





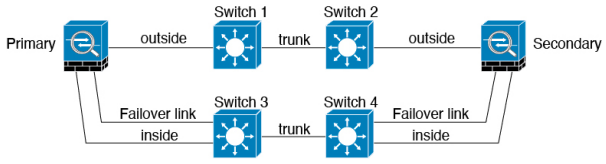


Figure 72: Connecting with a Cable

Scenario 3—Recommended

If the FTD data interfaces are connected to more than one set of switches, then a failover link can be connected to one of the switches, preferably the switch on the secure (inside) side of network, as shown in the following figure.

Figure 73: Connecting with a Secure Switch

MAC Addresses and IP Addresses in High Availability

When you configure your interfaces, you can specify an active IP address and a standby IP address on the same network. Generally, when a failover occurs, the new active unit takes over the active IP addresses and MAC addresses. Because network devices see no change in the MAC to IP address pairing, no ARP entries change or time out anywhere on the network.

Note Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state. You also cannot connect to the standby unit on that interface for management purposes.

The IP address and MAC address for the state link do not change at failover.

Active/Standby IP Addresses and MAC Addresses

For Active/Standby High Availability, see the following for IP address and MAC address usage during a failover event:

1. The active unit always uses the primary unit's IP addresses and MAC addresses.
2. When the active unit fails over, the standby unit assumes the IP addresses and MAC addresses of the failed unit and begins passing traffic.
3. When the failed unit comes back online, it is now in a standby state and takes over the standby IP addresses and MAC addresses.

However, if the secondary unit boots without detecting the primary unit, then the secondary unit becomes the active unit and uses its own MAC addresses, because it does not know the primary unit MAC addresses. When the primary unit becomes available, the secondary (active) unit changes the MAC addresses to those of the

primary unit, which can cause an interruption in your network traffic. Similarly, if you swap out the primary unit with new hardware, a new MAC address is used.

If you disable high availability and set the failover configurations to a disabled state, you will need to manually resume high availability, or reboot the device. It is recommended to use the command **configure high-availability resume** and resume the high availability instead of rebooting the device. If you reload the standby unit with the failover configuration disabled, the standby unit boots up as the active unit and uses the primary unit's IP addresses and MAC addresses. This leads to duplicate IP addresses and causes network traffic disruptions. Use the command **configure high-availability resume** to enable failover and restore the traffic flow.

Virtual MAC addresses guard against this disruption, because the active MAC addresses are known to the secondary unit at startup, and remain the same in the case of new primary unit hardware. We recommend that you configure the virtual MAC address on both the primary and secondary units to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not configure virtual MAC addresses, you might need to clear the ARP tables on connected routers to restore traffic flow. The FTD device does not send gratuitous ARPs for static NAT addresses when the MAC address changes, so connected routers do not learn of the MAC address change for these addresses.

Virtual MAC Addresses

The FTD device has multiple methods to configure virtual MAC addresses. We recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

For multi-instance capability, the FXOS chassis autogenerates only primary MAC addresses for all interfaces. You can overwrite the generated MAC address with a virtual MAC address with both the primary and secondary MAC addresses, but predefining the secondary MAC address is not essential; setting the secondary MAC address does ensure that to-the-box management traffic is not interrupted in the case of new secondary unit hardware.

MAC Address Table Update in Failover

During failover, the device that is designated as the new active device generates multicast packets for each MAC address entry in the MAC table and sends them to all the bridge group interfaces. This action prompts the upstream switches in the bridge group to update their routing tables with the new active device's interface to ensure accurate traffic forwarding.

The time taken to generate multicast packets and update the routing tables of the upstream switches depends on the number of entries in the MAC address table and the number of bridge group interfaces. Use the **show failover statistics state-switch-delay** command to display statistics related to the delays encountered during failover events.

Stateful Failover

During Stateful Failover, the active unit continually passes per-connection state information to the standby unit. After a failover occurs, the same connection information is available at the new active unit. Supported end-user applications are not required to reconnect to keep the same communication session.

Supported Features

For Stateful Failover, the following state information is passed to the standby FTD device:

- NAT translation table.

- TCP and UDP connections and states, including HTTP connection states. Other types of IP protocols, and ICMP, are not parsed by the active unit, because they get established on the new active unit when a new packet arrives.
- Snort connection states, inspection results, and pin hole information, including strict TCP enforcement.
- The ARP table
- The Layer 2 bridge table (for bridge groups)
- The ISAKMP and IPsec SA table
- GTP PDP connection database
- SIP signaling sessions and pin holes.
- Static and dynamic routing tables—Stateful Failover participates in dynamic routing protocols, like OSPF and EIGRP, so routes that are learned through dynamic routing protocols on the active unit are maintained in a Routing Information Base (RIB) table on the standby unit. Upon a failover event, packets travel normally with minimal disruption to traffic because the active secondary unit initially has rules that mirror the primary unit. Immediately after failover, the re-convergence timer starts on the newly active unit. Then the epoch number for the RIB table increments. During re-convergence, OSPF and EIGRP routes become updated with a new epoch number. Once the timer is expired, stale route entries (determined by the epoch number) are removed from the table. The RIB then contains the newest routing protocol forwarding information on the newly active unit.

Note Routes are synchronized only for link-up or link-down events on an active unit. If the link goes up or down on the standby unit, dynamic routes sent from the active unit may be lost. This is normal, expected behavior.

- DHCP Server—DHCP address leases are not replicated. However, a DHCP server configured on an interface will send a ping to make sure an address is not being used before granting the address to a DHCP client, so there is no impact to the service. State information is not relevant for DHCP relay or DDNS.
- Access control policy decisions—Decisions related to traffic matching (including URL, URL category, geolocation, and so forth), intrusion detection, malware, and file type are preserved during failover. However, for connections being evaluated at the moment of failover, there are the following caveats:
  - AVC—App-ID verdicts are replicated, but not detection states. Proper synchronization occurs as long as the App-ID verdicts are complete and synchronized before failover occurs.
  - Intrusion detection state—Upon failover, once mid-flow pickup occurs, new inspections are completed, but old states are lost.
  - File malware blocking—The file disposition must become available before failover.
  - File type detection and blocking—The file type must be identified before failover. If failover occurs while the original active device is identifying the file, the file type is not synchronized. Even if your file policy blocks that file type, the new active device downloads the file.
- User identity decisions from the identity policy, including the user-to-IP address mappings gathered passively through ISE Session Directory, and active authentication through captive portal. Users who are actively authenticating at the moment of failover might be prompted to authenticate again.

- Network AMP—Cloud lookups are independent from each device, so failover does not affect this feature in general. Specifically:
  - Signature Lookup—If failover occurs in the middle of a file transmission, no file event is generated and no detection occurs.
  - File Storage—If failover occurs when the file is being stored, it is stored on the original active device. If the original active device went down while the file was being stored, the file does not get stored.
  - File Pre-classification (Local Analysis)—If failover occurs in the middle of pre-classification, detection fails.
  - File Dynamic Analysis (Connectivity to the cloud)—If failover occurs, the system might submit the file to the cloud.
  - Archive File Support—If failover occurs in the middle of an analysis, the system loses visibility into the file/archive.
  - Custom Blocking—If failover occurs, no events are generated.
- Security Intelligence decisions. However, DNS-based decisions that are in process at the moment of failover are not completed.
- RA VPN—Remote access VPN end users do not have to reauthenticate or reconnect the VPN session after a failover. However, applications operating over the VPN connection could lose packets during the failover process and not recover from the packet loss.
- From all the connections, only established ones will be replicated on the Standby device.

Unsupported Features

For Stateful Failover, the following state information is not passed to the standby FTD device:

- Sessions in plaintext tunnels other than GREv0 and IPv4-in-IP. Sessions inside tunnels are not replicated and the new active node will not be able to reuse existing inspection verdicts to match the correct policy rules.
- Decrypted TLS/SSL connections—The decryption states are not synchronized, and if the active unit fails, then decrypted connections will be reset. New connections will need to be established to the new active unit. Connections that are not decrypted (in other words, those that match a TLS/SSL Do Not Decrypt rule action) are not affected and are replicated correctly.
- TCP state bypass connections
- Multicast routing.

Bridge Group Requirements for High Availability

There are special considerations for high availability when using bridge groups.

When the active unit fails over to the standby unit, the switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss on the bridge group member interfaces while the port is in a blocking state, you can configure one of the following workarounds:

- Switch port is in Access mode—Enable the STP PortFast feature on the switch:

```
interface interface_id
  spanning-tree portfast
```

The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.

- If the switch port is in Trunk mode, or you cannot enable STP PortFast, then you can use one of the following less desirable workarounds that impacts failover functionality or STP stability:
  - Disable interface monitoring on the bridge group and member interfaces.
  - Increase the interface hold time in the failover criteria to a high value that will allow STP to converge before the unit fails over.
  - Decrease the STP timers on the switch to allow STP to converge faster than the interface hold time.

Failover Health Monitoring

The Firepower Threat Defense device monitors each unit for overall health and for interface health. This section includes information about how the Firepower Threat Defense device performs tests to determine the state of each unit.

Unit Health Monitoring

The FTD device determines the health of the other unit by monitoring the failover link with hello messages. When a unit does not receive three consecutive hello messages on the failover link, the unit sends LANTEST messages on each data interface, including the failover link, to validate whether or not the peer is responsive. The action that the FTD device takes depends on the response from the other unit. See the following possible actions:

- If the FTD device receives a response on the failover link, then it does not fail over.
- If the FTD device does not receive a response on the failover link, but it does receive a response on a data interface, then the unit does not failover. The failover link is marked as failed. You should restore the failover link as soon as possible because the unit cannot fail over to the standby while the failover link is down.
- If the FTD device does not receive a response on any interface, then the standby unit switches to active mode and classifies the other unit as failed.

Interface Monitoring

When a unit does not receive hello messages on a monitored interface for 15 seconds, it runs interface tests. If one of the interface tests fails for an interface, but this same interface on the other unit continues to successfully pass traffic, then the interface is considered to be failed, and the device stops running tests.

If the threshold you define for the number of failed interfaces is met (see **Devices** > **Device Management** > **High Availability** > **Failover Trigger Criteria**), and the active unit has more failed interfaces than the standby unit, then a failover occurs. If an interface fails on both units, then both interfaces go into the “Unknown” state and do not count towards the failover limit defined by failover interface policy.

An interface becomes operational again if it receives any traffic. A failed device returns to standby mode if the interface failure threshold is no longer met.

If an interface has IPv4 and IPv6 addresses configured on it, the device uses the IPv4 addresses to perform the health monitoring. If an interface has only IPv6 addresses configured on it, then the device uses IPv6 neighbor discovery instead of ARP to perform the health monitoring tests. For the broadcast ping test, the device uses the IPv6 all nodes address (FE02::1).

Interface Tests

The Firepower Threat Defense device uses the following interface tests. The duration of each test is approximately 1.5 seconds.

1. Link Up/Down test—A test of the interface status. If the Link Up/Down test indicates that the interface is down, then the device considers it failed, and testing stops. If the status is Up, then the device performs the Network Activity test.
2. Network Activity test—A received network activity test. At the start of the test, each unit clears its received packet count for its interfaces. As soon as a unit receives any eligible packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the ARP test.
3. ARP test—A test for successful ARP replies. Each unit sends a single ARP request for the IP address in the most recent entry in its ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If the unit does not receive an ARP reply, then the device sends a single ARP request for the IP address in the *next* entry in the ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the Broadcast Ping test.
4. Broadcast Ping test—A test for successful ping replies. Each unit sends a broadcast ping, and then counts all received packets. If the unit receives any packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then testing starts over again with the ARP test. If both units continue to receive no traffic from the ARP and Broadcast Ping tests, then these tests will continue running in perpetuity.

Interface Status

Monitored interfaces can have the following status:

- Unknown—Initial status. This status can also mean the status cannot be determined.
- Normal—The interface is receiving traffic.
- Normal (Waiting)—The interface is up, but has not yet received a hello packet from the corresponding interface on the peer unit.
- Normal (Not-Monitored)—The interface is up, but is not monitored by the failover process.
- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface or VLAN is administratively down.

- Link Down (Waiting)—The interface or VLAN is administratively down and has not yet received a hello packet from the corresponding interface on the peer unit.
- Link Down (Not-Monitored)—The interface or VLAN is administratively down, but is not monitored by the failover process.
- No Link—The physical link for the interface is down.
- No Link (Waiting)—The physical link for the interface is down and has not yet received a hello packet from the corresponding interface on the peer unit.
- No Link (Not-Monitored)—The physical link for the interface is down, but is not monitored by the failover process.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover Triggers and Detection Timing

The following events trigger failover in a Firepower high availability pair:

- More than 50% of the Snort instances on the active unit are down.
- Disk space on the active unit is more than 90% full.
- The **no failover active** command is run on the active unit or the **failover active** command is run on the standby unit.
- The active unit has more failed interfaces than the standby unit.
- Interface failure on the active device exceeds the threshold configured.

  By default, failure of a single interface causes failover. You can change the default value by configuring a threshold for the number of interfaces or a percentage of monitored interfaces that must fail for the failover to occur. If the threshold breaches on the active device, failover occurs. If the threshold breaches on the standby device, the unit moves to **Fail** state.

  To change the default failover criteria, enter the following command in global configuration mode:

Table 22:

Command	Purpose
failover interface-policy num [%] `hostname (config)# failover interface-policy 20%`	Changes the default failover criteria. When specifying a specific number of interfaces, the *num* argument can be from 1 to 250. When specifying a percentage of interfaces, the *num* argument can be from 1 to 100.

The following table shows the failover triggering events and associated failure detection timing. If failover occurs, you can view the reason for the failover in the Message Center, along with various operations pertaining to the high availability pair. You can configure these thresholds to a value within the specified minimum-maximum range.

Table 23: FTD Failover Times

Failover Triggering Event	Minimum	Default	Maximum
Active unit loses power, hardware goes down, or the software reloads or crashes. When any of these occur, the monitored interfaces or failover link do not receives any hello message.	800 milliseconds	15 seconds	45 seconds
Active unit interface physical link down.	500 milliseconds	5 seconds	15 seconds
Active unit interface up, but connection problem causes interface testing.	5 seconds	25 seconds	75 seconds

About Active/Standby Failover

Active/Standby failover lets you use a standby FTD device to take over the functionality of a failed unit. When the active unit fails, the standby unit becomes the active unit.

Primary/Secondary Roles and Active/Standby Status

When setting up Active/Standby failover, you configure one unit to be primary and the other to be secondary. During configuration, the primary unit's policies are synchronized to the secondary unit. At this point, the two units act as a single device for device and policy configuration. However, for events, dashboards, reports and health monitoring, they continue to display as separate devices.

The main differences between the two units in a failover pair are related to which unit is active and which unit is standby, namely which IP addresses to use and which unit actively passes traffic.

However, a few differences exist between the units based on which unit is primary (as specified in the configuration) and which unit is secondary:

- The primary unit always becomes the active unit if both units start up at the same time (and are of equal operational health).
- The primary unit MAC addresses are always coupled with the active IP addresses. The exception to this rule occurs when the secondary unit becomes active and cannot obtain the primary unit MAC addresses over the failover link. In this case, the secondary unit MAC addresses are used.

Active Unit Determination at Startup

The active unit is determined by the following:

- If a unit boots and detects a peer already running as active, it becomes the standby unit.
- If a unit boots and does not detect a peer, it becomes the active unit.
- If both units boot simultaneously, then the primary unit becomes the active unit, and the secondary unit becomes the standby unit.

Failover Events

In Active/Standby failover, failover occurs on a unit basis.

The following table shows the failover action for each failure event. For each failure event, the table shows the failover policy (failover or no failover), the action taken by the active unit, the action taken by the standby unit, and any special notes about the failover condition and actions.

Table 24: Failover Events

Failure Event	Policy	Active Unit Action	Standby Unit Action	Notes
Active unit failed (power or hardware)	Failover	n/a	Become active Mark active as failed	No hello messages are received on any monitored interface or the failover link.
Formerly active unit recovers	No failover	Become standby	No action	None.
Standby unit failed (power or hardware)	No failover	Mark standby as failed	n/a	When the standby unit is marked as failed, then the active unit does not attempt to fail over, even if the interface failure threshold is surpassed.
Failover link failed during operation	No failover	Mark failover link as failed	Mark failover link as failed	You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.
Failover link failed at startup	No failover	Become active Mark failover link as failed	Become active Mark failover link as failed	If the failover link is down at startup, both units become active.
State link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.
Interface failure on active unit above threshold	Failover	Mark active as failed	Become active	None.
Interface failure on standby unit above threshold	No failover	No action	Mark standby as failed	When the standby unit is marked as failed, then the active unit does not attempt to fail over even if the interface failure threshold is surpassed.

Guidelines for High Availability

Model Support

- Firepower 1010:
  - You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High Availability, but a simpler setup is to use physical firewall interfaces instead.
  - You can only use a firewall interface as the failover link.
- Firepower 9300—Intra-chassis High Availability is not supported.
- The FTDv on public cloud networks such as Microsoft Azure and Amazon Web Services are not supported with High Availability because Layer 2 connectivity is required.

Additional Guidelines

- When the active unit fails over to the standby unit, the connected switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss while the port is in a blocking state, you can enable the STP PortFast feature on the switch:

  interface *interface_id* **spanning-tree portfast**

  This workaround applies to switches connected to both routed mode and bridge group interfaces. The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.
- Configuring port security on the switches connected to the FTD device failover pair can cause communication problems when a failover event occurs. This problem occurs when a secure MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.
- For Active/Standby High Availability and a VPN IPsec tunnel, you cannot monitor both the active and standby units using SNMP over the VPN tunnel. The standby unit does not have an active VPN tunnel,

and will drop traffic destined for the NMS. You can instead use SNMPv3 with encryption so the IPsec tunnel is not required.

- Both the peer devices go into unknown state and high-availability configuration fails if you run clish in any of the peer devices while creating a High Availability pair.
- Immediately after failover, the source address of syslog messages will be the failover interface address for a few seconds.
- For better convergence (during a failover), you must shut down the interfaces on a HA pair that are not associated with any configuration or instance.
- If you configure failover encryption in evaluation mode, the systems use DES for the encryption. If you then register the devices using an export-compliant account, the devices will use AES after a reboot. Thus, if a system reboots for any reason, including after installing an upgrade, the peers will be unable to communicate and both units will become the active unit. We recommend that you do not configure encryption until after you register the devices. If you do configure this in evaluation mode, we recommend you remove the encryption before registering the devices.
- When using SNMPv3 with failover, if you replace a failover unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.
- The device does not share SNMP client engine data with its peer.
- If you have a very large number of access control and NAT rules, the size of the configuration can prevent efficient configuration replication, resulting in the standby unit taking an excessively long time to reach standby ready state. This can also impact your ability to connect to the standby unit during replication through the console or SSH session. To enhance configuration replication performance, enable transactional commit for both access rules and NAT, using the **asp rule-engine transactional-commit access-group** and **asp rule-engine transactional-commit nat** commands.
- A unit in a High Availability pair transitioning to the standby role synchronizes its clock with the active unit.

  Example:

```
firepower#show clock
01:00:52 UTC Mar 1 2022

...
01:01:18 UTC Mar 1 2022 <======= Incorrect (previous) clock
Cold Standby              Sync Config               Detected an Active mate

19:38:21 UTC Apr 9 2022 <======= Updated clock
Sync Config               Sync File System          Detected an Active mate
...
firepower/sec/stby#show clock
19:38:40 UTC Apr 9 2022
```

- The units in High Availability do not dynamically synchronize the clock. Here are some examples of events when synchronization takes place:
  - A new High Availability pair is created.
  - High Availability is broken and re-created.
  - Communication over the failover link was disrupted and reestablished.

  - Failover status was manually changed at the CLI using the **no failover/failover** or **configure high-availability suspend/resume** (FTD) commands.

- Enabling High Availability forces all routes to be deleted and are re-added after the High Availability progression changes to the Active state. You could experience connection loss during this phase.
- If you replace the primary unit, then when you re-create high-availability, you should set the replacement unit as the *secondary* unit so that the configurations are replicated from the former secondary unit to the replacement unit. If you set the replacement unit as primary, you will accidentally overwrite the configuration that is present on the operational unit.
- Deploying Firepower 1100 and 2100 devices in high availability with hundreds of interfaces configured on them can result in increased delay in the failover time (seconds).
- In the High Availability configuration, short-lived connections, usually using port 53, are closed quickly and never transferred or synchronized from Active to Standby, so there might be a difference in the number of connections on both High Availability devices. This is expected behavior for short-lived connections. You can try to compare the connections that are long-lived (for example, more than 30-60 seconds).
- In the High Availability configuration, embryonic connections—connection requests that have not yet completed the three-way handshake process—are closed quickly and not synchronized between the active and standby devices. This design ensures HA system efficiency and security. For this reason, there might be a difference in the number of connections on both High Availability devices, which is to be expected.
- If the failover LAN link is not connected back-to-back and instead connected through one or more switches, a failure within the intermediate path can cause the active unit to lose connectivity with the standby unit, resulting in inconsistent active/standby states. Although this does not impact High Availability functionality, it is recommended to check and recover the failover-link path between the active and standby units.

  When the failover LAN link is down, it is not recommended to deploy any configuration, as it may not be replicated to the peer unit.
- See the Cisco Secure Firewall Threat Defense Virtual Getting Started Guide and review your FTDv device configurations for high availability.
- In transparent mode, if you have problems with the active unit losing the MAC address of the hot-standby router (HSRP), create a static mapping for the MAC address.
- UCAPL or CC compliance mode cannot be changed if the FTD device is in high availability. Modify the compliance mode before forming the high availability pair.

Add a High Availability Pair

When establishing an Active/Standby high-availability pair, you designate one of the devices as primary and the other as secondary. The FMC deploys a merged configuration to the paired devices. If there is a conflict, the primary device setting is used.

In a multidomain deployment, devices in a high-availability pair must belong to the same domain.

Note The failover link and the stateful failover link are in a private IP space and are only used for communication between peers in a high-availability pair. After high availability is established, selected interface links and encryption settings cannot be modified without breaking the high-availability pair and reconfiguring it.

Caution Creating or breaking a high-availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information. The system warns you that continuing to create a high-availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Before you begin

Confirm that both devices:

- Are the same model.
- Have the same number and type of interfaces.
- Are in the same domain and group.
- Have normal health status and are running the same software.
- Are either in routed or transparent mode.
- Have the same NTP configuration. See Time Synchronization, on page 529.
- Are fully deployed with no uncommitted changes.
- Do not have DHCP or PPPoE configured on any interfaces.

Note The high availability formation is possible between the two FTD devices when the certificate available on the primary device is not present on the secondary device. When high availability is formed, the certificate will be synched on the secondary device.

Procedure

Step 1 Add both devices to the FMC according to Add a Device, on page 27.

Step 2 Choose **Devices** > **Device Management**.

Step 3 From the **Add** drop-down menu, choose **High Availability**.

Step 4 Enter a display **Name** for the high-availability pair.

Step 5 Under **Device Type**, choose **Firepower Threat Defense**.

Step 6 Choose the **Primary Peer** device for the high-availability pair.

Step 7 Choose the **Secondary Peer** device for the high-availability pair.

Step 8 Click **Continue**.

Step 9 Under **LAN Failover Link**, choose an **Interface** with enough bandwidth to reserve for failover communications.

Note
Only interfaces that do not have a logical name and do not belong to a security zone, will be listed in the **Interface** drop-down in the **Add High Availability Pair** dialog.

Step 10 Type any identifying **Logical Name**.

Step 11 Type a **Primary IP** address for the failover link on the active unit.

This address should be on an unused subnet. This subnet can be 31-bits (255.255.255.254 or /31) with only two IP addresses.

Note
169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 12 Optionally, choose **Use IPv6 Address**.

Step 13 Type a **Secondary IP** address for the failover link on the standby unit. This IP address must be in the same subnet as the primary IP address.

Step 14 If IPv4 addresses are used, type a **Subnet Mask** that applies to both the primary and secondary IP addresses.

Step 15 Optionally, under **Stateful Failover Link**, choose the same **Interface**, or choose a different interface and enter the high availability configuration information.

This subnet can be 31-bits (255.255.255.254 or /31) with only two IP addresses.

Note
169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 16 Optionally, choose **Enabled** and choose the **Key Generation** method for IPsec Encryption between the failover links.

Step 17 Click **OK**. This process takes a few minutes as the process synchronizes system data.

What to do next

Back up the devices. You can use the backup to quickly replace the devices when they fail and to restore the high availability service without being delinked from the FMC. For more information, see Firepower Management Center Administration Guide.

Configure Optional High Availability Parameters

You can view the initial High Availability Configuration on the FMC. You cannot edit these settings without breaking the high availability pair and then re-establishing it.

You can edit the Failover Trigger Criteria to improve failover results. Interface Monitoring allows you to determine which interfaces are better suited for failover.

Configure Standby IP Addresses and Interface Monitoring

For each interface, set a standby IP address. Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state.

By default, monitoring is enabled on all physical interfaces, for the Firepower 1010 all VLAN interfaces, with logical names configured. You might want to exclude interfaces attached to less critical networks from affecting your failover policy. Firepower 1010 switch ports are not eligible for interface monitoring.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Click the **High Availability** tab.

Step 4 In the **Monitored Interfaces** area, click the **Edit** ( ) next to the interface you want to edit.

Step 5 Check the **Monitor this interface for failures** check box.

Step 6 On the **IPv4** tab, enter the **Standby IP Address**.

This address must be a free address on the same network as the active IP address.

Step 7 If you configured the IPv6 address manually, on the **IPv6** tab, click the **Edit** ( ) next to the active IP address, enter the **Standby IP Address**, and click **OK**.

This address must be a free address on the same network as the active IP address. For autogenerated and **Enforce EUI 64** addresses, the standby address is automatically generated.

Step 8 Click **OK**.

Edit High Availability Failover Criteria

You can customize failover criteria based on your network deployment.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Choose **High Availability**.

Step 4 Next to **Failover Trigger Criteria**, click the **Edit** ( ).

Step 5 Under **Interface Failure Threshold**, choose the number or percentage of interfaces that must fail before the device fails over.

Step 6 Under **Hello packet Intervals**, choose how often hello packets are sent over the failover link.

Note

If you use remote access VPN on the Firepower 2100, use the default hello packet intervals. Otherwise, you might see high CPU usage that can cause a failover to occur.

Step 7 Click **OK**.

Configure Virtual MAC Addresses

You can configure active and standby MAC addresses for failover using the following methods in the Firepower Management Center:

- From the **Advanced tab** on the **Edit Interface** page during interface configuration; see Configure the MAC Address, on page 425.
- From the **Add Interface MAC Address** dialog-box which is accessed from the **High Availability** page; see this procedure.

Note To configure the MAC address in both primary and secondary units (so that the MAC address is transferred to all sub-interfaces to both the high-availability units), the recommended approach is to use the **Interfaces** tab to replicate the MAC addresses on sub-interfaces over both active and standby high-availability units.

If you configure active and standby MAC addresses in both locations, the addresses defined during interface configuration take precedence for failover.

You can minimize loss of traffic during failover by designating active and standby MAC addresses to the physical interface. This feature offers redundancy against IP address mapping for failover.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Click **High Availability**.

Step 4 Click the **Add** ( ) icon next to Interface MAC Addresses.

Step 5 Choose a **Physical Interface**.

Step 6 Enter the **Active Interface Mac Address**.

Step 7 Enter the **Standby Interface Mac Address**.

Step 8 Click **OK**.

Note
For detailed information, see Task 2, steps from 10 to 14 in Configure FTD High Availability on Firepower Appliances.

.

Manage High Availability

This section describes how to manage High Availability units after you enable High Availability, including how to change the High Availability setup and how to force failover from one unit to another.

Switch the Active Peer in the FTD High Availability Pair

After you establish the FTD high availability pair, you can manually switch the active and standby units, effectively forcing failover for reasons such as persistent fault or health events on the current active unit. Both units should be fully deployed before you complete this procedure.

Before you begin

Refresh Node Status for a Single FTD High Availability Pair, on page 230. This ensures that the status on the FTD high availability device pair is in sync with the status on the FMC.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to change the active peer, click the **Switch Active Peer**.

Step 3 You can:

- Click **Yes** to immediately make the standby device the active device in the high availability pair.
- Click **No** to cancel and return to the Device Management page.

Refresh Node Status for a Single FTD High Availability Pair

Whenever active or standby devices in the FTD high availability pair are rebooted, the FMC may not display accurate high availability status for either device. This is because when the device reboots, the high availability status is immediately updated on the device and its corresponding event is sent to the FMC. However, the status may not be updated on the FMC because the communication between the device and the FMC is yet to be established.

Communication failures or weak communication channels between the FMC and devices may result in out of sync data. When you switch the active and standby devices in a high availability pair, the change may not be reflected in the FMC even after a significant time duration.

In these scenarios, you can refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to refresh the node status, click the **Refresh HA Node Status**.

Step 3 Click **Yes** to refresh the node status.

Suspend and Resume High Availability

You can suspend a unit in a high-availability pair, which is useful when:

- Both units are in an active-active situation, and fixing the communication on the failover link does not correct the problem.
- You want to troubleshoot an active or standby unit and do not want the units to fail over during that time.

When you suspend high availability, the currently active device remains active, handling all user connections. However, failover criteria are no longer monitored, and the system will never fail over to the now pseudo-standby device.

The key difference between suspending high availability and breaking high availability is that on a suspended high-availability device, the high-availability configuration is retained. When you break high availability, the configuration is erased. Thus, you have the option to resume high availability on a suspended system, which enables the existing configuration and makes the two devices function as a failover pair again.

To suspend high availability, use the **configure high-availability suspend** command.

```
> configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

If you suspend high availability from the active unit, the configuration is suspended on both the active and standby units. The standby unit interface configuration is also erased. If you suspend it from the standby unit, it is suspended on the standby unit only, but the active unit will not attempt to fail over to a suspended unit.

To resume failover, use the **configure high-availability resume** command.

```
> configure high-availability resume
Successfully resumed high-availablity.
```

You can resume a unit only if it is in Suspended state. The unit will negotiate active/standby status with the peer unit.

Note Suspending high availability is a temporary state. If you reload a unit, it resumes the high-availability configuration automatically and negotiates the active/standby state with the peer.

Replace a Unit in FTD High Availability Pair

To replace a failed unit in the FTD high availability pair using a backup file, see *Restoring FMCs and Managed Devices* in the Firepower Management Center Administration Guide.

If you do not have a backup of the failed device, you must break high availability. Then, register the replacement device to the Firepower Management Center and reestablish high availability. The process varies depending on whether the device is primary or secondary:

- Replace a Primary FTD HA Unit with no Backup, on page 232
- Replace a Secondary FTD HA Unit with no Backup, on page 233

Replace a Primary FTD HA Unit with no Backup

Follow the steps below to replace a failed primary unit in the FTD high availability pair. Failing to follow these steps can overwrite the existing high availability configuration.

Caution Creating or breaking the FTD high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Caution Never move a disk from sensor or FMC to another device without reimaging the disk. This is an unsupported configuration and can cause breakage in functionality.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair; see Break a High Availability Pair, on page 233.

Note
The break operation removes all the configuration related to HA from FTD and FMC, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the failed primary FTD device from the FMC; see Delete (Unregister) a Device from the FMC, on page 30.

Step 3 Register the replacement FTD to the FMC; see Add a Device, on page 27.

Step 4 Configure high availability, using the existing secondary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see Add a High Availability Pair, on page 225.

Replace a Secondary FTD HA Unit with no Backup

Follow the steps below to replace a failed secondary unit in the FTD high availability pair.

Caution Creating or breaking the FTD high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair; see Break a High Availability Pair, on page 233.

Note
The break operation removes all the configuration related to HA from FTD and FMC, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the secondary FTD device from the FMC; see Delete (Unregister) a Device from the FMC, on page 30.

Step 3 Register the replacement FTD to the FMC; see Add a Device, on page 27.

Step 4 Configure high availability, using the existing primary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see Add a High Availability Pair, on page 225.

Break a High Availability Pair

When you break a high-availability pair, the high-availability configuration is removed from both units.

The active unit remains up and passing traffic. The standby unit interface configuration is erased.

Policies that were not deployed to the active unit prior to the break operation continue to remain un-deployed after the break operation is complete. Deploy the policies on the standalone device after the break operation is complete.

Note

- When IPsec is enabled on high availability interfaces on the FTD device, the device cannot prioritize the encrypted packets into the high-priority receive queue. As a result, during high-volume data traffic scenarios, attempts to break high availability may fail as the device cannot efficiently manage and prioritize the large number of encrypted connections. To view the device's resource usage and the maximum throughput, use the `show resource usage` command.
- If you cannot reach the high-availability pair using the FMC, connect to the CLI on each device and enter **configure high-availability disable** to manually break high availability. See also Delete (Unregister) a High Availability Pair and Register to a New FMC, on page 235.

Caution Breaking the FTD high-availability pair immediately restarts the Snort process on the primary and secondary units, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 116 for more information.

Before you begin

- Refresh Node Status for a Single FTD High Availability Pair, on page 230. This ensures that the status on the high-availability pair is in sync with the status on the FMC.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high-availability pair you want to break, click **Break HA**.

Step 3 If the standby peer does not respond, check **Force Break**.

Step 4 Click **Yes**.

The Break operation removes the high-availability configuration from the active and standby units.

A FlexConfig policy deployed on the active unit may show a deployment failure after the break high-availability operation. You must alter and re-deploy the FlexConfig policy on the active unit.

What to do next

If you are using a FlexConfig policy on the active unit, alter and re-deploy the FlexConfig policy to eliminate deployment errors.

Note After you break high availability, the FTD device that was operating as the active unit will still have the standby unit's IP address listed in its configuration. To resolve this, do an additional deployment on the formerly active FTD device to remove the standby unit's IP address from its configuration.

Delete (Unregister) a High Availability Pair and Register to a New FMC

If the FMC can no longer reach the High Availability pair, you can unregister the pair and manually break High Availability at the CLI so you can later re-register them as standalone devices and optionally re-form High Availability. If you can still reach both units, we recommend that you instead use the **Break** option and then unregister the standalone devices. See Break a High Availability Pair, on page 233.

Unregistering a High Availability pair:

- Severs all communication between the FMC and the pair.
- Removes the pair from the **Device Management** page.
- Returns the pair to local time management if the pair's platform settings policy is configured to receive time from the FMC using NTP.
- Leaves the configuration intact, so the pair continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Before you begin

- This procedure requires CLI access.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the High Availability pair you want to unregister, click **More** (⋮) and choose **Delete**.

Step 3 Click **Yes**. The device High Availability pair is unregistered.

Step 4 You can register the pair to a new (or the same) FMC.

a) On each unit, access the FTD CLI, and enter the following command to break High Availability.

configure high-availability disable

You must break High Availability before you can re-add the units to a FMC. When you break High Availability, the active device remains up and passing traffic.

b) On each unit, identify the new FMC using the **configure manager add** command. See Modify FTD Management Interfaces at the CLI, on page 65.

c) Choose **Devices** > **Device Management**, and then click **Add Device** and add both units as standalone devices.

When you register the devices to the FMC, the configuration is removed, so the active unit will stop processing traffic at this point.

d) Re-form High Availability according to Add a High Availability Pair, on page 225.

Monitoring High Availability

This section lets you monitor the High Availability status.

View Failover History

You can view the failover history of both high availability devices in a single view. The history displays in chronological order and includes the reason for any failover.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **Summary**.

Step 4 Under General, click **View** ( ).

View Stateful Failover Statistics

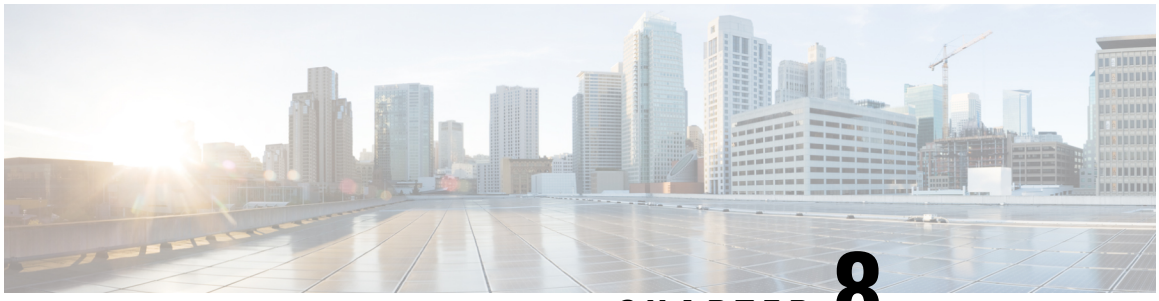
You can view the stateful failover link statistics of both the primary and secondary devices in the high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **High Availability**.



Step 4 Under Stateful Failover Link, click **View** ( ).

Step 5 Choose a device to view statistics.

History for High Availability

Feature	Minimum FMC	Minimum FTD	Details
Improvements to the upgrade workflow for clustered and high-availability devices	7.1	Any	We made the following improvements to the upgrade workflow for clustered and high-availability devices: • The upgrade wizard now correctly displays clustered and high-availability units as groups, rather than as individual devices. The system can identify, report, and preemptively require fixes for group-related issues you might have. For example, you cannot upgrade a cluster on the Firepower 4100/9300 if you have made unsynced changes on Firepower Chassis Manager. • We improved the speed and efficiency of copying upgrade packages to clusters and high-availability pairs. Previously, the FMC copied the package to each group member sequentially. Now, group members can get the package from each other as part of their normal sync process. • You can now specify the upgrade order of data units in a cluster. The control unit always upgrades last.
Clearing routes in a high-availability group or cluster.	7.1	Any	In previous releases, the **clear route** command cleared the routing table on the unit only. Now, when operating in a high-availability group or cluster, the command is available on the active or control unit only, and clears the routing table on all units in the group or cluster.

FTD High Availability Hardening	6.2.3	Any	Version 6.2.3 introduces the following features for FTD devices in high availability:
			• Whenever active or standby FTD devices in a high-availability pair restart, the FMC may not display accurate high-availability status for either managed device. However, the status may not upgrade on the FMC because the communication between the device and the FMC is not established yet. The **Refresh Node Status** option on the **Devices** > **Device Management** page allows you to refresh the high-availability unit status to obtain accurate information about the active and standby device in a high-availability pair.
			• The **Devices** > **Device Management** page of the FMC UI has a new **Switch Active Peer** icon.
			• Version 6.2.3 includes a new REST API object, **Device High Availability Pair Services**, that contains four functions:
			  • **DELETE ftddevicehapairs**
			  • **PUT ftddevicehapairs**
			  • **POST ftddevicehapairs**
			  • **GET ftddevicehapairs**

CHAPTER 8

Clustering for the Secure Firewall 3100

Clustering lets you group multiple FTD units together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported Features with Clustering, on page 274.

About Clustering for the Secure Firewall 3100

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single unit. To act as a cluster, the firewalls need the following infrastructure:

- Isolated, high-speed backplane network for intra-cluster communication, known as the *cluster control link*.
- Management access to each firewall for configuration and monitoring.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Spanned EtherChannels. Interfaces on multiple members of the cluster are grouped into a single EtherChannel; the EtherChannel performs load balancing between units.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Interfaces

You can configure data interfaces as Spanned EtherChannels. See About Cluster Interfaces, on page 246 for more information.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Note Individual interfaces are not supported, with the exception of a management interface.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link. See Cluster Control Link, on page 246 for more information.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the FMC, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster in the **Devices** > **Device Management** > **Cluster** > **License** area.

Note If you add the cluster before the FMC is licensed (and running in Evaluation mode), then when you license the FMC, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Clustering

Model Requirements

- Secure Firewall 3100—Maximum 8 units

User Roles

- Admin
- Access Admin
- Network Admin

Hardware and Software Requirements

All units in a cluster:

- Must be the same model.
- Must include the same interfaces.
- The FMC access must be from the Management interface; data interface management is not supported.
- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- Must be in the same firewall mode, routed or transparent.
- Must be in the same domain.
- Must be in the same group.
- Must not have any deployment pending or in progress.
- The control node must not have any unsupported features configured (see Unsupported Features with Clustering, on page 274).

- Data nodes must not have any VPN configured. The control node can have site-to-site VPN configured.

Switch Requirements

- Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 100 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for Clustering

Firewall Mode

The firewall mode must match on all units.

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

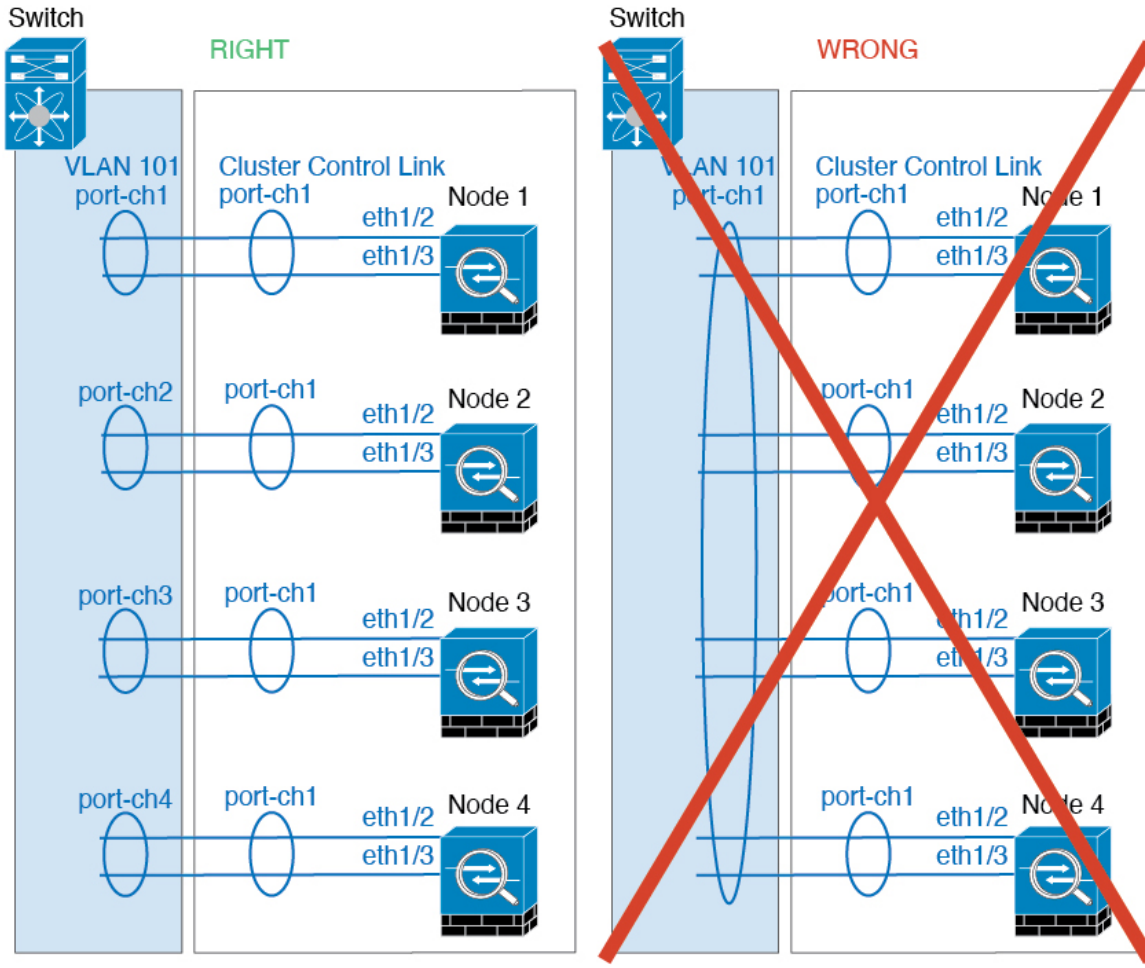
Switches

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.

- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.



- You should disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.

EtherChannels

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

- Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional Guidelines

- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.

- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Clustering

To add a cluster to the FMC, add each node to the FMC as a standalone unit, configure interfaces on the unit you want to make the control node, and then form the cluster.

About Cluster Interfaces

You can configure data interfaces as Spanned EtherChannels.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Each unit must also dedicate at least one hardware interface as the cluster control link.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link. We recommend using an EtherChannel for the cluster control link if available.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Cluster Control Link Interfaces and Network

You can use any physical interface or EtherChannel for the cluster control link. You cannot use a VLAN subinterface as the cluster control link. You also cannot use the Management/Diagnostic interface.

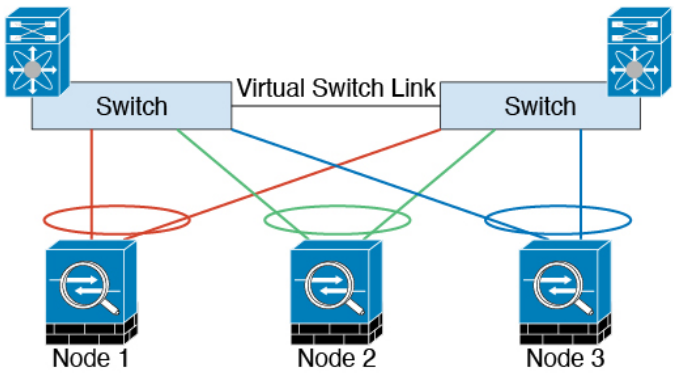
Each cluster control link has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

Note For a 2-member cluster, do not directly-connect the cluster control link from one node to the other node. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit. If you need to directly-connect the units (for testing purposes, for example), then you should configure and enable the cluster control link interface on both nodes before you form the cluster.

Size the Cluster Control Link

If possible, you should size the cluster control link to match the expected throughput of each chassis so the cluster control link can handle the worst-case scenarios.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features. For example:



- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

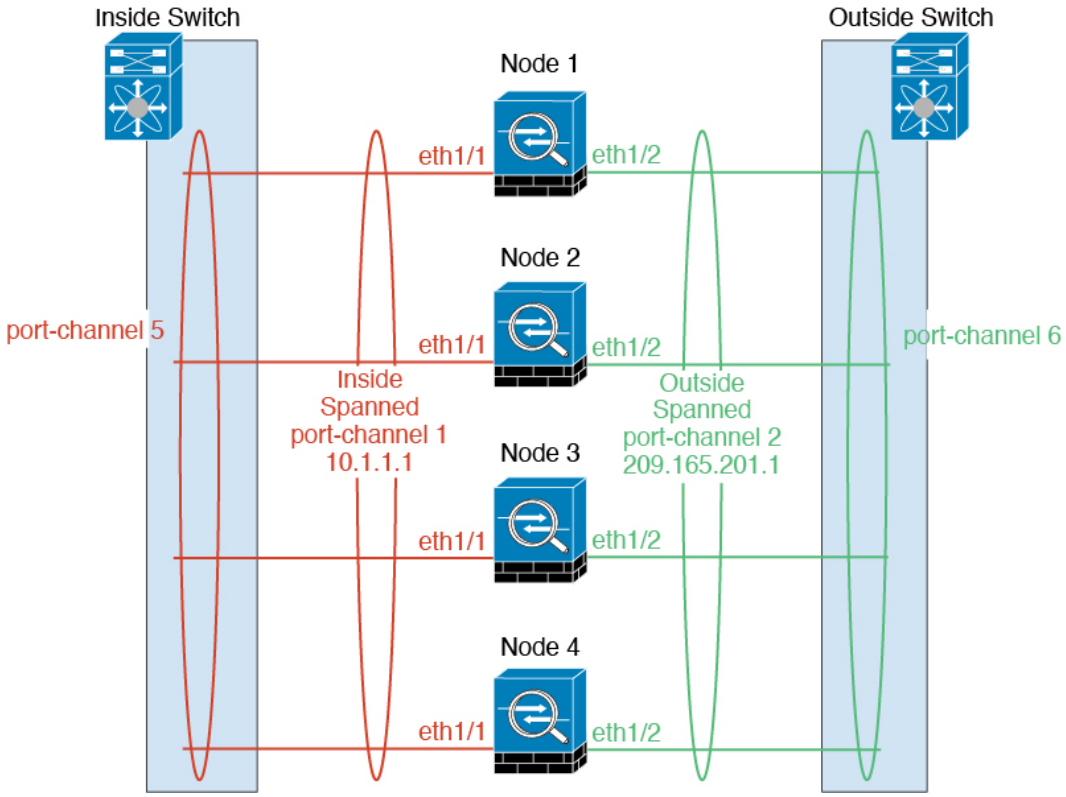
Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster Control Link Redundancy

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster Control Link Reliability

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.



The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

Guidelines for Maximum Throughput

To achieve maximum throughput, we recommend the following:

- Use a load-balancing hash algorithm that is “symmetric,” meaning that packets from both directions will have the same hash and will be sent to the same FTD in the Spanned EtherChannel. We recommend using the source and destination IP address (the default) or the source and destination port as the hashing algorithm.

- Use the same type of line cards when connecting the FTDs to the switch so that hashing algorithms applied to all packets are the same.

Load Balancing

The EtherChannel link is selected using a proprietary hash algorithm, based on source or destination IP addresses and TCP and UDP port numbers.

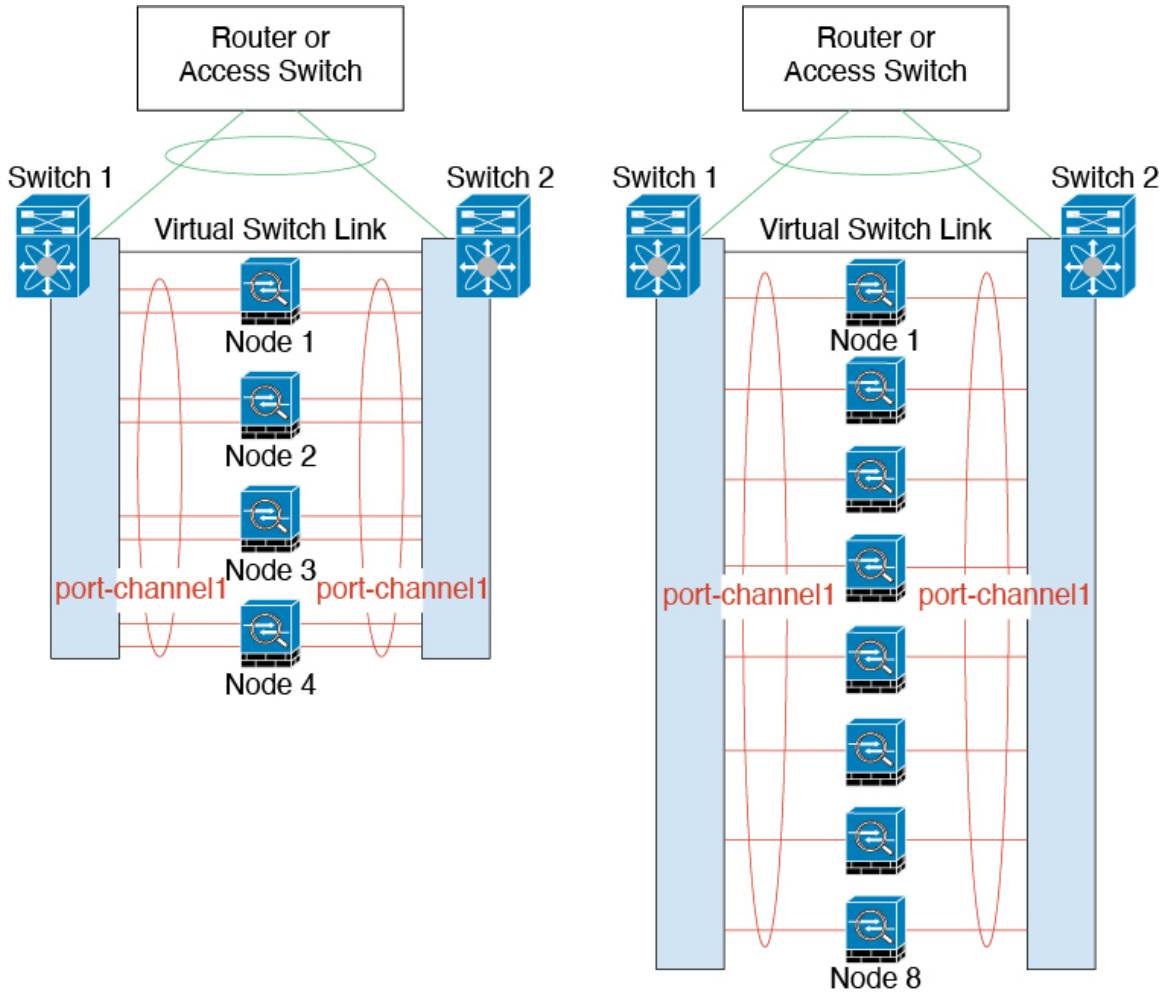
Note On the switch, we recommend that you use one of the following algorithms: **source-dest-ip** or **source-dest-ip-port** (see the Cisco Nexus OS or Cisco IOS **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the ASAs in a cluster.

The number of links in the EtherChannel affects load balancing.

Symmetric load balancing is not always possible. If you configure NAT, then forward and return packets will have different IP addresses and/or ports. Return traffic will be sent to a different unit based on the hash, and the cluster will have to redirect most returning traffic to the correct unit.

EtherChannel Redundancy

The EtherChannel has built-in redundancy. It monitors the line protocol status of all links. If one link fails, traffic is re-balanced between remaining links. If all links in the EtherChannel fail on a particular unit, but other units are still active, then the unit is removed from the cluster.



Connecting to a Redundant Switch System

You can include multiple interfaces per FTD in the Spanned EtherChannel. Multiple interfaces per FTD are especially useful for connecting to both switches in a VSS, vPC, StackWise, or StackWise Virtual system.

Depending on your switches, you can configure up to 32 active links in the spanned EtherChannel. This feature requires both switches in the vPC to support EtherChannels with 16 active links each (for example the Cisco Nexus 7000 with F2-Series 10 Gigabit Ethernet Module).

For switches that support 8 active links in the EtherChannel, you can configure up to 16 active links in the spanned EtherChannel when connecting to two switches in a redundant system.

The following figure shows a 16-active-link spanned EtherChannel in a 4-node cluster and an 8-node cluster.

Cable and Add Devices to the FMC

Before configuring clustering, you need to prepare your devices. In particular, the cluster will not come up unless all nodes can communicate over the cluster control link. Therefore, before you form the cluster, the cluster control link must be ready to go.

Procedure

Step 1 Cable the cluster control link network, management network, and data networks.

Step 2 Configure the upstream and downstream equipment.

a) For the cluster control link network, set the MTU to be at least 100 bytes higher than the data interface MTU.

By default, the data interface MTU is 1500 bytes, so the cluster control link MTU on the cluster node will be set to 1600 bytes. If you use higher MTUs on your data interfaces, increase the cluster control link MTU on connecting switches accordingly.

b) Configure cluster control link interfaces on upstream and downstream equipment, including for an optional EtherChannel.

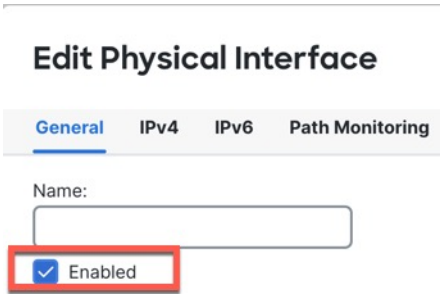
See Cluster Control Link Interfaces and Network, on page 246 for cluster control link requirements.

c) Configure data interfaces on upstream and downstream equipment, including Spanned EtherChannels.

See About Cluster Interfaces, on page 246 for information about how to cable Spanned EtherChannels.

Step 3 Add each node to the FMC as a standalone device in the same domain and group.

See Add a Device, on page 27. You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.



Step 4 Enable the cluster control link on the device you want to be the control node.

When you add the other nodes, they will inherit the cluster control link configuration.

Note
Do *not* configure the name or IP addressing for the cluster control link. You cannot yet set the MTU for the cluster control link (because it does not have a name). After you form the cluster, you can come back and set the MTU, which needs to be at least 100 bytes higher than data interfaces.

a) On the device you want to be the control node, choose **Devices** > **Device Management**, and click **Edit** ( ).
b) Click **Interfaces**.
c) Enable the interface. If you are going to use an EtherChannel for the cluster control link, enable all members. See Enable the Physical Interface and Configure Ethernet Settings, on page 355.

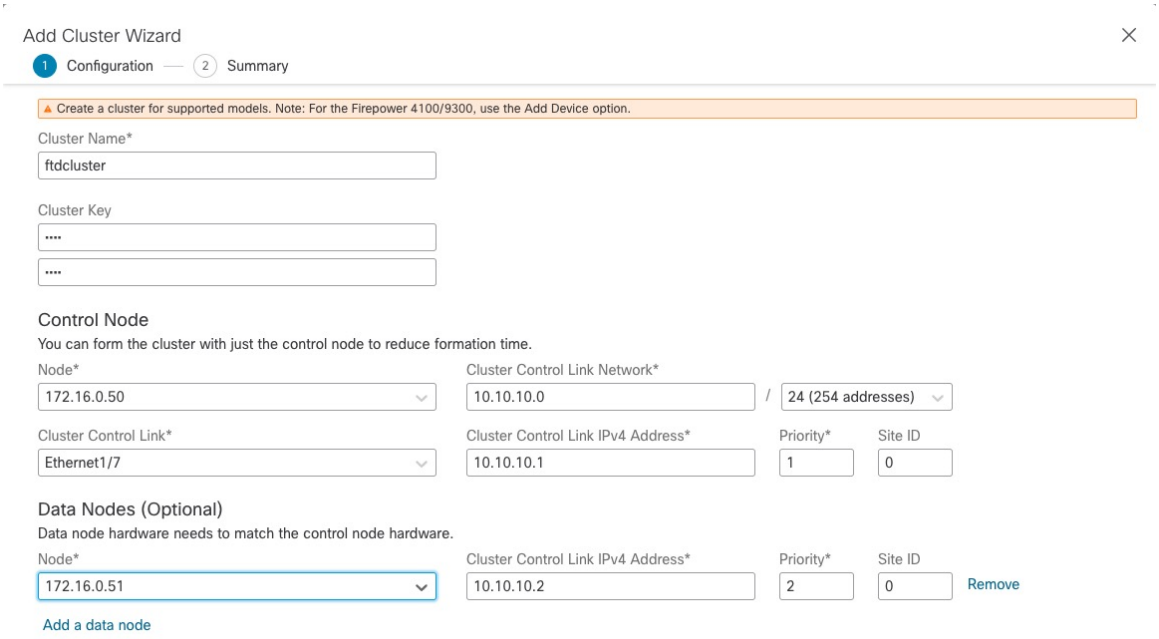
Figure 74: Enable the Cluster Control Link Interface

d) (Optional) Add an EtherChannel. See Configure an EtherChannel, on page 362.

We recommend using the On mode for cluster control link member interfaces to reduce unnecessary traffic on the cluster control link (Active mode is the default). The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network. **Note:** We recommend setting *data* EtherChannels to Active mode.

e) Click **Save** and then **Deploy** to deploy the interface changes to the control node.

Create a Cluster



Form a cluster from one or more devices in the FMC.

Procedure

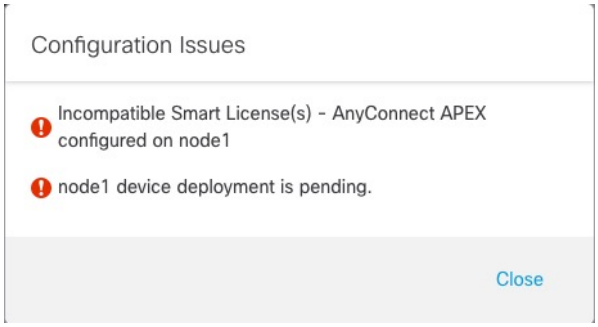
Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 75: Add Cluster Wizard

Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string from 1 to 38 characters.
- **Cluster Key**—An ASCII string from 1 to 63 characters. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.



Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the FMC forms the cluster, it will add this node to the cluster first so it will be the control node.

  Note

  If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 76: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **Cluster Control Link Network**—Specify an IPv4 subnet; IPv6 is not supported for this interface. Specify a **24**, **25**, **26**, or **27** subnet.
- **Cluster Control Link**—Choose the physical interface or EtherChannel you want to use for the cluster control link.
- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the first address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

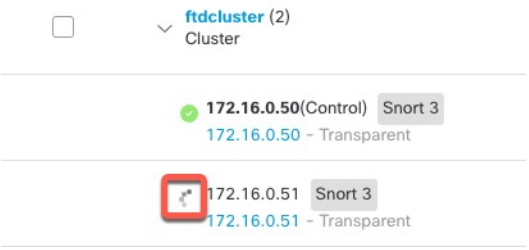
- **Node**—Choose the device that you want to add.

  Note

  If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

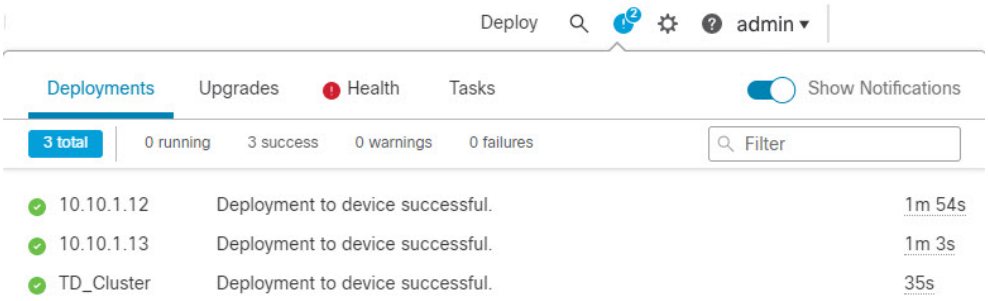
- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the next address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.



The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

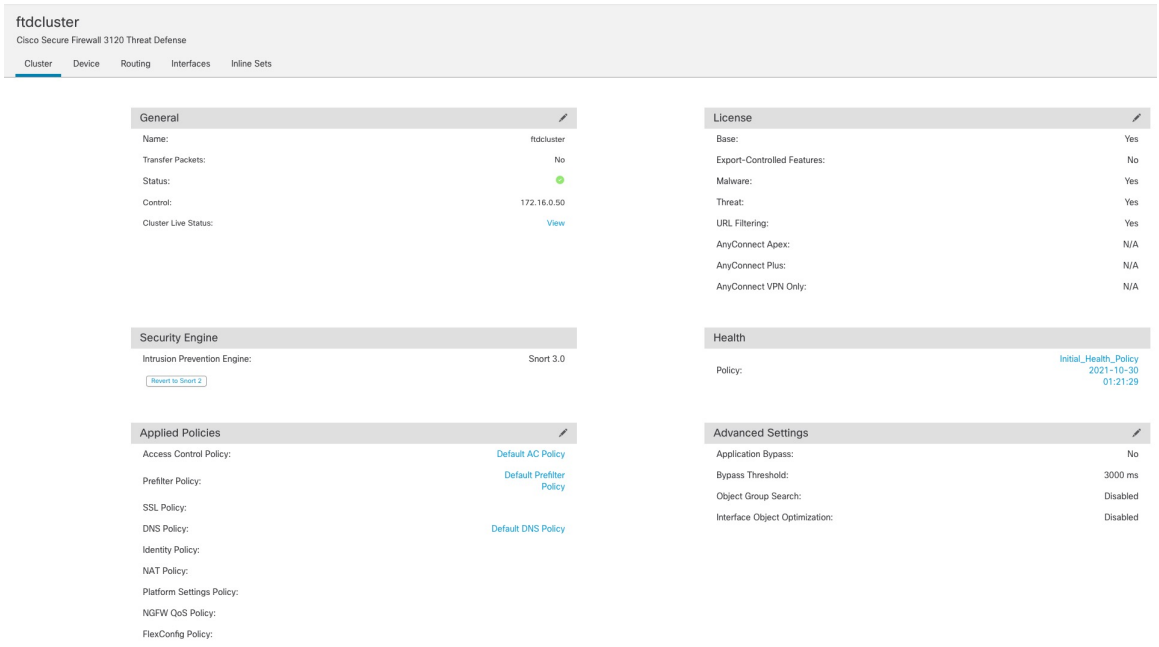
Figure 77: Cluster Management



A node that is currently registering shows the loading icon.

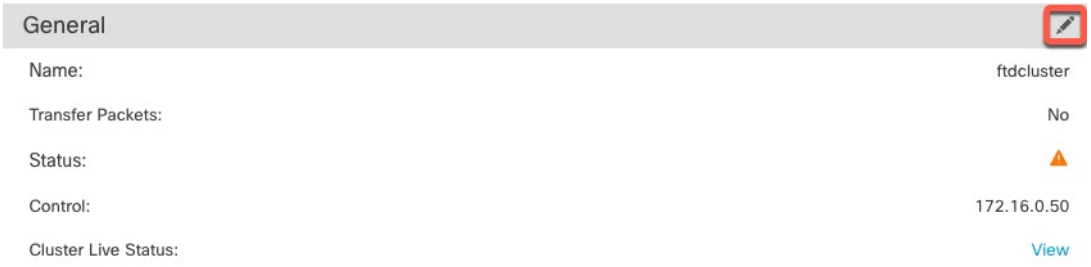
Figure 78: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The FMC updates the Cluster Registration task as each node registers.



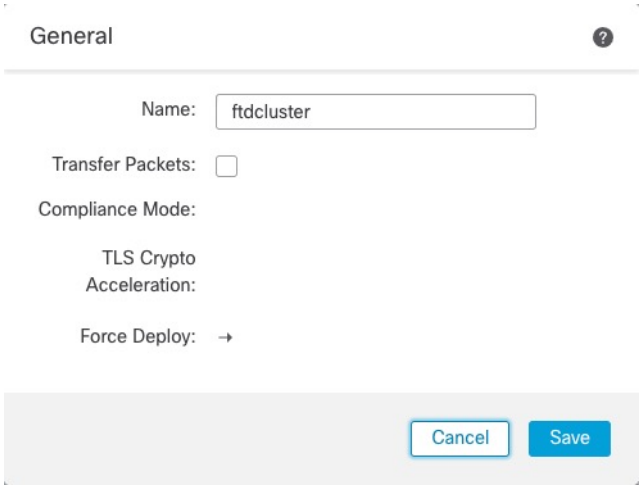
Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.



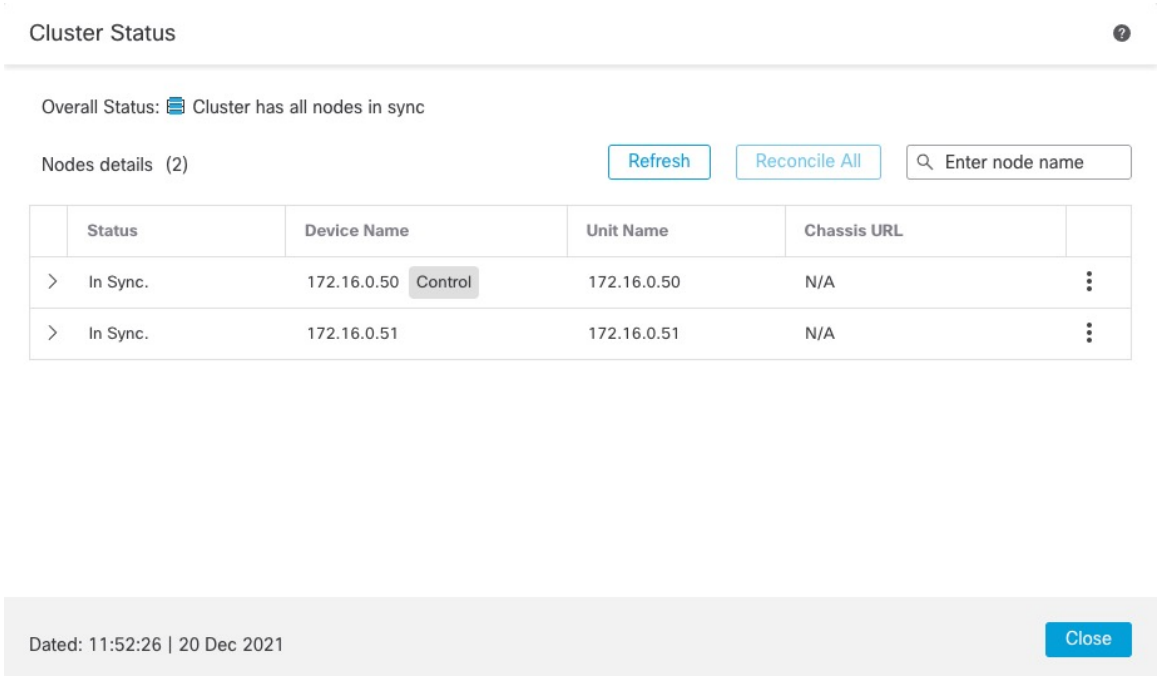
Step 7 On the **Devices** > **Device Management** > **Cluster** screen, you see **General** and other settings for the cluster.

Figure 79: Cluster Settings



See the following cluster-specific items in the **General** area:

- **General > Name**—Change the cluster display name by clicking the **Edit** ( ).



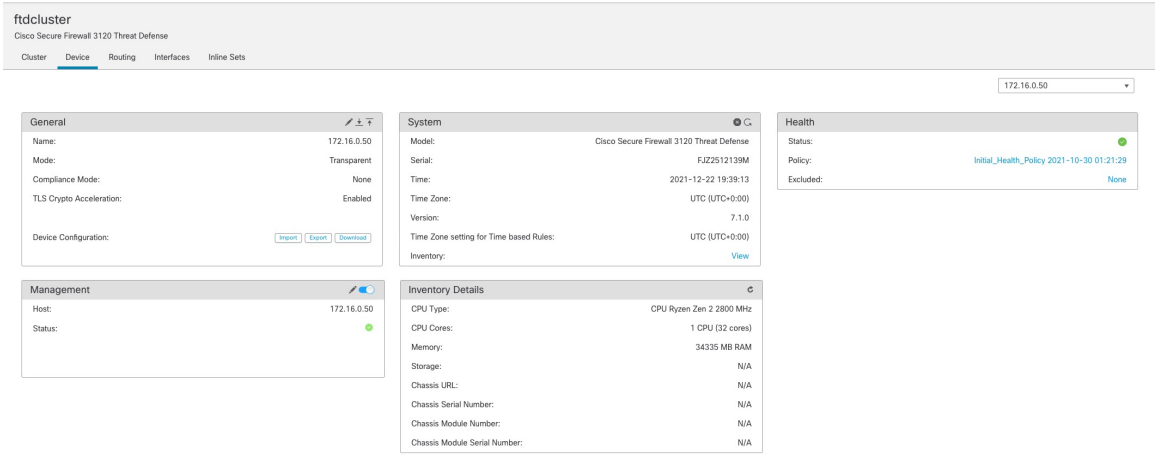
Then set the **Name** field.

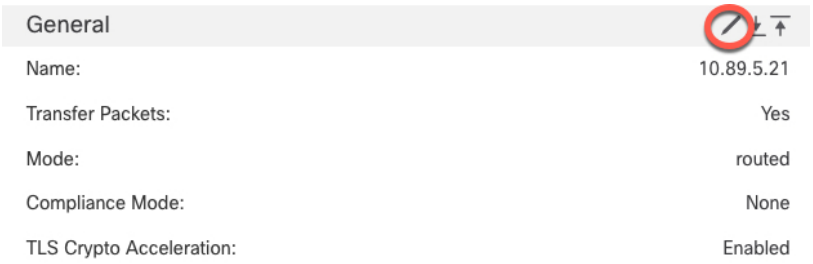
- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.

The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**.

Step 8 On the **Devices** > **Device Management** > **Devices**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

Figure 80: Device Settings





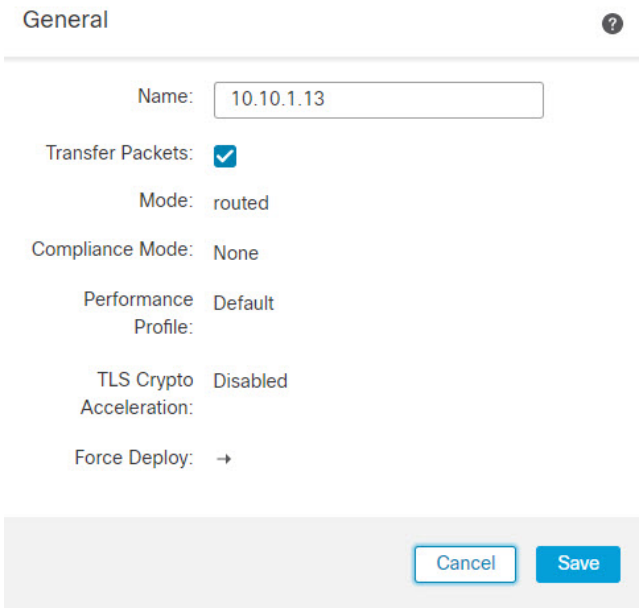


Figure 81: Choose Node

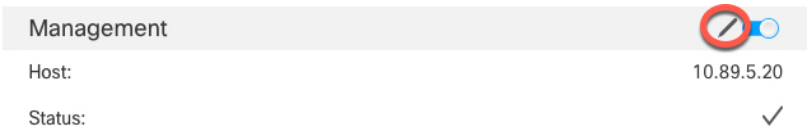


- **General** > **Name**—Change the cluster member display name by clicking the **Edit** ( ).

Then set the **Name** field.

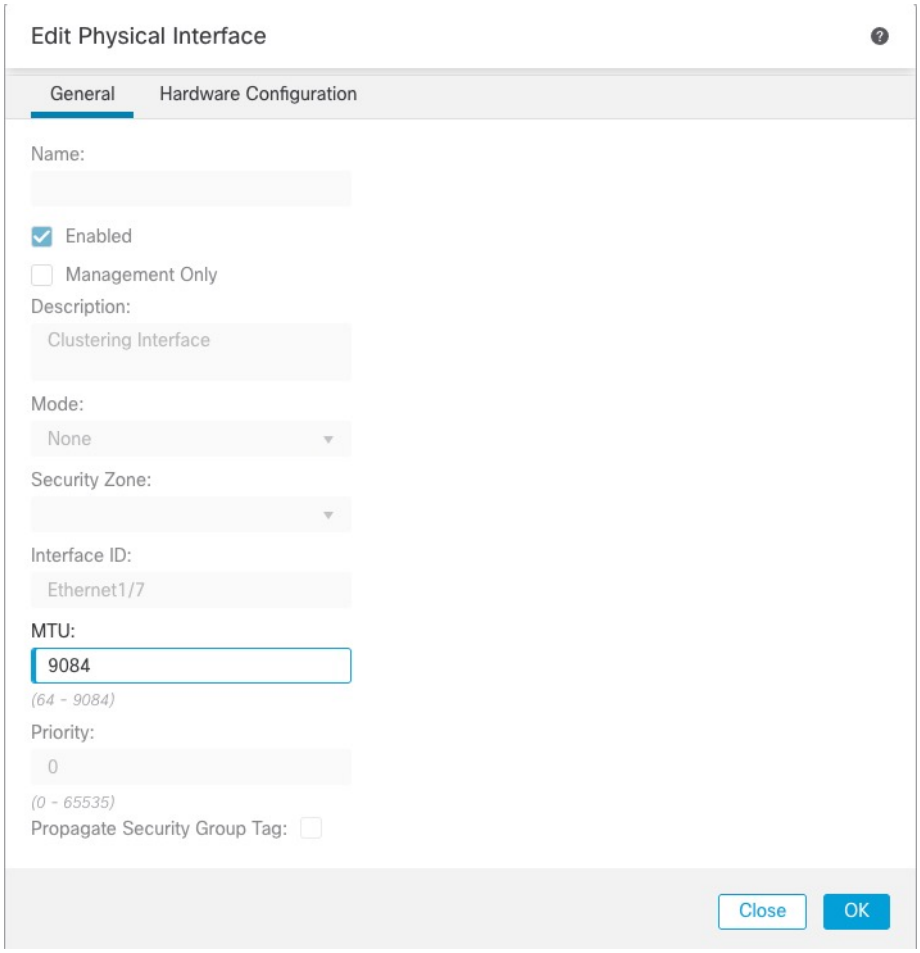
- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the FMC so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Configure Interfaces

Configure data interfaces as Spanned EtherChannels. For the cluster control link interface, you must increase the MTU from the default. You can also configure the Diagnostic interface, which is the only interface that can run as an individual interface.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.



Step 2 Click **Interfaces**.

Step 3 Set the MTU for the cluster control link.

a) Click **Edit** (✎) for the cluster control link interface.

b) On the **General** page, in the **MTU** field, enter a value 1400 bytes or higher. We highly recommend using the maximum MTU.

Figure 82: Set the MTU

Set the cluster control link MTU to be at least 100 bytes higher than the highest MTU of the data interfaces, but not between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. We highly recommend setting the MTU to the maximum; the minimum value is 1400 bytes. For example, if the maximum MTU is 9084, then the highest data interface MTU can be 8984, while the cluster control link can be set to 9084.

Note
Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation will fail.

c) Click **OK**.

Step 4 Configure Spanned EtherChannel data interfaces.

a) Configure one or more EtherChannels. See Configure an EtherChannel, on page 362.

You can include one or more member interfaces in the EtherChannel. Because this EtherChannel is spanned across all of the nodes, you only need one member interface per node; however, for greater throughput and redundancy, multiple members are recommended.

b) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the EtherChannel. The rest of this procedure applies to the subinterfaces. See Add a Subinterface, on page 396.

c) Click **Edit** ( ) for the EtherChannel interface.

d) Configure the name and other parameters. For regular firewall interfaces, see Configure Routed Mode Interfaces, on page 406 or, for transparent mode, Configure Bridge Group Interfaces, on page 411. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 433.

- If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface.
- For routed mode, DHCP, PPPoE, IPv6 autoconfig and manual link-local addresses are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.

e) Set a unique, manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

f) Click **OK**. Repeat the above steps for other data interfaces.

Step 5 (Optional) Configure the Diagnostic interface.

The Diagnostic interface is the only interface that can run in Individual interface mode. You can use this interface for syslog messages or SNMP, for example.

a) Choose **Objects** > **Object Management** > **Address Pools** to add an IPv4 and/or IPv6 address pool. See Address Pools, on page 859.

Include at least as many addresses as there are units in the cluster. The Virtual IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

b) On **Devices** > **Device Management** > **Interfaces**, click **Edit** ( ) for the Diagnostic interface.

c) On the **IPv4**, enter the **IP Address** and mask. This IP address is a fixed address for the cluster, and always belongs to the current control unit.

d) From the **IPv4 Address Pool** drop-down list, choose the address pool you created.

e) On **IPv6 > Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.

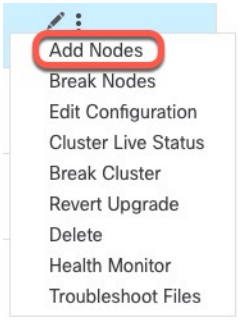
f) Configure other interface settings as normal.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Manage Cluster Nodes

After you deploy the cluster, you can change the configuration and manage cluster nodes.



Add a New Cluster Node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Add Nodes**.

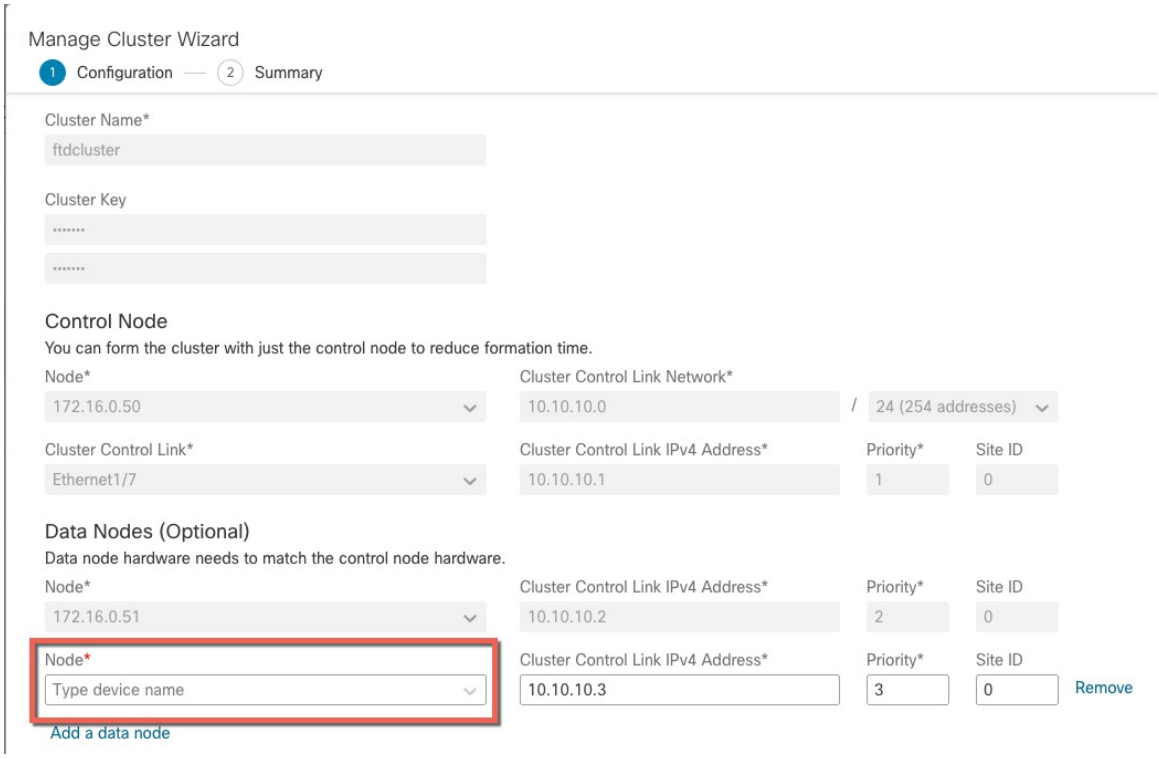


Figure 83: Add Nodes

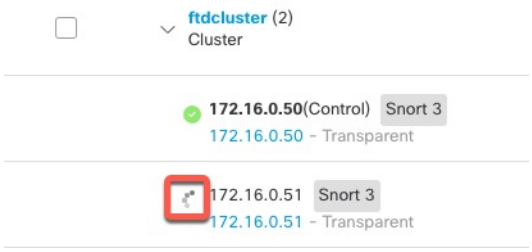
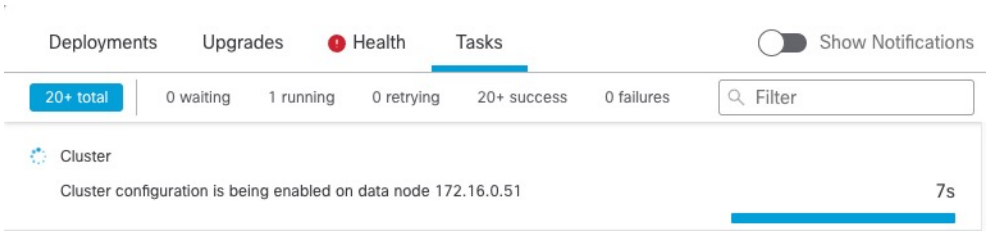
The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, adjust the IP address, priority, and Site ID if desired.

Figure 84: Manage Cluster Wizard



Step 3 To add additional nodes, click **Add a data node**.

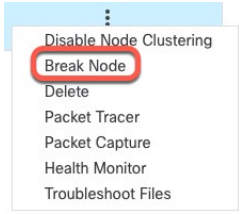


Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 85: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.



Break a Node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the node you want to break, and choose **Break Node**.

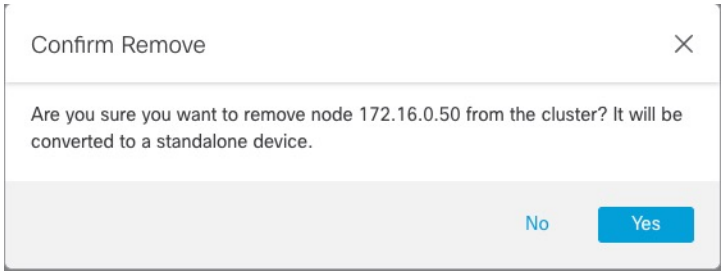


Figure 86: Break a Node

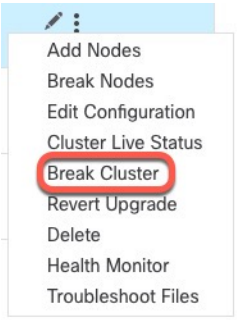
You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 87: Confirm Break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

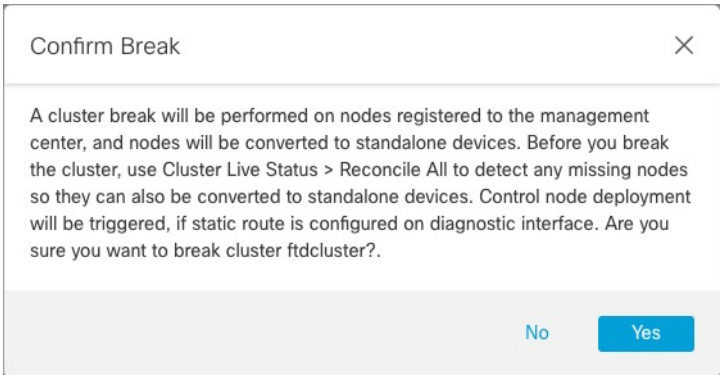
Break the Cluster



You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the FMC by reconciling nodes. See Reconcile Cluster Nodes, on page 268.



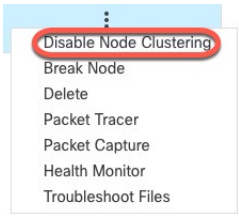
Step 2 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 88: Break Cluster

Step 3 You are prompted to break the cluster; click **Yes**.

Figure 89: Confirm Break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.



Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the FMC device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 90: Disable Clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, see Rejoin the Cluster, on page 265.

Rejoin the Cluster

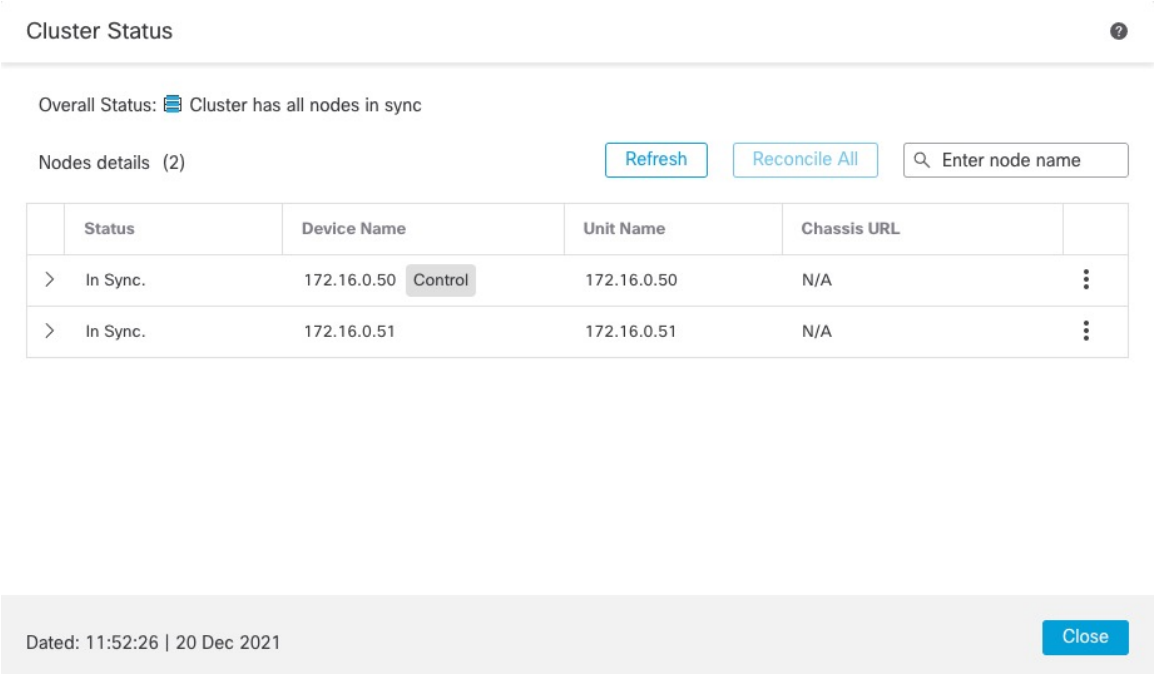
If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See Rejoining the Cluster, on page 281 for more information about why a node can be removed from a cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the unit.

Change the Control Node



Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

To change the control node, perform the following steps.

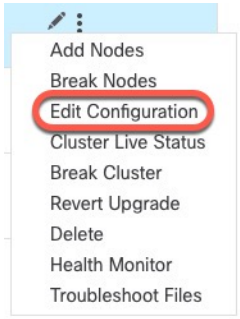
Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management** > **More** (⋮) > **Cluster Live Status**.

Figure 91: Cluster Status

Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the checkbox, and click **OK**.



Edit the Cluster Configuration

You can edit the cluster configuration. If you change the cluster key, cluster control link interface, or cluster control link network, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the cluster control link IP address for a node, node priority, or site ID, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Edit Configuration**.

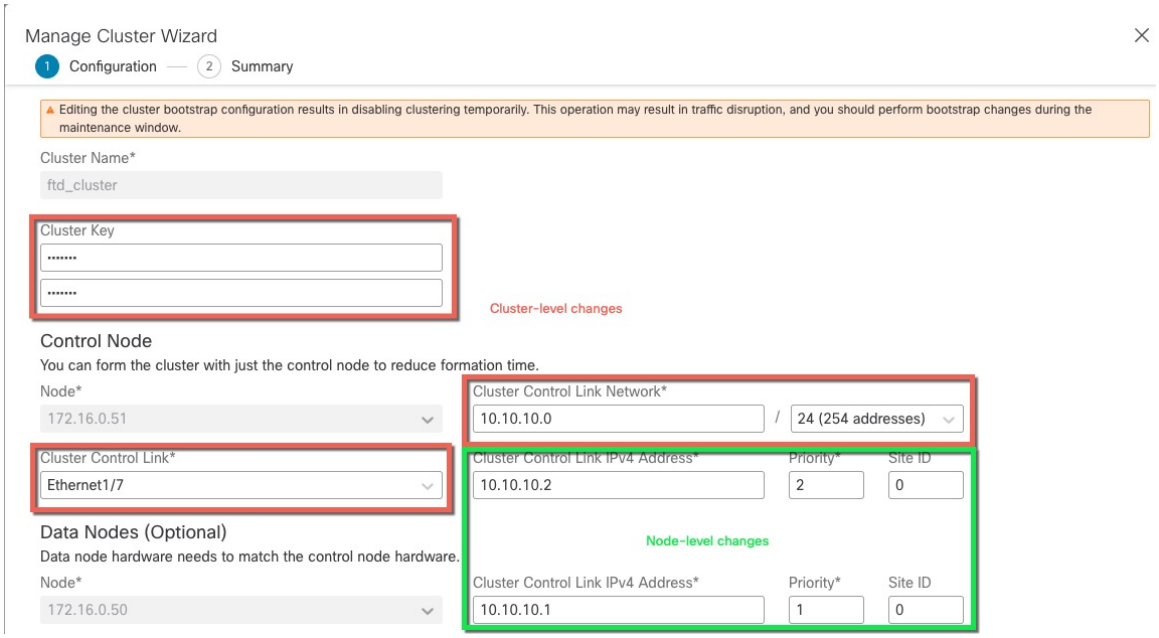


Figure 92: Edit Configuration

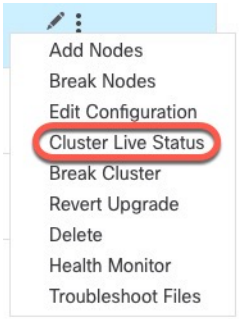
The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 93: Manage Cluster Wizard

If the cluster control link is an EtherChannel, you can edit the interface membership and LACP configuration by clicking **Edit** (✎) next to the interface drop-down menu.

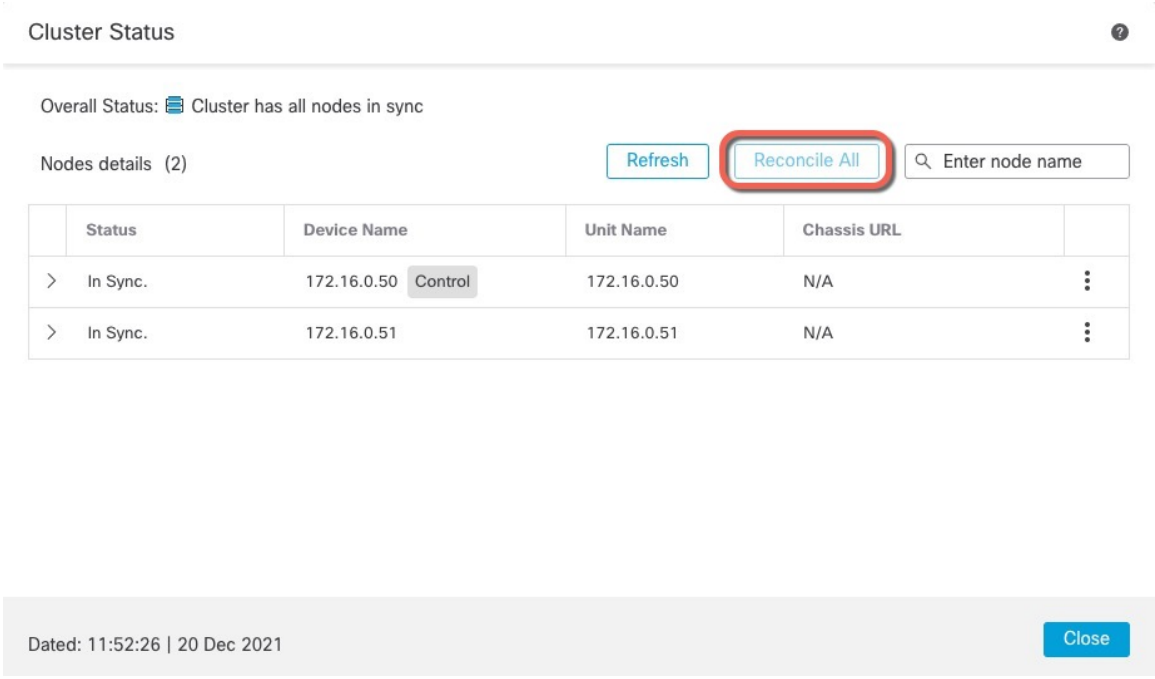
Step 3 Click **Continue**. Review the **Summary**, and then click **Save**



Reconcile Cluster Nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the FMC. For example, a data node might fail to register if the FMC is occupied with certain processes, or if there is a network issue.

Procedure



Step 1 Choose **Devices** > **Device Management** > **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 94: Cluster Live Status

Step 2 Click **Reconcile All**.

Figure 95: Reconcile All

For more information about the cluster status, see Monitoring the Cluster, on page 270.

Delete (Unregister) the Cluster or Nodes and Register to a New FMC

You can unregister the cluster from the FMC, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new FMC.

You can also unregister a node from the FMC without breaking the node from the cluster. Although the node is not visible in the FMC, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the FMC, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

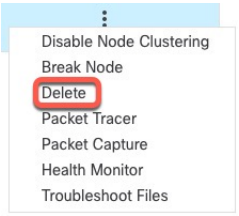
Unregistering a cluster:

- Severs all communication between the FMC and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the FMC using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different FMC causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the

cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.



Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Delete**.

Figure 96: Delete Cluster or Node

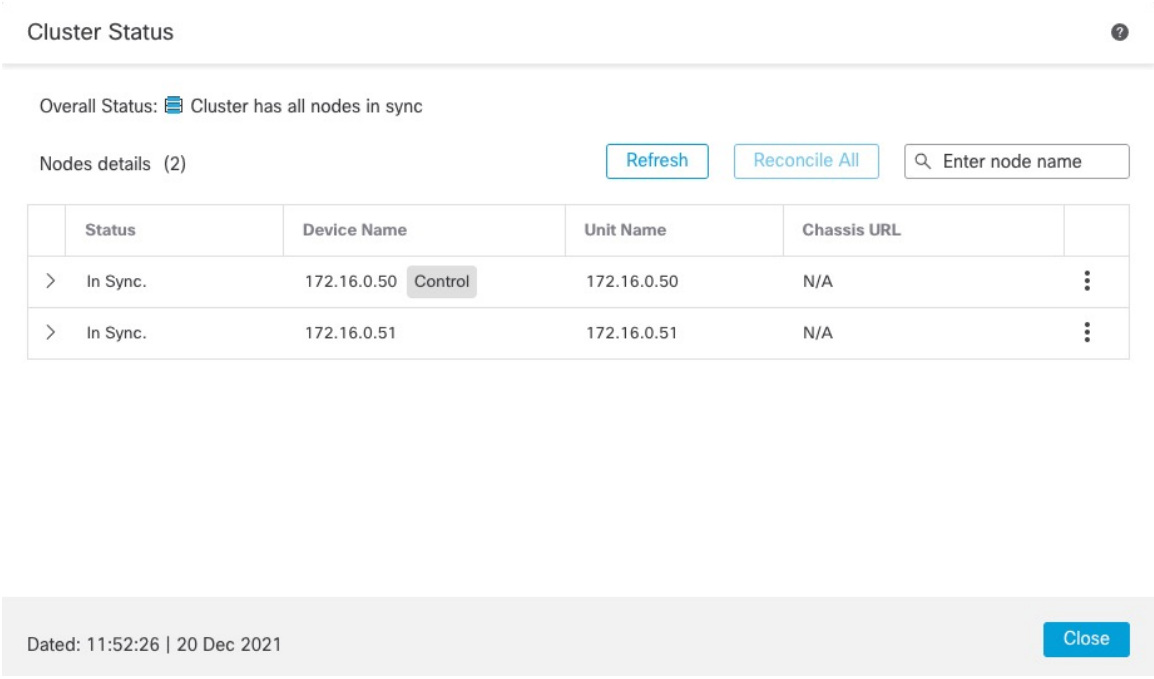
Step 2 You are prompted to delete the cluster or node; click **Yes**.

Step 3 You can register the cluster to a new (or the same) FMC by adding one of the cluster members as a new device.

You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.

a) Connect to one cluster node's CLI, and identify the new FMC using the **configure manager add** command. See Modify FTD Management Interfaces at the CLI, on page 65.

b) Choose **Devices** > **Device Management**, and then click **Add** > **Device**.



Step 4 To re-add an unregistered node, see Reconcile Cluster Nodes, on page 268.

Monitoring the Cluster

You can monitor the cluster in the FMC and at the FTD CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management** > **More** (⋮) icon or from the **Devices** > **Device Management** > **Cluster** page > **General** area > **Cluster Live Status** link.

Figure 97: Cluster Status

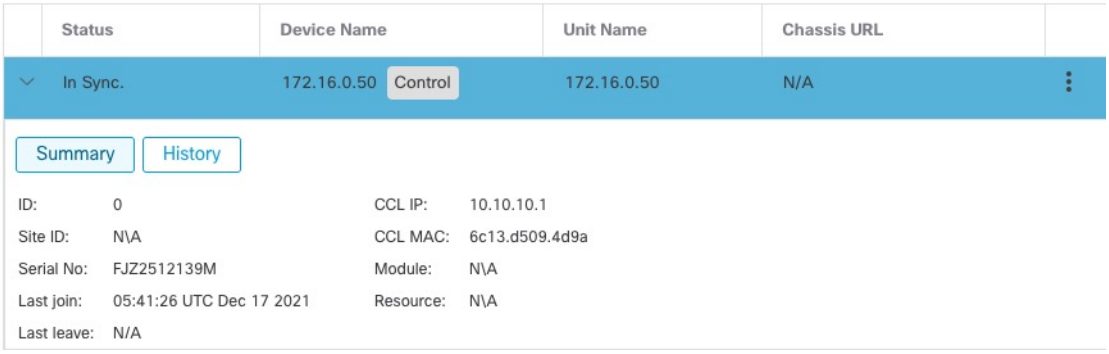
The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the FMC.
- Pending Registration—The node is part of the cluster, but has not yet registered with the FMC. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the FMC, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the FMC.

For each node, you can view the **Summary** or the **History**.

Figure 98: Node Summary



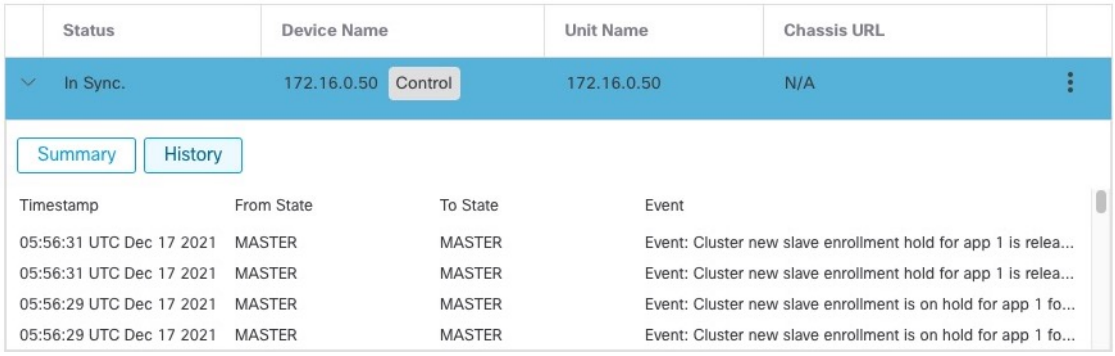


Figure 99: Node History

- **System** (⚙) > **Tasks** page.

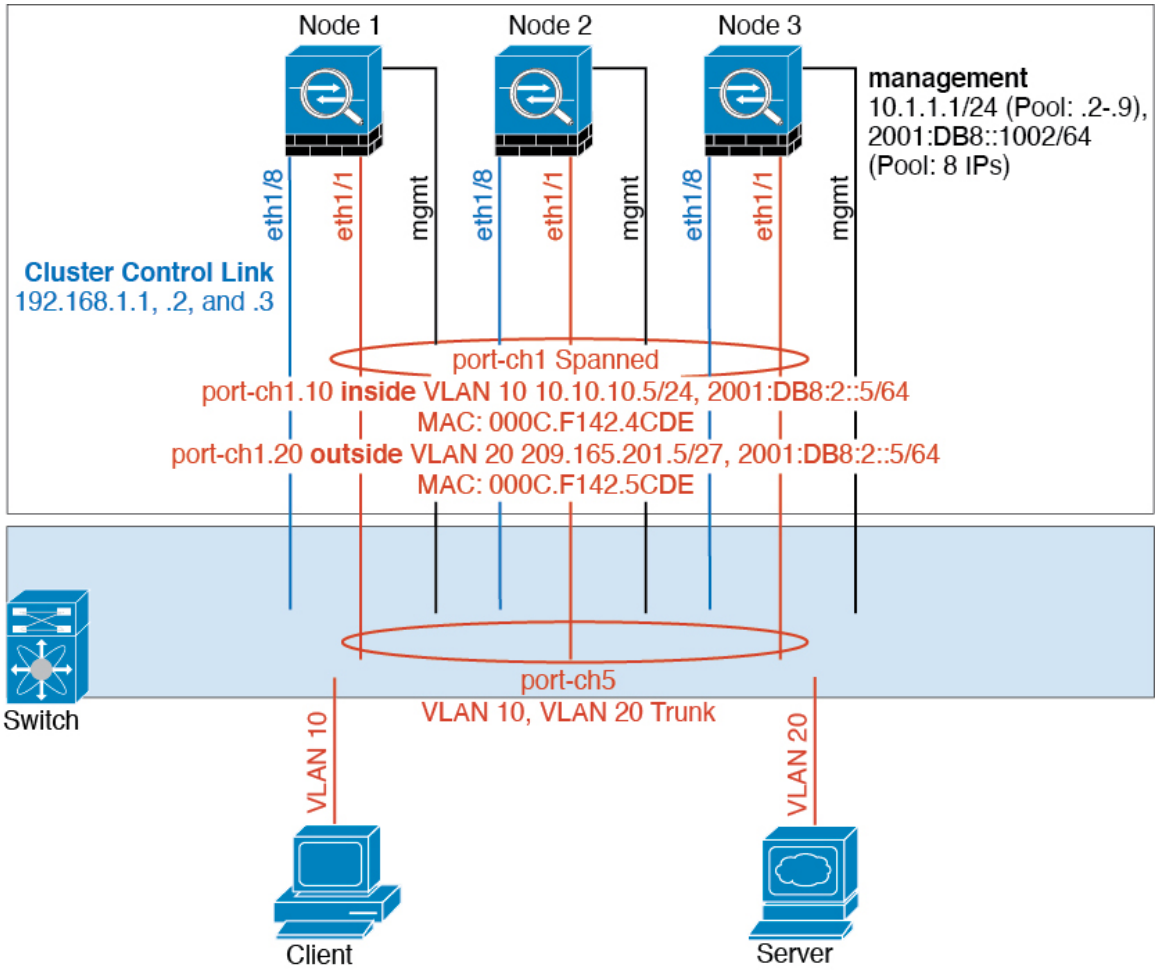
  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** > *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

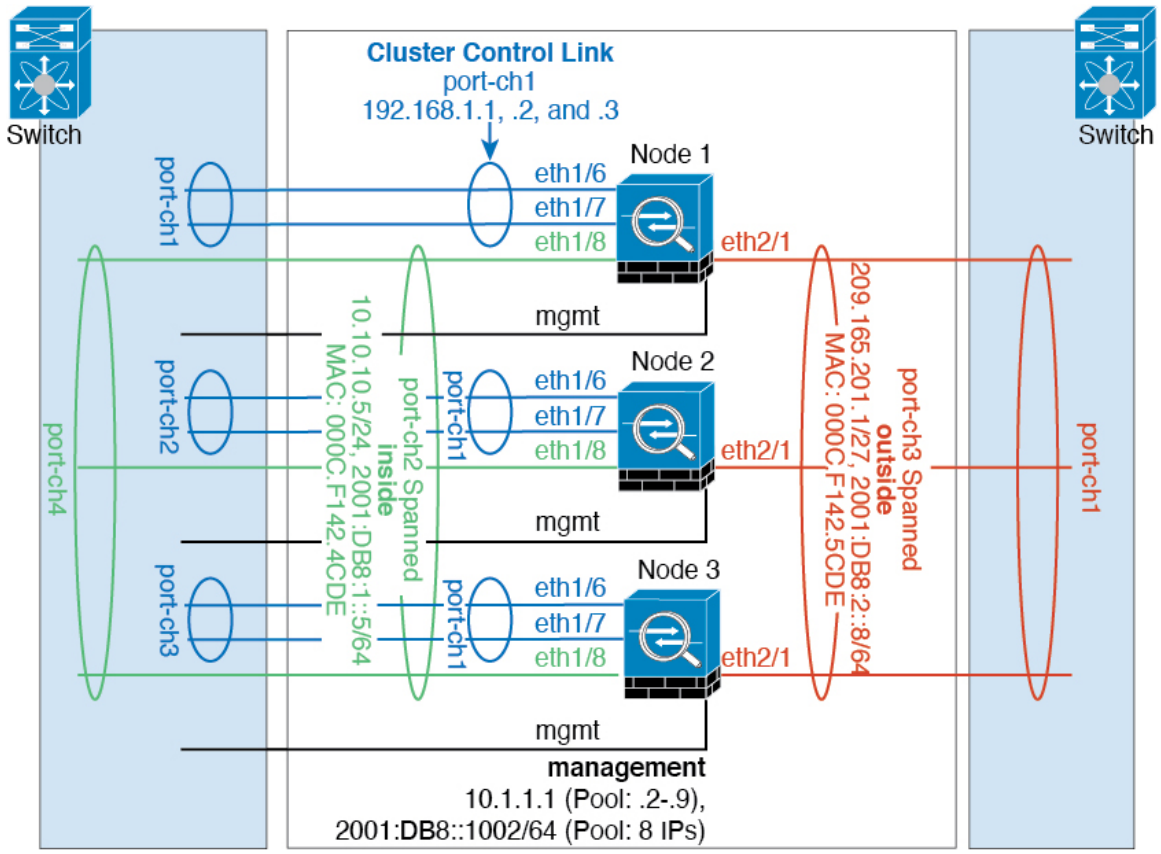


- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Examples for Clustering

These examples include examples for typical deployments.



Firewall on a Stick

Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic Segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

FTD Features and Clustering

Some FTD features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the FMC GUI. See FlexConfig Policies, on page 1893.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- FMC UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the FMC GUI. See FlexConfig Policies, on page 1893.

- The following application inspections:
  - DCERPC
  - ESMTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET

  - SUNRPC
  - TFTP
  - XDMCP
- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast Routing in Individual Interface Mode

In Individual interface mode, units do not act independently with multicast. All data and routing packets are processed and forwarded by the control unit, thus avoiding packet replication.

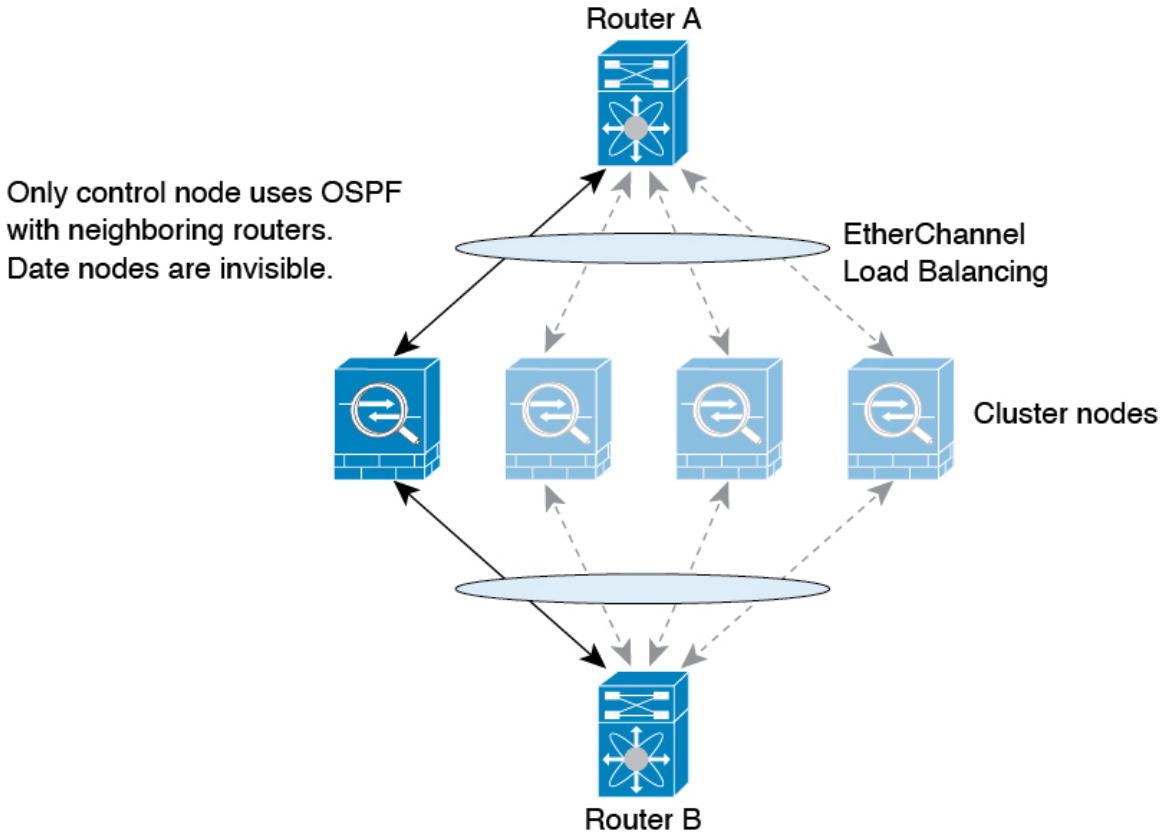
NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different FTDs in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the FTD that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.

- Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
- On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
- When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.



- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

Dynamic Routing

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 100: Dynamic Routing in Spanned EtherChannel Mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

An SNMP agent polls each individual FTD by its Diagnostic interface Local IP address. You cannot poll consolidated data for the cluster.

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned EtherChannel address, connections are automatically forwarded to the control node.

VPN-related keys and certificates are replicated to all nodes.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High Availability Within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

See Control Node Election, on page 280 for more information.

Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

- Spanned EtherChannel—Uses cluster Link Aggregation Control Protocol (cLACP). Each node monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel. The status is reported to the control node.

All physical interfaces (including the main EtherChannel) are monitored by default. Only named interfaces can be monitored. For example, the named EtherChannel must fail to be considered failed, which means all member ports of an EtherChannel must fail to trigger cluster removal.

A node is removed from the cluster if its monitored interfaces fail. The amount of time before the FTD removes a member from the cluster depends on whether the node is an established member or is joining the cluster. If the interface is down on an established member, then the FTD removes the member after 9 seconds. The FTD does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the FTD to be removed from the cluster. For non-EtherChannels, the node is removed after 500 ms, regardless of the member state.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The FTD automatically tries to rejoin the cluster, depending on the failure event.

Note When the FTD becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management/Diagnostic interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The FTD automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The FTD automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the FTD application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The FTD application attempts to rejoin the cluster every 5 seconds.

- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from FMC, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 25: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first

node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

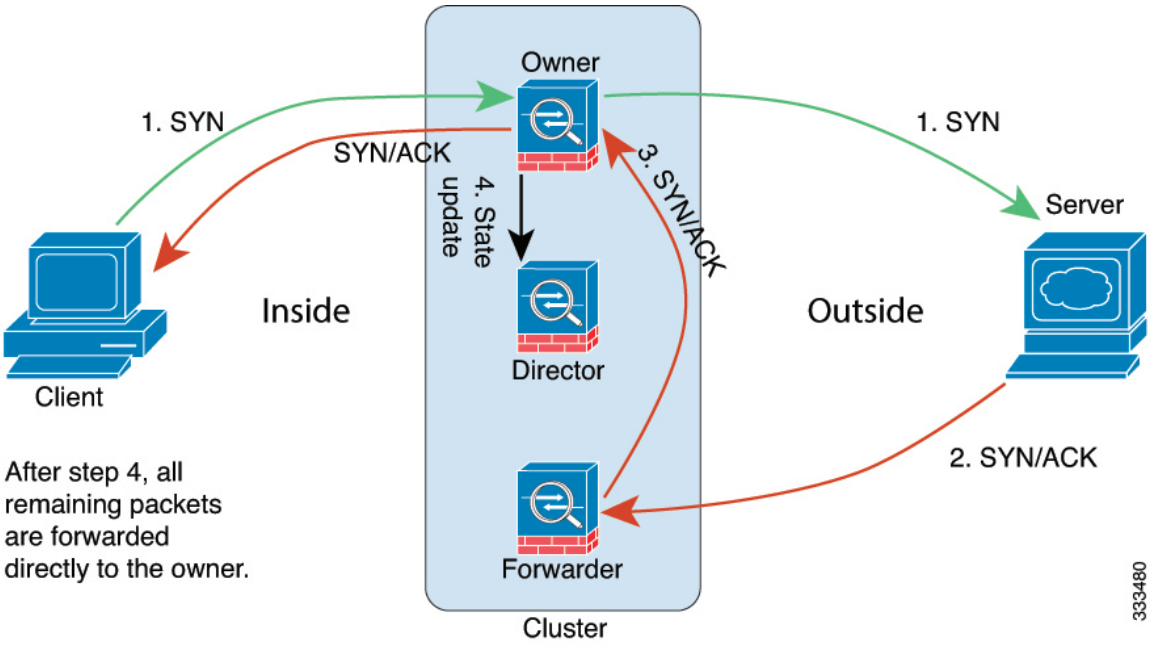
  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.

- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.



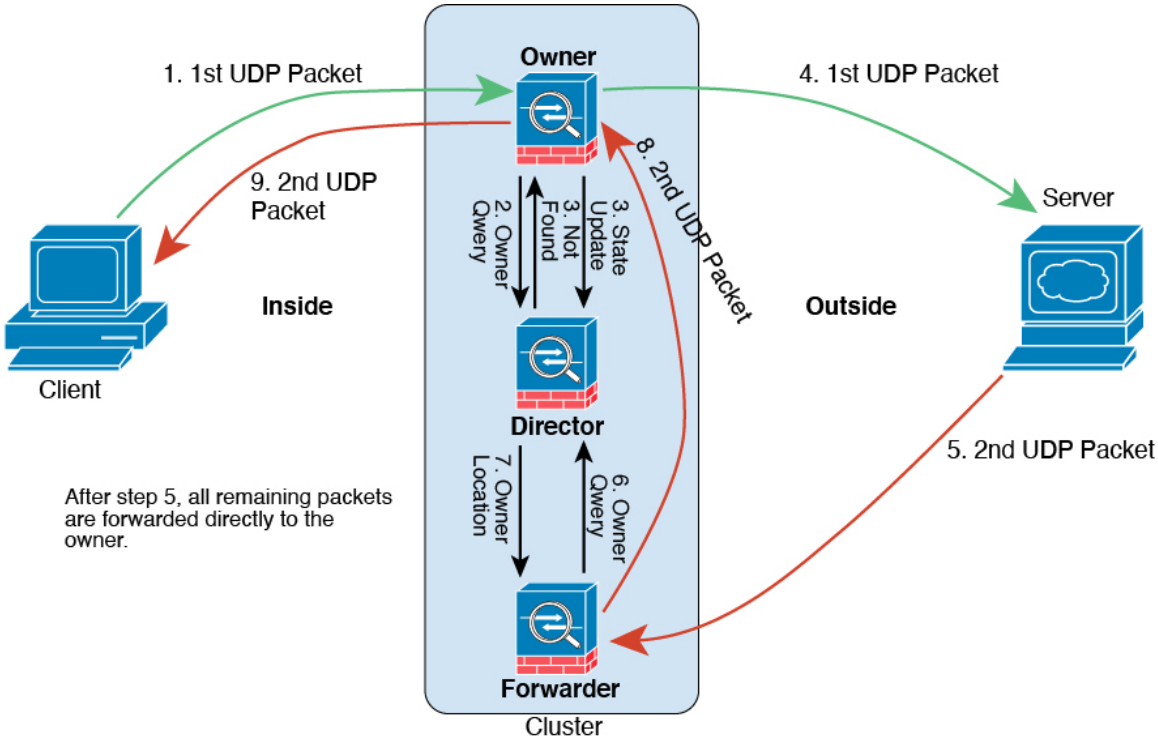
- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.

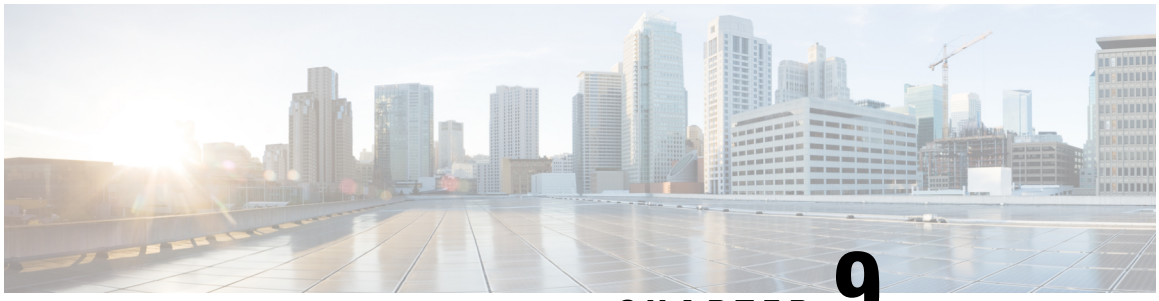


1. The SYN packet originates from the client and is delivered to one FTD (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different FTD (based on the load balancing method). This FTD is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. ***Figure 101: ICMP and UDP Data Flow***



The first UDP packet originates from the client and is delivered to one FTD (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Clustering

Feature	Minimum FMC	Minimum FTD	Details
Clustering for the Secure Firewall 3100	7.1.0	7.1.0	The Secure Firewall 3100 supports Spanned EtherChannel clustering for up to 8 nodes. New/modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Secure Firewall 3100

CHAPTER 9

Clustering for the Firepower 4100/9300

Clustering lets you group multiple FTD nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported Features with Clustering, on page 331.

About Clustering on the Firepower 4100/9300 Chassis

When you deploy a cluster on the Firepower 4100/9300 chassis, it does the following:

- For native instance clustering: Creates a *cluster-control link* (by default, port-channel 48) for node-to-node communication.

  For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

  For a cluster isolated to security modules within one Firepower 9300 chassis, this link utilizes the Firepower 9300 backplane for cluster communications.

  For clustering with multiple chassis, you need to manually assign physical interface(s) to this EtherChannel for communications between chassis.

- Creates the cluster bootstrap configuration within the application.

  When you deploy the cluster, the chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

- Assigns data interfaces to the cluster as *Spanned* interfaces.

  For a cluster isolated to security modules within one Firepower 9300 chassis, spanned interfaces are not limited to EtherChannels, like it is for clustering with multiple chassis. The Firepower 9300 supervisor uses EtherChannel technology internally to load-balance traffic to multiple modules on a shared interface, so any data interface type works for Spanned mode. For clustering with multiple chassis, you must use Spanned EtherChannels for all data interfaces.

Note Individual interfaces are not supported, with the exception of a management interface.

- Assigns a management interface to all units in the cluster.

See the following sections for more information about clustering.

Bootstrap Configuration

When you deploy the cluster, the Firepower 4100/9300 chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

Cluster Members

Cluster members work together to accomplish the sharing of the security policy and traffic flows.

One member of the cluster is the **control** unit. The control unit is determined automatically. All other members are **data** units.

You must perform all configuration on the control unit only; the configuration is then replicated to the data units.

Some features do not scale in a cluster, and the control unit handles all traffic for those features. .

Cluster Control Link

For native instance clustering: The cluster control link is automatically created using the Port-channel 48 interface.

For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

For a cluster isolated to security modules within one Firepower 9300 chassis, this interface has no member interfaces. This Cluster type EtherChannel utilizes the Firepower 9300 backplane for cluster communications. For clustering with multiple chassis, you must add one or more interfaces to the EtherChannel.

For a cluster with two chassis, do not directly connect the cluster control link from one chassis to the other chassis. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus

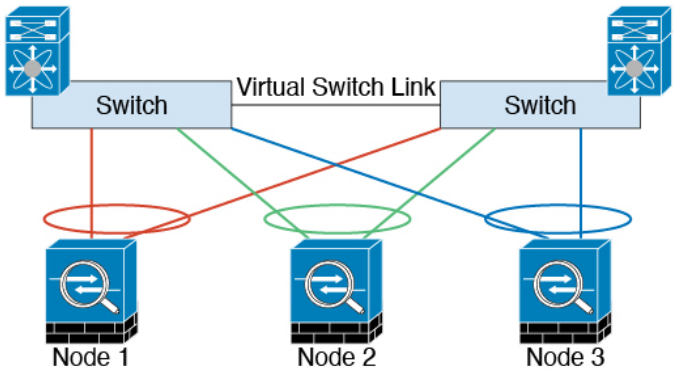
the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

Cluster control link traffic includes both control and data traffic.

Size the Cluster Control Link

If possible, you should size the cluster control link to match the expected throughput of each chassis so the cluster control link can handle the worst-case scenarios.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features. For example:



- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster Control Link Redundancy

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster Control Link Reliability for Inter-Chassis Clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Cluster Control Link Network

The Firepower 4100/9300 chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2.*chassis_id*.*slot_id*. For multi-instance clusters, which typically use different VLAN subinterfaces of the same EtherChannel, the same IP address can be used for different clusters because of VLAN separation. The cluster control link network cannot include any routers between units; only Layer 2 switching is allowed.

Management Network

We recommend connecting all units to a single management network. This network is separate from the cluster control link.

Management Interface

You must assign a Management type interface to the cluster. This interface is a special individual interface as opposed to a Spanned interface. The management interface lets you connect directly to each unit. This Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firepower Management Center. It uses its own local authentication, IP address, and static routing. Each cluster member uses a separate IP address on the management network that you set as part of the bootstrap configuration.

The management interface is shared between the Management logical interface and the *Diagnostic* logical interface. The Diagnostic logical interface is optional and is not configured as part of the bootstrap configuration. The Diagnostic interface can be configured along with the rest of the data interfaces. If you choose to configure the Diagnostic interface, configure a Main cluster IP address as a fixed address for the cluster that always belongs to the current control unit. You also configure a range of addresses so that each unit, including the current control unit, can use a Local address from the range. The Main cluster IP address provides consistent diagnostic access to an address; when a control unit changes, the Main cluster IP address moves to the new control unit, so access to the cluster continues seamlessly. For outbound management traffic such as TFTP or syslog, each unit, including the control unit, uses the Local IP address to connect to the server.

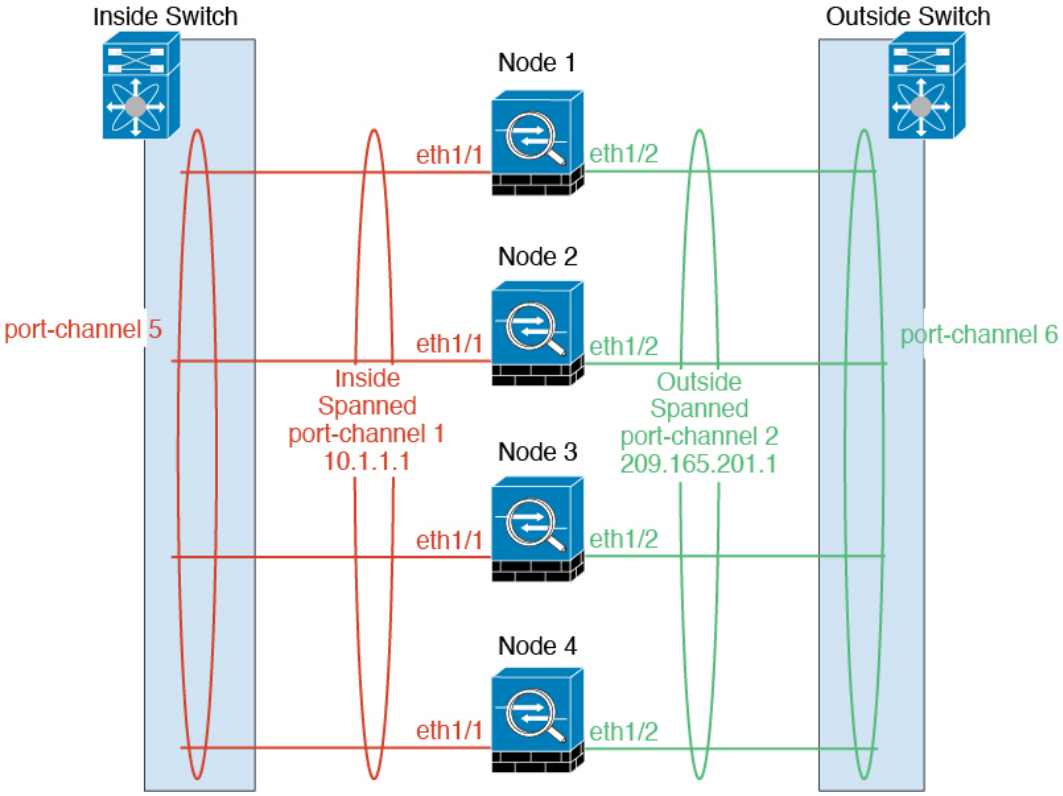
Cluster Interfaces

For a cluster isolated to security modules within one Firepower 9300 chassis, you can assign both physical interfaces or EtherChannels (also known as port channels) to the cluster. Interfaces assigned to the cluster are Spanned interfaces that load-balance traffic across all members of the cluster.

For clustering with multiple chassis, you can only assign data EtherChannels to the cluster. These Spanned EtherChannels include the same member interfaces on each chassis; on the upstream switch, all of these interfaces are included in a single EtherChannel, so the switch does not know that it is connected to multiple devices.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Individual interfaces are not supported, with the exception of a management interface.



Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

For multi-instance clusters, each cluster requires dedicated data EtherChannels; you cannot use shared interfaces or VLAN subinterfaces.

Connecting to a Redundant Switch System

We recommend connecting EtherChannels to a redundant switch system such as a VSS, vPC, StackWise, or StackWise Virtual system to provide redundancy for your interfaces.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Licenses for Clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add a cluster node to the FMC, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management** > **Cluster** > **License** area.

Note If you add the cluster before the FMC is licensed (and running in Evaluation mode), then when you license the FMC, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Clustering

Cluster Model Support

The FTD supports clustering on the following models:

- Firepower 9300— You can include up to 6 nodes in the cluster. For example, you can use 1 module in 6 chassis, or 2 modules in 3 chassis, or any combination that provides a maximum of 6 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 6 nodes using clustering with multiple chassis.

User Roles

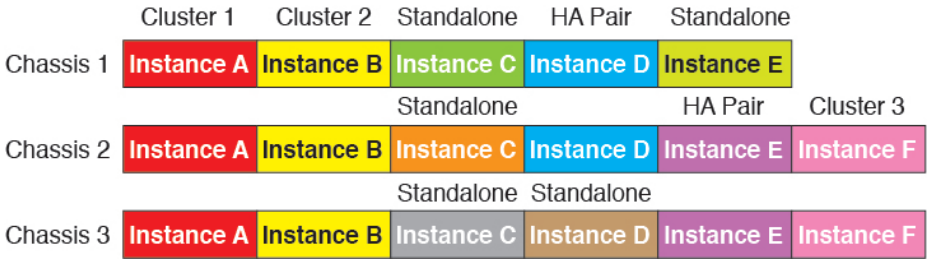
- Admin
- Access Admin
- Network Admin

Clustering Hardware and Software Requirements

All chassis in a cluster:

- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.

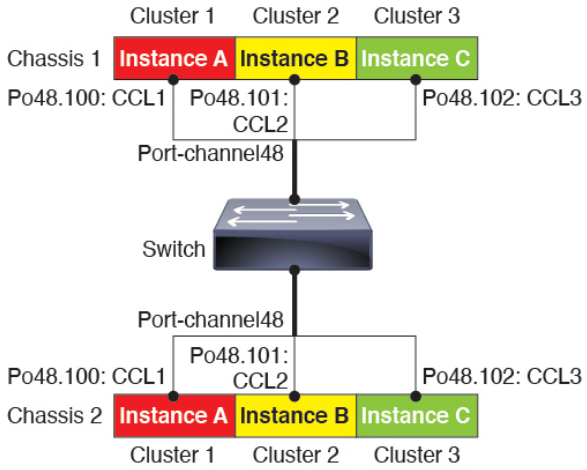
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



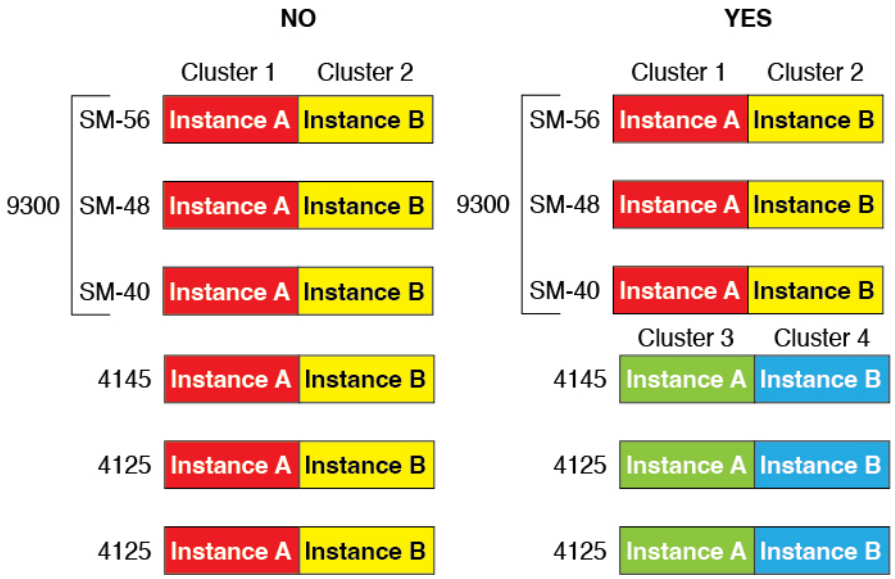
- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firepower Threat Defense, the FMC must also use the same NTP server. Do not set the time manually.

Multi-Instance Clustering Requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.



- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.



- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch Requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.

- For supported switch characteristics, see Cisco FXOS Compatibility.

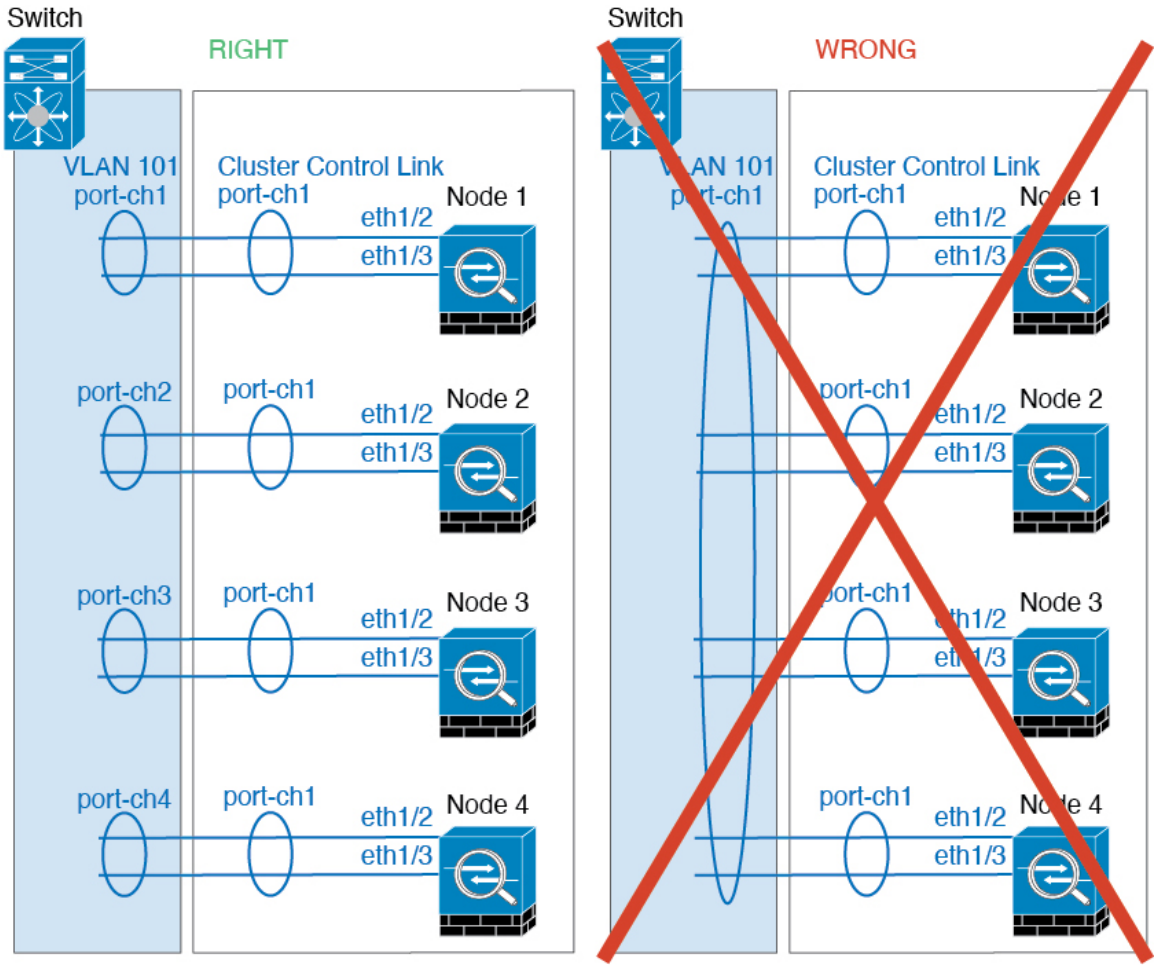
Clustering Guidelines and Limitations

Switches for Clustering

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.



- Firepower 4100/9300 clusters support LACP graceful convergence. So you can leave LACP graceful convergence enabled on connected Cisco Nexus switches.
- When you see slow bundling of a Spanned EtherChannel on the switch, you can enable LACP rate fast for an individual interface on the switch. FXOS EtherChannels have the LACP rate set to fast by default. Note that some switches, such as the Nexus series, do not support LACP rate fast when performing in-service software upgrades (ISSUs), so we do not recommend using ISSUs with clustering.

EtherChannels for Clustering

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

  - Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional Guidelines

- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang connections; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel interface, when the syslog server port is down, and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the cluster. These messages can result in some units of the cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- We recommend connecting EtherChannels to a VSS, vPC, StackWise, or StackWise Virtual for redundancy.
- Within a chassis, you cannot cluster some security modules and run other security modules in standalone mode; you must include all security modules in the cluster.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a

new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults

- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is set to unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is set to 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Clustering

You can easily deploy the cluster from the Firepower 4100/9300 supervisor. All initial configuration is automatically generated for each unit. You can then add the units to the FMC and group them into a cluster.

FXOS: Add a FTD Cluster

In native mode: You can add a cluster to a single Firepower 9300 chassis that is isolated to security modules within the chassis, or you can use multiple chassis.

In multi-instance mode: You can add one or more clusters to a single Firepower 9300 chassis that are isolated to security modules within the chassis (you must include an instance on each module), or add one or more clusters on multiple chassis.

For clusters on multiple chassis, you must configure each chassis separately. Add the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment

Create a FTD Cluster

You can easily deploy the cluster from the Firepower 4100/9300 chassis supervisor. All initial configuration is automatically generated for each unit.

For clustering on multiple chassis, you must configure each chassis separately. Deploy the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment.

In a Firepower 9300 chassis, you must enable clustering for all 3 module slots, or for container instances, a container instance in each slot, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.
- For container instances, if you do not want to use the default profile, add a resource profile according to Add a Resource Profile for Container Instances, on page 193.

- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the Reinitialize icon (). An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Management interface ID, IP addresses, and network mask
  - Gateway IP address
  - FMC IP address and/or NAT ID of your choosing
  - DNS server IP address
  - FTD hostname and domain name

Procedure

Step 1 Configure interfaces.

a) Add at least one Data type interface or EtherChannel (also known as a port-channel) before you deploy the cluster. See Add an EtherChannel (Port Channel), on page 189 or Configure a Physical Interface, on page 188.

For clustering on multiple chassis, all data interfaces must be Spanned EtherChannels with at least one member interface. Add the same EtherChannels on each chassis. Combine the member interfaces from all cluster units into a single EtherChannel on the switch. See Clustering Guidelines and Limitations, on page 296 for more information about EtherChannels.

For multi-instance clustering, you cannot use FXOS-defined VLAN subinterfaces or data-sharing interfaces in the cluster. Only application-defined subinterfaces are supported. See FXOS Interfaces vs. Application Interfaces, on page 156 for more information.

b) Add a Management type interface or EtherChannel. See Add an EtherChannel (Port Channel), on page 189 or Configure a Physical Interface, on page 188.

The management interface is required. Note that this management interface is not the same as the chassis management interface that is used only for chassis management (in FXOS, you might see the chassis management interface displayed as MGMT, management0, or other similar names).

For clustering on multiple chassis, add the same Management interface on each chassis.

For multi-instance clustering, you can share the same management interface across multiple clusters on the same chassis, or with standalone instances.

c) For clustering on multiple chassis, add a member interface to the cluster control link EtherChannel (by default, port-channel 48). See Add an EtherChannel (Port Channel), on page 189.

Do not add a member interface for a cluster isolated to security modules within one Firepower 9300 chassis. If you add a member, the chassis assumes this cluster will be using multiple chassis, and will only allow you to use Spanned EtherChannels, for example.

On the **Interfaces** tab, the port-channel 48 cluster type interface shows the **Operation State** as **failed** if it does not include any member interfaces. For a cluster isolated to security modules within one Firepower 9300 chassis, this EtherChannel does not require any member interfaces, and you can ignore this Operational State.

Add the same member interfaces on each chassis. The cluster control link is a device-local EtherChannel on each chassis. Use separate EtherChannels on the switch per device. See Clustering Guidelines and Limitations, on page 296 for more information about EtherChannels.

For multi-instance clustering, you can create additional Cluster type EtherChannels. Unlike the Management interface, the cluster control link is *not* sharable across multiple devices, so you will need a Cluster interface for each cluster. However, we recommend using VLAN subinterfaces instead of multiple EtherChannels; see the next step to add a VLAN subinterface to the Cluster interface.

d) For multi-instance clustering, add VLAN subinterfaces to the cluster EtherChannel so you have a subinterface for each cluster. See Add a VLAN Subinterface for Container Instances, on page 191.

If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

e) (Optional) Add an eventing interface. See Add an EtherChannel (Port Channel), on page 189 or Configure a Physical Interface, on page 188.

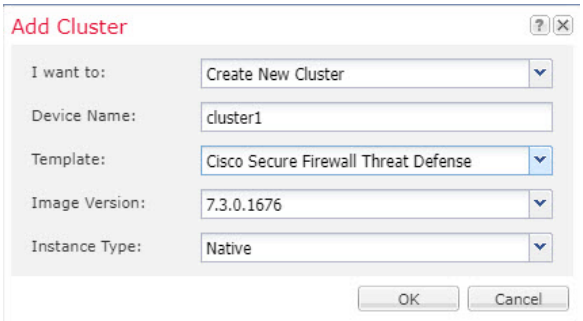
This interface is a secondary management interface for the FTD devices. To use this interface, you must configure its IP address and other parameters at the FTD CLI. For example, you can separate management traffic from events (such as web events). See the **configure network** commands in the FTD command reference.

For clustering on multiple chassis, add the same eventing interface on each chassis.

Step 2 Choose **Logical Devices**.

Step 3 Click **Add** > **Cluster**, and set the following parameters:

Figure 102: Native Cluster



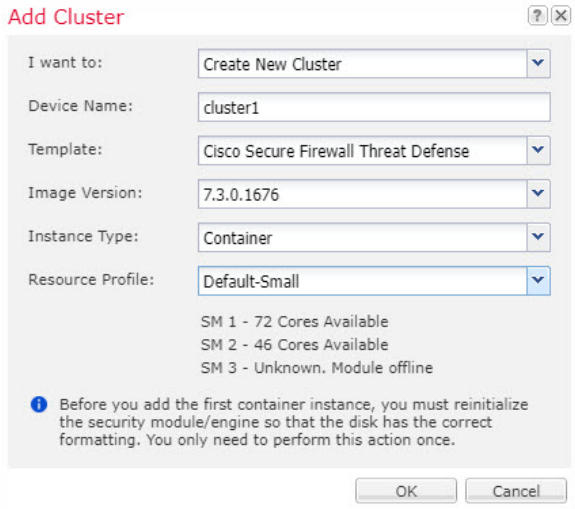


Figure 103: Multi-Instance Cluster

a) Choose **I want to:** > **Create New Cluster**
b) Provide a **Device Name**.

   This name is used internally by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

c) For the **Template**, choose **Cisco Firepower Threat Defense**.
d) Choose the **Image Version**.
e) For the **Instance Type**, choose either **Native** or **Container**.

   A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

f) (Container Instance only) For the **Resource Type**, choose one of the resource profiles from the drop-down list.

   For the Firepower 9300, this profile will be applied to each instance on each security module. You can set different profiles per security module later in this procedure; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model. We recommend choosing the correct profile before you create the cluster. If you need to create a new profile, cancel out of the cluster creation, and add one using Add a Resource Profile for Container Instances, on page 193.

   Note
   If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they reboot and come back up, you can apply the new profile to the control node.

g) Click **OK**.

   You see the Provisioning - *device name* window.

Step 4 Choose the interfaces you want to assign to this cluster.

For native mode clustering: All valid interfaces are assigned by default. If you defined multiple Cluster type interfaces, deselect all but one.

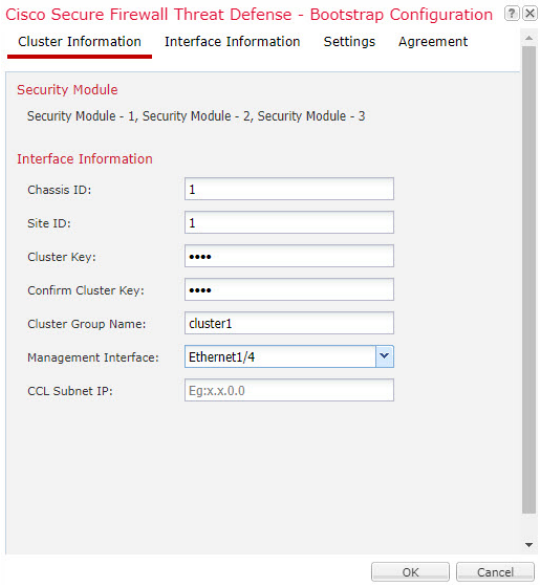
For multi-instance clustering: Choose each data interface you want to assign to the cluster, and also choose the Cluster type port-channel or port-channel subinterface.

Step 5 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 6 On the **Cluster Information** page, complete the following.

Figure 104: Native Cluster



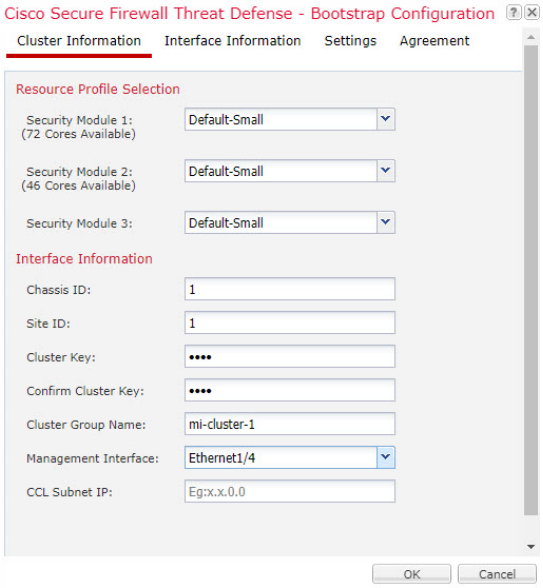


Figure 105: Multi-Instance Cluster

a) (Container Instance for the Firepower 9300 only) In the **Security Module (SM) and Resource Profile Selection** area, you can set a different resource profile per module; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model.

b) For clustering on multiple chassis, in the **Chassis ID** field, enter a chassis ID. Each chassis in the cluster must use a unique ID.

   This field only appears if you added a member interface to cluster control link Port-Channel 48.

c) For inter-site clustering, in the **Site ID** field, enter the site ID for this chassis between 1 and 8. FlexConfig feature. Additional inter-site cluster customizations to enhance redundancy and stability, such as director

localization, site redundancy, and cluster flow mobility, are only configurable using the FMC FlexConfig feature.

d) In the **Cluster Key** field, configure an authentication key for control traffic on the cluster control link.

The shared secret is an ASCII string from 1 to 63 characters. The shared secret is used to generate the key. This option does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

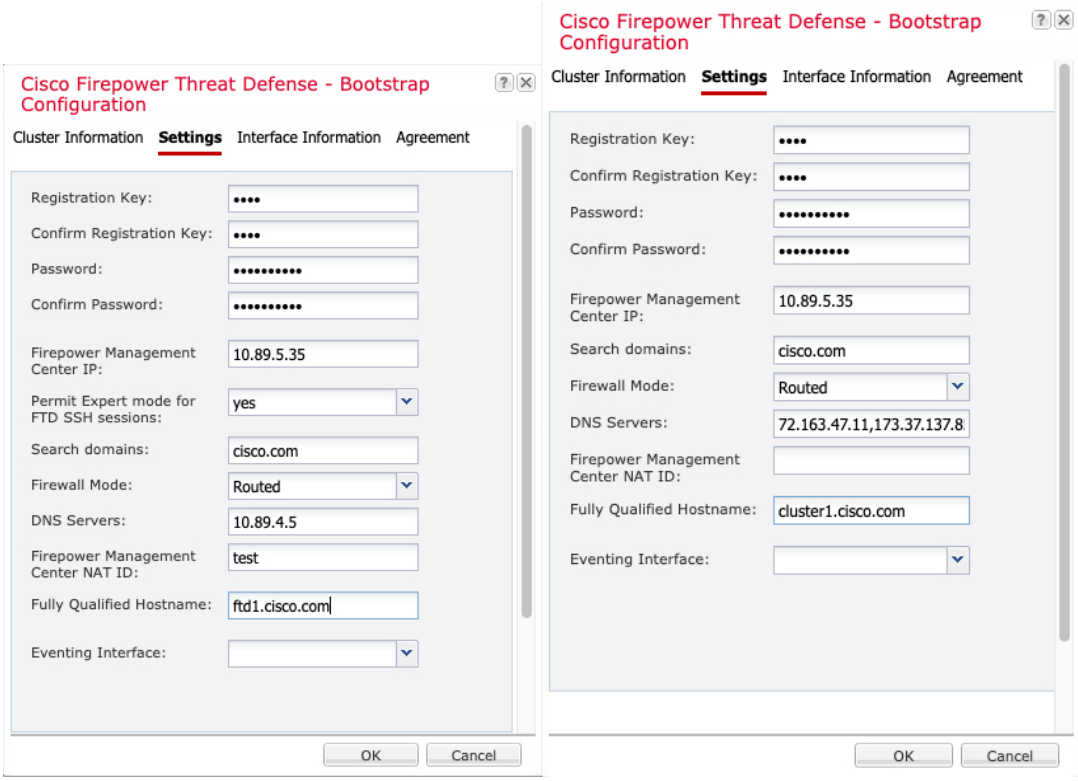
e) Set the **Cluster Group Name**, which is the cluster group name in the logical device configuration.

The name must be an ASCII string from 1 to 38 characters.

Important
From 2.4.1, spaces in cluster group name will be considered as special characters and may result in error while deploying the logical devices. To avoid this issue, you must rename the cluster group name without a space.

f) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.



If you assign a Hardware Bypass-capable interface as the Management interface, you see a warning message to make sure your assignment is intentional.

g) (Optional) Set the **CCL Subnet IP** as ***a.b*.0.0**.

By default, the cluster control link uses the 127.2.0.0/16 network. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. In this case, specify any /16 network address on a unique network for the cluster, except for loopback (127.0.0.0/8), multicast (224.0.0.0/4), and internal (169.254.0.0/16) addresses. If you set the value to 0.0.0.0, then the default network is used.

The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: *a.b.chassis_id.slot_id*.

Step 7 On the **Settings** page, complete the following.

a) In the **Registration Key** field, enter the key to be shared between the FMC and the cluster members during registration.

   You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the FMC when you add the Firepower Threat Defense.

b) Enter a **Password** for the Firepower Threat Defense admin user for CLI access.

c) In the **Firepower Management Center IP** field, enter the IP address of the managing FMC. If you do not know the FMC IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

d) (Optional) For a container instance, **Permit Expert mode from FTD SSH sessions**: **Yes** or **No**. Expert Mode provides Firepower Threat Defense shell access for advanced troubleshooting.

   If you choose **Yes** for this option, then users who access the container instance directly from an SSH sesssion can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

   Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firepower Threat Defense CLI.

e) (Optional) In the **Search Domains** field, enter a comma-separated list of search domains for the management network.

f) (Optional) From the **Firewall Mode** drop-down list, choose **Transparent** or **Routed**.

   In routed mode, the Firepower Threat Defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.

The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

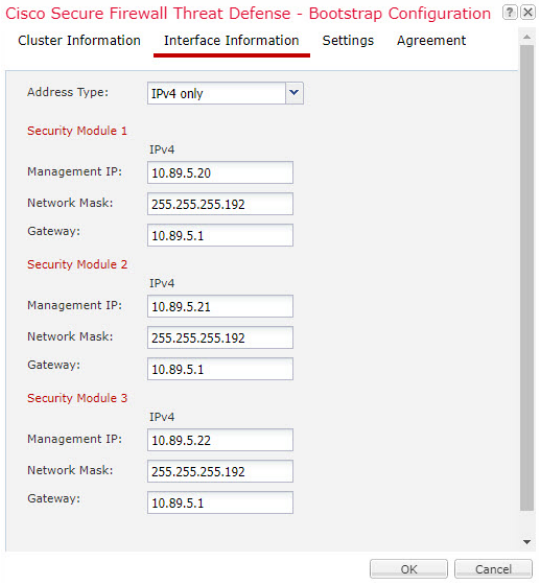
g) (Optional) In the **DNS Servers** field, enter a comma-separated list of DNS servers.

The Firepower Threat Defense uses DNS if you specify a hostname for the FMC, for example.

h) (Optional) In the **Firepower Management Center NAT ID** field, enter a passphrase that you will also enter on the FMC when you add the cluster as a new device.

Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the FMC specifies the device IP address, and the device specifies the FMC IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. You can specify any text string as the NAT ID, from 1 to 37 characters. The FMC and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

i) (Optional) In the **Fully Qualified Hostname** field, enter a fully qualified name for the Firepower Threat Defense device.



Valid characters are the letters from a to z, the digits from 0 to 9, the dot (.), and the hyphen (-); maximum number of characters is 253.

j) (Optional) From the **Eventing Interface** drop-down list, choose the interface on which events should be sent. If not specified, the management interface will be used.

To specify a separate interface to use for events, you must configure an interface as a *firepower-eventing* interface. If you assign a Hardware Bypass-capable interface as the Eventing interface, you see a warning message to make sure your assignment is intentional.

Step 8 On the **Interface Information** page, configure a management IP address for each security module in the cluster. Select the type of address from the **Address Type** drop-down list and then complete the following for each security module.

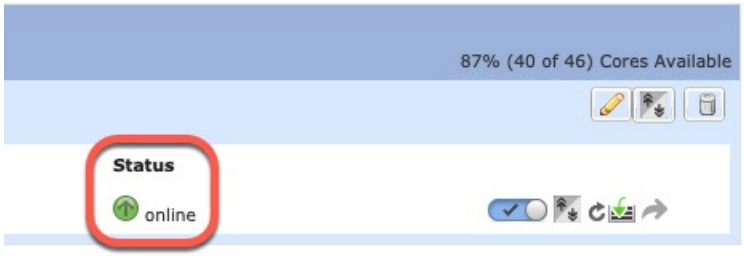
Note
You must set the IP address for all 3 module slots in a chassis, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

a) In the **Management IP** field, configure an IP address.

   Specify a unique IP address on the same network for each module.

b) Enter a **Network Mask** or **Prefix Length**.

c) Enter a **Network Gateway** address.



Step 9 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 10 Click **OK** to close the configuration dialog box.

Step 11 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can add the remaining cluster chassis, or for a cluster isolated to security modules within one Firepower 9300 chassis, start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

Step 12 For clustering on multiple chassis, add the next chassis to the cluster:

a) On the first chassis of the Firepower Chassis Manager, click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

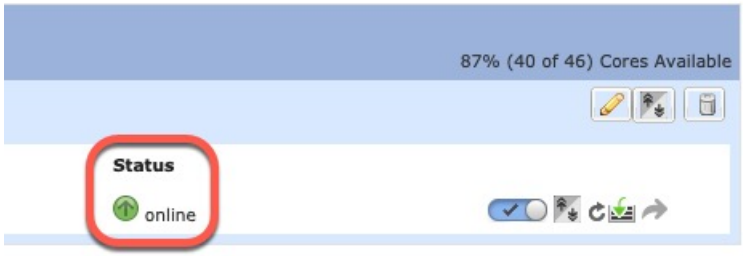
b) Connect to the Firepower Chassis Manager on the next chassis, and add a logical device according to this procedure.

c) Choose **I want to: > Join an Existing Cluster**.

d) Click **OK**.

e) In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.

f) Click the device icon in the center of the screen. The cluster information is mostly pre-filled, but you must change the following settings:



- **Chassis ID**—Enter a unique chassis ID.
- **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FMC FlexConfig feature.
- **Cluster Key**—(Not prefilled) Enter the same cluster key.
- **Management IP**—Change the management address for each module to be a unique IP address on the same network as the other cluster members.

Click **OK**.

g) Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

Step 13 Add the control unit to the FMC using the management IP address.

All cluster units must be in a successfully-formed cluster on FXOS prior to adding them to FMC.

The FMC then automatically detects the data units.

Add More Cluster Nodes

Add or replace the Firepower Threat Defense cluster node in an existing cluster. When you add a new cluster node in FXOS, the FMC adds the node automatically.

Note The FXOS steps in this procedure only apply to adding a new *chassis*; if you are adding a new module to a Firepower 9300 where clustering is already enabled, the module will be added automatically.

Before you begin

- In the case of a replacement, you must delete the old cluster node from the FMC. When you replace it with a new node, it is considered to be a new device on the FMC.
- The interface configuration must be the same on the new chassis. You can export and import FXOS chassis configuration to make this process easier.

Procedure

Step 1 If you previously upgraded the Firepower Threat Defense image using the FMC, perform the following steps *on each chassis in the cluster*.

When you upgraded from the FMC, the startup version in the FXOS configuration was not updated, and the standalone package was not installed on the chassis. Both of these items need to be set manually so the new node can join the cluster using the correct image version.

Note
If you only applied a patch release, you can skip this step. Cisco does not provide standalone packages for patches.

a) Install the running Firepower Threat Defense image on the chassis using the **System** > **Updates** page.
b) Click **Logical Devices** and click the Set Version icon ( ). For a Firepower 9300 with multiple modules, set the version for each module.

The **Startup Version** shows the original package you deployed with. The **Current Version** shows the version you upgraded to.

c) In the **New Version** drop-down menu, choose the version that you uploaded. This version should match the **Current Version** displayed, and will set the startup version to match the new version.
d) On the new chassis, make sure the new image package is installed.

Step 2 On an existing cluster chassis Firepower Chassis Manager, click **Logical Devices**.

Step 3 Click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

Step 4 Connect to the Firepower Chassis Manager on the new chassis, and click **Add** > **Cluster**.

Step 5 For the **Device Name**, provide a name for the logical device.

Step 6 Click **OK**.

Step 7 In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.

Step 8 Click the device icon in the center of the screen. The cluster information is partly pre-filled, but you must fill in the following settings:

Figure 106: Cluster Information

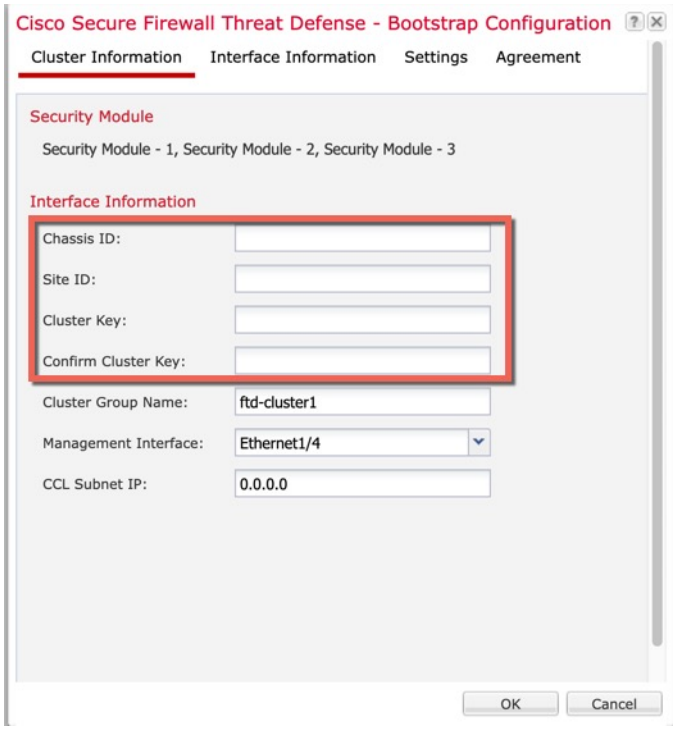


Figure 107: Interface Information

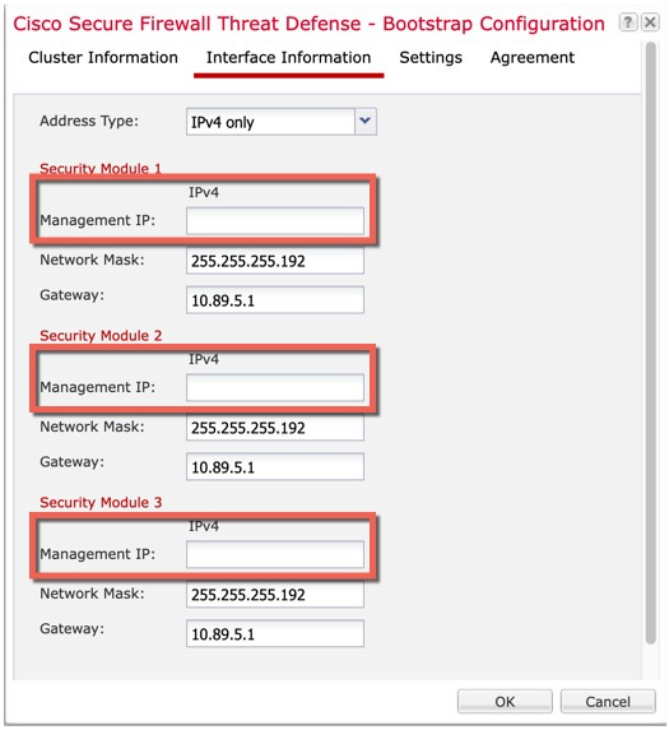

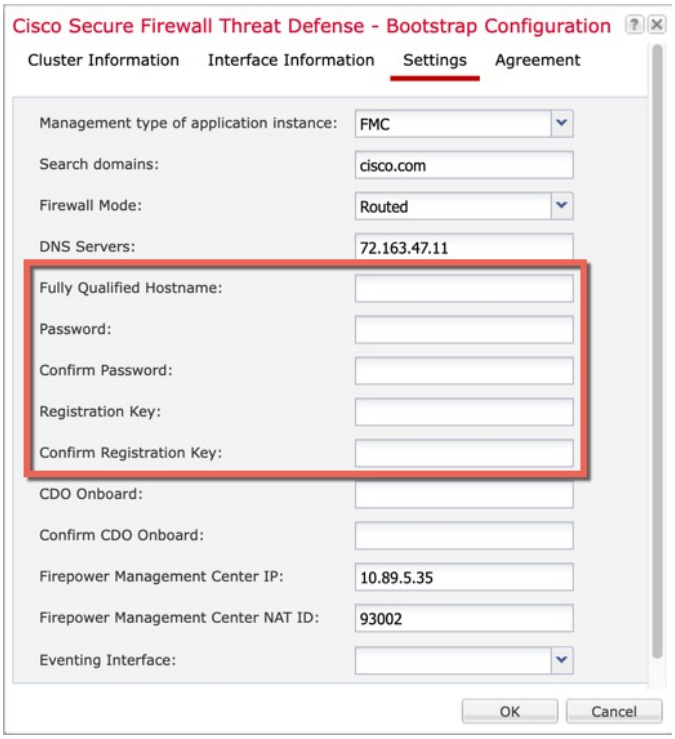

Figure 108: Settings

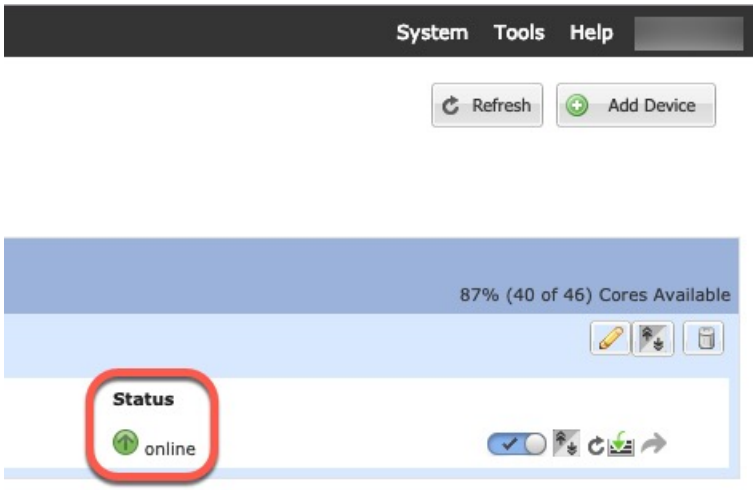


- **Chassis ID**—Enter a *unique* chassis ID.

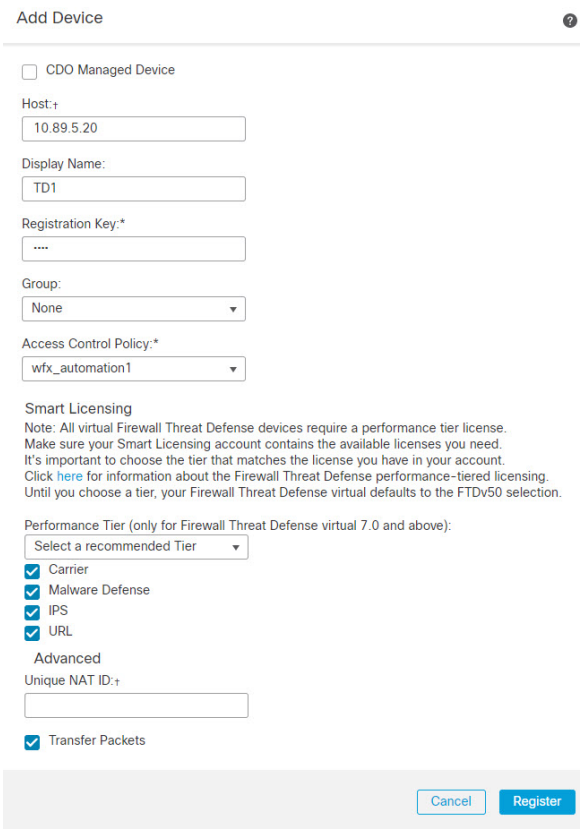
- **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. This feature is only configurable using the FMC FlexConfig feature.
- **Cluster Key**—Enter the *same* cluster key.
- **Management IP**—Change the management address for each module to be a *unique* IP address on the same network as the other cluster members.
- **Fully Qualified Hostname**—Enter the *same* hostname.
- **Password**—Enter the *same* password.
- **Registration Key**—Enter the *same* registration key.

Click **OK**.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

FMC: Add a Cluster



Add one of the cluster units as a new device to the Firepower Management Center; the FMC auto-detects all other cluster members.

Before you begin

- All cluster units must be in a successfully-formed cluster on FXOS prior to adding the cluster to the FMC. You should also check which unit is the control unit. Refer to the Firepower Chassis Manager **Logical Devices** screen or use the FTD **show cluster info** command.

Procedure

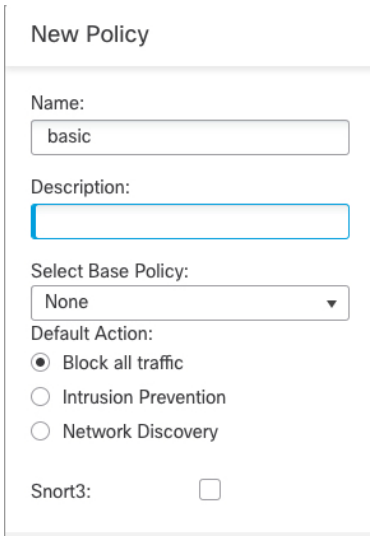
Step 1 In the FMC, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address you assigned when you deployed the cluster.

a) In the **Host** field, enter the IP address or hostname of the control unit.

We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

If you used a NAT ID during device setup, you may not need to enter this field. For more information, see NAT Environments, on page 6.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the FMC.



This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used when you deployed the cluster in FXOS. The registration key is a one-time-use shared secret.

d) (Optional) Add the device to a device **Group**.

e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

f) Choose licenses to apply to the device.

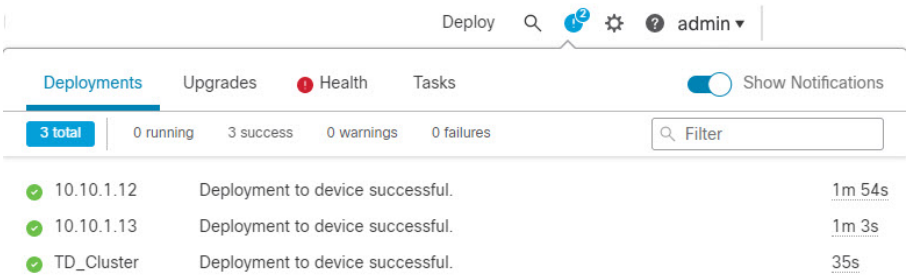
g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.

h) Check the **Transfer Packets** check box to allow the device to transfer packets to the FMC.

This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the FMC for inspection. If you disable it, only event information will be sent to the FMC but packet data is not sent.

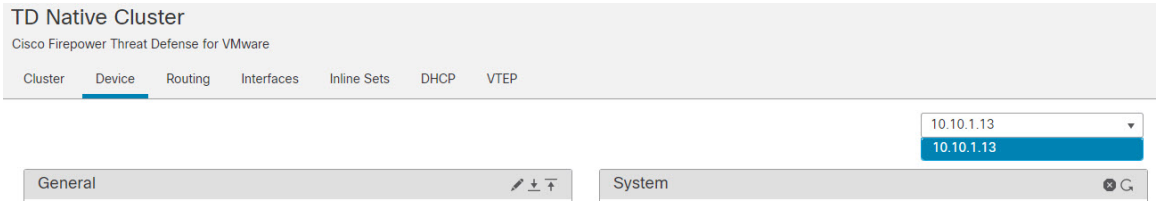
i) Click **Register**.

The FMC identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up on the chassis, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.



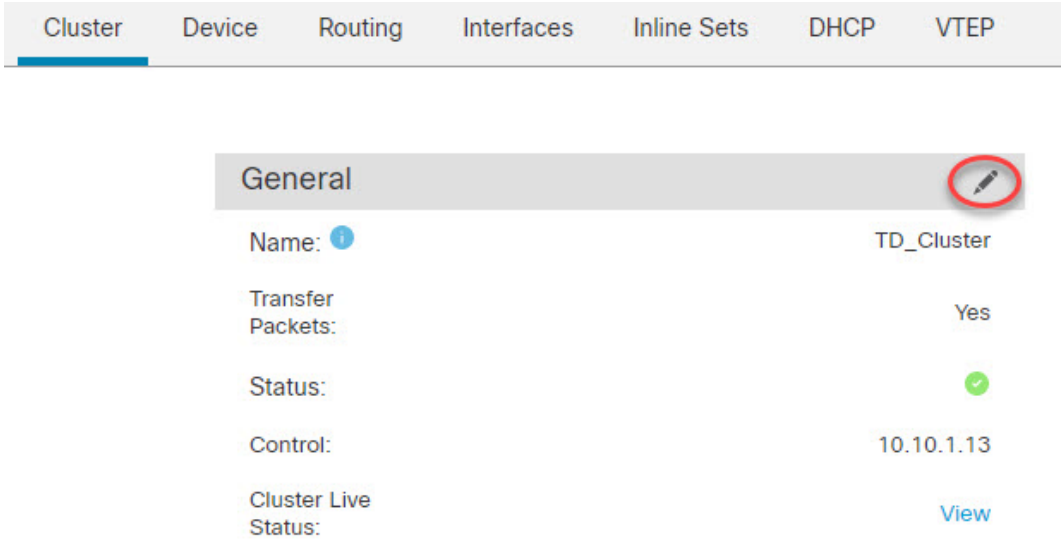
The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

A unit that is currently registering shows the loading icon.



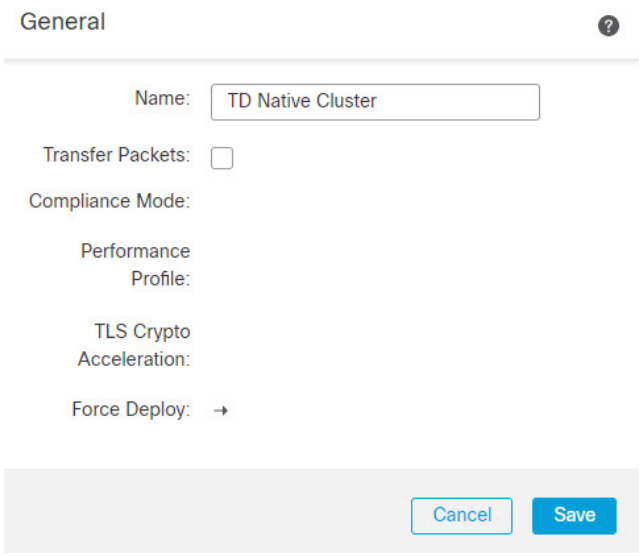
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The FMC updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile Cluster Members, on page 327.

Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

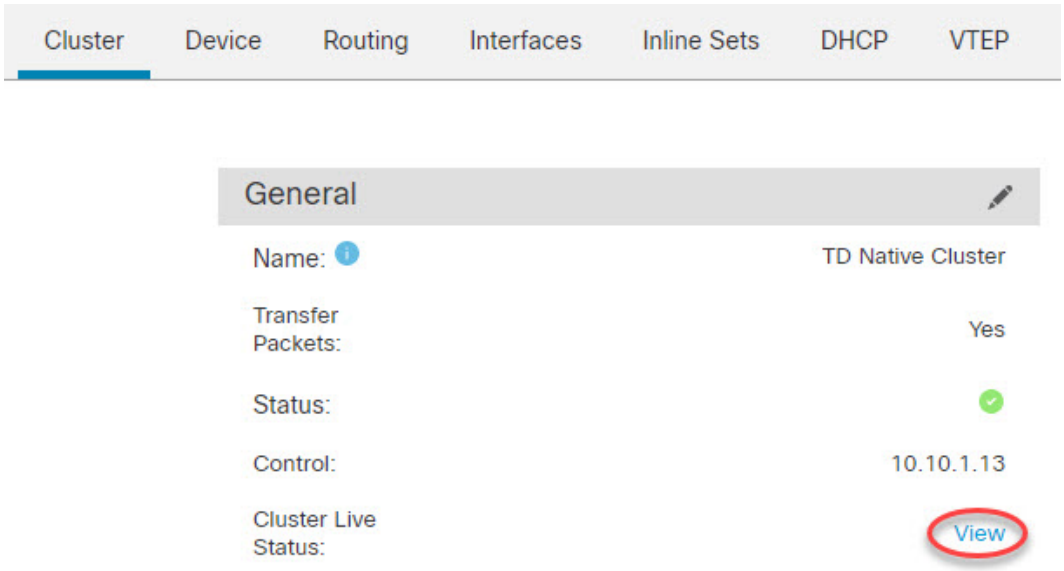


Most configuration can be applied to the cluster as a whole, and not member units in the cluster. For example, you can change the display name per unit, but you can only configure interfaces for the whole cluster.

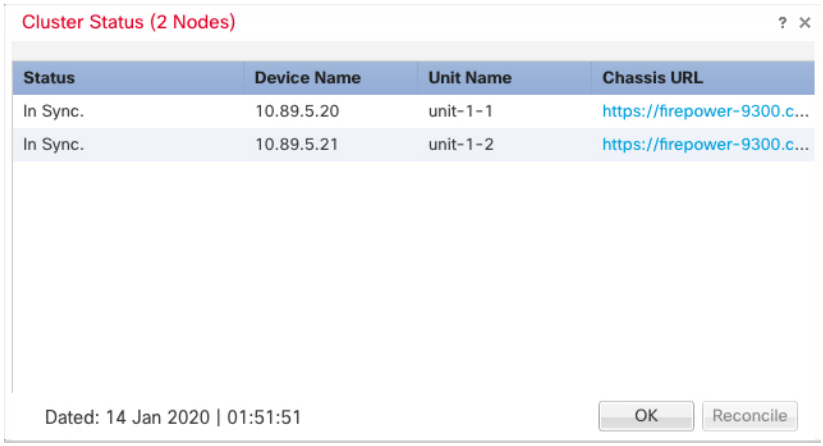
Step 3 On the **Devices** > **Device Management** > **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.



See the following cluster-specific items:

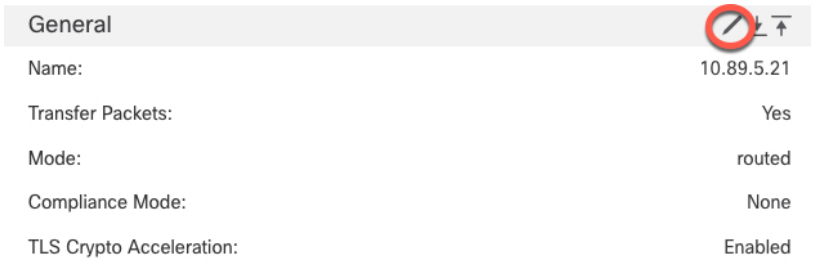


- **General** > **Name**—Change the cluster display name by clicking the **Edit** (✎).

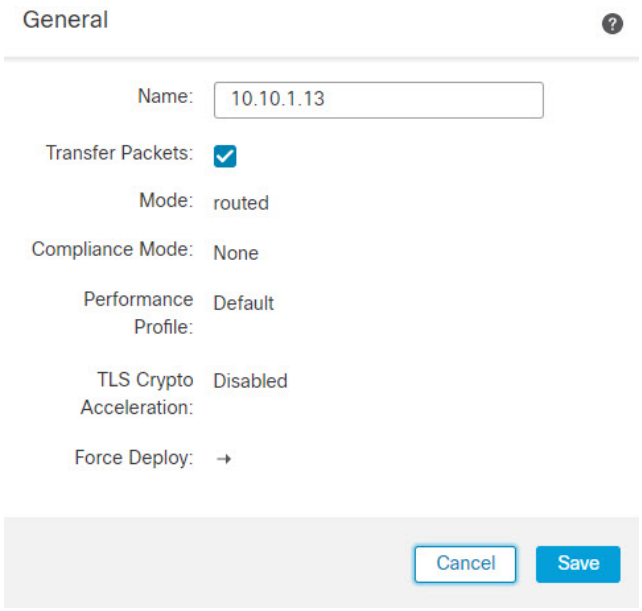


Then set the **Name** field.

- **General > View cluster status**—Click the **View cluster status** link to open the **Cluster Status** dialog box.

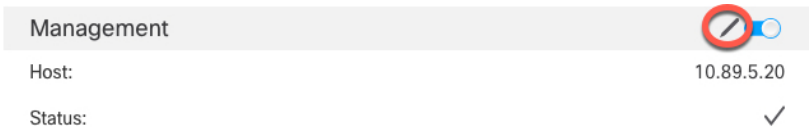


The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.



- **License**—Click **Edit** ( ) to set license entitlements.

Step 4 On the **Devices** > **Device Management** > **Devices**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.



- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ).

Then set the **Name** field.

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the FMC so that it can reach the device on the network; edit the **Host** address in the **Management** area.

FMC: Configure Cluster, Data, and Diagnostic Interfaces

This procedure configures basic parameters for each data interface that you assigned to the cluster when you deployed it in FXOS. For clustering on multiple chassis, data interfaces are always Spanned EtherChannel interfaces. For the cluster control link interface for a cluster isolated to security modules within one Firepower 9300 chassis, you must increase the MTU from the default. You can also configure the Diagnostic interface, which is the only interface that can run as an individual interface.

Note When using Spanned EtherChannels for clustering on multiple chassis, the port-channel interface will not come up until clustering is fully enabled. This requirement prevents traffic from being forwarded to a unit that is not an active unit in the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure the cluster control link.

For clustering on multiple chassis, set the cluster control link MTU to be at least 100 bytes higher than the highest MTU of the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. We suggest setting the MTU to the maximum of 9184; the minimum value is 1400 bytes. For example, because the maximum MTU is 9184, then the highest data interface MTU can be 9084, while the cluster control link can be set to 9184.

For native clusters: The cluster control link interface is Port-Channel48 by default. If you don't know which interface is the cluster control link, check the FXOS configuration for chassis for the Cluster-type interface assigned to the cluster.

a) Click **Edit** (✎) for the cluster control link interface.
b) On the **General** page, in the **MTU** field, enter a value between 1400 and 9184but not between 2561 and 8362. Due to block pool handling, this MTU size is not optimal for system operation. We suggest using the maximum, 9184.
c) Click **OK**.

Step 4 Configure data interfaces.

a) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the data interface. The rest of this procedure applies to the subinterfaces. See Add a Subinterface, on page 396.
b) Click **Edit** (✎) for the data interface.
c) Configure the name and other parameters. For regular firewall interfaces, see Configure Routed Mode Interfaces, on page 406 or, for transparent mode, Configure Bridge Group Interfaces, on page 411. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 433..

Note
If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. See, Step 3, on page 320 to increase the cluster control link MTU, after which you can continue configuring the data interfaces.

d) For clustering on multiple chassis, set a unique. manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

e) Click **OK**. Repeat the above steps for other data interfaces.

Step 5 (Optional) Configure the Diagnostic interface.

The Diagnostic interface is the only interface that can run in Individual interface mode. You can use this interface for syslog messages or SNMP, for example.

a) Choose **Objects** > **Object Management** > **Address Pools** to add an IPv4 and/or IPv6 address pool. See Address Pools, on page 859.

Include at least as many addresses as there are units in the cluster. The Virtual IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

b) On **Devices** > **Device Management** > **Interfaces**, click **Edit** ( ) for the Diagnostic interface.
c) On the **IPv4**, enter the **IP Address** and mask. This IP address is a fixed address for the cluster, and always belongs to the current control unit.
d) From the **IPv4 Address Pool** drop-down list, choose the address pool you created.
e) On **IPv6 > Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.
f) Configure other interface settings as normal.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

FXOS: Remove a Cluster Node

The following sections describe how to remove nodes temporarily or permanently from the cluster.

Temporary Removal

A cluster node will be automatically removed from the cluster due to a hardware or network failure, for example. This removal is temporary until the conditions are rectified, and it can rejoin the cluster. You can also manually disable clustering.

To check whether a device is currently in the cluster, check the cluster status on the Firepower Chassis Manager **Logical Devices** page:

For FTD using the FMC, you should leave the device in the FMC device list so that it can resume full functionality after you reenable clustering.

- Disable clustering in the application—You can disable clustering using the application CLI. Enter the **cluster remove unit** *name* command to remove any node other than the one you are logged into. The bootstrap configuration remains intact, as well as the last configuration synced from the control node, so you can later re-add the node without losing your configuration. If you enter this command on a data node to remove the control node, a new control node is elected.

  When a device becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, re-enable clustering. The Management interface remains up using the IP address the node received from the bootstrap configuration. However if you reload, and the node is still inactive in the cluster , the Management interface is disabled.

  To reenable clustering, on the FTD enter **cluster enable**.

- Disable the application instance—In the Firepower Chassis Manager on the **Logical Devices** page, click the **Slider enabled** (). You can later reenable it using the **Slider disabled** ().
- Shut down the security module/engine—In the Firepower Chassis Manager on the **Security Module/Engine** page, click the **Power Off icon**.
- Shut down the chassis—In the Firepower Chassis Manager on the **Overview** page, click the **Shut Down icon**.

Permanent Removal

You can permanently remove a cluster node using the following methods.

For FTD using the FMC, be sure to remove the node from the FMC device list after you disable clustering on the chassis.

- Delete the logical device—In the Firepower Chassis Manager on the **Logical Devices** page, click the **Delete** (). You can then deploy a standalone logical device, a new cluster, or even add a new logical device to the same cluster.
- Remove the chassis or security module from service—If you remove a device from service, you can add replacement hardware as a new node of the cluster.

FMC: Manage Cluster Members

After you deploy the cluster, you can change the configuration and manage cluster members.

Add a New Cluster Member

When you add a new cluster member in FXOS, the Firepower Management Center adds the member automatically.

Before you begin

- Make sure the interface configuration is the same on the replacement unit as for the other chassis.

Procedure

Step 1 Add the new unit to the cluster in FXOS. See the FXOS configuration guide.

Wait for the new unit to be added to the cluster. Refer to the Firepower Chassis Manager **Logical Devices** screen or use the FTD **show cluster info** command to view cluster status.

Step 2 The new cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (which is available from the **Devices** > **Device Management More** (⋮) icon or from the **Devices** > **Device Management** > **Cluster** tab > **General** area > **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the FMC attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile**.
- System status > **Tasks** —The FMC shows all registration events and failures.
- **Devices** > **Device Management**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

Replace a Cluster Member

You can replace a cluster member in an existing cluster. The FMC auto-detects the replacement unit. However, you must manually delete the old cluster member in the FMC. This procedure also applies to a unit that was reinitialized; in this case, although the hardware remains the same, it appears to be a new member.

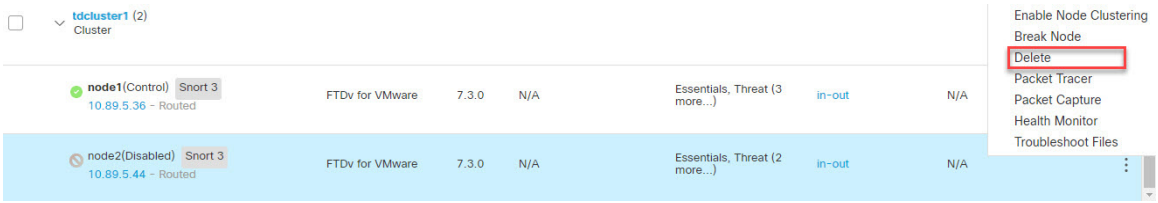
Before you begin

- Make sure the interface configuration is the same on the replacement unit as for other chassis.

Procedure

Step 1 For a new chassis, if possible, backup and restore the configuration from the old chassis in FXOS.

If you are replacing a module in a Firepower 9300, you do not need to perform these steps.



If you do not have a backup FXOS configuration from the old chassis, first perform the steps in Add a New Cluster Member, on page 322.

For information about all of the below steps, see the FXOS configuration guide.

a) Use the configuration export feature to export an XML file containing logical device and platform configuration settings for your Firepower 4100/9300 chassis.
b) Import the configuration file to the replacement chassis.
c) Accept the license agreement.

d) If necessary, upgrade the logical device application instance version to match the rest of the cluster.

Step 2 In the FMC for the old unit, choose **Devices** > **Device Management** > **More** (⋮) > **Delete** .

Step 3 Confirm that you want to delete the unit.

The unit is removed from the cluster and from the FMC devices list.

Step 4 The new or reinitialized cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

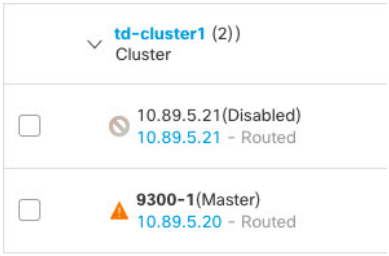
- **Cluster Status** dialog box (**Devices** > **Device Management** > **More** (⋮) icon or **Devices** > **Device Management** > **Cluster** page > **General** area > **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the FMC attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile All**.
- **System** (⚙) > **Tasks**—The FMC shows all registration events and failures.
- **Devices** > **Device Management**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

Deactivate a Member

You may want to deactivate a member in preparation for deleting the unit, or temporarily for maintenance. This procedure is meant to temporarily deactivate a member; the unit will still appear in the FMC device list.

Note When a unit becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, reenable clustering. The Management interface remains up using the IP address the unit received from the bootstrap configuration. However if you reload, and the unit is still inactive in the cluster, the management interface is disabled. You must use the console for any further configuration.

Procedure



Step 1 For the unit you want to deactivate, choose **Devices** > **Device Management** > **More** (⋮) > **Disable Clustering**.

You can also deactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management** > **More** (⋮) > **Cluster Live Status**).

Step 2 Confirm that you want to disable clustering on the unit.

The unit will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, see Rejoin the Cluster, on page 325.

Rejoin the Cluster

If a unit was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See Rejoining the Cluster, on page 339 for more information about why a unit can be removed from a cluster.

Procedure

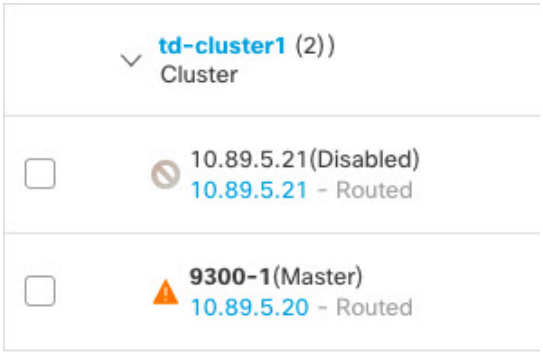
Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management** > **More** (⋮) > **Enable Clustering**.

You can also reactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management** > **More** (⋮) > **Cluster Live Status**).

Step 2 Confirm that you want to enable clustering on the unit.

Delete (Unregister) a Data Node

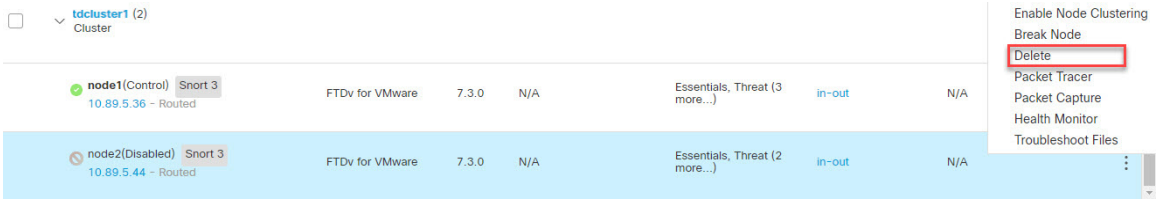
If you need to permanently remove a cluster node (for example, if you remove a module on the Firepower 9300, or remove a chassis), then you should unregister it from the FMC.



Do not unregister the node if it is still a healthy part of the cluster, or if you only want to disable the node temporarily. To remove it permanently from the cluster in FXOS, see FXOS: Remove a Cluster Node, on page 321. If you unregister it from the FMC, and it is still part of the cluster, it will continue to pass traffic, and could even become the control node—a control node that the FMC can no longer manage.

Before you begin

To manually deactivate the node, see Deactivate a Member, on page 324. Before you unregister a node, the node must be inactive, either manually or because of a health failure.



Procedure

Step 1 Make sure the node is ready to be unregistered from the FMC. On **Devices** > **Device Management**, make sure the node shows **(Disabled)**.

You can also view each node's status on the **Cluster Status** dialog box available from **More** (⋮). If the status is stale, click **Reconcile All** on the **Cluster Status** dialog box to force an update.

Step 2 In the FMC for the data node you want to delete, choose **Devices** > **Device Management** > **More** (⋮) > **Delete**.

Step 3 Confirm that you want to delete the node.

The node is removed from the cluster and from the FMC devices list.

Change the Control Unit

Caution The best method to change the control unit is to disable clustering on the control unit, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control unit, use the procedure in this section. Note that for centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

To change the control unit, perform the following steps.

Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management** > **More** (⋮) > **Cluster Live Status**.

You can also access the **Cluster Status** dialog box from **Devices** > **Device Management** > **Cluster** page > **General** area > **Cluster Live Status** link.

Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the checkbox, and click **OK**.

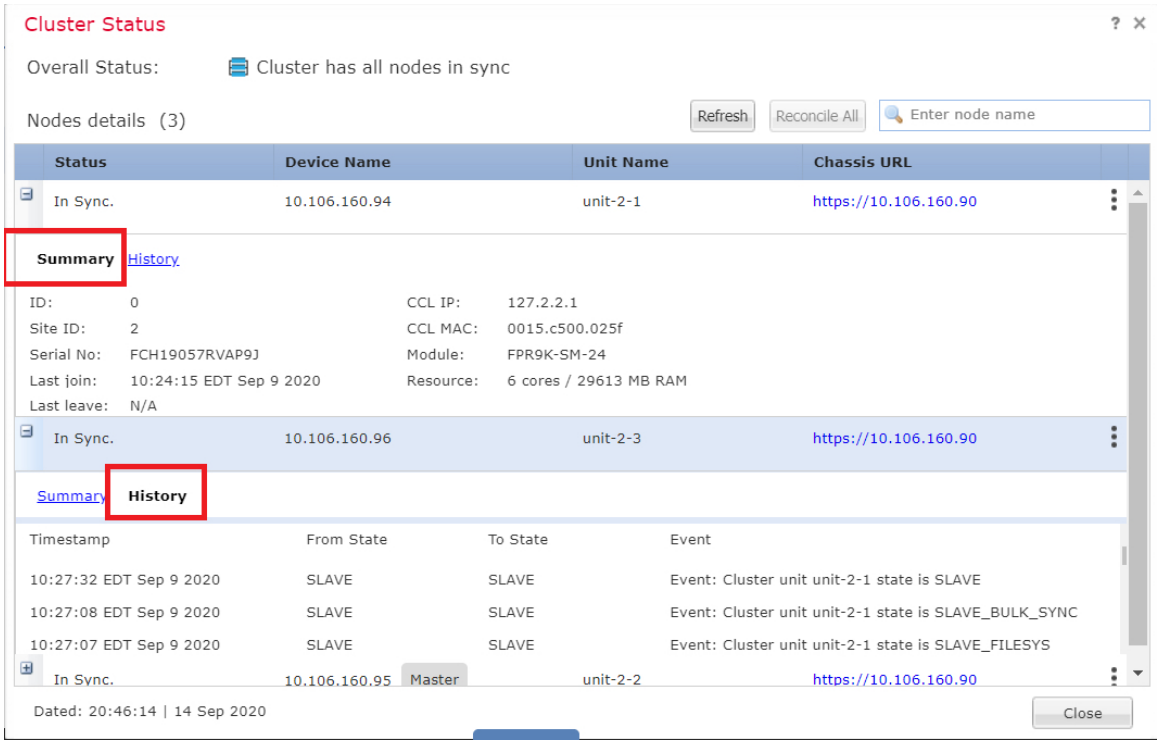
Reconcile Cluster Members

If a cluster member fails to register, you can reconcile the cluster membership from the chassis to the Firepower Management Center. For example, a data unit might fail to register if the FMC is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management** > **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

You can also open the **Cluster Status** dialog box from the **Devices** > **Device Management** > **Cluster** page > **General** area > **Cluster Live Status** link.



Step 2 Click **Reconcile All**.

For more information about the cluster status, see FMC: Monitoring the Cluster, on page 327.

FMC: Monitoring the Cluster

You can monitor the cluster in Firepower Management Center and at the FTD CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management** > **More** (⋮) icon or from the **Devices** > **Device Management** > **Cluster** page > **General** area > **Cluster Live Status** link.

The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The unit is registered with the FMC.
- Pending Registration—The unit is part of the cluster, but has not yet registered with the FMC. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The unit is registered with the FMC, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- Joining cluster...—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the FMC.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** (⋮) menu , you can perform the following status changes:

- **Disable Clustering**
- **Enable Clustering**
- **Change Role to Control**

- **System** (⚙) > **Tasks** page.

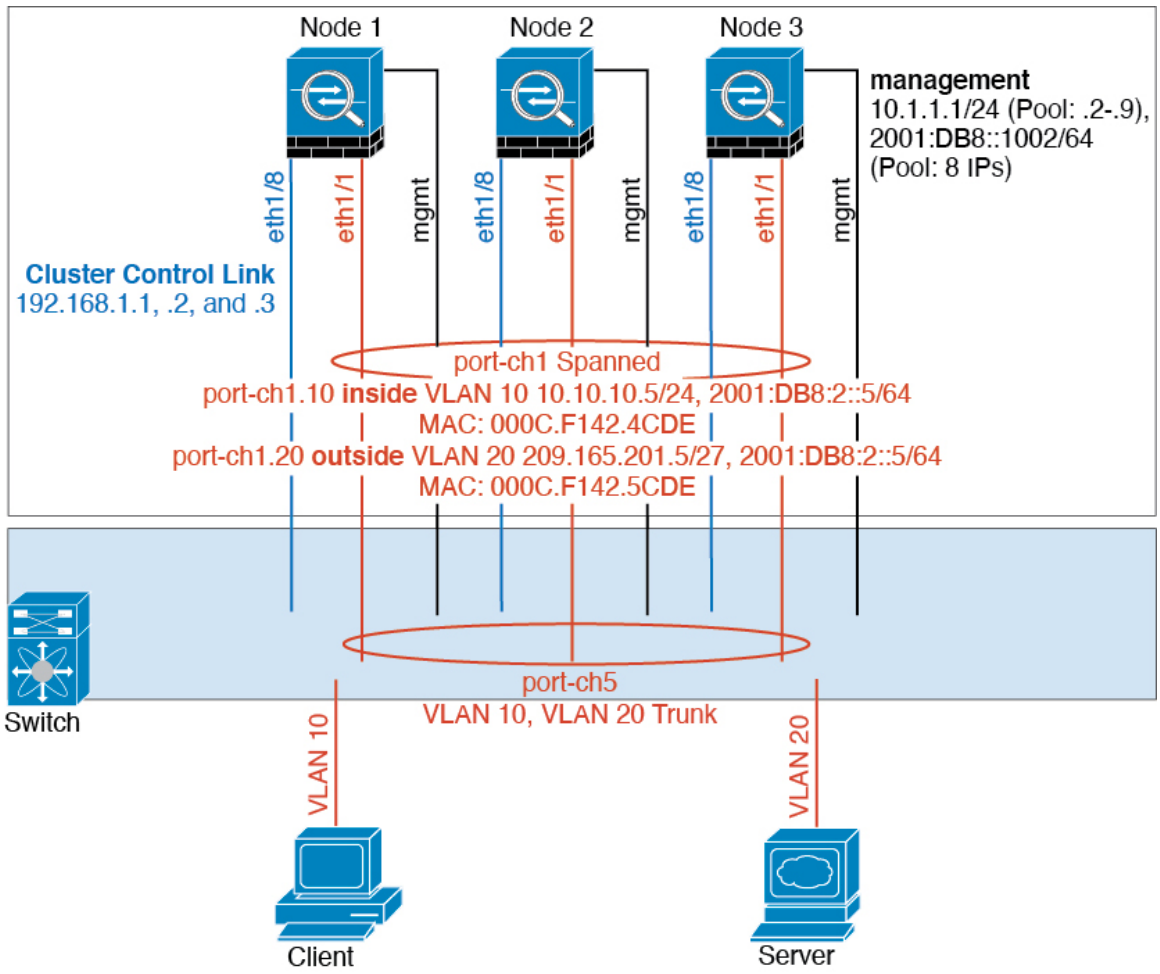
The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

- **Devices** > **Device Management** > *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

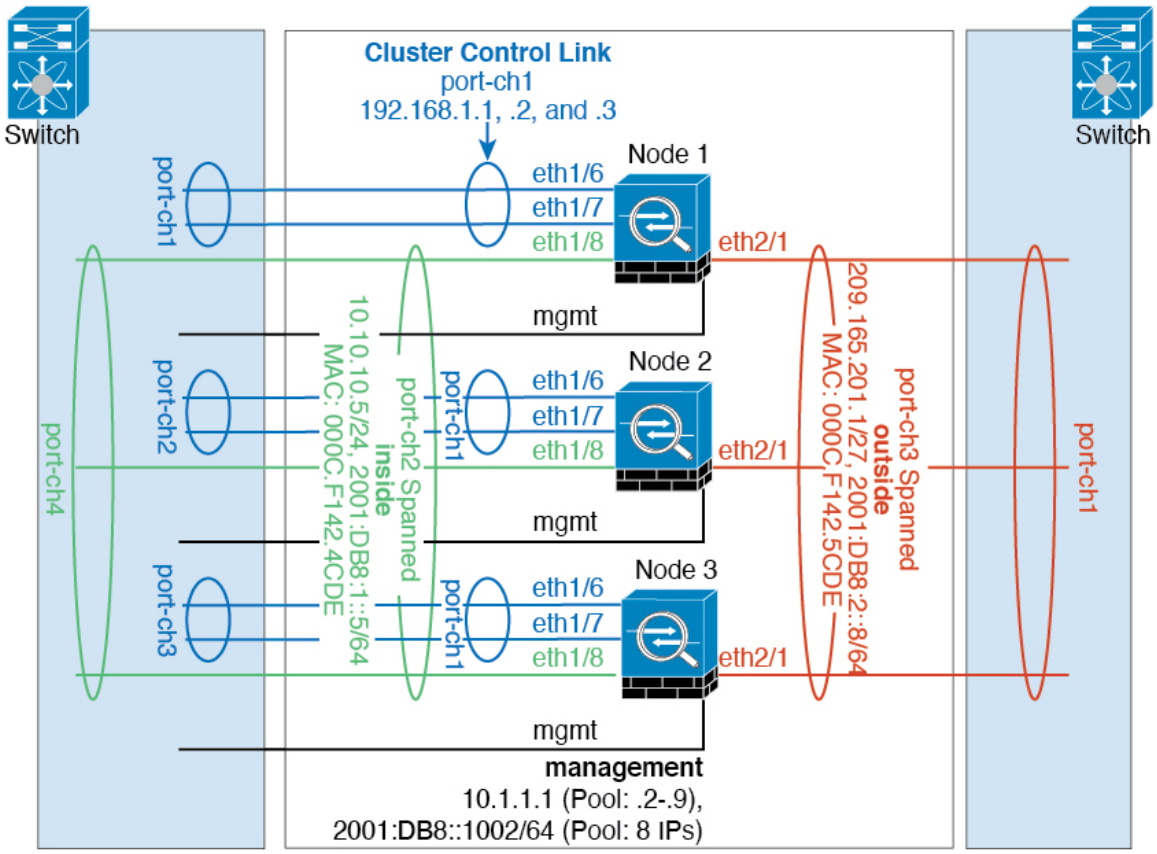


- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Examples for Clustering

These examples include typical deployments.



Firewall on a Stick

Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic Segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

FTD Features and Clustering

Some FTD features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the FMC GUI. See FlexConfig Policies, on page 1893.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- FMC UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

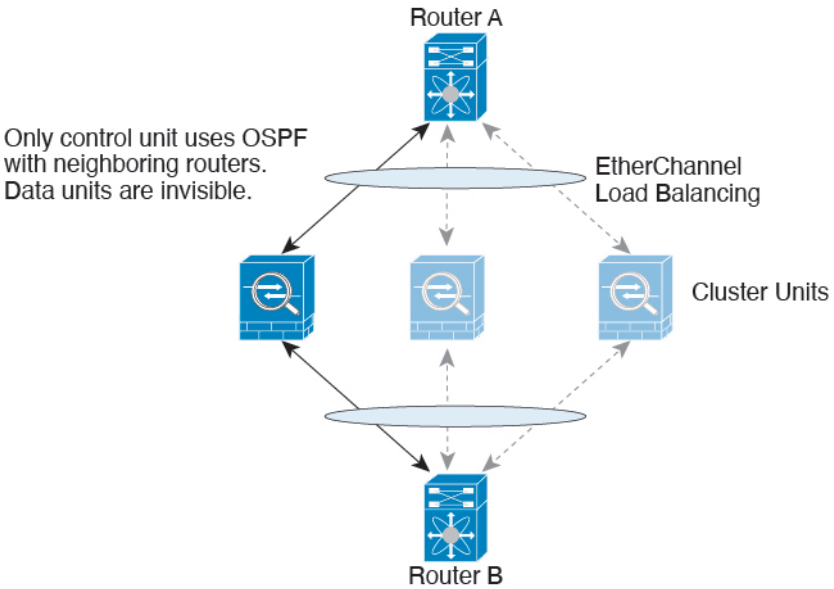
For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the FMC GUI. See FlexConfig Policies, on page 1893.

- The following application inspections:
  - DCERPC
  - ESMTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET

- SUNRPC
- TFTP
- XDMCP

- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing



Connection Settings

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic Routing and Clustering

The routing process only runs on the control unit, and routes are learned through the control unit and replicated to secondaries. If a routing packet arrives at a data unit, it is redirected to the control unit.

Figure 109: Dynamic Routing

After the data units learn the routes from the control unit, each unit makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control unit to data units. If there is a control unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast Routing and Clustering

The control unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each data unit can forward multicast data packets.

NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different FTDs in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the FTD that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the

nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.

- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

An SNMP agent polls each individual FTD by its Diagnostic interface Local IP address. You cannot poll consolidated data for the cluster.

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

TLS/SSL Connections and Clustering

The decryption states of TLS/SSL connections are not synchronized, and if the connection owner fails, then the decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control unit supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control unit and does not take advantage of the cluster high availability capabilities. If the control unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control unit is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the control unit.

VPN-related keys and certificates are replicated to all units.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, for TCP throughput, the Firepower 9300 with 3 SM-40 modules can handle approximately 135 Gbps of real world firewall traffic when running alone. For 2 chassis, the maximum combined throughput will be approximately 80% of 270 Gbps (2 chassis x 135 Gbps): 216 Gbps.

Control Unit Election

Members of the cluster communicate over the cluster control link to elect a control unit as follows:

1. When you deploy the cluster, each unit broadcasts an election request every 3 seconds.
2. Any other units with a higher priority respond to the election request; the priority is set when you deploy the cluster and is not configurable.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes the control unit.

Note If multiple units tie for the highest priority, the cluster unit name and then the serial number is used to determine the control unit.

4. If a unit later joins the cluster with a higher priority, it does not automatically become the control unit; the existing control unit always remains as the control unit unless it stops responding, at which point a new control unit is elected.
5. In a "split brain" scenario when there are temporarily multiple control units, then the unit with highest priority retains the role while the other units return to data unit roles.

Note You can manually force a unit to become the control unit. For centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

High Availability Within the Cluster

Clustering provides high availability by monitoring chassis, unit, and interface health and by replicating connection states between units.

Chassis-Application Monitoring

Chassis-application health monitoring is always enabled. The Firepower 4100/9300 chassis supervisor checks the FTD application periodically (every second). If the FTD device is up and cannot communicate with the Firepower 4100/9300 chassis supervisor for 3 seconds, the FTD device generates a syslog message and leaves the cluster.

If the Firepower 4100/9300 chassis supervisor cannot communicate with the application after 45 seconds, it reloads the FTD device. If the FTD device cannot communicate with the supervisor, it removes itself from the cluster.

Unit Health Monitoring

Each unit periodically sends a broadcast keepaliveheartbeat packet over the cluster control link. If the control node does not receive any keepaliveheartbeat packets or other packets from a data node within the timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining node.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role. See Control Unit Election, on page 337 for more information.

Interface Monitoring

Each node monitors the link status of all hardware interfaces in use, and reports status changes to the control node. For clustering on multiple chassis, Spanned EtherChannels use the cluster Link Aggregation Control Protocol (cLACP). Each chassis monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel, and informs the FTD application if the interface is down. All physical interfaces are monitored by default (including the main EtherChannel for EtherChannel interfaces). Only named interfaces that are in an Up state can be monitored. For example, all member ports of an EtherChannel must fail before a *named* EtherChannel is removed from the cluster.

If a monitored interface fails on a particular node, but it is active on other nodes, then the node is removed from the cluster. The amount of time before the FTD device removes a node from the cluster depends on whether the node is an established member or is joining the cluster. The FTD device does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the FTD device to be removed from the cluster. For an established member, the node is removed after 500 ms.

For clustering on multiple chassis, if you add or delete an EtherChannel from the cluster, interface health-monitoring is suspended for 95 seconds to ensure that you have time to make the changes on each chassis.

Decorator Application Monitoring

When you install a decorator application on an interface, such as the Radware DefensePro application, then both the FTD device and the decorator application must be operational to remain in the cluster. The unit does not join the cluster until both applications are operational. Once in the cluster, the unit monitors the decorator application health every 3 seconds. If the decorator application is down, the unit is removed from the cluster.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The FTD automatically tries to rejoin the cluster, depending on the failure event.

Note When the FTD becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management/Diagnostic interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The FTD automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The FTD automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the FTD application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The FTD application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from FMC, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.
- Failed Chassis-Application Communication—When the FTD application detects that the chassis-application health has recovered, it tries to rejoin the cluster automatically.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 26: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—

Traffic	State Support	Notes
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

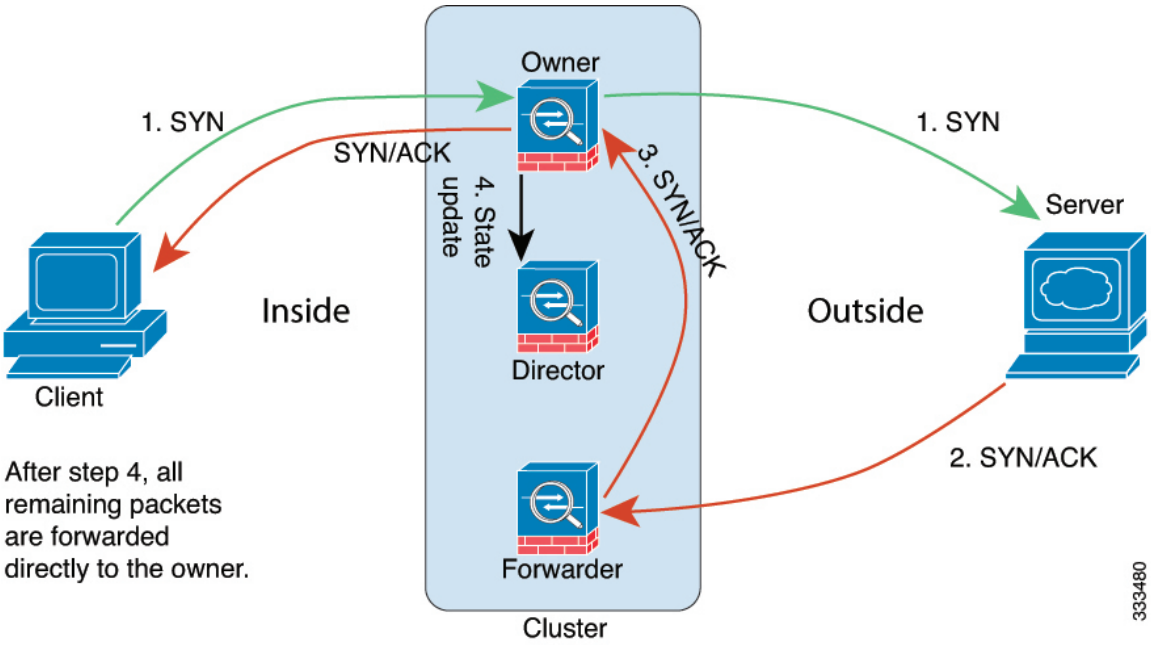
  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not

used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.



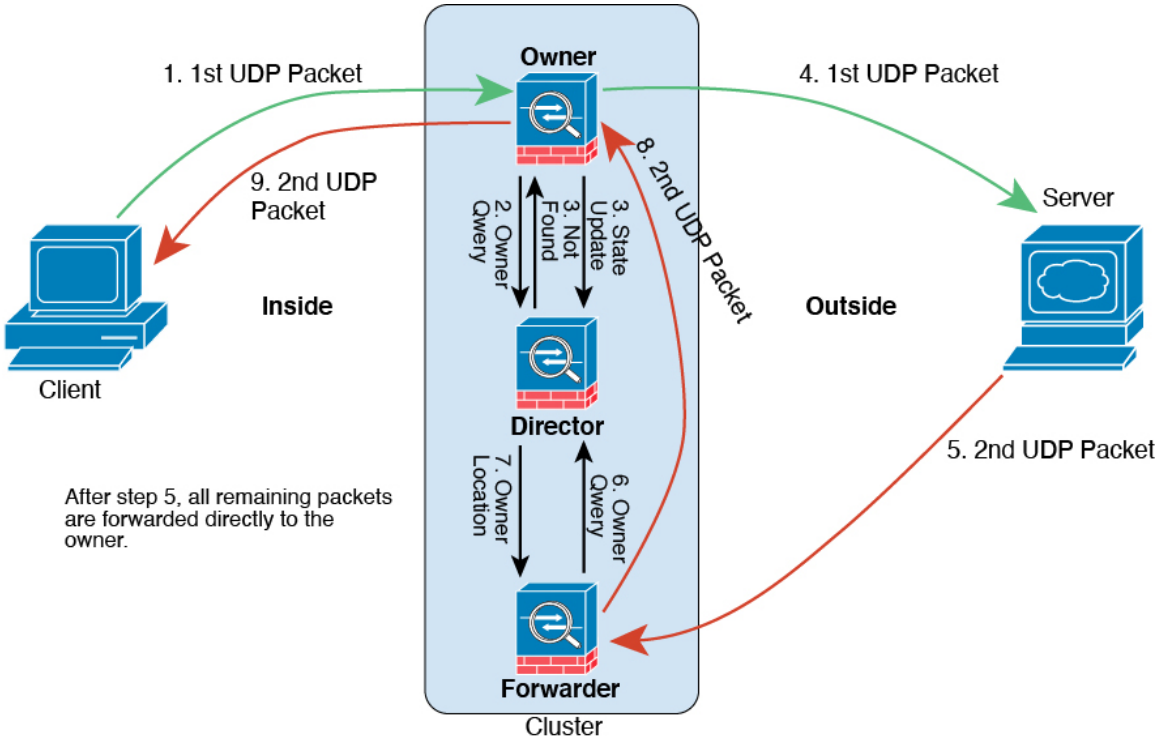
- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.



1. The SYN packet originates from the client and is delivered to one FTD (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different FTD (based on the load balancing method). This FTD is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 110: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one FTD (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

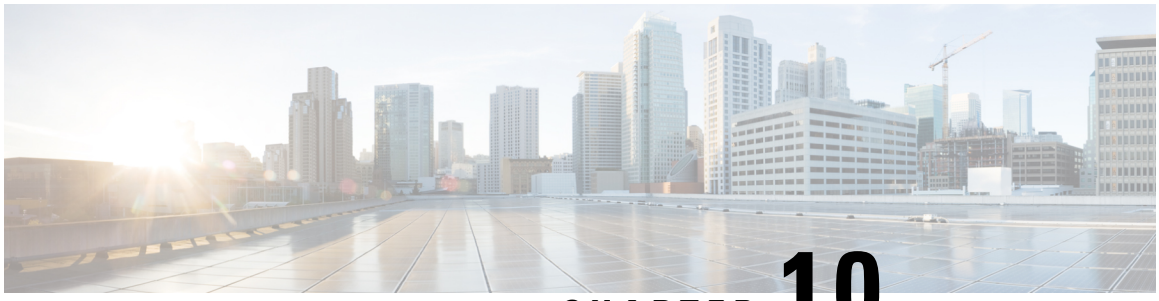
History for Clustering

Table 27:

Feature	Minimum FMC	Minimum FTD	Details
Cluster deployment for firewall changes completes faster.	7.1.0	7.1.0	Cluster deployment for firewall changes now completes faster. New/Modified screens: none.
Improved PAT port block allocation for clustering.	7.0.0	7.0.0	The improved PAT port block allocation ensures that the control unit keeps ports in reserve for joining nodes, and proactively reclaims unused ports. To best optimize the allocation, you can set the maximum nodes you plan to have in the cluster using the **cluster-member-limit** command using FlexConfig. The control unit can then allocate port blocks to the planned number of nodes, and it will not have to reserve ports for extra nodes you don't plan to use. The default is 16 nodes. You can also monitor syslog 747046 to ensure that there are enough ports available for a new node. New/Modified commands: **cluster-member-limit** (FlexConfig), **show nat pool cluster** [**summary**], **show nat pool ip detail**
Cluster deployment for Snort changes completes faster, and fails faster when there is an event.	6.7.0	6.7.0	Cluster deployment for Snort changes now completes faster. Also, when a cluster has an event that causes a FMC deployment to fail, the failure now occurs more quickly. New/Modified screens: none.
Improved cluster management.	6.7.0	6.7.0	FMC has improved cluster management functionality that formerly you could only accomplish using the CLI, including: • Enable and disable cluster units • Show cluster status from the Device Management page, including History and Summary per unit • Change the role to the control unit New/Modified screens: • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** > **General** area **> Cluster Live Status** link **Cluster Status** Supported platforms: Firepower 4100/9300

Feature	Minimum FMC	Minimum FTD	Details
Multi-instance clustering.	6.6.0	6.6.0	You can now create a cluster using container instances. On the Firepower 9300, you must include one container instance on each module in the cluster. You cannot add more than one container instance to the cluster per security engine/module. We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. New/Modified FXOS commands: **set port-type cluster** New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Add Cluster** • **Interfaces** > **All Interfaces** > **Add New** drop-down menu **> Subinterface > Type** field Supported platforms: FTD on the Firepower 4100/9300
Configuration sync to data units in parallel.	6.6.0	6.6.0	The control unit now syncs configuration changes with data units in parallel by default. Formerly, synching occurred sequentially. New/Modified screens: none.
Messages for cluster join failure or eviction added to **show cluster history**.	6.6.0	6.6.0	New messages were added to the **show cluster history** command for when a cluster unit either fails to join the cluster or leaves the cluster. New/Modified commands: **show cluster history** New/Modified screens: none.
Initiator and responder information for Dead Connection Detection (DCD), and DCD support in a cluster.	6.5.0	6.5.0	If you enable Dead Connection Detection (DCD), you can use the **show conn detail** command to get information about the initiator and responder. Dead Connection Detection allows you to maintain an inactive connection, and the **show conn** output tells you how often the endpoints have been probed. In addition, DCD is now supported in a cluster. New/Modified commands: **show conn** (output only). Supported platforms: FTD on the Firepower 4100/9300

Feature	Minimum FMC	Minimum FTD	Details
Adding clusters is easier.	6.3.0	6.3.0	You can now add any unit of a cluster to the FMC, and the other cluster units are detected automatically. Formerly, you had to add each cluster unit as a separate device, and then group them into a cluster. Adding a cluster unit is also now automatic. Note that you must delete a unit manually. New/Modified screens: **Devices** > **Device Management** > **Add** drop-down menu > **Device** > **Add Device** dialog box **Devices** > **Device Management** > **Cluster** tab > **General** area > **Cluster Registration Status** > **Current Cluster Summary** link > **Cluster Status** dialog box Supported platforms: FTD on the Firepower 4100/9300
Support for site-to-site VPN with clustering as a centralized feature.	6.2.3.3	6.2.3.3	You can now configure site-to-site VPN with clustering. Site-to-site VPN is a centralized feature; only the control unit supports VPN connections. Supported platforms: FTD on the Firepower 4100/9300
Automatically rejoin the cluster after an internal failure.	6.2.3	6.2.3	Formerly, many internal error conditions caused a cluster unit to be removed from the cluster, and you were required to manually rejoin the cluster after resolving the issue. Now, a unit will attempt to rejoin the cluster automatically at the following intervals: 5 minutes, 10 minutes, and then 20 minutes. Internal failures include: application sync timeout; inconsistent application statuses; and so on. New/Modified command: **show cluster info auto-join** No modified screens. Supported platforms: FTD on the Firepower 4100/9300
Clustering on multiple chassis for 6 modules; Firepower 4100 support.	6.2.0	6.2.0	With FXOS 2.1.1, you can now enable clustering on multiple chassis of the Firepower 9300 and 4100. For the Firepower 9300, you can include up to 6 modules. For example, you can use 1 module in 6 chassis, or 2 modules in 3 chassis, or any combination that provides a maximum of 6 modules. For the Firepower 4100, you can include up to 6 chassis. **Note** Inter-site clustering is also supported. However, customizations to enhance redundancy and stability, such as site-specific MAC and IP addresses, director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature. No modified screens. Supported platforms: FTD on the Firepower 4100/9300



Feature	Minimum FMC	Minimum FTD	Details
Clustering on multiple modules with one Firepower 9300 chassis.	6.0.1	6.0.1	You can cluster up to 3 security modules within the Firepower 9300 chassis. All modules in the chassis must belong to the cluster. New/Modified screens: **Devices** > **Device Management** > **Add** > **Add Cluster** **Devices** > **Device Management** > **Cluster** Supported platforms: FTD on the Firepower 9300

- Sync Interface Changes with the FMC, on page 366
- Manage the Network Module for the Secure Firewall 3100, on page 369
- History for Interfaces, on page 380

Management/Diagnostic Interface

The physical management interface is shared between the Diagnostic logical interface and the Management logical interface.

Management Interface

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the FMC. It uses its own IP address and static routing. You can configure its settings at the CLI using the **configure network** command. If you change the IP address at the CLI after you add it to the FMC, you can match the IP address in the Firepower Management Center in the **Devices** > **Device Management** > **Devices** > **Management** area.

You can alternatively manage the FTD using a data interface instead of the Management interface.

Diagnostic Interface

The Diagnostic logical interface can be configured along with the rest of the data interfaces on the **Devices** > **Device Management** > **Interfaces** screen. Using the Diagnostic interface is optional (see the routed and transparent mode deployments for scenarios). The Diagnostic interface only allows management traffic, and

does not allow through traffic. It does not support SSH; you can SSH to data interfaces or to the Management interface only. The Diagnostic interface is useful for SNMP or syslog monitoring.

Note Although the Diagnostic and Management interfaces share a physical port, you must assign different IP addresses to each interface on the same network.

Interface Mode and Types

You can deploy FTD interfaces in two modes: Regular firewall mode and IPS-only mode. You can include both firewall and IPS-only interfaces on the same device.

Regular Firewall Mode

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 143 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the FTD device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the FTD device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

IPS-Only Mode

You can configure your device in either a passive or inline IPS deployment. In a passive deployment, you deploy the system out-of-band from the flow of network traffic. In an inline deployment, you configure the system transparently on a network segment by binding two interfaces together.

Security Zones and Interface Groups

Each interface can be assigned to a *security zone* and/or *interface group*. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface on one or more devices to the "inside" zone; and the "outside" interfaces to the "outside" zone. You can then configure your access control policy to enable traffic to go from the inside zone to the outside zone for every device using the same zones.

To view the interfaces that belong to each object, choose **Objects** > **Object Management** and click **Interface**. This page lists the security zones and interface groups configured on your managed devices. You can expand each interface object to view the type of interfaces in each interface object.

Note Policies that apply to **any** zone (a global policy) apply to interfaces in zones as well as any interfaces that are not assigned to a zone.

Note The Diagnostic/Management interface does not belong to a zone or interface group.

Security Zones Vs. Interface Groups

There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

  You can use interface groups in NAT policies, prefilter policies, and QoS policies, as well as features that let you specify the interface name directly, such as Syslog servers or DNS servers.

Some policies only support security zones, while other policies support zones and groups. Unless you need the functionality an interface group provides, you should default to using security zones because security zones are supported for all features.

You cannot change an existing security zone to an interface group or vice-versa; instead you must create a new interface object.

Note Although tunnel zones are not interface objects, you can use them in place of security zones in certain configurations; see Tunnel Zones and Prefiltering, on page 1278.

Interface Object Types

See the following interface object types:

- Passive—For IPS-only passive or ERSPAN interfaces.
- Inline—For IPS-only inline set interfaces.
- Switched—For regular firewall bridge group interfaces.
- Routed—For regular firewall routed interfaces.
- ASA—(Security zones only) For legacy ASA FirePOWER device interfaces.

All interfaces in an interface object must be of the same type. After you create an interface object, you cannot change the type of interfaces it contains.

Interface Names

Note that the interface (or zone name) itself does not provide any default behavior in regards to the security policy. We recommend using names that are self-describing to avoid mistakes in future configuration. A good name signifies a logical segment or traffic specification, for example:

- Names of internal interfaces—InsideV110, InsideV160, InsideV195
- Names of DMZ interfaces—DMZV11, DMZV12, DMZV-TEST
- Names of external interfaces—Outside-ASN78, Outside-ASN91

Auto-MDI/MDIX Feature

For RJ-45 interfaces, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Default Settings for Interfaces

This section lists default settings for interfaces.

Default State of Interfaces

The default state of an interface depends on the type.

- Physical interfaces—Disabled. The exception is the Management interface that is enabled for initial setup. Physical interfaces includes switch ports.
- VLAN subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces (ISA 3000)—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.
- EtherChannel port-channel interfaces (Firepower and Secure Firewall models)—Disabled.

Note For the Firepower 4100/9300, you can administratively enable and disable interfaces in both the chassis and in the FMC. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and FMC.

Default Speed and Duplex

By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.

By default, the speed and duplex for fiber (SFP) interfaces are set to the maximum speed, with auto-negotiation enabled.

For the Secure Firewall 3100, the speed is set to detect the installed SFP speed.

Create Security Zone and Interface Group Objects

Add security zones and interface groups to which you can assign device interfaces.

Tip You can create empty interface objects and add interfaces to them later. To add an interface, the interface must have a name. You can also create security zones (but not interface groups) while configuring interfaces.

Before you begin

Understand the usage requirements and restrictions for each type of interface object. See Security Zones and Interface Groups, on page 352.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Interface** from the list of object types.

Step 3 Click **Add** > **Security Zone** or **Add** > **Interface Group**.

Step 4 Enter a **Name**.

Step 5 Choose an **Interface Type**.

Step 6 (Optional) From the **Device** > **Interfaces** drop-down list, choose a device that contains interfaces you want to add.

You do not need to assign interfaces on this screen; you can instead assign interfaces to the zone or group when you configure the interface.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Enable the Physical Interface and Configure Ethernet Settings

This section describes how to:

- Enable the physical interface. By default, physical interfaces are disabled (with the exception of the Diagnostic interface).
- Set a specific speed and duplex. By default, speed and duplex are set to Auto.

This procedure only covers a small subset of Interface settings. Refrain from setting other parameters at this point. For example, you cannot name an interface that you want to use as part of an EtherChannel interface.

Note For the Firepower 4100/9300, you configure basic interface settings in FXOS. See Configure a Physical Interface, on page 188 for more information.

Note For Firepower 1010 switch ports, see Configure Firepower 1010 Switch Ports, on page 383.

Before you begin

If you changed the physical interfaces on the device after you added it to the FMC, you need to refresh the interface listing by clicking **Sync Interfaces from device** on the top left of **Interfaces**. For the Secure Firewall 3100, which supports hot swapping, see Manage the Network Module for the Secure Firewall 3100, on page 369 before you change interfaces on a device.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
- **Forward Error Correction Mode**—(Secure Firewall 3100 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 28: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate

Step 6 (Optional) (Firepower 1100) Enable Link Layer Discovery Protocol (LLDP) by clicking **Hardware Configuration** > **LLDP**.

- **Enable LLDP Receive**—Enables the firewall to receive LLDP packets from its peers.
- **Enable LLDP Transmit**—Enables the firewall to send LLDP packets to its peers.

Step 7 In the **Mode** drop-down list, choose one of the following:.

- **None**—Choose this setting for regular firewall interfaces and inline sets. The mode will automatically be changed to Routed, Switched, or Inline based on further configuration.
- **Passive**—Choose this setting for passive IPS-only interfaces.
- **Erspan**—Choose this setting for ERSPAN passive IPS-only interfaces.

Step 8 In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to distribute the traffic across multiple egress interfaces.

Step 9 Click **OK**.

Step 10 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 11 Continue configuring interfaces.

- Regular Firewall Interfaces, on page 383
- Inline Sets and Passive Interfaces, on page 433

Configure EtherChannel Interfaces

This section tells how to configure EtherChannel interfaces.

Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. See Add an EtherChannel (Port Channel), on page 189 for more information.

About EtherChannels

This section describes EtherChannels.

About EtherChannels

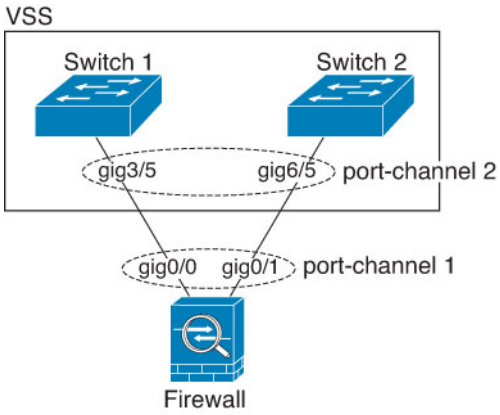
An 802.3ad EtherChannel is a logical interface (called a port-channel interface) consisting of a bundle of individual Ethernet links (a channel group) so that you increase the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels, depending on how many interfaces your model supports.

Channel Group Interfaces

Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.



The EtherChannel aggregates the traffic across all the available active interfaces in the channel. The interface is selected using a proprietary hash algorithm, based on source or destination MAC addresses, IP addresses, TCP and UDP port numbers and VLAN numbers.

Connecting to an EtherChannel on Another Device

The device to which you connect the FTD EtherChannel must also support 802.3ad EtherChannels; for example, you can connect to the Catalyst 6500 switch or the Cisco Nexus 7000.

When the switch is part of a Virtual Switching System (VSS) or Virtual Port Channel (vPC), then you can connect FTD interfaces within the same EtherChannel to separate switches in the VSS/vPC. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch.

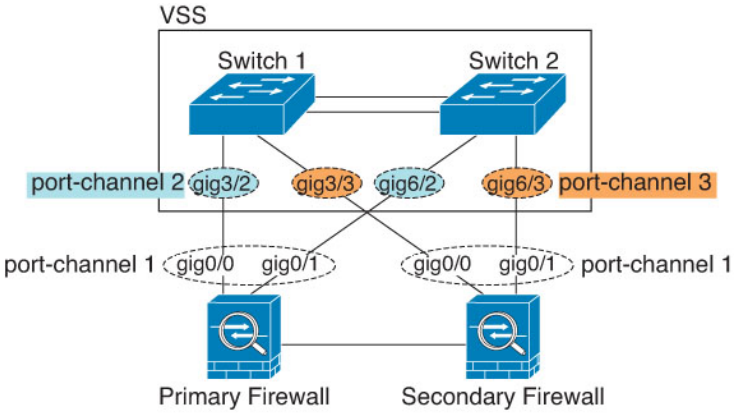


Figure 111: Connecting to a VSS/vPC

Note If the FTD device is in transparent firewall mode, and you place the FTD device between two sets of VSS/vPC switches, then be sure to disable Unidirectional Link Detection (UDLD) on any switch ports connected to the FTD device with an EtherChannel. If you enable UDLD, then a switch port may receive UDLD packets sourced from both switches in the other VSS/vPC pair. The receiving switch will place the receiving interface in a down state with the reason "UDLD Neighbor mismatch".

If you use the FTD device in an Active/Standby failover deployment, then you need to create separate EtherChannels on the switches in the VSS/vPC, one for each FTD device. On each FTD device, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both FTD devices (in this case, the EtherChannel will not be established because of the separate FTD system IDs), a single EtherChannel would not be desirable because you do not want traffic sent to the standby FTD device.

Figure 112: Active/Standby Failover and VSS/vPC

Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- Passive—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. Not supported on hardware models.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

Load Balancing

The FTD device distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable). The resulting hash is divided by the number of active links in a modulo operation where the resulting remainder determines which interface owns the flow. All packets with a *hash_value* **mod** *active_links* result of 0 go to the first interface in the EtherChannel, packets with a result of 1 go to the second interface, packets with a result of 2 go to the third interface, and so on. For example, if you have 15 active links, then the modulo operation provides values from 0 to 14. For 6 active links, the values are 0 to 5, and so on.

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

EtherChannel MAC Address

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

Firepower and Secure Firewall Hardware

The port-channel interface uses the MAC address of the internal interface Internal-Data 0/1. Alternatively you can manually configure a MAC address for the port-channel interface. All EtherChannel interfaces on a chassis use the same MAC address, so be aware that if you use SNMP polling, for example, multiple interfaces will have the same MAC address.

Note Member interfaces only use the Internal-Data 0/1 MAC address after a reboot. Prior to rebooting, the member interface uses its own MAC address. If you add a new member interface after a reboot, you will have to perform another reboot to update its MAC address.

Guidelines for EtherChannels

Bridge Group

In routed mode, FMC-defined EtherChannels are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

High Availability

- When you use an EtherChannel interface as a High Availability link, it must be pre-configured on both units in the High Availability pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because *the High Availability link itself is required for replication*.
- If you use an EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal. For the Firepower 4100/9300 chassis, all interfaces, including EtherChannels, need to be pre-configured on both units.
- You can monitor EtherChannel interfaces for High Availability. When an active member interface fails over to a standby interface, this activity does not cause the EtherChannel interface to appear to be failed when being monitored for device-level High Availability. Only when all physical interfaces fail does the EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable).
- If you use an EtherChannel interface for a High Availability or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a High Availability link. To alter the configuration, you need to temporarily disable High Availability, which prevents High Availability from occurring for the duration.

Model Support

- You cannot add EtherChannels in the FMC for the Firepower 4100/9300 or the FTDv. The Firepower 4100/9300 supports EtherChannels, but you must perform all hardware configuration of EtherChannels in FXOS on the chassis.
- You cannot use Firepower 1010 switch ports or VLAN interfaces in EtherChannels.

General EtherChannel Guidelines

- You can configure up to 48 EtherChannels, depending on how many interfaces are available on your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 3100, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

- The device to which you connect the FTD EtherChannel must also support 802.3ad EtherChannels.
- The FTD device does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the FTD device will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch.
- The LACP rate depends on the model. When you set the rate (normal or fast), the device requests that rate from the connecting switch. In return, the device will send at the rate requested by the connecting switch. We recommend that you set the same rate on both sides.
  - Firepower 4100/9300—The LACP rate is set to fast by default in FXOS, but you can configure it as normal (also known as slow).
  - Secure Firewall 3100—The LACP rate is set to normal (slow) by default, but you can configure it as fast on the device.
  - All other models—The LACP rate set to normal (also known as slow), and it is not configurable, which means the device will always request a slow rate from the connecting switch. We recommend setting the rate on the switch to slow, so both sides send LACP messages at the same rate.
- In Cisco IOS software versions earlier than 15.1(1)S2, FTD did not support connecting an EtherChannel to a switch stack. With default switch settings, if the FTD EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- All the FTD configuration refers to the logical EtherChannel interface instead of the member physical interfaces.

Configure an EtherChannel

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

Guidelines

- You can configure up to 48 EtherChannels, depending on the number of interfaces for your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 3100, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

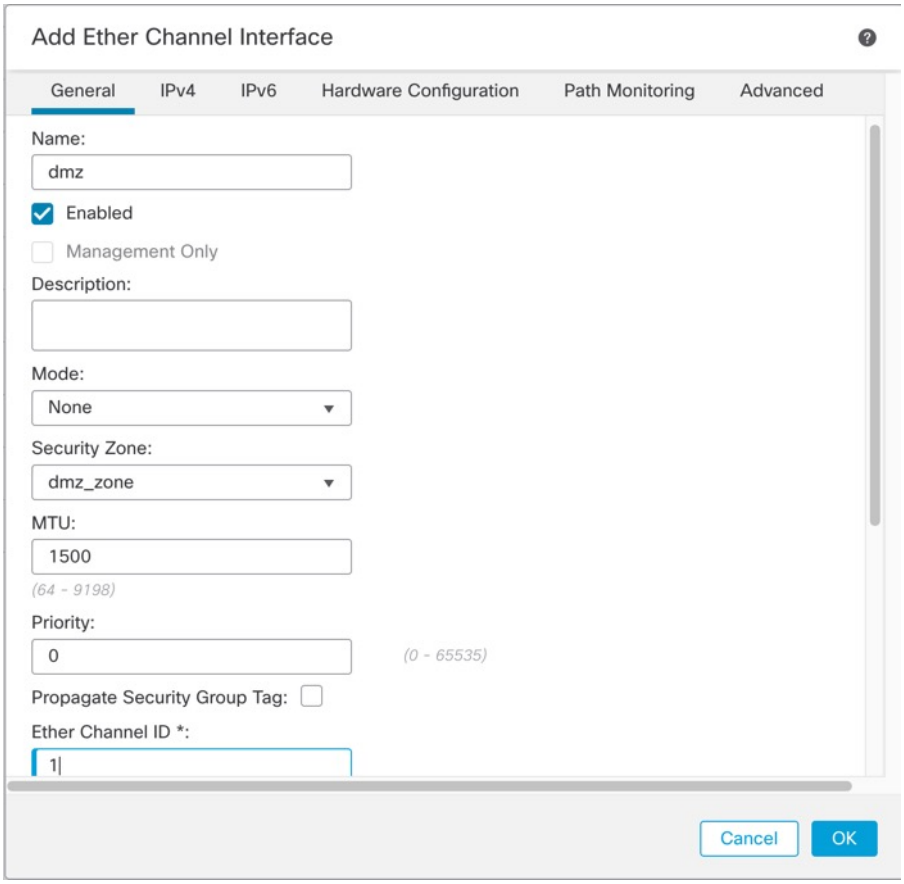
Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. See Add an EtherChannel (Port Channel), on page 189 for more information.

Before you begin

- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name.

Note If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

Procedure



Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Enable the member interfaces according to Enable the Physical Interface and Configure Ethernet Settings, on page 355.

Step 3 Click **Add Interfaces** > **Ether Channel Interface**.

Step 4 On the **General** tab, set the **Ether Channel ID** to a number between 1 and 48 (1 and 8 for the Firepower 1010).

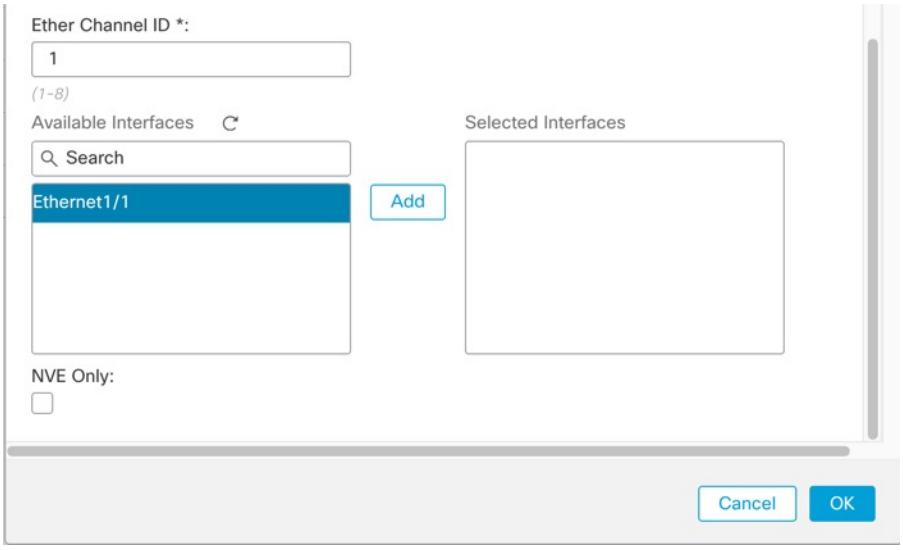


Figure 113: Add EtherChannel Interface

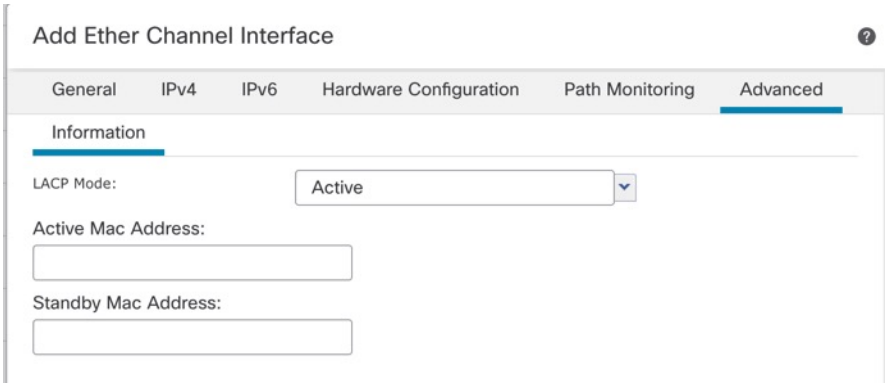
Step 5 In the **Available Interfaces** area, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members.



Make sure all interfaces are the same type and speed capability.

Figure 114: Available Interfaces

Step 6 (Optional) Click the **Advanced** tab to customize the EtherChannel. Set the following parameters on the **Information** sub-tab:

Figure 115: Advanced

- (ISA 3000 only) **Load Balancing**—Select the criteria used to load balance the packets across the group channel interfaces. By default, the FTD device balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see Load Balancing, on page 360.
- **LACP Mode**—Choose Active, Passive, or On. We recommend using Active mode (the default). Passive mode is only available for the ISA 3000 only.
- (Secure Firewall 3100 only) **LACP Rate**—Choose Default, Normal, or Fast. The defualt is Normal (also known as slow). Sets the LACP data unit receive rate for a physical interface in the channel group. We recommend that you set the same rate on both sides.

- (ISA 3000 only) **Active Physical Interface: Range**—From the left drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 16. The default is 1. From the right drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 16. The default is 16. If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer.
- **Active Mac Address**—Set a manual MAC address if desired. The mac_address is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

Step 7 Click the **Hardware Configuration** tab and set the Duplex and Speed for all member interfaces.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 10 (Optional) For regular firewall interfaces, add a VLAN subinterface. See Add a Subinterface, on page 396.

Step 11 For regular firewall interfaces, configure the routed or transparent mode interface parameters: Configure Routed Mode Interfaces, on page 406 or Configure Bridge Group Interfaces, on page 411. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 433.

Sync Interface Changes with the FMC

Interface changes on the device can cause the FMC and the device to get out of sync. The FMC can detect interface changes by one of the following methods:

- Event sent from the device
- Sync when you deploy from the FMC

  If the FMC detects interface changes when it attempts to deploy, the deployment will fail. You must first accept the interface changes.
- Manual sync

There are two types of interface changes performed outside of FMC that need to be synched:

- Addition or deletion of physical interfaces—Adding a new interface, or deleting an unused interface has minimal impact on the FTD configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the FTD configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the FMC.

  When the FMC detects changes, the **Interface** page shows status (removed, changed, or added) to the left of each interface.
- FMC access interface changes—If you configure a data interface for managing FMC using the **configure network management-data-interface** command, you must manually make matching configuration changes in FMC and then acknowledge the changes. These interface changes cannot be made automatically.

This procedure describes how to manually sync interface changes if required and how to acknowledge the detected changes. If interface changes are temporary, you should not save the changes in the FMC; you should wait until the device is stable, and then re-sync.

Before you begin

- User Roles:
  - Admin
  - Access Admin
  - Network Admin

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

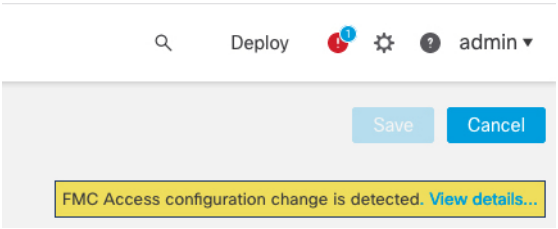
Step 2 If required, click **Sync Device** on the top left of **Interfaces**.

Step 3 After the changes are detected, see the following steps.

Addition or Deletion of Physical Interfaces

a) You will see a red banner on **Interfaces** indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

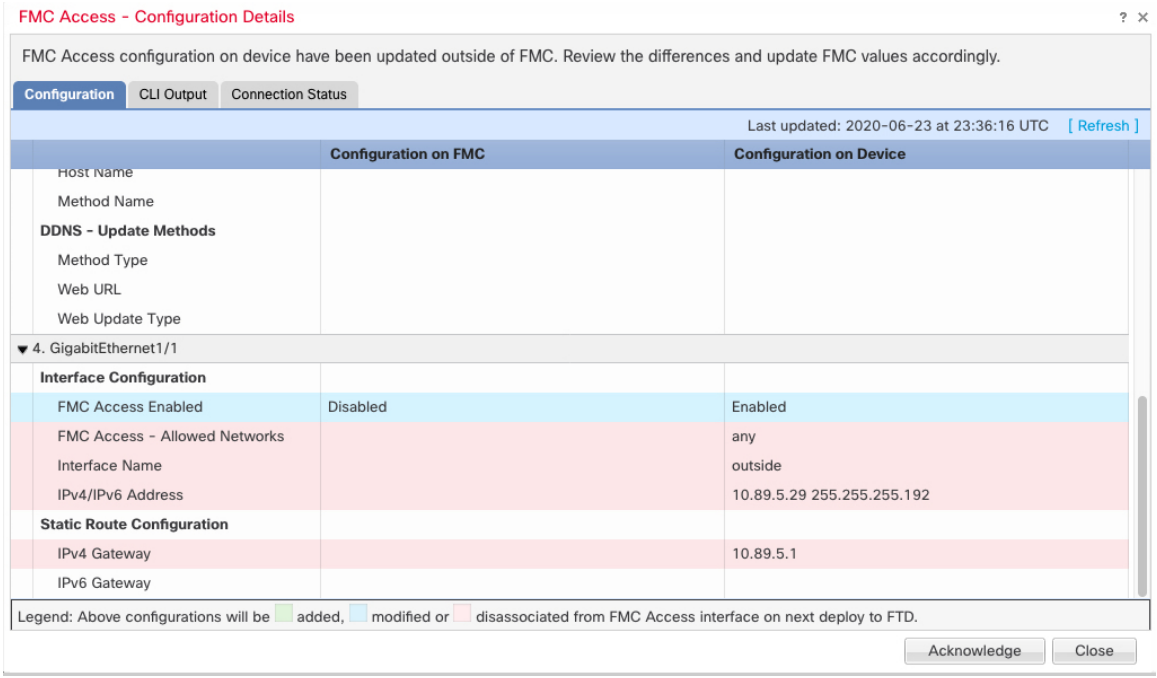


If there are any errors, you need to change your policy and rerun the validation.

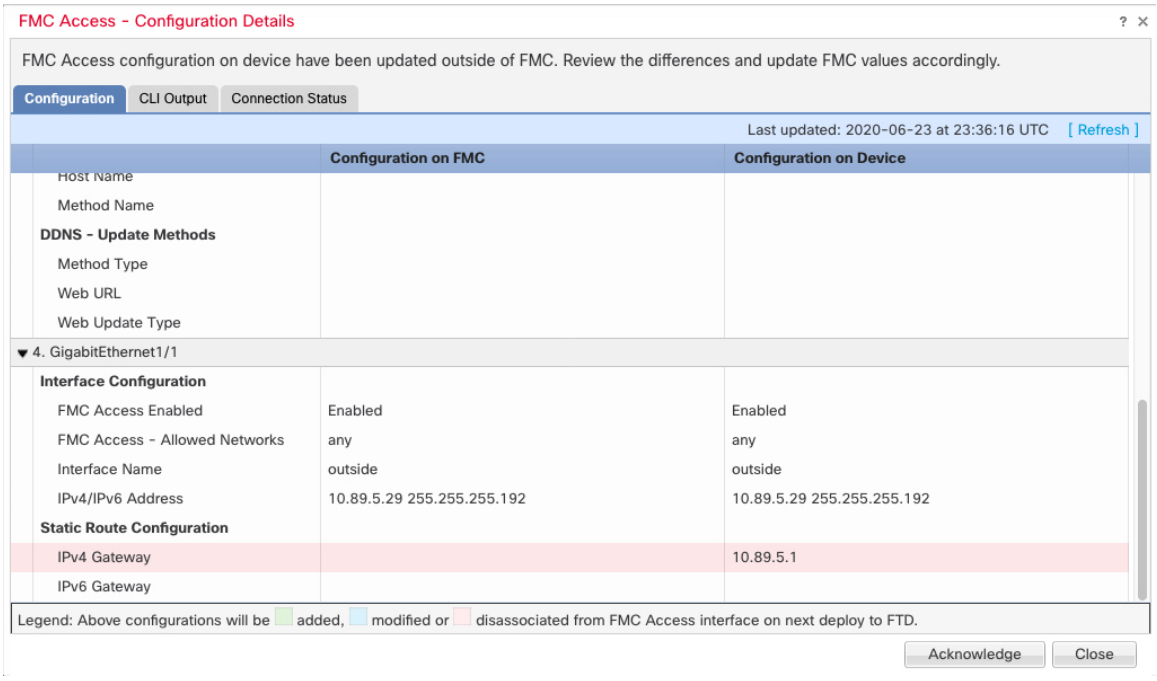
c) Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.

FMC Access Interface Changes



a) You will see a yellow banner in the top right of the **Device** page indicating that the FMC access configuration has changed. Click the **View details** link to view the interface changes.



The **FMC Access - Configuration Details** dialog box opens.

b) Take note of all highlighted configurations, especially the pink highlighted ones. You need to match any values on the FTD by manually configuring them on the FMC.

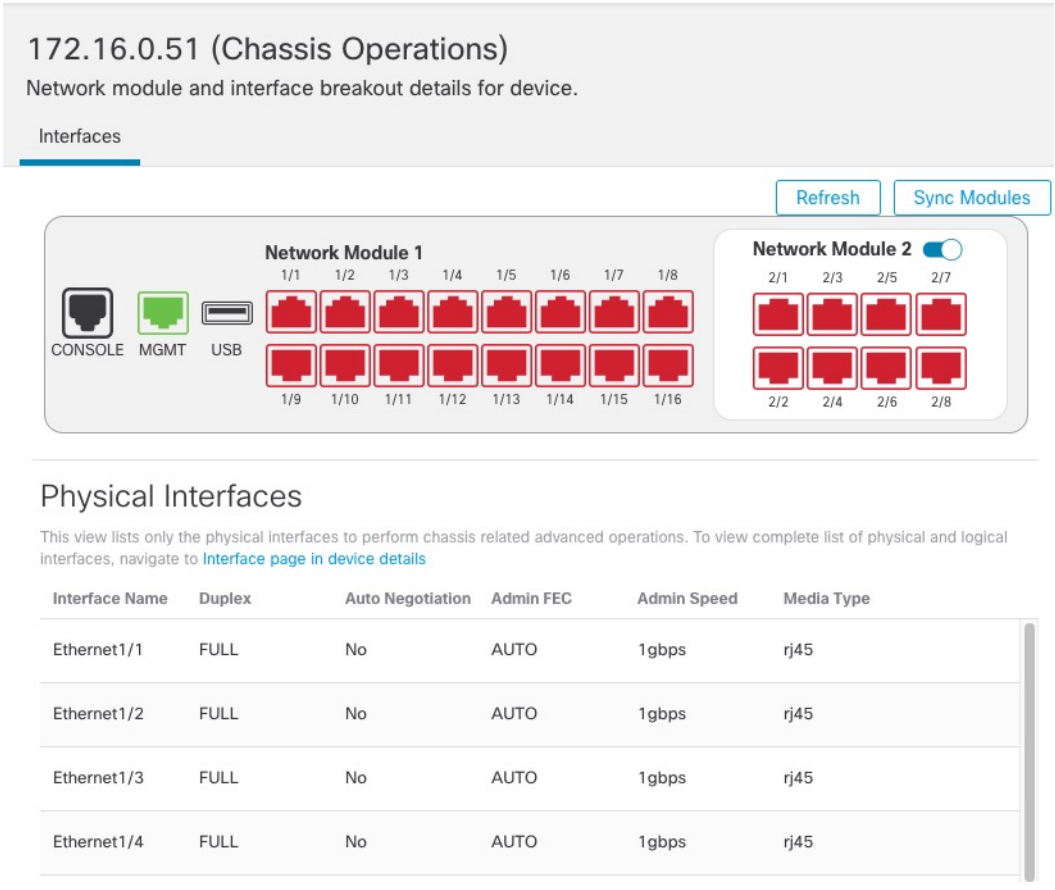
For example, the pink highlights below show configuration that exists on the FTD but not yet on the FMC.

The following example shows this page after configuring the interface in FMC; the interface settings match, and the pink highlight was removed.

c) Click **Acknowledge**.

We recommend that you do not click **Acknowledge** until you have finished the FMC configuration, and are ready to deploy. Clicking **Acknowledge** removes the block on deployment. The next time you deploy,

the FMC configuration will overwrite any remaining conflicting settings on the FTD. It is your responsibility to manually fix the configuration in the FMC before you re-deploy.



d) You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.

Manage the Network Module for the Secure Firewall 3100

If you install a network module before you first power on the device, no action is required; the network module is enabled and ready for use.

To view physical interface details for the device, and to manage the network module, open the **Chassis Operations** page. From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit. The **Chassis Operations** page opens for the device.

Figure 116: Chassis Operations

Click **Refresh** to refresh interface status. Click **Sync Modules** if you made a hardware change on the device that you need to detect.

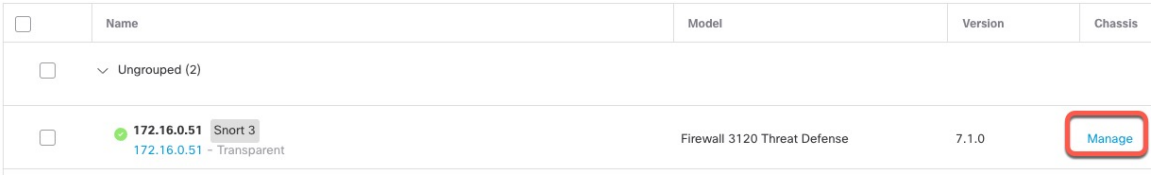
If you need to make changes to your network module installation after initial bootup, then see the following procedures.

Add a Network Module

To add a network module to a firewall after initial bootup, perform the following steps. Adding a new module requires a reboot.

Procedure

Step 1 Install the network module according to the hardware installation guide.



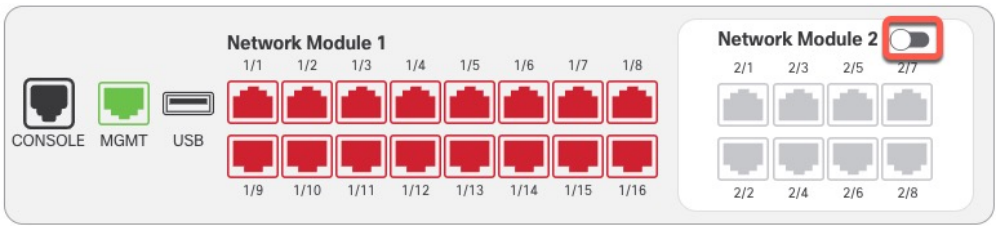
For clustering or High Availability, install the network module on all nodes.

Step 2 Reboot the firewall; see Shut Down or Restart the Device, on page 32.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node (see Change the Control Node, on page 266) or active unit (see Switch the Active Peer in the FTD High Availability Pair, on page 230), and reboot the former control node/active unit.

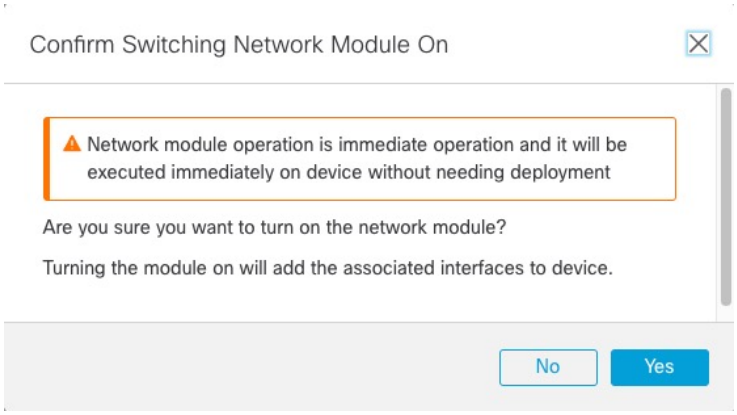
Step 3 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 117: Manage Chassis



The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 4 Click **Sync Modules** to update the page with the new network module details.



Step 5 On the interfaces graphic, click the slider ( ) to enable the network module.

Figure 118: Enable the Network Module

Step 6 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 119: Confirm Enable

Step 7 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 120: Go to Interface Page

Step 8 (Optional) At the top of the **Interfaces** page, you see a message that the interface configuration has changed. You can click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 121: View Interface Changes

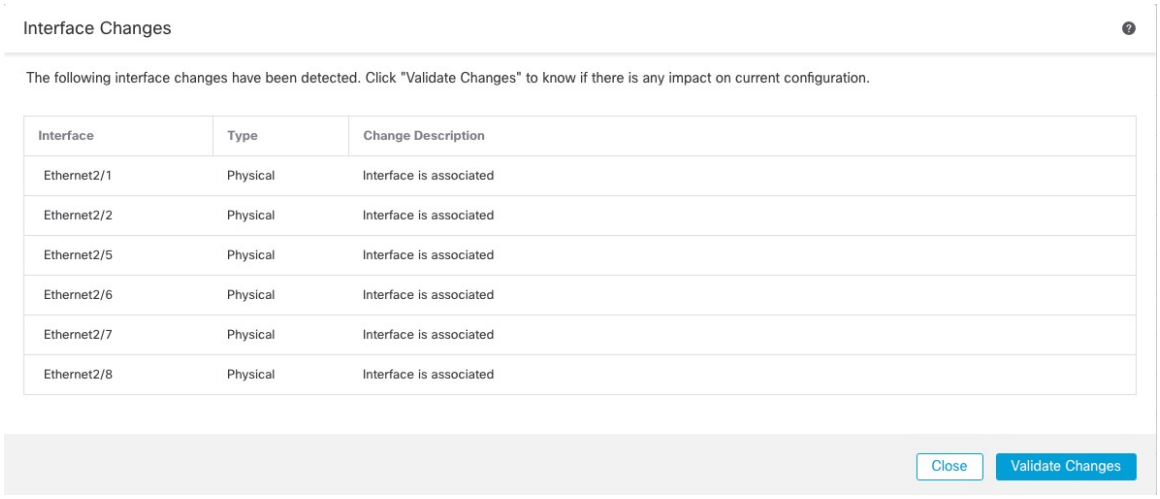


Figure 122: Interface Changes

Click **Close** to return to the **Interfaces** page. (Because you are adding a new module, there shouldn't be any configuration impact, so you do not need to click **Validate Changes**.)

Step 9 Click **Save** to save the interface changes to the firewall.

Hot Swap the Network Module

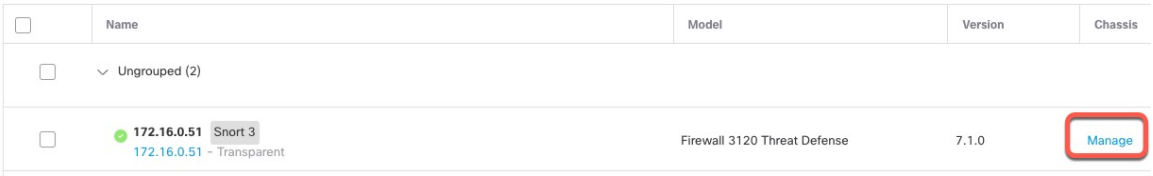
You can hot swap a network module for a new module of the same type without having to reboot. However, you must shut down the current module to remove it safely. This procedure describes how to shut down the old module, install a new module, and enable it.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit. You cannot disable a network module if the cluster control link/failover link is on the module.

Before you begin

Procedure

Step 1 For clustering or High Availability, perform the following steps.



- **Clustering**—Ensure the unit you want to perform the hot swap on is a data node (see Change the Control Node, on page 266); then break the node so it is no longer in the cluster. See Break a Node, on page 263.

  You will add the node back to the cluster after you perform the hot swap. Alternatively, you can perform all operations on the control node, and the network module changes will sync to all data nodes. However, you will lose use of those interfaces on all nodes during the hot swap.

- **High Availability**—To avoid failing over when you disable the network module:
  - If the failover link is on the network module, you must break High Availability. See Break a High Availability Pair, on page 233. Disabling the network module with an active failover link is not allowed.
  - Disable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 228.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

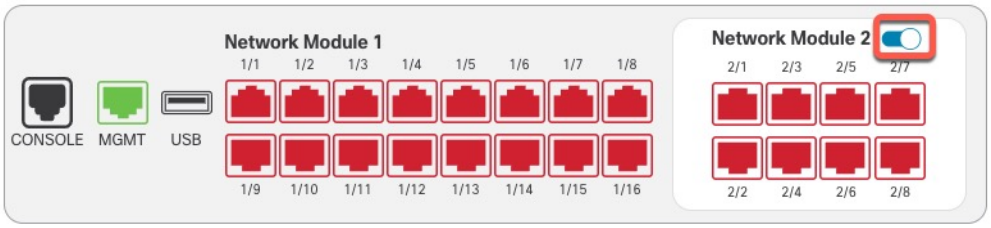


Figure 123: Manage Chassis

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

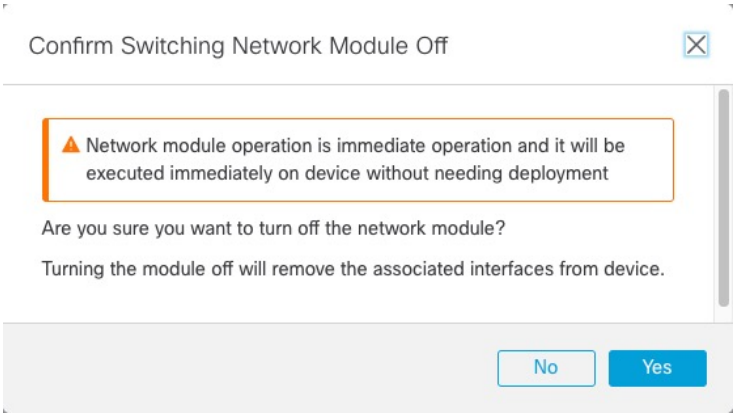

Figure 124: Disable the Network Module

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

Step 4 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

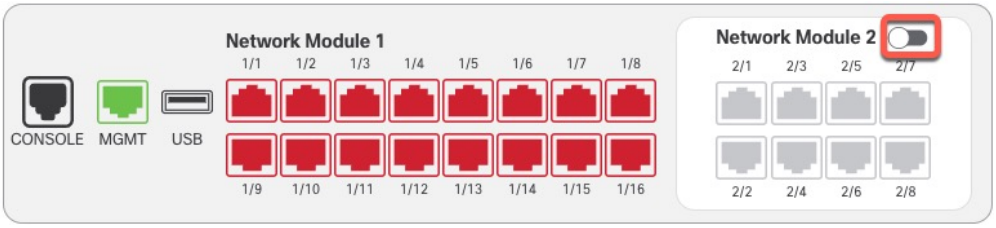

Figure 125: Confirm Disable

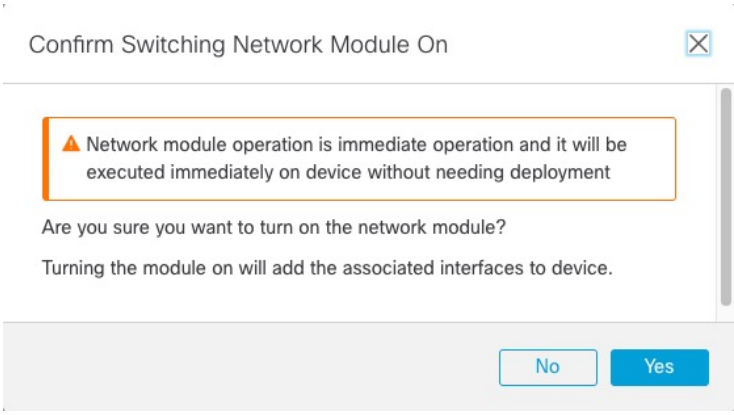
Step 5 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.



Step 6 In the FMC, enable the new module by clicking the slider ( ).

Figure 126: Enable the Network Module

Step 7 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 127: Confirm Enable

Step 8 For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster. See Add a New Cluster Node, on page 261.
- **High Availability**—
  - If you broke High Availability, then reform High Availability. See Add a High Availability Pair, on page 225.
  - Reenable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 228.

Replace the Network Module with a Different Type

If you replace a network module with a different type, then a reboot is required. If the new module has fewer interfaces than the old module, you will have to manually remove any configuration related to interfaces that will no longer be present.

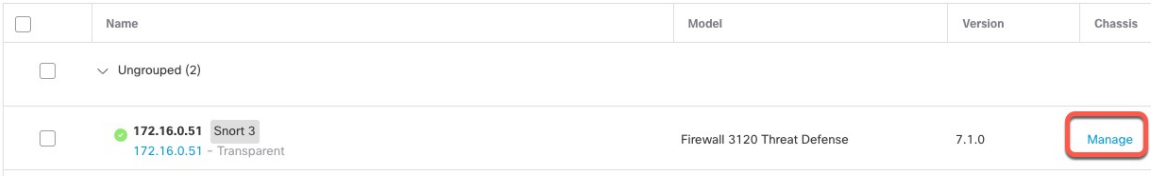
For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

Before you begin

For High Availability, you cannot disable a network module if the failover link is on the module. You will have to break High Availability (see Break a High Availability Pair, on page 233), which means you will have downtime when you reboot the active unit. After the units finish rebooting, you can reform High Availability.

Procedure

Step 1 For clustering or High Availability, perform the following steps.



- **Clustering**—To avoid downtime, you can break each node one at a time so it is no longer in the cluster while you perform the network module replacement. See Break a Node, on page 263.

  You will add the node back to the cluster after you perform the replacement.

- **High Availability**—To avoid failing over when you replace the network module, disable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 228.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 128: Manage Chassis

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

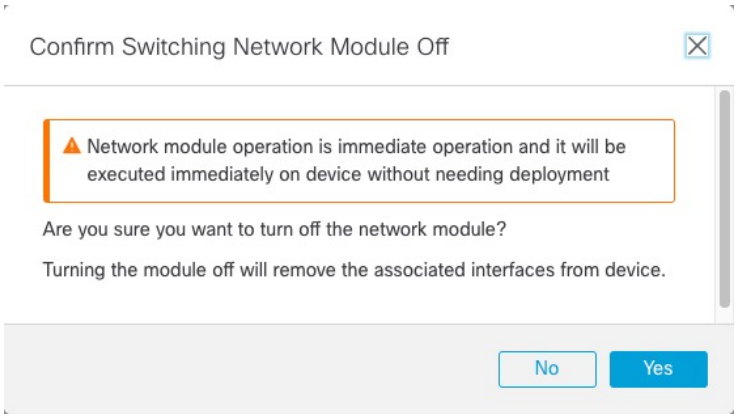


Figure 129: Disable the Network Module

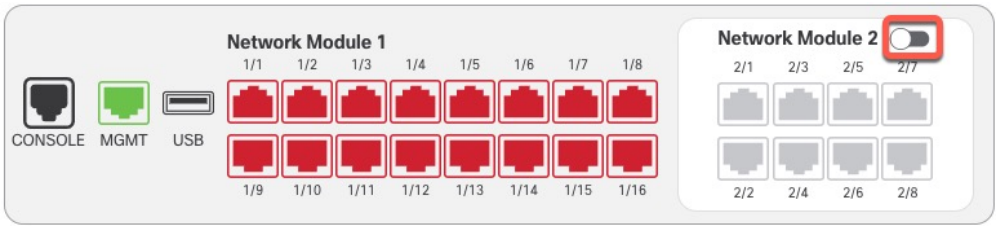
Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

Step 4 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 130: Confirm Disable

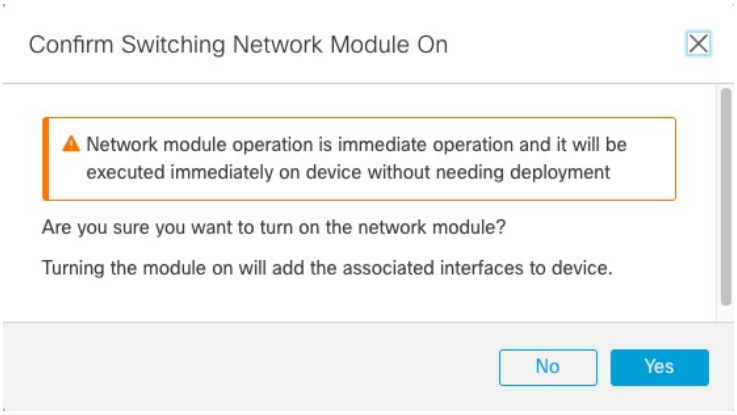
Step 5 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.



Step 6 Reboot the firewall; see Shut Down or Restart the Device, on page 32.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node (see Change the Control Node, on page 266) or active unit (see Switch the Active Peer in the FTD High Availability Pair, on page 230), and reboot the former control node/active unit.

Step 7 In the FMC, click **Sync Modules** to update the page with the new network module details.



Step 8 Enable the new module by clicking the slider ( ).

Figure 131: Enable the Network Module

Step 9 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 132: Confirm Enable

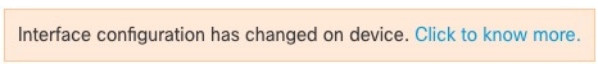
Step 10 Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 133: Go to Interface Page

Step 11 If the network module has *fewer* interfaces:

a) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

Figure 134: View Interface Changes



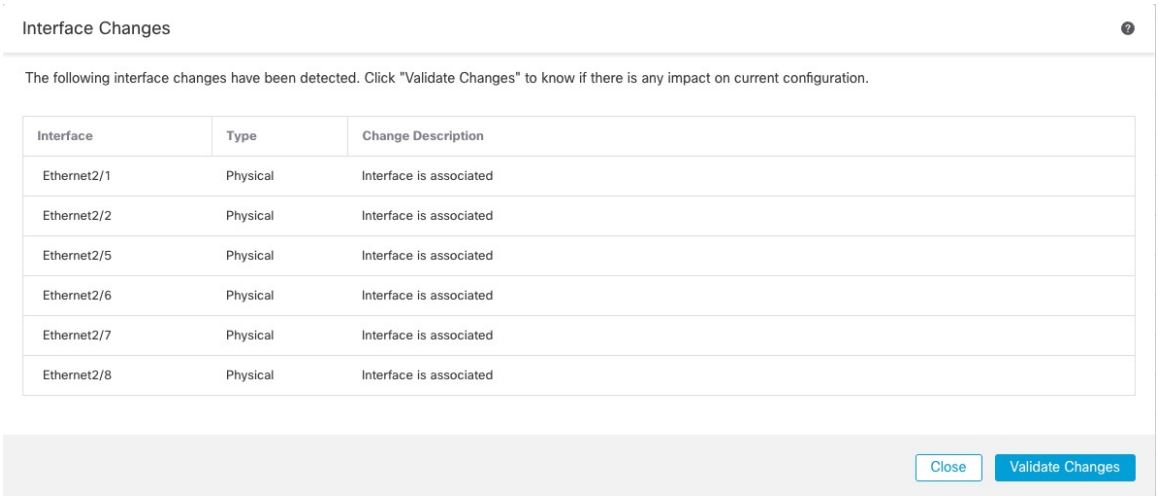


Figure 135: Interface Changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 12 To change the interface speed, see Enable the Physical Interface and Configure Ethernet Settings, on page 355.

The default speed is set to Detect SFP, which detects the correct speed from the SFP installed. You only need to fix the speed if you manually set the speed to a particular value and you now need a new speed.

Step 13 Click **Save** to save the interface changes to the firewall.

Step 14 If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the network module changes.

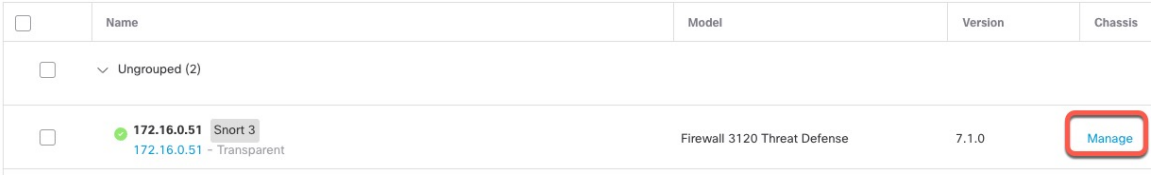
Step 15 For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster. See Add a New Cluster Node, on page 261.
- **High Availability**—Reenable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 228.

Remove the Network Module

If you want to permanently remove the network module, follow these steps. Removing a network module requires a reboot.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.



Before you begin

For clustering or High Availability, make sure the cluster/failover link is not on the network module.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

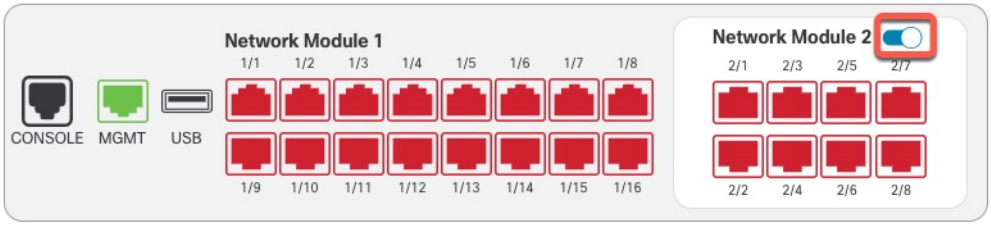


Figure 136: Manage Chassis

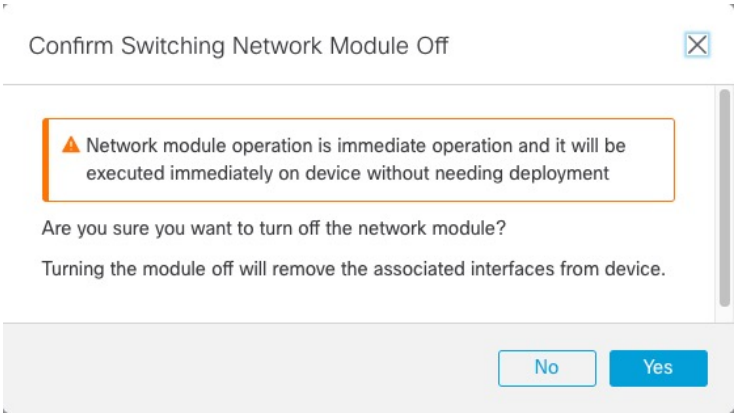
The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.



Step 2 On the interfaces graphic, click the slider ( ) to disable the network module.

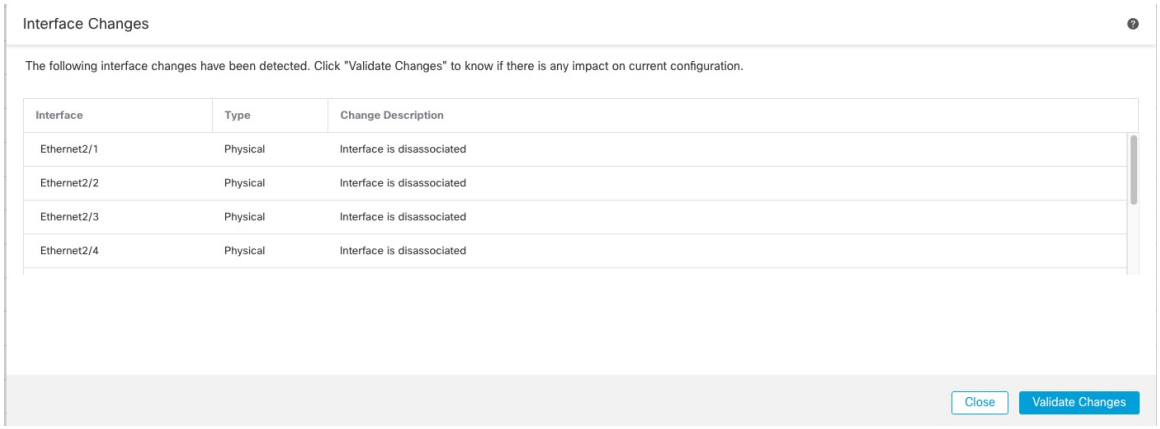
Figure 137: Disable the Network Module

Step 3 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 138: Confirm Disable

Step 4 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 139: Go to Interface Page



Step 5 At the top of the **Interfaces** page, you see a message that the interface configuration has changed.

Figure 140: View Interface Changes

a) Click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 141: Interface Changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

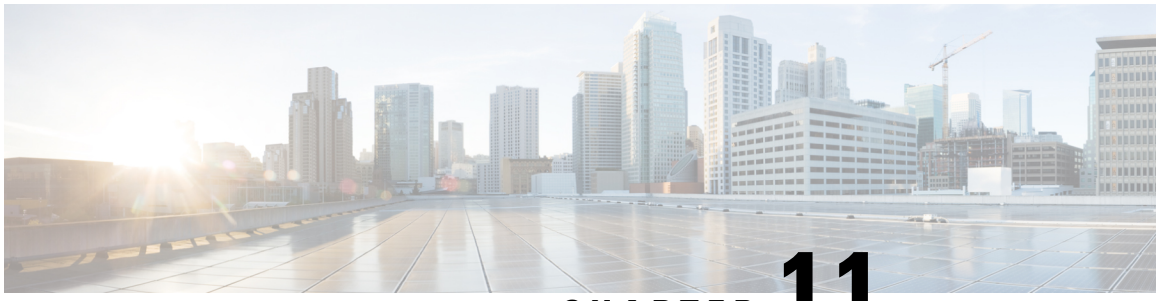
If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 6 Click **Save** to save the interface changes to the firewall.

Step 7 If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.



Step 8 Reboot the firewall; see Shut Down or Restart the Device, on page 32.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node (see Change the Control Node, on page 266) or active unit (see Switch the Active Peer in the FTD High Availability Pair, on page 230), and reboot the former control node/active unit.

History for Interfaces

Feature	Minimum FMC	Minimum FTD	Details
Support for hot swapping the network module for the Secure Firewall 3100	7.1.0	7.1.0	You can add or remove the network module on the Secure Firewall 3100 while the firewall is powered up. To replace a module with another module of the same type, you do not need to reboot. After initial bootup, adding a module, permanently removing a module, or replacing a module with a new type requires a reboot. New/Modified screens: **Devices** > **Device Management** > **Chassis Operations**
Support for Forward Error Correction for the Secure Firewall 3100	7.1.0	7.1.0	Secure Firewall 3100 25 Gbps interfaces support Forward Error Correction (FEC). FEC is enabled by default and set to Auto. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
Support for setting the speed based on the SFP for the Secure Firewall 3100	7.1.0	7.1.0	The Secure Firewall 3100 supports speed detection for interfaces based on the SFP installed. Detect SFP is enabled by default. This option is useful if you later change the network module to a different model, and want the speed to update automatically. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
LLDP support for the Firepower 1100.	7.1.0	7.1.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 1100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **LLDP** New/Modified commands: **show lldp status, show lldp neighbors, show lldp statistics**
Interface auto-negotiation is now set independently from speed and duplex, interface sync improved.	7.1.0	7.1.0	Interface auto-negotiation is now set independently from speed and duplex. Also, when you sync the interfaces in FMC, hardware changes are detected more effectively. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed** Supported platforms: Firepower 1000, 2100, Secure Firewall 3100

Feature	Minimum FMC	Minimum FTD	Details
Firepower 1100/2100 series fiber interfaces now support disabling auto-negotiation.	6.7.0	6.7.0	You can now configure a Firepower 1100/2100 series fiber interface to disable flow control and link status negotiation. Previously, when you set the fiber interface speed (1000 or 10000 Mbps) on these devices, flow control and link status negotiation was automatically enabled. You could not disable it. Now, you can deselect **Auto-negotiation** and set the speed to 1000 to disable flow control and link status negotiation. You cannot disable negotiation at 10000 Mbps. New/modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed**

CHAPTER 11

Regular Firewall Interfaces

This chapter includes regular firewall FTD interface configuration including EtherChannels, VLAN subinterfaces, IP addressing, and more.

Note For initial interface configuration on the Firepower 4100/9300, see Configure Interfaces, on page 188.

- Requirements and Prerequisites for Regular Firewall Interfaces, on page 383
- Configure Firepower 1010 Switch Ports, on page 383

Configure Firepower 1010 Switch Ports

You can configure each Firepower 1010 interface to run as a regular firewall interface or as a Layer 2 hardware switch port. This section includes tasks for starting your switch port configuration, including enabling or

disabling the switch mode and creating VLAN interfaces and assigning them to switch ports. This section also describes how to customize Power over Ethernet (PoE) on supported interfaces.

About Switch Ports

This section describes the switch ports of the 1010.

Understanding Switch Ports and Interfaces

Ports and Interfaces

For each physical 1010 interface, you can set its operation as a firewall interface or as a switch port. See the following information about physical interface and port types as well as logical VLAN interfaces to which you assign switch ports:

- Physical firewall interface—In routed mode, these interfaces forward traffic between networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces are bridge group members that forward traffic between the interfaces on the same network at Layer 2, using the configured security policy to apply firewall services. In routed mode, you can also use Integrated Routing and Bridging with some interfaces as bridge group members and others as Layer 3 interfaces. By default, the Ethernet 1/1 interface is configured as a firewall interface. You can also configure these interfaces to be IPS-only (inline sets and passive interfaces).
- Physical switch port—Switch ports forward traffic at Layer 2, using the switching function in hardware. Switch ports on the same VLAN can communicate with each other using hardware switching, and traffic is not subject to the FTD security policy. Access ports accept only untagged traffic, and you can assign them to a single VLAN. Trunk ports accept untagged and tagged traffic, and can belong to more than one VLAN. By default, Ethernet 1/2 through 1/8 are configured as access switch ports on VLAN 1. You cannot configure the Diagnostic interface as a switch port.
- Logical VLAN interface—These interfaces operate the same as physical firewall interfaces, with the exception being that you cannot create subinterfaces, IPS-only interfaces (inline sets and passive interfaces), or EtherChannel interfaces. When a switch port needs to communicate with another network, then the FTD device applies the security policy to the VLAN interface and routes to another logical VLAN interface or firewall interface. You can even use Integrated Routing and Bridging with VLAN interfaces as bridge group members. Traffic between switch ports on the same VLAN are not subject to the FTD security policy, but traffic between VLANs in a bridge group are subject to the security policy, so you may choose to layer bridge groups and switch ports to enforce the security policy between certain segments.

Power Over Ethernet

PoE is available on Ethernet 1/7 and Ethernet 1/8 using IEEE 802.3af (PoE) and 802.3at (PoE+) up to 30 watts per port.

PoE+ uses Link Layer Discovery Protocol (LLDP) to negotiate the power level. Power is only supplied when needed.

If you shut down the interface, then you disable power to the device.

Auto-MDI/MDIX Feature

For all switch ports, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. When the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Guidelines and Limitations for Switch Ports

High Availability and Clustering

- No cluster support.
- You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High Availability, but a simpler setup is to use physical firewall interfaces instead.
- You can only use a firewall interface as the failover link.

Logical VLAN Interfaces (SVIs)

- You can create up to 60 VLAN interfaces.
- If you also use VLAN subinterfaces on a firewall interface, you cannot use the same VLAN ID as for a logical VLAN interface.
- MAC Addresses:
  - Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC Address, on page 425.
  - Transparent firewall mode—Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC Address, on page 425.

Bridge Groups

You cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.

VLAN Interface and Switch Port Unsupported Features

VLAN interfaces and switch ports do not support:

- Dynamic routing

- Multicast routing
- Equal-Cost Multi-Path routing (ECMP)
- Inline sets or Passive interfaces
- EtherChannels—Switch ports cannot be part of an EtherChannel. PoE is also not supported on a port in an EtherChannel.
- Failover and state link
- Security group tagging (SGT)

Other Guidelines and Limitations

- You can configure a maximum of 60 named interfaces on the Firepower 1010.
- You cannot configure the Diagnostic interface as a switch port.

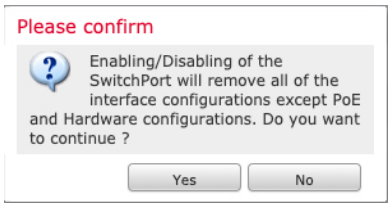
Default Settings

- Ethernet 1/1 is a firewall interface.
- Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- Default Speed and Duplex—By default, the speed and duplex are set to auto-negotiate.

Configure Switch Ports and Power Over Ethernet

To configure switch ports and PoE, complete the following tasks.

Enable or Disable Switch Port Mode



You can set each interface independently to be either a firewall interface or a switch port. By default, Ethernet 1/1 is a firewall interface, and the remaining Ethernet interfaces are configured as switch ports.

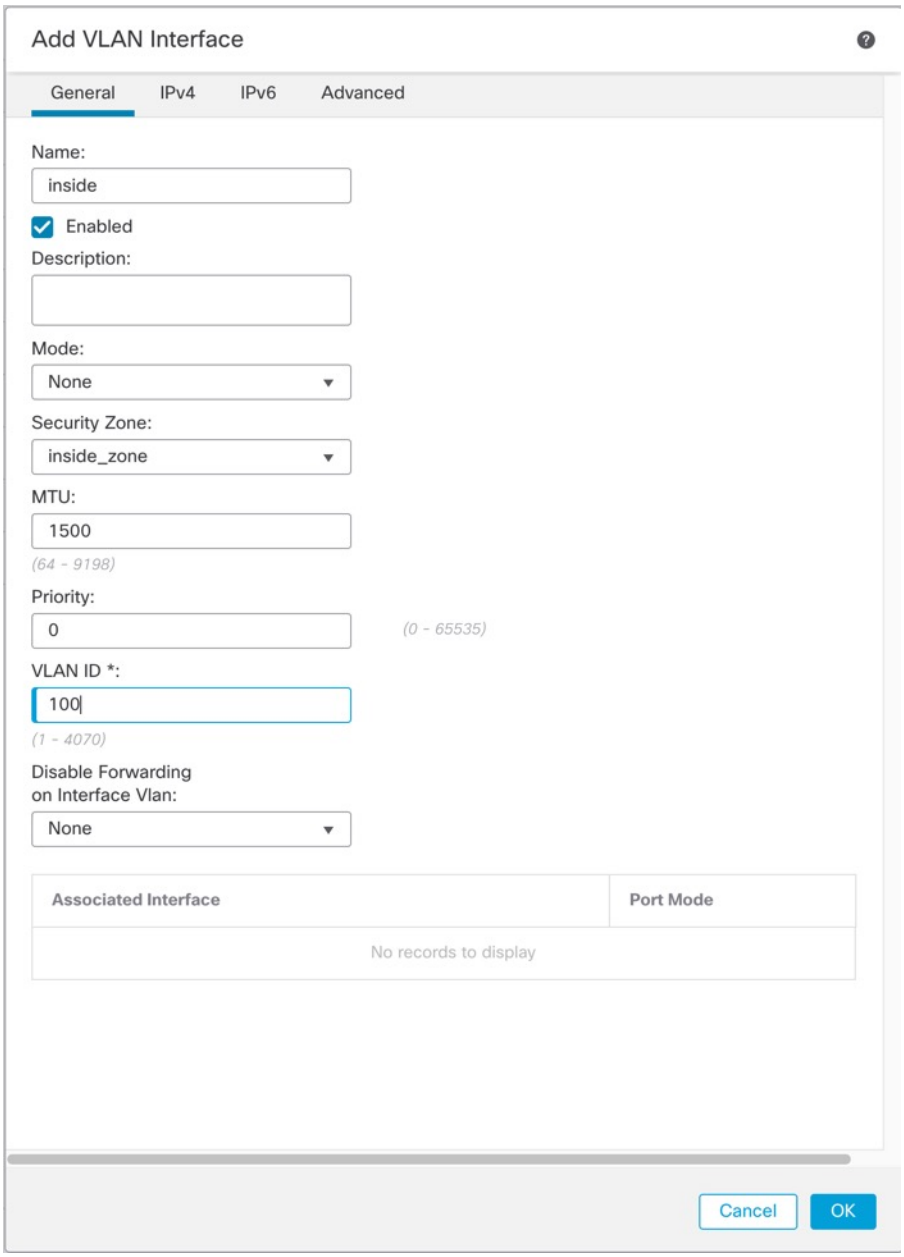
Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Set the switch port mode by clicking the slider in the **SwitchPort** column so it shows as **Slider enabled** ( ) or **Slider disabled** ( ).

By default, switch ports are set to access mode in VLAN 1. You must manually add a logical VLAN 1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the FTD security policy (see Configure a VLAN Interface, on page 387). You cannot set the Management interface to switch port mode. When you change the switch port mode, all unsupported configuration is removed:

Configure a VLAN Interface



This section describes how to configure VLAN interfaces for use with associated switch ports. By default, switch ports are assigned to VLAN1; however, you must manually add the logical VLAN1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the FTD security policy.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Add Interfaces** > **VLAN Interface**.

Step 3 On **General**, set the following VLAN-specific parameters:

If you are editing an existing VLAN interface, the **Associated Interface** table shows switch ports on this VLAN.

a) Set the **VLAN ID**, between 1 and 4070, excluding IDs in the range 3968 to 4047, which are reserved for internal use.

   You cannot change the VLAN ID after you save the interface; the VLAN ID is both the VLAN tag used, and the interface ID in your configuration.

b) (Optional) Choose a VLAN ID for **Disable Forwarding on Interface VLAN** to disable forwarding to another VLAN.

For example, you have one VLAN assigned to the outside for internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can disable forwarding on the home VLAN; the business network can access the home network, but the home network cannot access the business network.

Step 4 To complete the interface configuration, see one of the following procedures:

- Configure Routed Mode Interfaces, on page 406
- Configure General Bridge Group Member Interface Parameters, on page 411

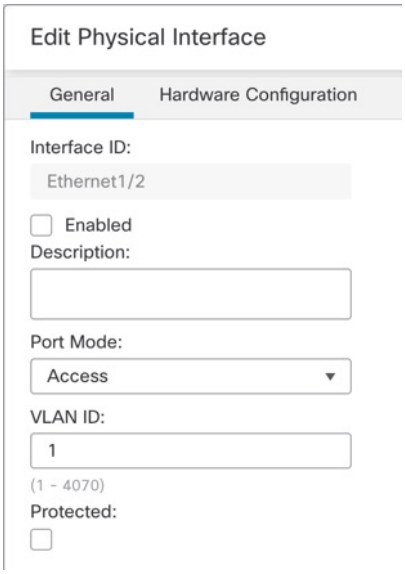
Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Switch Ports as Access Ports

To assign a switch port to a single VLAN, configure it as an access port. Access ports accept only untagged traffic. By default, Ethernet1/2 through Ethernet 1/8 switch ports are assigned to VLAN 1.



Note The device does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the FTD does not end up in a network loop.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 142: Edit Physical Interface

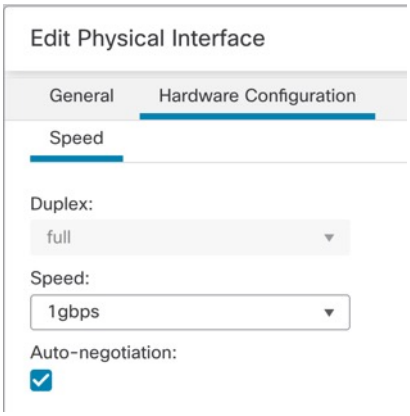
Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Access**.

Step 6 In the **VLAN ID** field, set the VLAN for this switch port, between 1 and 4070.



The default VLAN ID is 1.

Step 7 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Figure 143: Hardware Configuration

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

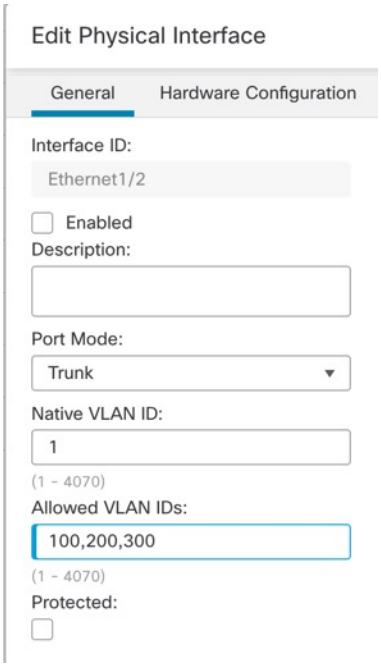
Step 9 Click **OK**.

Step 10 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Switch Ports as Trunk Ports

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk ports accept untagged and tagged traffic. Traffic on allowed VLANs pass through the trunk port unchanged.



When the trunk receives untagged traffic, it tags it to the native VLAN ID so that the ASA can forward the traffic to the correct switch ports, or can route it to another firewall interface. When the ASA sends native VLAN ID traffic out of the trunk port, it removes the VLAN tag. Be sure to set the same native VLAN on the trunk port on the other switch so that the untagged traffic will be tagged to the same VLAN.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 144: Set Trunk Port Mode

Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Trunk**.

Step 6 In the **Native VLAN ID** field, set the native VLAN for this switch port, between 1 and 4070.

The default native VLAN ID is 1.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

Step 7 In the **Allowed VLAN IDs** field, enter the VLANs for this trunk port between 1 and 4070.

You can identify up to 20 IDs in one of the following ways:

- A single number (n)
- A range (n-x)
- Numbers and ranges separated by commas, for example:

  5,7-10,13,45-100

  You can enter spaces instead of commas.

If you include the native VLAN in this field, it is ignored; the trunk port always removes the VLAN tagging when sending native VLAN traffic out of the port. Moreover, it will not receive traffic that still has native VLAN tagging.

Step 8 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 9 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

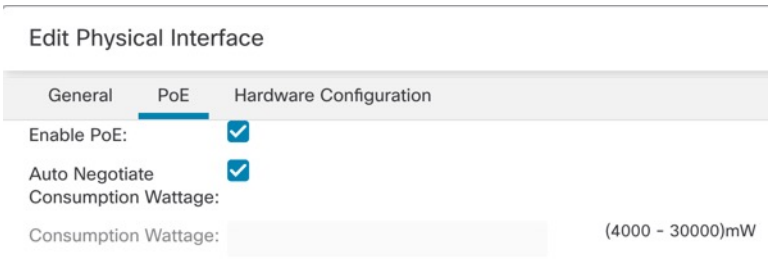
Step 10 Click **OK**.

Step 11 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Power Over Ethernet

Power over Ethernet (PoE) ports provide power for devices such as IP phones or wireless access points. PoE is enabled by default. This procedure describes how to disable and enable PoE and how to set optional parameters.



Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for Ethernet1/7 or 1/8.

Step 3 Click **PoE**.

Figure 145: PoE

Step 4 Check the **Enable PoE** check box.

PoE is enabled by default.

Step 5 Choose autonegotiation or manual power.

- **Auto Negotiate Consumption Wattage**—Delivers power automatically to the powered device using a wattage appropriate to the class of the powered device. The firewall uses LLDP to further negotiate the correct wattage. When you connect a device of a certain class, it will be provisioned up to the maximum for that class in case it ever needs to use more power. For example, if you add a class 4 device that requests 12.95W, it will be allocated 30W even if it doesn't currently use all that power. Some devices can renegotiate power needs. If you know your device needs less power than is allocated, you can instead set the **Consumption Wattage** manually to free up the power for other devices.
- **Consumption Wattage**—Uncheck the **Auto Negotiate Consumption Wattage** check box to set the manual wattage to manually specify the wattage in milliwatts, from 4000 to 30000. Use this option if you want to set the watts manually and disable LLDP negotiation. For manual allocation, the class will show in **show power inline** output as **n/a** because the class is not used to decide the power consumption.

  View the current PoE status using the **show power inline** command.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure VLAN Subinterfaces and 802.1Q Trunking

VLAN subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs let you keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

Guidelines and Limitations for VLAN Subinterfaces

Model Support

- Firepower 1010—VLAN subinterfaces are not supported on switch ports or VLAN interfaces.

High Availability and Clustering

You cannot use a subinterface for the failover or state link or for the cluster control link. The exception is for multi-instance mode: you can use a *chassis*-defined subinterface for these links.

Additional Guidelines

- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. This property is also true for the active physical interface in a redundant interface pair and for EtherChannel links. Because the physical, redundant, or EtherChannel interface must be enabled for the subinterface to pass traffic, ensure that the physical, redundant, or EtherChannel interface does not pass traffic by not configuring a name for the interface. If you want to let the physical, redundant, or EtherChannel interface pass untagged packets, you can configure the name as usual.
- You cannot configure subinterfaces on the Management interface, either the dedicated Management interface configured at the CLI nor a data interface used for manager access.
- All subinterfaces on the same parent interface must be either bridge group members or routed interfaces; you cannot mix and match.
- The FTD does not support the Dynamic Trunking Protocol (DTP), so you must configure the connected switch port to trunk unconditionally.
- You might want to assign unique MAC addresses to subinterfaces defined on the FTD, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the FTD.

Note If you manually assign a MAC address, be sure to assign MAC addresses to all subinterfaces on the same physical interface to avoid unexpected behavior and outages.

Maximum Number of VLAN Subinterfaces by Device Model

The device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface.

The following table explains the limits for each device model.

Model	Maximum VLAN Subinterfaces
Firepower 1010	60

Model	Maximum VLAN Subinterfaces
Firepower 1120	512
Firepower 1140, 1150	1024
Firepower 2100	1024
Secure Firewall 3100	1024
Firepower 4100	1024
Firepower 9300	1024
FTDv	50
ISA 3000	100

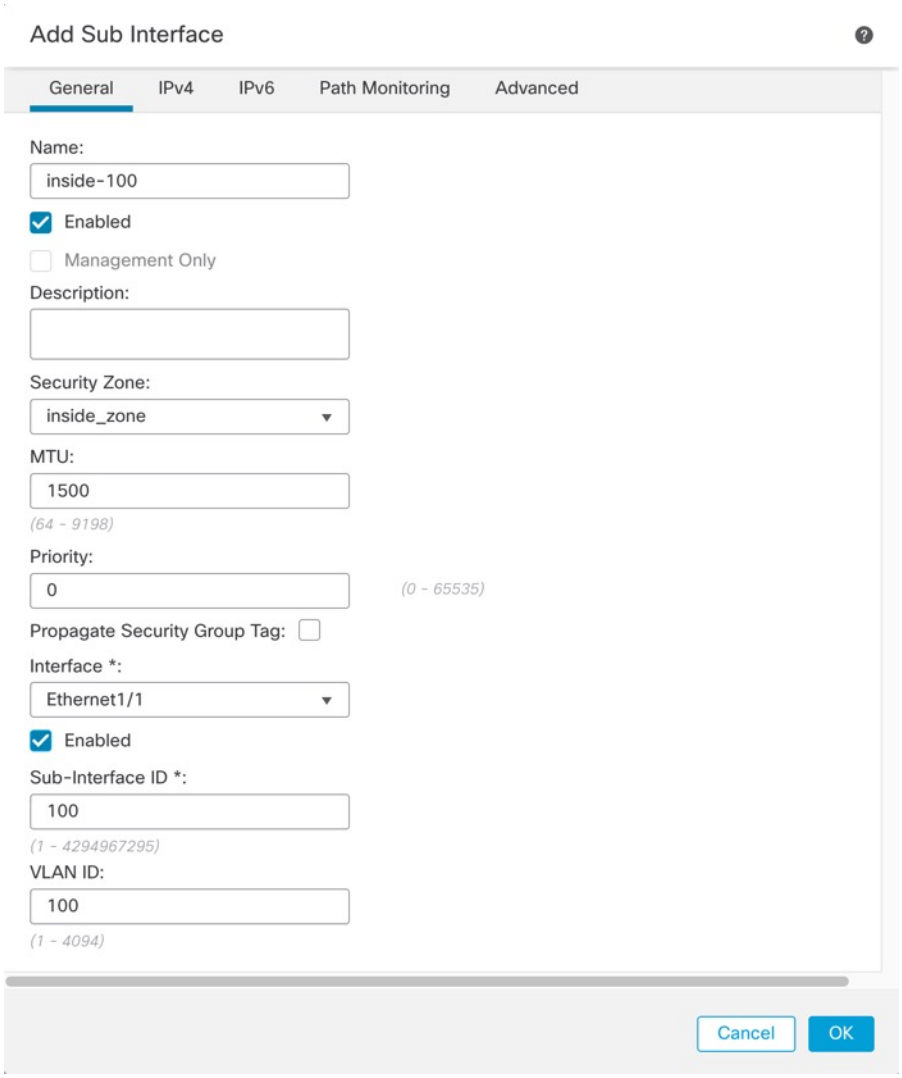
Add a Subinterface

Add one or more subinterfaces to a physical, redundant, or port-channel interface.

For the Firepower 4100/9300, you can configure subinterfaces in FXOS for use with container instances; see Add a VLAN Subinterface for Container Instances, on page 191. These subinterfaces appear in the FMC interface list. You can also add subinterfaces in FMC, but only on parent interfaces that do not already have subinterfaces defined in FXOS.

Note The parent physical interface passes untagged packets. You may not want to pass untagged packets, so be sure not to include the parent interface in your security policy.

Procedure



Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Enable the parent interface according to Enable the Physical Interface and Configure Ethernet Settings, on page 355.

Step 3 Click **Add Interfaces** > **Sub Interface**.

Step 4 On **General**, set the following parameters:

Figure 146: Add Subinterface

a) **Interface**—Choose the physical, redundant, or port-channel interface to which you want to add the subinterface.

b) **Sub-Interface ID**—Enter the subinterface ID as an integer between 1 and 4294967295. The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.

c) **VLAN ID**—Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

   This VLAN ID must be unique.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 7 Configure the routed or transparent mode interface parameters. See Configure Routed Mode Interfaces, on page 406 or Configure Bridge Group Interfaces, on page 411.

Configure Geneve Interfaces

This chapter tells how to configure Geneve interfaces. Geneve interfaces act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks.

About Geneve Interfaces

Geneve is an encapsulation network protocol similar to Virtual eXtensible Local Area Network (VXLAN).

The FTDv supports Amazon Web Services (AWS) Gateway Load Balancer, which combines a transparent network gateway (that is, a single entry and exit point for all traffic) and a load balancer that distributes traffic and scales the virtual appliances such as the FTDv with the demand.

The FTDv deployed on AWS platform supports only the single-arm proxy mode.

Geneve Encapsulation

Geneve has a flexible inner header that is not limited to the MAC address. Geneve encapsulation is required for transparent routing of packets between an Amazon Web Services (AWS) Gateway Load Balancer and appliances, and for sending extra information.

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces to which you apply your security policy, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

The underlying IP network between VTEPs is independent of the VXLAN overlay. Encapsulated packets are routed based on the outer IP address header, which has the initiating VTEP as the source IP address and the terminating VTEP as the destination IP address. The destination IP address can be a multicast group when the remote VTEP is not known. With Geneve, the FTD only supports static peers. The destination port for Geneve is 6081.

VTEP Source Interface

The VTEP source interface is a regular interface with which you plan to associate all VNI interfaces. You can configure one VTEP source interface per FTDv.

The VTEP source interface can be devoted wholly to Geneve traffic, although it is not restricted to that use. If desired, you can use the interface for regular traffic and apply a security policy to the interface for that traffic. For Geneve traffic, however, all security policy must be applied to the VNI interfaces. The VTEP interface serves as a physical port only.

VNI Interfaces

VNI interfaces are similar to VLAN interfaces: they are virtual interfaces that keep network traffic separated on a given physical interface by using tagging. You apply your security policy directly to each VNI interface.

You can only add one VTEP interface, and all VNI interfaces are associated with the same VTEP interface.

VXLAN Packet Processing

Traffic entering and exiting the VTEP source interface is subject to Geneve processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the Geneve header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is set the peer IP address that you configured.

Decapsulation; the ASA only decapsulates a Geneve packet if:

- It is a UDP packet with the destination port set to 6081 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The Geneve packet format is compliant with the standard.

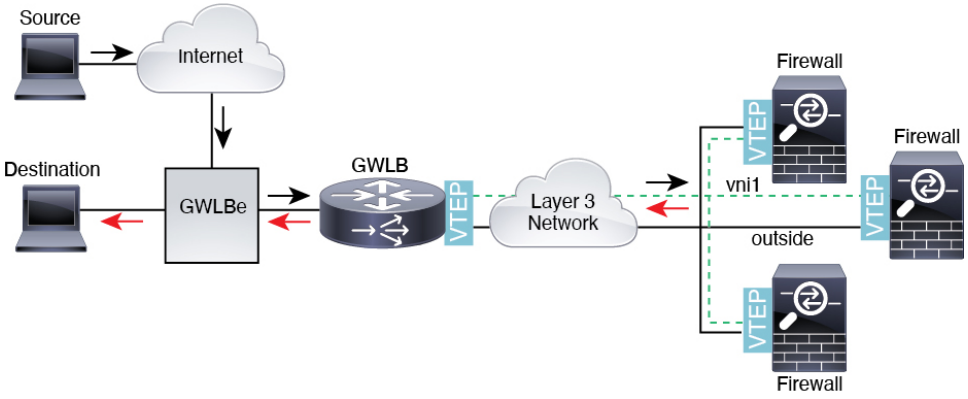
Peer VTEPs

When the FTD sends a packet to a device behind a peer VTEP, the FTD needs two important pieces of information:

- The destination MAC address of the remote device
- The destination IP address of the peer VTEP

The FTD maintains a mapping of destination MAC addresses to remote VTEP IP addresses for the VNI interfaces.

The FTDv only supports statically defined peers. You can define the FTDv peer IP address on the AWS Gateway Load Balancer. Because the FTDv never initiates traffic to the Gateway Load Balancer, you do not also have to specify the Gateway Load Balancer IP address on the FTDv; it learns the peer IP address when it receives Geneve traffic.



Geneve Single-Arm Proxy Use Case

Note This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The FTDv supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple FTDvs, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Figure 147: Geneve Single-Arm Proxy

Requirements and Prerequisites for Geneve Interfaces

Model Requirements

- Geneve encapsulation is supported for the following models:
  - FTDv in Amazon Web Services (AWS)

Guidelines for Geneve Interfaces

Firewall Mode

- Geneve interfaces are only supported in routed firewall mode.

IPv6

- The VNI interface supports both IPv4 and IPv6 traffic.
- The VTEP source interface IP address only supports IPv4.

Routing

- Only static routing or Policy Based Routing is supported on the VNI interface; dynamic routing protocols are not supported.

VPN

You cannot configure the VTEP source interface for VPN or use it as a VTI.

MTU

- If the source interface MTU is less than 1806 bytes, then the FTD automatically raises the MTU to 1806 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 306 bytes. This MTU requires a restart to enable jumbo frame reservation.

Configure Geneve Interfaces

To configure Geneve interfaces for FTDv, perform the following steps.

1. Configure the VTEP Source Interface, on page 401.
2. Configure the VNI, on page 402.
3. Allow Gateway Load Balancer Health Checks, on page 402.

Configure the VTEP Source Interface

You can configure one VTEP source interface per FTDv device. The VTEP is defined as a Network Virtualization Endpoint (NVE); Geneve VTEP is the only natively supported NVE at this time.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **VTEP**.

Step 4 Check **Enable NVE**.

Step 5 Click **Add VTEP**.

Step 6 Enter the value for the **Encapsulation port** within the specified range.

We do not recommend changing the Geneve port; AWS requires a port of 6081.

Step 7 Select the **VTEP Source Interface**.

You can select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1806 bytes, then the FMC automatically raises the MTU to 1806 bytes.

Step 8 Click **OK**.

Step 9 Click **Save**.

Step 10 Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI

Add a VNI, associate it with (VTEP) source interface, and configure basic interface parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

Step 5 In the **Name** and **Description** fields, provide relevant information.

Step 6 In the **VNI ID** field, enter a value between 1 and 10000.

Note
This ID is only an internal interface identifier.

Step 7 Check the **Enable Proxy** check box.

Note
When the AWS proxy is enabled on the VNI interface of your device, configuring NAT is not allowed.

This option enables single-arm proxy, and allows traffic to exit the same interface it entered (U-turn traffic). If you later edit the interface, you cannot disable single-arm proxy. To do that, you need to delete the existing interface and create a new VNI interface.

This option is only available for a Geneve VTEP.

Step 8 Select **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 9 Click **OK**.

Step 10 Click **Save**.

What to do next

Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Allow Gateway Load Balancer Health Checks

The AWS GWLB requires appliances to answer a health check properly. The GWLB will only send traffic to appliances that are considered healthy. You must configure the FTDv to respond to an SSH, HTTP, or HTTPS health check.

Configure one of the following methods.

Procedure

Step 1 Configure SSH. See Configure Secure Shell

Allow SSH from the GWLB IP address. The GWLB will attempt to establish a connection to the FTDv, and the FTDv's prompt to log in is taken as proof of health. An SSH login attempt will time out after 1 minute. You will need to configure a longer health check interval on the GWLB to accommodate this timeout.

Step 2 Configure HTTP(S) Redirection Using Static Interface NAT with Port Translation.

You can configure the FTDv to redirect health checks to a metadata HTTP(S) server. For HTTP(S) health checks, the HTTP(S) server must reply to the GWLB with a status code in the range 200 to 399. Because the FTDv has limits on the number of simultaneous management connections, you may choose to offload the health check to an external server.

Static interface NAT with port translation lets you redirect a connection to a port (such as port 80) to a different IP address. For example, translate an HTTP packet from the GWLB with a destination of the FTDv outside interface so that it appears to be from the FTDv outside interface with a destination of the HTTP server. The FTDv then forwards the packet to the mapped destination address. The HTTP server responds to the FTDv outside interface, and then the FTDv forwards the response back to the GWLB. You need an access rule that allows traffic from the GWLB to the HTTP server.

a) Permit HTTP(S) traffic on the outside interface from the GWLB network in an access rule. See Access Control Rules, on page 1181.
b) For HTTP(S), translate the source GWLB IP address to the FTDv outside interface IP address; then translate the destination of the outside interface IP address to the HTTP(S) server IP address. See Configure Static Manual NAT, on page 577.

Configure Routed and Transparent Mode Interfaces

This section includes tasks to complete the regular interface configuration for all models in routed or transparent firewall mode.

About Routed and Transparent Mode Interfaces

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 143 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the FTD device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the

network. In routed mode, the FTD device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

Dual IP Stack (IPv4 and IPv6)

The FTD device supports both IPv6 and IPv4 addresses on an interface. Make sure you configure a default route for both IPv4 and IPv6.

31-Bit Subnet Mask

For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 FTDs only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog.

31-Bit Subnet and Clustering

You can use a 31-bit subnet mask for cluster interfaces, excluding the management interface and the Cluster Control Link.

31-Bit Subnet and Failover

For failover, when you use a 31-bit subnet for the FTD interface IP address, you cannot configure a standby IP address for the interface because there are not enough addresses. Normally, an interface for failover should have a standby IP address so the active unit can perform interface tests to ensure standby interface health. Without a standby IP address, the FTD cannot perform any network tests; only the link state can be tracked.

For the failover and optional separate state link, which are point-to-point connections, you can also use a 31-bit subnet.

31-Bit Subnet and Management

If you have a directly-connected management station, you can use a point-to-point connection for SSH or HTTP on the FTD, or for SNMP or Syslog on the management station.

31-Bit Subnet Unsupported Features

The following features do not support the 31-Bit subnet:

- BVI interfaces for bridge groups—The bridge group requires at least 3 host addresses: the BVI, and two hosts connected to two bridge group member interfaces. you must use a /29 subnet or smaller.
- Multicast Routing

Guidelines and Limitations for Routed and Transparent Mode Interfaces

High Availability, Clustering, and Multi-Instance

- Do not configure failover links with the procedures in this chapter. See the High Availability chapter for more information.

- For cluster interfaces, see the clustering chapter for requirements.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- When you use High Availability, you must set the IP address and standby address for data interfaces manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. See the High Availability chapter for more information.

IPv6

- IPv6 is supported on all interfaces.
- You can only configure IPv6 addresses manually in transparent mode.
- The FTD device does not support IPv6 anycast addresses.

Model Guidelines

- For the FTDv on VMware with bridged ixgbevf interfaces, bridge groups are not supported.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.

Transparent Mode and Bridge Group Guidelines

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The FTD device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the FTD device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the FTDv on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.
- For the Firepower 1010, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.

- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the FTD as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- In transparent mode, PPPoE is not supported for the Diagnostic interface.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, FTD-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the FTD when using bridge group members. If there are two neighbors on either side of the FTD running BFD, then the FTD will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Additional Guidelines and Requirements

- The FTD supports only one 802.1Q header in a packet and does not support multiple headers (known as Q-in-Q support) for firewall interfaces.**Note:** For inline sets and passive interfaces, the FTD supports Q-in-Q up to two 802.1Q headers in a packet, with the exception of the Firepower 4100/9300, which only supports one 802.1Q header.
- Interface problems, such as frequent up/down status changes, can prevent the floating connection timer from applying correctly to the connections going through the interface. If you have problems with an interface's status, consider clearing all connections after the status becomes stable to clear invalid connections.

Configure Routed Mode Interfaces

This procedure describes how to set the name, security zone, and IPv4 address.

Note Not all fields are supported for all interface types.

Before you begin

- **Firepower 4100/9300**
  1. Configure a Physical Interface, on page 188
  2. (Optional) Configure any special interfaces.

- Add an EtherChannel (Port Channel), on page 189
- Add a VLAN Subinterface for Container Instances, on page 191 in FXOS
- Add a Subinterface, on page 396 in FMC

- (Optional) **All other models:**
  - Configure an EtherChannel, on page 362
  - Add a Subinterface, on page 396
  - FTDv on AWS: Configure Geneve Interfaces, on page 401
  - Firepower 1010: Configure a VLAN Interface, on page 387

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

Step 6 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 7 In the **Mode** drop-down list, choose **None**.

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types.

Step 8 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

The routed interface is a Routed-type interface, and can only belong to Routed-type zones.

Step 9 See Configure the MTU, on page 425 for information about the **MTU**.

Step 10 In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to route the traffic across multiple egress interfaces. For more information, see Configure Policy-Based Routing Policy, on page 828.

Step 11 Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability, clustering interfaces only support static IP address configuration; DHCP and PPPoE are not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254 or /31). In this case, no IP addresses are reserved for the network or broadcast addresses. You cannot set the standby IP address in this case. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.
- **Use PPPoE**—If the interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, configure the following parameters:
  - **VPDN Group Name**—Specify a group name of your choice to represent this connection.
  - **PPPoE User Name**—Specify the username provided by your ISP.
  - **PPPoE Password/Confirm Password**—Specify and confirm the password provided by your ISP.
  - **PPP Authentication**—Choose **PAP**, **CHAP**, or **MSCHAP**.

    PAP passes a cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.
  - **PPPoE route metric**—Assign an administrative distance to the learned route. Valid values are from 1 to 255. By default, the administrative distance for the learned routes is 1.
  - **Enable Route Settings**—To manually configure the PPPoE IP address, check this box and then enter the **IP Address**.

    If you select the **Enable Route Settings** check box and leave the **IP Address** blank, the **ip address pppoe setroute** command is applied as shown in this example:

    ```
    interface GigabitEthernet0/2
    nameif inside2_pppoe
    cts manual
      propagate sgt preserve-untag
      policy static sgt disabled trusted
    security-level 0
    pppoe client vpdn group test
    pppoe client route distance 10
    ip address pppoe setroute
    ```
  - **Store Username and Password in Flash**—Stores the username and password in flash memory.

    The FTD device stores the username and password in a special location of NVRAM.

Step 12 (Optional) See Configure IPv6 Addressing, on page 414 to configure IPv6 addressing on the **IPv6** tab.

Step 13 (Optional) See Configure the MAC Address, on page 425 to manually configure the MAC address on the **Advanced** tab.

Step 14 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
- **Forward Error Correction Mode**—(Secure Firewall 3100 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 29: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate

Step 15 (Optional) Enable FMC manager access on a data interface on the **FMC Access** page.

You can enable manager access from a data interface when you first setup the FTD. If you want to enable or disable manager access after you added the FTD to the FMC, see:

- Enable manager access: Change the Manager Access Interface from Management to Data, on page 56

  Note
  You cannot enable manager access unless you first initiate the manager interface migration from Management to a data interface. After you initiate the migration, you can enable manager access on the **FMC Access** page and save the configuration successfully.

- Disable manager access: Change the Manager Access Interface from Data to Management, on page 59

If you want to change the manager access interface from one data interface to another data interface, you must disable manager access on the original data interface, but do not disable the interface itself yet; the original data interface must be used to perform the deployment. If you want to use the same IP address on the new manager access interface, you can delete or change the IP configuration on the original interface; this change should not affect the deployment. If you use a different IP address for the new interface, then also change the device IP address shown in the FMC; see Update the Hostname or IP Address in the FMC, on page 52. Be sure to also update related configuration to use the new interface such as static routes, DDNS, and DNS settings.

Manager access from a data interface has the following limitations:

- You can only enable manager access on one physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the FTD and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the FMC. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For FTDv on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- You cannot use separate management and event-only interfaces.
- Clustering is not supported. You must use the Management interface in this case.
- High availability is not supported. You must use the Management interface in this case.

- Check **Enable management on this interface for the Firepower Management Center** to use this data interface for management instead of the dedicated Management interface.
- (Optional) In the **Allowed Management Networks** box, add the networks from which you want to allow manager access. By default, any networks are allowed.

Step 16 Click **OK**.

Step 17 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Bridge Group Interfaces

A bridge group is a group of interfaces that the Firepower Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. For more information about bridge groups, see About Bridge Groups, on page 145.

To configure bridge groups and associated interfaces, perform these steps.

Configure General Bridge Group Member Interface Parameters

This procedure describes how to set the name and security zone for each bridge group member interface. The same bridge group can include different types of interfaces: physical interfaces, VLAN subinterfaces, Firepower 1010 VLAN interfaces, EtherChannels, and redundant interfaces. The Management interface is not supported. In routed mode, EtherChannels are not supported. For the Firepower 4100/9300, data-sharing type interfaces are not supported.

Before you begin

- **Firepower 4100/9300**
  1. Configure a Physical Interface, on page 188
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (Port Channel), on page 189
     - Add a VLAN Subinterface for Container Instances, on page 191 in FXOS
     - Add a Subinterface, on page 396 in FMC
- (Optional) **All other models:**
  - Configure an EtherChannel, on page 362
  - Add a Subinterface, on page 396
  - Firepower 1010: Configure a VLAN Interface, on page 387

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

Step 6 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 7 In the **Mode** drop-down list, choose **None**.

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types. After you assign this interface to a bridge group, the mode will show as **Switched**.

Step 8 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

The bridge group member interface is a Switched-type interface, and can only belong to Switched-type zones. Do not configure any IP address settings for this interface. You will set the IP address for the Bridge Virtual Interface (BVI) only. Note that the BVI does not belong to a zone, and you cannot apply access control policies to the BVI.

Step 9 See Configure the MTU, on page 425 for information about the **MTU**.

Step 10 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
- **Forward Error Correction Mode**—(Secure Firewall 3100 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 30: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate

Step 11 (Optional) See Configure IPv6 Addressing, on page 414 to configure IPv6 addressing on the **IPv6** tab.

Step 12 (Optional) See Configure the MAC Address, on page 425 to manually configure the MAC address on the **Advanced** tab.

Step 13 Click **OK**.

Step 14 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure the Bridge Virtual Interface (BVI)

Each bridge group requires a BVI for which you configure an IP address. The FTD uses this IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the connected network. For IPv4 traffic, the BVI IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

For routed mode, if you provide a name for the BVI, then the BVI participates in routing. Without a name, the bridge group remains isolated as in transparent firewall mode.

Note For a separate Diagnostic interface, a non-configurable bridge group (ID 301) is automatically added to your configuration. This bridge group is not included in the bridge group limit.

Before you begin

You cannot add the BVI to a security zone; therefore, you cannot apply Access Control policies to the BVI. You must apply your policy to the bridge group member interfaces based on their zones.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Choose **Add Interfaces** > **Bridge Group Interface**.

Step 3 (Routed Mode) In the **Name** field, enter a name up to 48 characters in length.

You must name the BVI if you want to route traffic outside the bridge group members, for example, to the outside interface or to members of other bridge groups. The name is not case-sensitive.

Step 4 In the **Bridge Group ID** field, enter the bridge group ID between 1 and 250.

Step 5 In the **Description** field, enter a description for this bridge group.

Step 6 On the **Interfaces** tab, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members of the bridge group.

Step 7 (Transparent Mode) Click the **IPv4** tab. In the **IP Address** field, enter the IPv4 address and subnet mask.

Do not assign a host address (/32 or 255.255.255.255) to the BVI. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The FTD device drops all ARP packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the FTD device drops the ARP request from the downstream router to the upstream router.

For High Availability, set the standby IP address on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

Step 8 (Routed Mode) Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability and clustering interfaces only support static IP address configuration; DHCP is not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.

Step 9 (Optional) See Configure IPv6 Addressing, on page 414 to configure IPv6 addressing.

Step 10 (Optional) See Add a Static ARP Entry, on page 426 and Add a Static MAC Address and Disable MAC Learning for a Bridge Group, on page 427 (for transparent mode only) to configure the **ARP** and **MAC** settings.

Step 11 Click **OK**.

Step 12 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 Addressing

This section describes how to configure IPv6 addressing in routed and transparent mode.

About IPv6

This section includes information about IPv6.

IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. For a bridge group, this address needs to be configured for the BVI, and not per member interface. You can also configure a global IPv6 address for the management interface in transparent mode.

- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Neighbor Discovery functions such as address resolution. In a bridge group, only member interfaces have link-local addresses; the BVI does not have a link-local address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. For bridge group member interfaces, when you configure the global address on the BVI, the FTD device automatically generates link-local addresses for member interfaces. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The FTD device can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link.

Configure a Global IPv6 Address

To configure a global IPv6 address for any routed mode interface and for the transparent or routed mode BVI, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately. For bridge groups, configuring the global address on the BVI automatically configures link-local addresses on all member interfaces.

For subinterfaces defined on the FTD, we recommend that you also set the MAC address manually, because they use the same burned-in MAC address of the parent interface. IPv6 link-local addresses are generated based on the MAC address, so assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the FTD. See Configure the MAC Address, on page 425.

Before you begin

For IPv6 neighbor discovery for bridge groups, you must explicitly allow Neighbor Solicitation (ICMPv6 type 135) and Neighbor Advertisement (ICMPv6 type 136) packets through the FTD bridge group member interfaces using a bidirectional access rule.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **IPv6** page.

For routed mode, the **Basic** page is selected by default. For transparent mode, the **Address** page is selected by default.

Step 4 (Optional) On the **Basic** page, check **Enable IPv6**.

Use this option if you want to only configure the link-local addresses. Otherwise, configuring an IPv6 address enabled IPv6 processing automatically.

Step 5 Configure the global IPv6 address using one of the following methods.

For failover and clustering, you must set the IP address manually. For clustering, manually configuring the link-local address is also not supported.

- (Routed interface) Stateless autoconfiguration—Check the **Autoconfiguration** check box.

  Enabling stateless autoconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.

  Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the FTD device does send Router Advertisement messages in this case. Uncheck the **IPv6** > **Settings** > **Enable RA** check box to suppress messages.

- Manual configuration—To manually configure a global IPv6 address:

  a. Click the **Address** page, and click ( )**Add Address**.

  The **Add Address** dialog box appears.

  b. In the **Address** field, enter either a full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. (Routed Mode) If you only enter the prefix, then be sure to check the **Enforce EUI 64** check box to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked).

  For High Availability (if you did not set **Enforce EUI 64**), set the standby IP address on the **Devices** > **Device Management** > **High Availability** page in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

Step 6 For Routed interfaces, you can optionally set the following values on the **Basic** page:

- To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.
- To manually set the link-local address, enter an address in the **Link-Local address** field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

Clustering does not support manual link-local addresses.

- Check the **Enable DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- Check the **Enable DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

Step 7 For Routed interfaces, see Configure IPv6 Neighbor Discovery, on page 417 to configure settings on the **Prefixes** and **Settings** pages. For BVI interfaces, see the following parameters on the **Settings** page:

- **DAD attempts**—The maximum number of DAD attempts, between 1 and 600. Set the value to 0 to disable duplicate address detection (DAD) processing. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. 1 attempt is the default.
- **NS Interval**—The interval between IPv6 neighbor solicitation retransmissions on an interface, between 1000 and 3600000 ms. The default value is 1000 ms.
- **Reachable Time**—The amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, between 0 and 3600000 ms. The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 Neighbor Discovery

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cached values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

Before you begin

Supported in Routed mode only. For IPv6 neighbor settings supported in transparent mode, see Configure a Global IPv6 Address, on page 415.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click **IPv6**, and then **Prefixes**.

Step 4 (Optional) To configure which IPv6 prefixes are included in IPv6 router advertisements, perform the following steps:

a) Click ( )**Add Prefix**.
b) In the **Address** field, enter the IPv6 address with the prefix length or check the **Default** check box to use the default prefix.
c) (Optional) Uncheck the **Advertisement** check box to indicate that the IPv6 prefix is not advertised. For the **Default** prefix, this setting only applies to on-link prefixes. Off-link prefixes will still be advertised unless you uncheck **Advertisement** for a specific off-link prefix.
d) Check the **Off Link** check box to indicate that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.
e) To use the specified prefix for autoconfiguration, check the **Autoconfiguration** check box.
f) For the **Prefix Lifetime**, click **Duration** or **Expiration Date**.

- **Duration**—Enter a **Preferred Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days). Enter a **Valid Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days). Alternatively, check the **Infinite** check box to set an unlimited duration.
- **Expiration Date**—Choose a **Valid** and **Preferred** date and time.

g) Click **OK**.

Step 5 Click **Settings**.

Step 6 (Optional) Set the maximum number of **DAD attempts**, between 1 and 600. 1 attempt is the default. Set the value to 0 to disable duplicate address detection (DAD) processing.

This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses.

During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces.

When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

```
325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used.

Step 7 (Optional) Configure the interval between IPv6 neighbor solicitation retransmissions in the **NS Interval** field, between 1000 and 3600000 ms.

The default value is 1000 ms.

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICPMv6 Type 136) on the local link.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link.

Step 8 (Optional) Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred in the **Reachable Time** field, between 0 and 3600000 ms.

The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 9 (Optional) To suppress the router advertisement transmissions, uncheck the **Enable RA** check box. If you enable router advertisement transmissions, you can set the RA lifetime and interval.

Router advertisement messages (ICMPv6 Type 134) are automatically sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You may want to disable these messages on any interface for which you do not want the FTD to supply the IPv6 prefix (for example, the outside interface).

- **RA Lifetime**—Configure the router lifetime value in IPv6 router advertisements, between 0 and 9000 seconds.

  The default is 1800 seconds.

- **RA Interval**—Configure the interval between IPv6 router advertisement transmissions, between 3 and 1800 seconds.

The default is 200 seconds.

To prevent synchronization with other IPv6 nodes, the firewall randomly adjusts the value that you set (jitter).

Step 10 Click **OK**.

Step 11 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Advanced Interface Settings

This section describes how to configure MAC addresses for regular firewall mode interfaces, how to set the maximum transmission unit (MTU), and how to set other advanced parameters.

About Advanced Interface Configuration

This section describes advanced interface settings.

About MAC Addresses

You can manually assign MAC addresses to override the default. For container instances, the FXOS chassis automatically generates unique MAC addresses for all interfaces.

Note You might want to assign unique MAC addresses to subinterfaces defined on the FTD, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the FTD device.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Default MAC Addresses

For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- VLAN interfaces (Firepower 1010)—Routed firewall mode: All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique

MAC addresses, you can manually assign MAC addresses. See Configure the MAC Address, on page 425.

Transparent firewall mode: Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC Address, on page 425.

- EtherChannels (Firepower Models)—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.
- EtherChannels (ASA Models)—The port-channel interface uses the lowest-numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can configure a MAC address for the port-channel interface. We recommend configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.
- Subinterfaces (FTD-defined)—All subinterfaces of a physical interface use the same burned-in MAC address. You might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the FTD.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces, on page 175.

About the MTU

The MTU specifies the maximum frame *payload* size that the FTD device can transmit on a given Ethernet interface. The MTU value is the frame size *without* Ethernet headers, VLAN tagging, or other overhead. For example, when you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when using VLAN. Do not set the MTU value higher to accommodate these headers.

For Geneve, the entire Ethernet datagram is being encapsulated, so the new IP packet is larger and requires a larger MTU: you should set the ASA VTEP source interface MTU to be the network MTU + 306 bytes.

Path MTU Discovery

The FTD device supports Path MTU Discovery (as defined in RFC 1191), which lets all devices in a network path between two hosts coordinate the MTU so they can standardize on the lowest MTU in the path.

Default MTU

The default MTU on the FTD device is 1500 bytes. This value does not include the 18-22 bytes for the Ethernet header, VLAN tagging, or other overhead.

MTU and Fragmentation

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For TCP packets, the endpoints typically use their MTU to determine the TCP maximum segment size (MTU - 40, for example). If additional TCP headers are added along the way, for example for site-to-site VPN tunnels, then the TCP MSS might need to be adjusted down by the tunneling entity. See About the TCP MSS, on page 422.

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

Note The FTD device can receive frames larger than the configured MTU as long as there is room in memory.

MTU and Jumbo Frames

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network. See the following guidelines:

- Matching MTUs on the traffic path—We recommend that you set the MTU on all FTD interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.
- Accommodating jumbo frames—You can set the MTU 9000 bytes or higher when you enable jumbo frames. The maximum depends on the model.

About the TCP MSS

The TCP maximum segment size (MSS) is the size of the TCP payload *before* any TCP and IP headers are added. UDP packets are not affected. The client and the server exchange TCP MSS values during the three-way handshake when establishing the connection.

You can set the TCP MSS on the FTD device for through traffic using the Sysopt_Basic object in FlexConfig; see FlexConfig Policies, on page 1893; by default, the maximum TCP MSS is set to 1380 bytes. This setting is useful when the FTD device needs to add to the size of the packet for IPsec VPN encapsulation. However, for non-IPsec endpoints, you should disable the maximum TCP MSS on the FTD device.

If you set a maximum TCP MSS, if either endpoint of a connection requests a TCP MSS that is larger than the value set on the FTD device, then the FTD device overwrites the TCP MSS in the request packet with the FTD device maximum. If the host or server does not request a TCP MSS, then the FTD device assumes the RFC 793-default value of 536 bytes (IPv4) or 1220 bytes (IPv6), but does not modify the packet. For example, you leave the default MTU as 1500 bytes. A host requests an MSS of 1500 minus the TCP and IP header length, which sets the MSS to 1460. If the FTD device maximum TCP MSS is 1380 (the default), then the FTD device changes the MSS value in the TCP request packet to 1380. The server then sends packets with 1380-byte payloads. The FTD device can then add up to 120 bytes of headers to the packet and still fit in the MTU size of 1500.

You can also configure the minimum TCP MSS; if a host or server requests a very small TCP MSS, the FTD device can adjust the value up. By default, the minimum TCP MSS is not enabled.

For to-the-box traffic, including for SSL VPN connections, this setting does not apply. The FTD device uses the MTU to derive the TCP MSS: MTU - 40 (IPv4) or MTU - 60 (IPv6).

Default TCP MSS

By default, the maximum TCP MSS on the FTD device is 1380 bytes. This default accommodates IPv4 IPsec VPN connections where the headers can equal up to 120 bytes; this value fits within the default MTU of 1500 bytes.

Suggested Maximum TCP MSS Setting

The default TCP MSS assumes the FTD device acts as an IPv4 IPsec VPN endpoint and has an MTU of 1500. When the FTD device acts as an IPv4 IPsec VPN endpoint, it needs to accommodate up to 120 bytes for TCP and IP headers.

If you change the MTU value, use IPv6, or do not use the FTD device as an IPsec VPN endpoint, then you should change the TCP MSS setting using the Sysopt_Basic object in FlexConfig.

Note Even if you explicitly set an MSS, if a component such as TLS/SSL decryption or server discovery needs a particular MSS, it will set that MSS based on the interface MTU and ignore your MSS setting.

See the following guidelines:

- Normal traffic—Disable the TCP MSS limit and accept the value established between connection endpoints. Because connection endpoints typically derive the TCP MSS from the MTU, non-IPsec packets usually fit this TCP MSS.
- IPv4 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 120. For example, if you use jumbo frames and set the MTU to 9000, then you need to set the TCP MSS to 8880 to take advantage of the new MTU.
- IPv6 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 140.

ARP Inspection for Bridge Group Traffic

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the FTD device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the FTD device drops the packet.

- If the ARP packet does not match any entries in the static ARP table, then you can set the FTD device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Diagnostic interface never floods packets even if this parameter is set to flood.

MAC Address Table

When you use bridge groups, the FTD learns and builds a MAC address table in a similar way as a normal bridge or switch: when a device sends a packet through the bridge group, the FTD adds the MAC address to its table. The table associates the MAC address with the source interface so that the FTD knows to send any packets addressed to the device out the correct interface. Because traffic between bridge group members is subject to the FTD security policy, if the destination MAC address of a packet is not in the table, the FTD does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the following packets for directly-connected devices or for remote devices:

- Packets for directly-connected devices—The FTD generates an ARP request for the destination IP address, so that it can learn which interface receives the ARP response.
- Packets for remote devices—The FTD generates a ping to the destination IP address so that it can learn which interface receives the ping reply.

The original packet is dropped.

Default Settings

- If you enable ARP inspection, the default setting is to flood non-matching packets.
- The default timeout value for dynamic MAC address table entries is 5 minutes.
- By default, each interface automatically learns the MAC addresses of entering traffic, and the FTD device adds corresponding entries to the MAC address table.

Note Firepower Threat Defense device generates a reset packet to reset a connection that is denied by a stateful inspection engine. Here, the destination MAC address of the packet is not determined based on the ARP table lookup but instead it is taken directly from the packets (connections) that are being denied.

Guidelines for ARP Inspection and the MAC Address Table

- ARP inspection is only supported for bridge groups.
- MAC address table configuration is only supported for bridge groups.

Configure the MTU

Customize the MTU on the interface, for example, to allow jumbo frames.

For the ISA 3000 and the FTDv: Changing the MTU above 1500 bytes automatically enables jumbo-frame reservation. You must restart the system before you can use jumbo frames. After you restart, you cannot disable jumbo-frame reservation. If you use an interface in an inline set, the MTU setting is not used. However, the jumbo-frame reservation setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo-frame reservation, you must set the MTU of *any* interface above 1500 bytes.

Jumbo frames are enabled by default on other platforms.

Caution Changing the highest MTU value on the device for a data interface restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Inspection is interrupted on all data interfaces, not just the interface you modified. Whether this interruption drops traffic or passes it without further inspection depends on the model of the managed device and the interface type. This caution does not apply to the Diagnostic interface or management-only interfaces. See Snort Restart Traffic Behavior, on page 116 for more information.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 On the **General** tab, set the **MTU**. The minimum and maximum depends on your platform.

The default is 1500 bytes.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 6 For the ISA 3000 and the FTDv, if you set the MTU above 1500 bytes, restart the system to enable jumbo-frame reservation. See Shut Down or Restart the Device, on page 32.

Configure the MAC Address

You might need to manually assign a MAC address. You can also set the Active and Standby MAC addresses on the **Devices** > **Device Management** > **High Availability** tab. If you set the MAC address for an interface on both screens, the addresses on the **Interfaces** > **Advanced** tab take precedence.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Advanced** tab.
The **Information** tab is selected.

Step 4 Set the active and standby MAC addresses.

a) In the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

b) In the **Standby MAC Address** field, enter a MAC address for use with High Availability.

If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a Static ARP Entry

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection (see ARP Inspection, on page 479). ARP inspection compares ARP packets with *static* ARP entries in the ARP table.

For routed interfaces, you can enter static ARP entries, but normally dynamic entries are sufficient. For routed interfaces, the ARP table is used to deliver packets to directly-connected hosts. Although senders identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is

incorrect (for example, the MAC address changes for a given IP address), the entry needs to time out before it can be updated with the new information.

For transparent mode, the FTD only uses dynamic ARP entries in the ARP table for traffic to and from the FTD device, such as management traffic.

Before you begin

This screen is only available for named interfaces.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP** tab (called **ARP and MAC** for transparent mode).

Step 4 Click ( )**Add ARP Config**.
The **Add ARP Config** dialog box appears.

Step 5 In the **IP Address** field, enter the IP address of the host.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.

Step 7 To perform proxy ARP for this address, check the **Enable Alias** check box.

If the FTD device receives an ARP request for the specified IP address, then it responds with the specified MAC address.

Step 8 Click **OK**, and then click **OK** again to exit the Advanced settings.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a Static MAC Address and Disable MAC Learning for a Bridge Group

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can disable MAC address learning; however, unless you statically add MAC addresses to the table, no traffic can pass through the FTD device. You can also add static MAC addresses to the MAC address table. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry, then the FTD device drops the traffic and generates a system message. When you add a static ARP entry (see Add a Static ARP Entry, on page 426), a static MAC address entry is automatically added to the MAC address table.

Before you begin

This screen is only available for named BVIs in transparent mode.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP and MAC** tab.

Step 4 (Optional) Disable MAC learning by unchecking the **Enable MAC Learning** check box.

Step 5 To add a static MAC address, click **Add MAC Config**.
The **Add MAC Config** dialog box appears.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b. Click **OK**.

Step 7 Click **OK** to exit the Advanced settings.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Set Security Configuration Parameters

This section describes how to prevent IP spoofing, allow full fragment reassembly, and override the default fragment setting set for at the device level in **Platform Settings** .

Anti-Spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the FTD device only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the device to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the FTD device, the device routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the FTD device can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the device uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the FTD device drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the device drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Fragment per Packet

By default, the FTD device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the FTD device. Fragmented packets are often used as DoS attacks.

Fragment Reassembly

The FTD device performs the following fragment reassembly processes:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed.
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow.
- IP fragments that terminate at the FTD device are always fully reassembled.
- If **Full Fragment Reassembly** is disabled (the default), the fragment set is forwarded to the transport layer for further processing.
- If **Full Fragment Reassembly** is enabled, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

Before you begin

This screen is only available for named interfaces.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **Security Configuration** tab.

Step 4 To enable Unicast Reverse Path Forwarding, check the **Enable Anti Spoofing** check box.

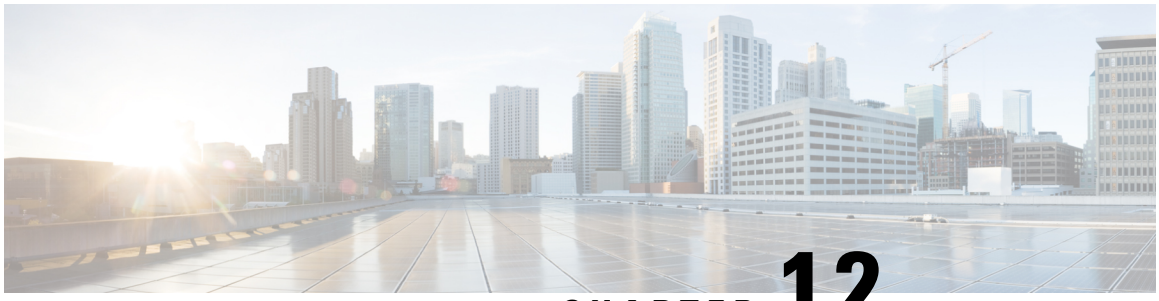
Step 5 To enable full fragment reassembly, check the **Allow Full Fragment Reassembly** check box.

Step 6 To change the number of fragments allowed per packet, check the **Override Default Fragment Setting** check box, and set the following values:

- **Size**—Set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200. Set this value to 1 to disable fragments.
- **Chain**—Set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.
- **Timeout**—Set the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.

Step 7 Click **OK**.

Step 8 Click **Save**.



You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

History for Regular Firewall Interfaces

Feature	Minimum FMC	Minimum FTD	Details
Geneve support for the FTDv	7.1	Any	Geneve encapsulation support was added for the FTDv to support single-arm proxy for the Amazon Web Services (AWS) Gateway Load Balancer. The AWS Gateway Load Balancer combines a transparent network gateway (with a single entry and exit point for all traffic) and a load balancer that distributes traffic and scales FTDv to match the traffic demand. This feature requires Snort 3. New/Modified screens: • **Devices** > **Device Management** > **Device** > **VTEP** • **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** • **Devices** > **Device Management** > **Device** > **Interfaces** edit physical interface **> General** Supported platforms: FTDv in AWS
31-bit Subnet Mask	7.0	Any	For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 FTDs only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog. This feature is not supported for BVIs for bridge groups or with multicast routing. New/Modified screens: **Devices** > **Device Management** > **Interfaces**

Feature	Minimum FMC	Minimum FTD	Details
Synchronization between the FTD operational link state and the physical link state for the Firepower 4100/9300	6.7	Any	The Firepower 4100/9300 chassis can now synchronize the FTD operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The FTD application interface admin state is not considered. Without synchronization from FTD, data interfaces can be in an Up state physically before the FTD application has completely come online, for example, or can stay Up for a period of time after you initiate an FTD shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the FTD before the FTD can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS. **Note** This feature is not supported for clustering, container instances, or FTD with a Radware vDP decorator. It is also not supported for ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices > Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled**, **show interface expand detail** Supported platforms: Firepower 4100/9300
Firepower 1010 hardware switch support	6.5	Any	The Firepower 1010 supports setting each Ethernet interface to be a switch port or a firewall interface. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** • **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** • **Devices** > **Device Management** > **Interfaces** > **Add VLAN Interface**
Firepower 1010 PoE+ support on Ethernet 1/7 and Ethernet 1/8	6.5	Any	The Firepower 1010 supports Power over Ethernet+ (PoE+) on Ethernet 1/7 and Ethernet 1/8 when they are configured as switch ports. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **PoE**

Feature	Minimum FMC	Minimum FTD	Details
VLAN subinterfaces for use with container instances	6.3.0	Any	To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances. New/Modified Firepower Management Center screens: **Devices** > **Device Management** > **Edit** icon **> Interfaces** tab New/Modified Firepower Chassis Manager screens: **Interfaces** > **All Interfaces** > **Add New** drop-down menu **> Subinterface** New/Modified FXOS commands: **create subinterface, set vlan, show interface,show subinterface** Supported platforms: Firepower 4100/9300
Data-sharing interfaces for container instances	6.3.0	Any	To provide flexible physical interface use, you can share interfaces between multiple instances. New/Modified Firepower Chassis Manager screens: **Interfaces** > **All Interfaces** > **Type** New/Modified FXOS commands: **set port-type data-sharing, show interface** Supported platforms: Firepower 4100/9300
Integrated Routing and Bridging	6.2.0	Any	Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. A bridge group is a group of interfaces that the FTD bridges instead of routes. The FTD is not a true bridge in that the FTD continues to act as a firewall: access control between interfaces is controlled, and all of the usual firewall checks are in place. Previously, you could only configure bridge groups in transparent firewall mode, where you cannot route between bridge groups. This feature lets you configure bridge groups in routed firewall mode, and to route between bridge groups and between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group. Integrated Routing and Bridging provides an alternative to using an external Layer 2 switch if you have extra interfaces on the FTD to assign to the bridge group. In routed mode, the BVI can be a named interface and can participate separately from member interfaces in some features, such as access rules and DHCP server. The following features that are supported in transparent mode are not supported in routed mode: clustering. The following features are also not supported on BVIs: dynamic routing and multicast routing. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** • **Devices** > **Device Management** > **Interfaces** > **Add Interfaces** > **Bridge Group Interface** Supported platforms: All except for the Firepower 2100 and the FTDv

CHAPTER 12

Inline Sets and Passive Interfaces

You can configure IPS-only passive interfaces, passive ERSPAN interfaces, and inline sets.

- About IPS Interfaces, on page 433
- Requirements and Prerequisites for Inline Sets, on page 436
- Guidelines for Inline Sets and Passive Interfaces, on page 437
- Configure a Passive Interface, on page 439
- Configure an Inline Set, on page 440
- History for Inline Sets and Passive Interfaces, on page 444

About IPS Interfaces

IPS interfaces include passive interfaces, passive ERSPAN interfaces, and inline sets. IPS-only mode interfaces bypass many firewall checks and only support IPS security policy (Snort). You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

IPS-only mode interfaces bypass many firewall checks and only support IPS security policy (Snort). You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

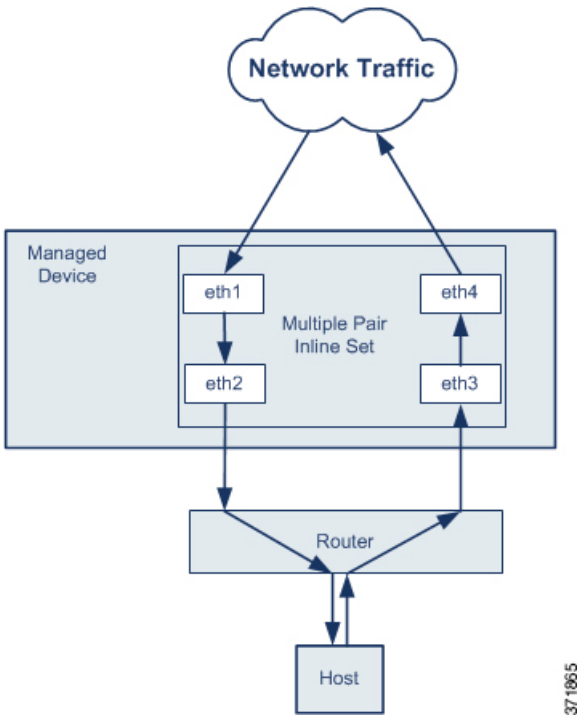
Inline Sets

An inline set acts like a bump on the wire, and binds one or more interface pairs together to slot into an existing network. This function allows the FTD to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of the other interface in the inline pair unless explicitly dropped. When you have multiple inline pairs in an inline set, traffic can only pass between the interfaces in the pair; it can't pass between interfaces in different pairs.

With tap mode, the FTD is deployed inline, but the network traffic flow is undisturbed. Instead, the FTD makes a copy of each packet so that it can analyze the packets. Note that rules of these types do generate

intrusion events when they are triggered, and the table view of intrusion events indicates that the triggering packets would have dropped in an inline deployment. There are benefits to using tap mode with FTDs that are deployed inline. For example, you can set up the cabling between the FTD and the network as if the FTD were inline and analyze the kinds of intrusion events the FTD generates. Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency. When you are ready to deploy the FTD inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the FTD and the network.

Note Tap mode *significantly* impacts FTD performance, depending on the traffic.



Note Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

Multiple Inline Pairs and Asynchronous Routing

You can configure the interfaces to route traffic between a host on your network and external hosts through different inline pairs, depending on whether the traffic is inbound or outbound. This is an *asynchronous routing* configuration. If you deploy asynchronous routing, but you include only one inline pair in an inline set, the device might not correctly analyze your network traffic because it might see only half of the traffic.

Adding multiple inline pairs to the same inline set lets the system identify the inbound and outbound traffic as part of the same traffic flow. For passive interfaces only, you can also achieve this by including the interface pairs in the same security zone.

Figure 148: Asynchronous Routing

Note If you assign multiple inline pairs to a single inline set, but you experience issues with duplicate traffic, you might need to reassign your inline pairs to separate inline sets or modify your security zones.

If fragments of a packet are received on different interface pairs, they are not reassembled and get dropped. Make sure all the fragments of the packet are received and sent on the same interface pair.

Passive Interfaces

Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the switch. This function provides the system visibility within the network without being in the flow of network traffic. When you configure the FTD in a passive deployment, the FTD cannot take certain actions such as blocking or shaping traffic. Passive interfaces receive all traffic unconditionally. and no traffic received on these interfaces is retransmitted. Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches, and uses GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the FTD is in routed firewall mode.

Note Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See Intel Ethernet Products for more information on Intel network adapters.

About Hardware Bypass for Inline Sets

For certain interface modules on the supported models (see Requirements and Prerequisites for Inline Sets, on page 436), you can enable the Hardware Bypass feature. Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures.

Hardware Bypass Triggers

Hardware Bypass can be triggered in the following scenarios:

- FTD crash
- FTD reboot
- Security Module reboot
- Chassis crash
- Chassis reboot
- Manual trigger
- Chassis power loss
- Security Module power loss

Note Hardware bypass is intended for unplanned/unexpected failure scenarios, and is not automatically triggered during planned software upgrades. Hardware bypass only engages at the end of a planned upgrade process, when the FTD application reboots.

Hardware Bypass Switchover

When switching from normal operation to hardware bypass or from hardware bypass back to normal operation, traffic may be interrupted for several seconds. A number of factors can affect the length of the interruption; for example, copper port auto-negotiation; behavior of the optical link partner such as how it handles link faults and de-bounce timing; spanning tree protocol convergence; dynamic routing protocol convergence; and so on. During this time, you may experience dropped connections.

You may also experience dropped connections due to application identification errors when analyzing connections midstream after the return to normal operations.

Snort Fail Open vs. Hardware Bypass

For inline sets other than those in tap mode, you can use the Snort Fail Open option to either drop traffic or allow traffic to pass without inspection when the Snort process is busy or down. Snort Fail Open is supported on all inline sets except those in tap mode, not just on interfaces that support Hardware Bypass.

The Hardware Bypass functionality allows traffic to flow during a hardware failure, including a complete power outage, and certain limited software failures. A software failure that triggers Snort Fail Open does not trigger a Hardware Bypass.

Hardware Bypass Status

If the system has power, then the Bypass LED indicates the Hardware Bypass status. See the Firepower chassis hardware installation guide for LED descriptions.

Requirements and Prerequisites for Inline Sets

User Roles

- Admin
- Access Admin
- Network Admin

Hardware Bypass Support

The FTD supports Hardware Bypass for interface pairs on specific network modules on the following models:

- Firepower 2130 and 2140
- Firepower 4100
- Firepower 9300

Note The ISA 3000 has a separate implementation for Hardware Bypass, which you can enable using FlexConfig only (see FlexConfig Policies, on page 1893). Do not use this chapter to configure ISA 3000 Hardware Bypass.

Note You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

The supported Hardware Bypass network modules for these models include:

- Firepower 2130 and 2140:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR2K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR2K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR2K-NM-6X10LR-F)
- Firepower 4100:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR4K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR4K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR4K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR4K-NM-2X40G-F)
  - Firepower 8-port 1G Copper FTW Network Module single-wide (FPR-NM-8X1G-F)
- Firepower 9300:
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR9K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR9K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR9K-NM-2X40G-F)

Hardware Bypass can only use the following port pairs:

- 1 & 2
- 3 & 4
- 5 & 6
- 7 & 8

Guidelines for Inline Sets and Passive Interfaces

Firewall Mode

- ERSPAN interfaces are only allowed when the device is in routed firewall mode.

Clustering

- Link State Propagation for an inline set is not supported with clustering.

Multi-Instance Mode

- Multi-instance shared interfaces are not supported. You must use an unshared interface.
- Multi-instance chassis-defined subinterfaces are not supported. You must use a physical interface or EtherChannel.

General Guidelines

- Inline sets and passive interfaces support physical interfaces and EtherChannels only, and cannot use VLANs or other virtual interfaces, including multi-instance chassis-defined subinterfaces.
- Since IPS interfaces do not support regular firewall protections, the IPS security policy (Snort) requires that traffic flows pass through the same FTD so that all traffic can be inspected.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the FTD when using inline sets. If there are two neighbors on either side of the FTD running BFD, then the FTD will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.
- For inline sets and passive interfaces, the FTD supports up to two 802.1Q headers in a packet (also known as Q-in-Q support), with the exception of the Firepower 4100/9300, which only supports one 802.1Q header. **Note:** Firewall-type interfaces do not support Q-in-Q, and only support one 802.1Q header.

Hardware Bypass Guidelines

- Hardware Bypass ports are supported only for inline sets.
- Hardware Bypass ports cannot be part of an EtherChannel.
- Hardware Bypass is not supported in high availability mode.
- Hardware Bypass ports are supported with intra-chassis clustering on the Firepower 9300. Ports are placed in Hardware Bypass mode when the last unit in the chassis fails. Inter-chassis clustering is not supported, because inter-chassis clustering only supports Spanned EtherChannels; Hardware Bypass ports cannot be part of an EtherChannel.
- If all modules in an intra-chassis cluster on the Firepower 9300 fail, then Hardware Bypass is triggered on the final unit, and traffic continues to pass. When units come back up, Hardware Bypass returns to standby mode. However, when you use rules that match application traffic, those connections may be dropped and need to be reestablished. Connections are dropped because state information is not retained on the cluster unit, and the unit cannot identify the traffic as belonging to an allowed application. To avoid a traffic drop, use a port-based rule instead of an application-based rule, if appropriate for your deployment.
- You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

Unsupported Firewall Features on IPS Interfaces

- DHCP server
- DHCP relay
- DHCP client
- TCP Intercept
- Routing
- NAT
- VPN
- Application inspection
- QoS
- NetFlow
- VXLAN

Configure a Passive Interface

This section describes how to:

- Enable the interface. By default, interfaces are disabled.
- Set the interface mode to Passive or ERSPAN. For ERSPAN interfaces, you will set the ERSPAN parameters and the IP address.
- Change the MTU. By default, the MTU is set to 1500 bytes. For more information about the MTU, see About the MTU, on page 421.
- Set a specific speed and duplex (if available). By default, speed and duplex are set to Auto.

Note For the Firepower Threat Defense on the FXOS chassis, you configure basic interface settings on the Firepower 4100/9300. See Configure a Physical Interface, on page 188 for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 362.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your FTD device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 In the **Mode** drop-down list, choose **Passive** or **Erspan**.

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 In the **Name** field, enter a name up to 48 characters in length.

Step 6 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

Step 7 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 8 (Optional) On **General**, set the **MTU** between 64 and 9198 bytes; for the Firepower Threat Defense Virtual and Firepower Threat Defense on the FXOS chassis, the maximum is 9000 bytes.

The default is 1500 bytes.

Step 9 For ERSPAN interfaces, set the following parameters:

- **Flow Id**—Configure the ID used by the source and destination sessions to identify the ERSPAN traffic, between 1 and 1023. This ID must also be entered in the ERSPAN destination session configuration.
- **Source IP**—Configure the IP address used as the source of the ERSPAN traffic.

Step 10 For ERSPAN interfaces, set the IPv4 address and mask on **IPv4**.

Step 11 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

Step 12 Click **OK**.

Step 13 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure an Inline Set

This section enables and names two physical interfaces or EtherChannels per inline pair that you can add to an inline set. You can add multiple inline pairs per inline set. You can also optionally enable Hardware Bypass for supported inline pairs.

Note For the Firepower 4100/9300, you configure basic interface settings in FXOS on the chassis. See Configure a Physical Interface, on page 188 for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 362.
- We recommend that you set STP PortFast for STP-enabled switches that connect to the FTD inline pair interfaces. This setting is especially useful for Hardware Bypass configurations and can reduce bypass times.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your FTD device. The **Interfaces** page is selected by default.

Step 2 For each interface in the inline pair, name the interface and enable it. You can also configure other hardware settings. Be sure to match the hardware settings for each interface in the inline pair. You can configure multiple pairs of interfaces.

a) Click **Edit** ( ) for the interface you want to edit.
b) In the **Name** field, enter a name up to 48 characters in length.
c) Enable the interface by checking the **Enabled** check box.
d) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

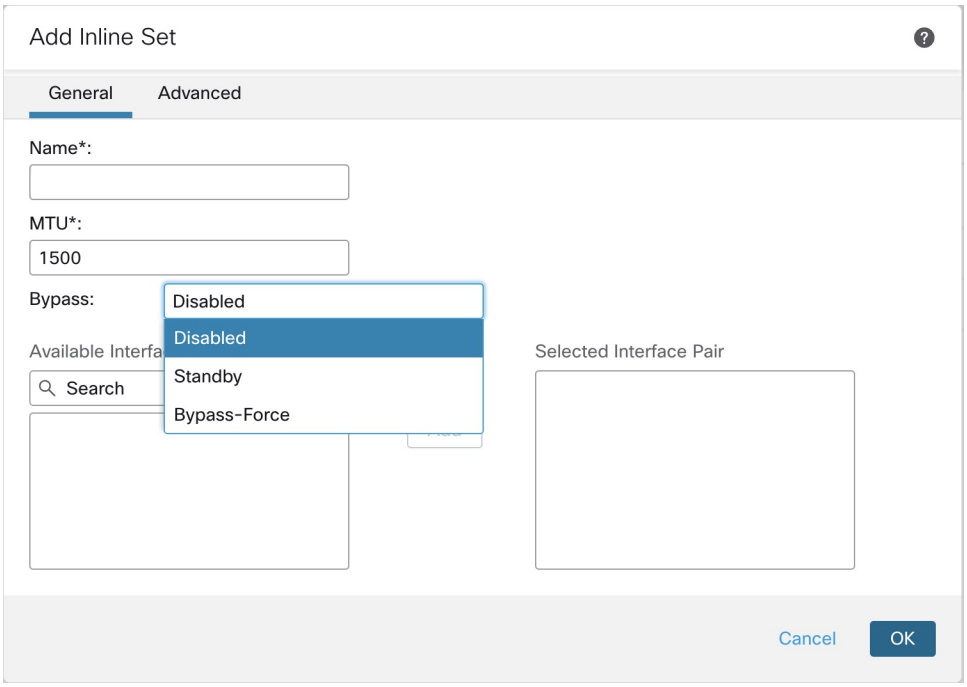
e) Leave the **Mode** as **None**.

After you add this interface to an inline set, this field will show Inline for the mode.

f) Do not set the security zone yet; you must set it after you create the inline set later in this procedure.
g) (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.



h) Click **OK**.

Do not set any other settings for this interface.

Step 3 Click **Inline Sets**.

Step 4 Click **Add Inline Set**.

Figure 149: Add Inline Set

The **Add Inline Set** dialog box appears with **General** selected.

Step 5 In the **Name** field, enter a name for the set.

Step 6 (Optional) Change the **MTU** to enable jumbo frames.

For inline sets, the MTU setting is not used. However, the jumbo frame setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo frames, you must set the MTU of *any* interface on the device above 1500 bytes.

Step 7 Configure Hardware Bypass.

a) For the **Bypass** mode, choose one of the following options:

- **Disabled**—Set Hardware Bypass to disabled for interfaces where Hardware Bypass is supported, or use interfaces where Hardware Bypass is not supported.
- **Standby**—Set Hardware Bypass to the standby state on supported interfaces. Only pairs of Hardware Bypass interfaces are shown. In the standby state, the interfaces remain in normal operation until there is a trigger event.
- **Bypass-Force**—Manually forces the interface pair to go into a bypass state. **Inline Sets** shows **Yes** for any interface pairs that are in Bypass-Force mode.

b) In the **Available Interfaces Pairs** area, click a pair and then click **Add** to move it to the **Selected Interface Pair** area.

All possible pairings between named and enabled interfaces with the mode set to None show in this area.

Step 8 (Optional) Click **Advanced** to set the following optional parameters:

- **Tap Mode**—Set to inline tap mode.

Note that you cannot enable this option and strict TCP enforcement on the same inline set.

Note
If you need to enable or disable the Tap mode, you should do so during a maintenance window. Changing the mode while the device is passing traffic can cause traffic disruption.

Note
Tap mode *significantly* impacts the FTD performance, depending on the traffic.

- **Propagate Link State**—Configure link state propagation.

  Link state propagation automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the device senses the change and updates the link state of the other interface to match it. Note that devices require up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

  Note
  Do not enable **Propagate Link State** when using clustering.

- **Snort Fail Open**—Enable or disable either or both of the **Busy** and **Down** options if you want new and existing traffic to pass without inspection (enabled) or drop (disabled) when the Snort process is busy or down.

  By default, traffic passes without inspection when the Snort process is down, and drops when it is busy.

  When the Snort process is:

  - Busy—It cannot process traffic fast enough because traffic buffers are full, indicating that there is more traffic than the device can handle, or because of other software resource issues.
  - Down—It is restarting because you deployed a configuration that requires it to restart. See Configurations that Restart the Snort Process When Deployed or Activated, on page 118.

  When the Snort process is down and comes back up, it inspects *new* connections. To prevent false positives and false negatives, it does not inspect existing connections on inline, routed, or transparent interfaces because initial session information might have been lost while it was down.

  Note
  When Snort fails open, features that rely on the Snort process do not function. These include application control and deep inspection. The system performs only basic access control using simple, easily determined transport and network layer characteristics.

  Note
  The **Strict TCP Enforcement** option is not supported.

Step 9 Set the security zone for each interface.

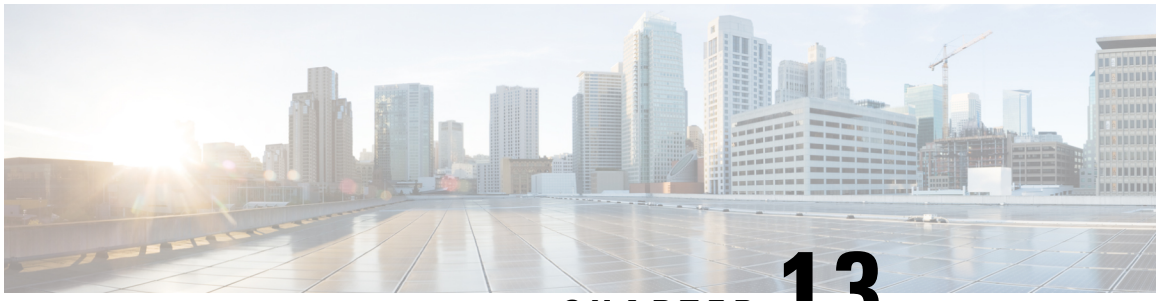
a) Click **Interfaces**.

b) Click **Edit** ( ) for the member interface.

c) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

You can only set the zone after you add the interface to the inline set; adding it to an inline set configures the mode to Inline and lets you choose inline-type security zones.

d) Click **OK**.



Step 10 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

History for Inline Sets and Passive Interfaces

Feature	Minimum FMC	Minimum FTD	Details
Synchronization between the FTD operational link state and the physical link state for the Firepower 4100/9300	6.7	Any	The Firepower 4100/9300 chassis can now synchronize the FTD operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The FTD application interface admin state is not considered. Without synchronization from FTD, data interfaces can be in an Up state physically before the FTD application has completely come online, for example, or can stay Up for a period of time after you initiate a shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the FTD before the FTD can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS. **Note** This feature is not supported for clustering, container instances, or FTD with a Radware vDP decorator. It is also not supported for ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices > Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled**, **show interface expand detail** Supported platforms: Firepower 4100/9300
Hardware bypass support on the Firepower 2130 and 2140 for supported network modules	6.3.0	Any	The Firepower 2130 and 2140 now support hardware bypass functionality when using the hardware bypass network modules. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Firepower 2130 and 2140
Support for EtherChannels in FTD inline sets or passive interface	6.2.0	Any	You can now use EtherChannels in a FTD inline set or passive interface.

Feature	Minimum FMC	Minimum FTD	Details
Hardware bypass support on the Firepower 4100/9300 for supported network modules	6.1.0	Any	Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** Supported platforms: Firepower 4100/9300
Inline set link state propagation support for the FTD	6.1.0	Any	When you configure an inline set in the FTD application and enable link state propagation, the FTD sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. New/Modified FXOS commands: **show fault |grep link-down**, **show interface detail**

CHAPTER 13

DHCP and DDNS

The following topics explain DHCP and DDNS services and how to configure them on Threat Defense devices.

- About DHCP and DDNS Services, on page 447
- Requirements and Prerequisites for DHCP and DDNS, on page 448
- Guidelines for DHCP and DDNS Services, on page 448
- Configure the DHCPv4 Server, on page 450
- Configure the DHCP Relay Agent, on page 452
- Configure Dynamic DNS, on page 453

About DHCP and DDNS Services

The following topics describe the DHCP server, DHCP relay agent, and DDNS update.

About the DHCPv4 Server

DHCP provides network configuration parameters, such as IP addresses, to DHCP clients. The FTD device can provide a DHCP server to DHCP clients attached to FTD device interfaces. The DHCP server provides network configuration parameters directly to DHCP clients.

An IPv4 DHCP client uses a broadcast rather than a multicast address to reach the server. The DHCP client listens for messages on UDP port 68; the DHCP server listens for messages on UDP port 67.

The DHCP server for IPv6 is not supported; you can, however, enable DHCP relay for IPv6 traffic.

DHCP Options

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. The configuration parameters are carried in tagged items that are stored in the Options field of the DHCP message and the data are also called options. Vendor information is also stored in Options, and all of the vendor information extensions can be used as DHCP options.

For example, Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.
- DHCP option 66 gives the IP address or the hostname of a single TFTP server.

- DHCP option 3 sets the default route.

A single request might include both options 150 and 66. In this case, the DHCP server provides values for both options in the response if they are already configured on the FTD.

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients; DHCP option 15 is used for the DNS domain suffix. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

For example, you can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

About the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the FTD device because it does not forward broadcast traffic. The DHCP relay agent lets you configure the interface of the FTD device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

Requirements and Prerequisites for DHCP and DDNS

Model Support

FTD

User Roles

- Admin
- Access Admin
- Network Admin

Guidelines for DHCP and DDNS Services

This section includes guidelines and limitations that you should check before configuring DHCP and DDNS services.

Firewall Mode

- DHCP Relay is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCP Server is supported in transparent firewall mode on a bridge group member interface. In routed mode, the DHCP server is supported on the BVI interface, not the bridge group member interface. The BVI must have a name for the DHCP server to operate.
- DDNS is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.

IPv6

Does not support IPv6 for DHCP server; IPv6 for DHCP relay is supported.

DHCPv4 Server

- The maximum available DHCP pool is 256 addresses.
- You can configure a DHCP server on any interface with a name and IP address, such as a physical interface, a subinterface, or a BVI in routed mode.
- You can configure only one DHCP server on each interface. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure an interface as a DHCP client if that interface also has DHCP server enabled; you must use a static IP address.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- The FTD does not support QIP DHCP servers for use with the DHCP proxy service.
- The DHCP server does not support BOOTP requests.

DHCP Relay

- You can configure a maximum of 10 DHCPv4 relay servers per virtual router, global (VRF) and interface-specific servers combined, with a maximum of 4 servers per interface.
- You can configure a maximum of 10 DHCPv6 relay servers per virtual router. Interface-specific servers for IPv6 are not supported.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- DHCP relay services are not available in transparent firewall mode or in routed mode on the BVI or bridge group member interface. You can, however, allow DHCP traffic through using an access rule. To allow DHCP requests and replies through the FTD, you need to configure two access rules, one that allows DCHP requests from the inside interface to the outside (UDP destination port 67), and one that allows the replies from the server in the other direction (UDP destination port 68).
- For IPv4, clients must be directly-connected to the FTD and cannot send requests through another relay agent or a router. For IPv6, the FTD supports packets from another relay server.

- The DHCP clients must be on different interfaces from the DHCP servers to which the FTD relays requests.
- You cannot enable DHCP Relay on an interface in a traffic zone.

DDNS Service

The firewall's DDNS supports only DynDNS service. Hence, ensure that the DDNS is configured with update URL in the following syntax:

https://*username***:***password***@***provider-domain***/***path***?hostname=<h>&myip=<a>**.

Configure the DHCPv4 Server

See the following steps to configure a DHCPv4 server.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **DHCP** > **DHCP Server**.

Step 3 Configure the following DHCP server options:

- **Ping Timeout**—The amount of time in milliseconds that FTD device waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.

  To avoid address conflicts, the FTD device sends two ICMP ping packets to an address before assigning that address to a DHCP client.
- **Lease Length**—The amount of time in seconds that the client may use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).
- (Routed mode) **Auto-configuration**—Enables DHCP auto configuration on the FTD device. Auto-configuration enables the DHCP server to provide the DHCP clients with the DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. Otherwise, you can disable auto configuration and add the values yourself in Step 4.
- (Routed mode) **Interface**—Specifies the interface to be used for auto configuration. For a device with virtual routing capability, this interface can only be a global virtual router interface.

Step 4 To override auto-configured settings, do the following:

- Enter the domain name of the interface. For example, your device may be in the Your_Company domain.
- From the drop-down list, choose the DNS servers (primary and secondary) configured for the interface. To add a new DNS server, see Creating Network Objects, on page 880.
- From the drop-down list, choose the WINS servers (primary and secondary) configured for the interface. To add a new WINS server, see Creating Network Objects, on page 880.

Step 5 Select **Server**, click **Add**, and configure the following options:

- **Interface**—Choose the interface from the drop-down list. In transparent mode, specify a named bridge group member interface. In routed mode, specify a named routed interface or a named BVI; do not specify the bridge group member interface. Note that each bridge group member interface for the BVI must also be named for the DHCP server to operate.
- **Address Pool**—The range of IP addresses from lowest to highest that is used by the DHCP server. The range of IP addresses must be on the same subnet as the selected interface and cannot include the IP address of the interface itself.
- **Enable DHCP Server**—Enables the DHCP server on the selected interface.

Step 6 Click **OK** to save the DHCP server configuration.

Step 7 (Optional) Select **Advanced**, click **Add**, and specify the type of information you want the option to return to the DHCP client:

- **Option Code**—The FTD device supports the DHCP options listed in RFC 2132, RFC 2562, and RFC 5510 to send information. All DHCP options (1 through 255) are supported except for 1, 12, 50–54, 58–59, 61, 67, and 82. See About the DHCPv4 Server, on page 447for more information on DHCP option codes.

  Note
  The FTD device does not verify that the option type and value that you provide match the expected type and value for the option code, as defined in RFC 2132. For more information about option codes and their associated types and expected values, see RFC 2132.

- **Type**—DHCP option type. Available options include **IP**, **ASCII**, and **HEX**. If you chose IP, you must add IP addresses in the IP Address fields. If you chose ASCII, you must add the ASCII value in the ASCII field. If you chose HEX, you must add the HEX value in the HEX field.
- **IP Address 1** and **IP Address 2**—The IP address(es) to be returned with this option code. To add a new IP address, see Creating Network Objects, on page 880.
- **ASCII**—The ASCII value that is returned to the DHCP client. The string cannot include spaces.
- **HEX**—The HEX value that is returned to the DHCP client. The string must have an even number of digits and no spaces. You do not need to use a 0x prefix.

Step 8 Click **OK** to save the option code configuration.

Step 9 Click **Save** on the DHCP page to save your changes.

Step 10 To view DHCP bindings, use the following command.

show dhcpd binding

Example:

```
> show dhcpd binding
IP Address Client-id         Lease Expiration  Type
10.0.1.100 0100.a0c9.868e.43 84985 seconds     automatic
```

Configure the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the FTD device because it does not forward broadcast traffic.

You can remedy this situation by configuring the interface of the FTD device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

Note DHCP Relay is not supported in transparent firewall mode.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **DHCP** > **DHCP Relay**.

Step 3 In the **IPv4 Relay Timeout** and **IPv6 Relay Timeout** fields, enter the amount of time in seconds that the FTD device waits to time out the DHCP relay agent. Valid values range from 1 to 3600 seconds. The default value is 60 seconds.

The timeout is for address negotiation through the local DHCP Relay agent.

Step 4 On **DHCP Relay Agent**, click **Add**, and configure the following options:

- **Interface**—The interface connected to the DHCP clients.
- **Enable IPv4 Relay**—Enables IPv4 DHCP Relay for this interface.
- **Set Route**—(For IPv4) Changes the default gateway address in the DHCP message from the server to that of the FTD device interface that is closest to the DHCP client, which relayed the original DHCP request. This action allows the client to set its default route to point to the FTD device even if the DHCP server specifies a different router. If there is no default router option in the packet, the FTD device adds one containing the interface address.
- **Enable IPv6 Relay**—Enables IPv6 DHCP Relay for this interface.

Step 5 Click **OK** to save the DHCP relay agent changes.

Step 6 On **DHCP Servers**, click **Add**, and configure the following options:

Add the IPv4 and IPv6 server addresses as separate entries, even if they belong to the same server.

- **Server**—The IP address of the DHCP server. Chose an IP address from the drop-down list. To add a new one, see Creating Network Objects, on page 880
- **Interface**—The interface to which the specified DHCP server is attached. The DHCP Relay agent and the DHCP server cannot be configured on the same interface.

Step 7 Click **OK** to save the DHCP server changes.

Step 8 Click **Save** on the DHCP page to save your changes.

Configure Dynamic DNS

When an interface uses DHCP IP addressing, the assigned IP address can change when the DHCP lease is renewed. When the interface needs to be reachable using a fully qualified domain name (FQDN), the IP address change can cause the DNS server resource records (RRs) to become stale. Dynamic DNS (DDNS) provides a mechanism to update DNS RRs whenever the IP address or hostname changes. You can also use DDNS for static or PPPoE IP addressing.

DDNS updates the following RRs on the DNS server: the A RR includes the name-to-IP address mapping, while the PTR RR maps addresses to names.

The FTD supports the following DDNS update methods:

- Standard DDNS—The standard DDNS update method is defined by RFC 2136.

  With this method, the FTD and the DHCP server use DNS requests to update the DNS RRs. The FTD or DHCP server sends a DNS request to its local DNS server for information about the hostname and, based on the response, determines the main DNS server that owns the RRs. The FTD or DHCP server then sends an update request directly to the main DNS server. See the following typical scenarios.

  - The FTD updates the A RR, and the DHCP server updates the PTR RR.

    Typically, the FTD "owns" the A RR, while the DHCP server "owns" the PTR RR, so both entities need to request updates separately. When the IP address or hostname changes, the FTD sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request a PTR RR update.

  - The DHCP server updates both the A and PTR RR.

    Use this scenario if the FTD does not have the authority to update the A RR. When the IP address or hostname changes, the FTD sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request an A and PTR RR update.

  You can configure different ownership depending on your security needs and the requirements of the main DNS server. For example, for a static address, the FTD should own the updates for both records.

- Web—The Web update method uses the DynDNS Remote API specification (https://help.dyn.com/remote-access-api/).

  With this method when the IP address or hostname changes, the FTD sends an HTTP request directly to a DNS provider with which you have an account.

The **DDNS** page also supports setting DHCP server settings relating to DDNS.

Note DDNS is not supported on the BVI or bridge group member interfaces.

Before you begin

- Configure a DNS server group on **Objects** > **Object Management** > **DNS Server Group**, and then enable the group for the interface on **Devices** > **Platform Settings** > **DNS**. See DNS, on page 481.
- Configure the device hostname. You can configure the hostname when you perform the FTD initial setup, or by using the **configure network hostname** command. If you do not specify the hostname per interface, then the device hostname is used.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **DHCP** > **DDNS**.

Step 3 Standard DDNS method: Configure a DDNS update method to enable DNS requests from the FTD.

You do not need to configure a DDNS update method if the DHCP server will perform all requests.

a) On **DDNS Update Methods**, click **Add**.
b) Set the **Method Name**.
c) Click **DDNS**.
d) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.
e) Set the **Update Records** you want the FTD to update.

This setting only affects the records you want to update directly from the FTD; to determine the records you want the DHCP server to update, configure the DHCP client settings per interface or globally. See, Step 5, on page 455.

- **Not Defined**—Disables DNS updates from the FTD.
- **Both A and PTR Records**—Sets the FTD to update both A and PTR RRs. Use this option for static or PPPoE IP addressing.
- **A Records**—Sets the FTD to update the A RR only. Use this option if you want the DHCP server to update the PTR RR.

f) Click **OK**.
g) Assign this method to the interface in Step 5, on page 455.

Step 4 Web method: Configure a DDNS update method to enable HTTP update requests from the FTD.

a) On **DDNS Update Methods**, click **Add**.
b) Set the **Method Name**.
c) Click **Web**.
d) Set the **Web Update Type** to update IPv4, IPv6, or both types of addresses.
e) Set the **Web URL**. Specify the update URL. Check with your DNS provider for the URL required.

Use the following syntax:

https://*username***:***password***@***provider-domain***/***path***?hostname=<h>&myip=<a>**

Example:

https://jcrichton:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>

f) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.

g) Click **OK**.

h) Assign this method to the interface in Step 5, on page 455.

i) The web type method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection. See, Step 9, on page 456.

Step 5 Configure interface settings for DDNS, including setting the update method, DHCP client settings, and the hostname for this interface.

a) On **DDNS Interface Settings**, click **Add**.

b) Choose the **Interface** from the drop-down list.

c) Choose the **Method Name** that you created on the **DDNS Update Methods** page.

(Standard DDNS method) You do not need to assign a method if you want the DHCP server to perform all updates.

d) Set the **Host Name** for this interface.

If you do not set the hostname, the device hostname is used. If you do not specify an FQDN, then the default domain from the DNS server group is appended (for static or PPPoE IP addressing) or the domain name from the DHCP server is appended (for DHCP IP addressing).

e) Standard DDNS method: Configure the **DHCP Client requests DHCP server to update requests** to determine which records you want the DHCP server to update.

The FTD sends DHCP client requests to the DHCP server. Note that the DHCP server must also be configured to support DDNS. The server can be configured to honor the client requests, or it can override the client (in which case, it will reply to the client so the client does not also try to perform updates that the server is performing).

For static or PPPoE IP addressing, these settings are ignored.

Note
You can also set these values globally for all interfaces on the **DDNS** page. The per-interface settings take precedence over the global settings.

- **Not Selected**—Disables DDNS requests to the DHCP server. Even if the client does not request DDNS updates, the DHCP server can be configured to send updates anyway.
- **No Update**—Requests the DHCP server not to perform updates. This setting works in conjunction with a DDNS update method with **Both A and PTR Records** enabled.
- **Only PTR**—Requests that the DHCP server perform the PTR RR update. This setting works in conjunction with a DDNS update method with **A Records** enabled.
- **Both A and PTR Records**—Requests that the DHCP server perform both A and PTR RR updates. This setting does not require a DDNS update method to be associated with the interface.

f) Click **OK**.

Note
The **Dynamic DNS Update** settings relate to DHCP server settings when you enable a DHCP server on the FTD. See, Step 6, on page 456 for more information.

Step 6 If you enable the DHCP server on an FTD, you can configure DHCP server settings for DDNS.

To enable the DHCP server, see Configure the DHCPv4 Server, on page 450). You can configure the server behavior when DHCP clients use the standard DDNS update method. If the server performs any updates, then if the client lease expires (and is not renewed), the server will request that the DNS server remove the RRs for which it was responsible.

a) You can configure server settings globally or per interface. For global settings, see the main **DDNS** page. For per-interface settings, see the **DDNS Interface Settings** page. Interface settings take precedence over global settings.

b) Configure which DNS RRs you want the DHCP server to update under **Dynamic DNS Update**.

- **Not Selected**—DDNS updates are disabled, even if the client requests them.
- **Only PTR**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will only update the PTR RR. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.
- **Both A and PTR Records**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will update both the A and PTR RRs. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.

c) To override the update actions requested by the DHCP client, check **Override DHCP Client Requests**.

The server will reply to the client that the request was overridden, so the client does not also try to perform updates that the server is performing.

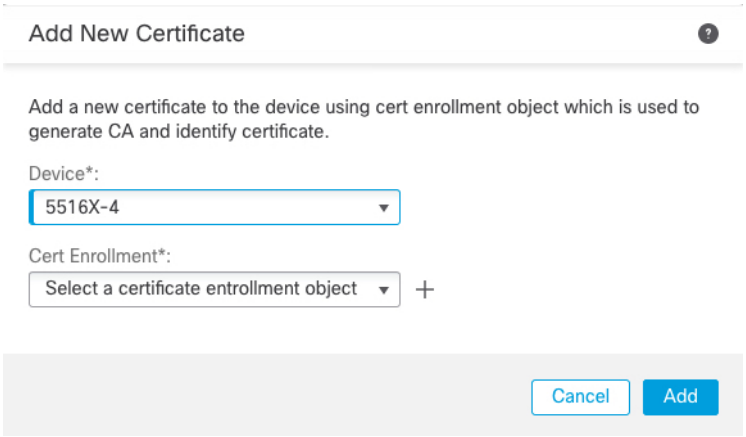
Step 7 (Optional) Configure general DHCP client settings. These settings are not related to DDNS, but are related to how the DHCP client behaves.

a) On the **DDNS** page, check **Enable DHCP Client Broadcast** to request that the DHCP server broadcast the DHCP reply (DHCP option 1).

b) To force a MAC address to be stored inside a DHCP request packet for option 61 instead of the default internally generated string, on **DDNS** > **DHCP Client ID Interface**, choose the interface from the **Available Interfaces** list, and then click **Add** to move it to the **Selected Interfaces** list.

Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned. This setting does not directly relate to DDNS, but is a general DHCP client setting.

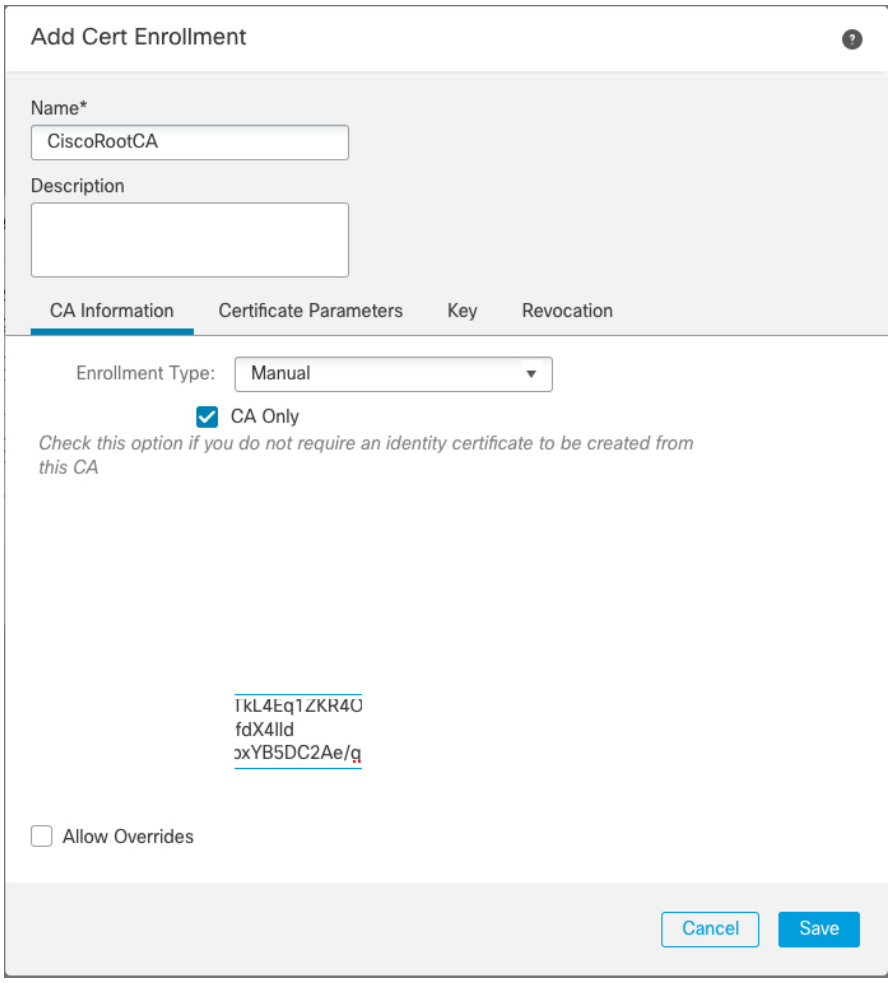
Step 8 Click **Save** on the Device page to save your changes.



Step 9 The Web method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection.

The following example shows how to add a DDNS server's CA as a trustpoint.

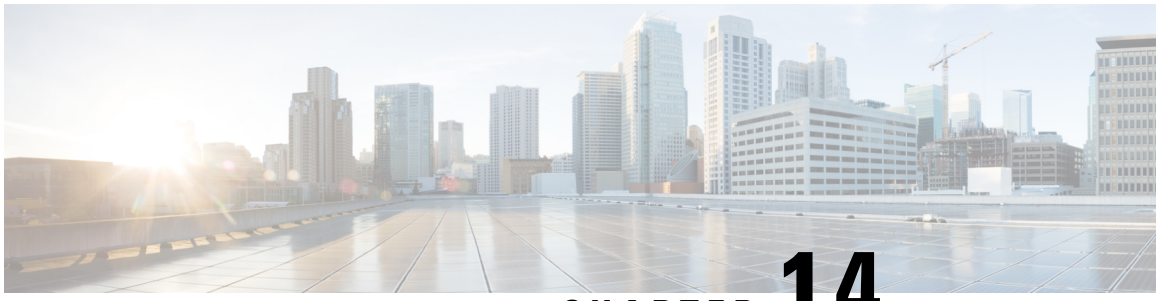
a) Obtain the DDNS server CA certificate. This procedure shows a manual import using PEM format, but you can also use PKCS12.



b) In FMC, choose **Devices** > **Certificates**, and click **Add**.

c) Select a **Device**, and click **Add** (+).

The **Add Cert Enrollment** dialog box appears.



d) Enter the following fields, and click **Save**:

- Enter a **Name**.
- Choose **Enrollment Type** > **Manual**.

- Click **CA Only**.
- Paste in the CA text from step 9.a, on page 456.

e) Click **Save**.

CHAPTER 14

SNMP for the Firepower 1000/2100

This chapter describes how to configure SNMP for the Firepower 1000/2100.

- About SNMP for the Firepower 1000/2100, on page 459
- Enabling SNMP and Configuring SNMP Properties for Firepower 1000/2100, on page 459
- Creating an SNMP Trap for Firepower 1000/2100, on page 461
- Creating an SNMP User for Firepower 1000/2100, on page 462

About SNMP for the Firepower 1000/2100

The Simple Network Management Protocol (SNMP) is an application-layer protocol that provides a message format for communication between SNMP managers and agents. SNMP provides a standardized framework and a common language used for the monitoring and management of devices in a network.

The SNMP framework consists of three parts:

- An SNMP manager—The system used to control and monitor the activities of network devices using SNMP.
- An SNMP agent—The software component within the Firepower 1000/2100 chassis that maintains the data for the Firepower chassis and reports the data, as needed, to the SNMP manager. The Firepower chassis includes the agent and a collection of MIBs. To enable the SNMP agent and create the relationship between the manager and agent, enable and configure SNMP in the FMC.
- A managed information base (MIB)—The collection of managed objects on the SNMP agent.

The Firepower 1000/2100 chassis supports SNMPv1, SNMPv2c and SNMPv3. Both SNMPv1 and SNMPv2c use a community-based form of security.

Enabling SNMP and Configuring SNMP Properties for Firepower 1000/2100

Note This procedure only applies to the Firepower 1000/2100.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 Complete the following fields:

Name	Description
Admin State check box	Whether SNMP is enabled or disabled. Enable this service only if your system includes integration with an SNMP server.
Port field	The port on which the Firepower chassis communicates with the SNMP host. You cannot change the default port.
Community field	The default SNMPv1 or v2 community name or SNMP v3 username and password that the Firepower chassis includes on any trap messages it sends to the SNMP host. Enter a valid community string for SNMPv1 and SNMPv2: • Alphanumeric string between 1 and 32 characters and special characters ! (exclamation), - (hyphen), ~ (tilde), && (double ampersand), [ ] (square brackets), ^ (carat), ' (single quote), " (double quotes), and < > (angle brackets). • Do not use @ (at sign), \ (backslash), ? (question mark) or an empty space. • The string can also be in ASCII characters ranging 0x21 to 0x7E inclusive, excluding HTML interjection vectors, namely single quote ('), double quotes ("), and angle brackets (< >). Enter a valid username and password for SNMPv3: • Username can be alphanumeric string and can include @ (at sign), \ (backslash), . (period), _ (underscore), and - (hyphen). • The password restrictions are same as the community string restrictions. Note that if the **Community** field is already set, the text to the right of the empty field reads **Set: Yes**. If the **Community** field is not yet populated with a value, the text to the right of the empty field reads **Set: No**.
System Admin Name field	The contact person responsible for the SNMP implementation. Enter a string of up to 255 characters, such as an email address or a name and telephone number.
Location field	The location of the host on which the SNMP agent (server) runs. Enter an alphanumeric string up to 510 characters.

Step 4 Click **Save**.

What to do next

Create SNMP traps and users.

Creating an SNMP Trap for Firepower 1000/2100

Note This procedure only applies to the Firepower 1000/2100.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 In the **SNMP Traps Configuration** area, click **Add**.

Step 4 In the **SNMP Trap Configuration** dialog box, complete the following fields:

Name	Description
Host Name field	The hostname or IP address of the SNMP host to which the Firepower chassis should send the trap.
Community field	The SNMP v1 or v2 community name or the SNMP v3 username the Firepower chassis includes when it sends the trap to the SNMP host. This must be the same as the community or username that is configured for the SNMP service. Enter an alphanumeric string between 1 and 32 characters. Do not use @ (at sign), \ (backslash), " (double quote), ? (question mark) or an empty space.
Port field	The port on which the Firepower chassis communicates with the SNMP host for the trap. Enter an integer between 1 and 65535.
Version field	The SNMP version and model used for the trap. This can be one of the following: • **V1** • **V2** • **V3**

Name	Description
Type field	If you select **V2** or **V3** for the version, the type of trap to send. This can be one of the following: • **Traps** • **Informs**
Privilege field	If you select **V3** for the version, the privilege associated with the trap. This can be one of the following: • **Auth**—Authentication but no encryption • **Noauth**—No authentication or encryption • **Priv**—Authentication and encryption

Step 5 Click **OK** to close the **SNMP Trap Configuration** dialog box.

Step 6 Click **Save**.

Creating an SNMP User for Firepower 1000/2100

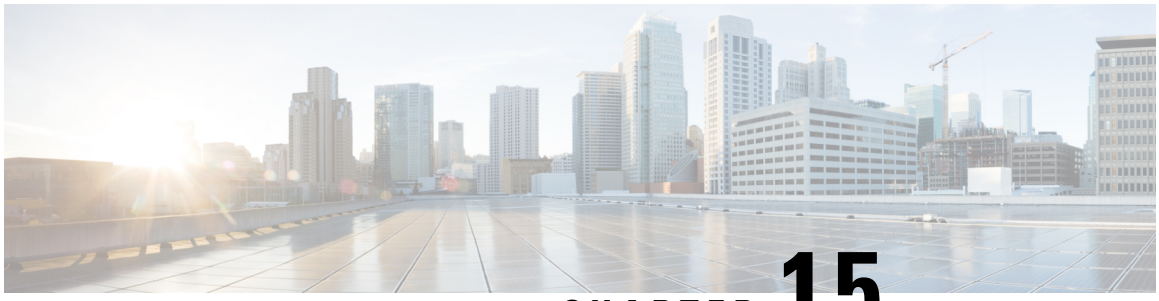
Note This procedure only applies to the Firepower 1000/2100.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **SNMP**.

Step 3 In the **SNMP Users Configuration** area, click **Add**.



Step 4 In the **SNMP User Configuration** dialog box, complete the following fields:

Name	Description
Username field	The username assigned to the SNMP user. Enter up to 32 letters or numbers. The name must begin with a letter and you can also specify _ (underscore), . (period), @ (at sign), and - (hyphen).
Auth Algorithm Type field	The authorization type: **SHA**.

Name	Description
Use AES-128 checkbox	If checked, this user uses AES-128 encryption. **Note** SNMPv3 does not support DES. If you leave the AES-128 box unchecked, no privacy encryption will be done and any configured privacy password will have no effect.
Authentication Password field	The password for the user.
Confirm field	The password again for confirmation purposes.
Encryption Password field	The privacy password for the user.
Confirm field	The privacy password again for confirmation purposes.

Step 5 Click **OK** to close the **SNMP User Configuration** dialog box.

Step 6 Click **Save**.

CHAPTER 15

Quality of Service

The following topics describe how to use the Quality of Service (QoS) feature to police network traffic using FTD devices:

- Introduction to QoS, on page 465
- About QoS Policies, on page 465
- Requirements and Prerequisites for QoS, on page 466
- Rate Limiting with QoS Policies, on page 466
- History for QoS, on page 475

Introduction to QoS

Quality of Service, or QoS, rate limits (polices) network traffic that is allowed or trusted by access control. The system does not rate limit traffic that was fastpathed.

Though QoS is supported only on the routed interfaces of FTD devices, it is not supported on site-to-site VPN and VTI interfaces.

Logging Rate-Limited Connections

There are no logging configurations for QoS. A connection can be rate limited without being logged, and you cannot log a connection simply because it was rate limited. To view QoS information in connection events, you must independently log the ends of the appropriate connections to the FMC database. See *Other Connections You Can Log* in the Firepower Management Center Administration Guide for more information.

Connection events for rate-limited connections contain information on how much traffic was dropped, and which QoS configurations limited the traffic. You can view this information in event views (workflows), dashboards, and reports.

About QoS Policies

QoS policies deployed to managed devices govern rate limiting. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

The system matches traffic to QoS rules in the order you specify. The system rate limits traffic according to the first rule where all rule conditions match the traffic. Traffic that does not match any of the rules is not rate limited.

Note The total number of rules including QoS rules on the device cannot exceed 255. When this threshold is reached, a deployment warning message is displayed. You need to reduce the number of rules for a successful deployment.

You must constrain QoS rules by source or destination (routed) interfaces. The system enforces rate limiting *independently* on *each* of those interfaces; you cannot specify an aggregate rate limit for a set of interfaces.

QoS rules can also rate limit traffic by other network characteristics, as well as contextual information such as application, URL, user identity, and custom Security Group Tags (SGTs).

You can rate limit download and upload traffic independently. The system determines download and upload directions based on the connection initiator.

Note QoS is not subordinate to a main access control configuration; you configure QoS independently. However, the access control and QoS policies deployed to the same device share identity configurations; see Associating Other Policies with Access Control, on page 1177.

Requirements and Prerequisites for QoS

Model Support

FTD

Supported Domains

Any

User Roles

Admin

Access Admin

Network Admin

Rate Limiting with QoS Policies

To perform policy-based rate limiting, configure and deploy QoS policies to managed devices. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

Procedure

Step 1 Choose **Devices** > **QoS**.

Step 2 Click **New Policy** to create a new QoS policy and, optionally, assign target devices; see Creating a QoS Policy, on page 467.

You can also **Copy** ( ) or **Edit** ( ) an existing policy.

Step 3 Configure QoS rules; see Configuring QoS Rules, on page 468 and QoS Rule Conditions, on page 470.

The Rules in the QoS policy editor lists each rule in evaluation order, and displays a summary of the rule conditions and rate limiting configurations. A right-click menu provides rule management options, including moving, enabling, and disabling.

Helpful in larger deployments, you can **Filter by Device** to display only the rules that affect a specific device or group of devices. You can also search for and within rules; the system matches text you enter in the **Search Rules** field to rule names and condition values, including objects and object groups.

Note
Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. Icons represent comments, warnings, and errors. If issues exist, click **Show Warnings** to display a list. For more information, see Best Practices for Access Control Rules, on page 1157.

Step 4 Click **Policy Assignments** to identify the managed devices targeted by the policy; see Setting Target Devices for a QoS Policy, on page 468.

If you identified target devices during policy creation, verify your choices.

Step 5 Save the QoS policy.

Step 6 Because this feature must allow some packets to pass, you must configure your system to examine those packets. See Best Practices for Handling Packets That Pass Before Traffic Identification, on page 1948 and Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 1948.

Step 7 Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Creating a QoS Policy

A new QoS policy with no rules performs no rate limiting.

Procedure

Step 1 Choose **Devices** > **QoS**.

Step 2 Click **New Policy**.

Step 3 Enter a **Name** and, optionally, a **Description**.

Step 4 (Optional) Choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy**, or drag and drop to the **Selected Devices**. To narrow the devices that appear, type a search string in the **Search** field.

You must assign devices before you deploy the policy.

Step 5 Click **Save**.

What to do next

- Configure and deploy the QoS policy; see Rate Limiting with QoS Policies, on page 466.

Setting Target Devices for a QoS Policy

Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Procedure

Step 1 In the QoS policy editor, click **Policy Assignments**.

Step 2 Build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete—Click **Delete** ( ) next to a single device, or choose multiple devices, right-click, then choose **Delete Selected**.
- Search—Enter a search string in the search field. Click **Clear** ( ) to clear the search.

Step 3 Click **OK** to save policy assignments.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Configuring QoS Rules

When you create or edit a rule, use the upper portion of the rule editor to configure general rule properties. Use the lower portion of the rule editor to configure rule conditions and comments.

Procedure

Step 1 On Rules of the QoS policy editor:

- Add Rule—Click **Add Rule**.
- Edit Rule—Click **Edit** ( ).

Step 2 Enter a **Name**.

Step 3 Configure rule components:

- Enabled—Specify whether the rule is **Enabled**.
- Apply QoS On—Choose the interfaces you want to rate limit, either **Interfaces in Destination Interface Objects** or **Interfaces in Source Interface Objects**. Your choice must correspond with a populated interface constraint (not **any**).
- Traffic Limit Per Interface—Enter a **Download Limit** and an **Upload Limit** in Mbits/sec. The default value of **Unlimited** prevent matching traffic from being rate limited in that direction.
- Conditions—Click the corresponding condition you want to add. You must configure a source or destination interface condition, corresponding to your choice for **Apply QoS On**.
- Comments—Click **Comments**. To add a comment click **New Comment**, enter a comment, and click **OK**. You can edit or delete this comment until you save the rule.

For detailed information on rule components, see QoS Rule Components, on page 469.

Step 4 Save the rule.

Step 5 In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste.

Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Best Practices for Access Control Rules, on page 1157

QoS Rule Components

State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

Interfaces (Apply QoS On)

You cannot save a QoS rule that rate limits all traffic. For each QoS rule, you must apply QoS on either:

- Interfaces in Source Interface Objects—Rate limits traffic through the rule's source interfaces. If you choose this option, you must add at least one source interface constraint (cannot be **any**).
- Interfaces in Destination Interface Objects—Rate limits traffic through the rule's destination interfaces. If you choose this option, you must add at least one destination interface constraint (cannot be **any**).

Traffic Limit Per Interface

A QoS rule enforces rate limiting *independently* on *each* of the interfaces you specify with the Apply QoS On option. You cannot specify an aggregate rate limit for a set of interfaces.

You can rate limit traffic by Mbits per second. The default value of **Unlimited** prevents matching traffic from being rate limited.

You can rate limit download and upload traffic independently. The system determines download and upload directions based on the connection initiator.

If you specify a limit greater than the maximum throughput of an interface, the system does not rate limit matching traffic. Maximum throughput may be affected by an interface's hardware configuration, which you specify in each device's properties (**Devices** > **Device Management**).

Conditions

Conditions specify the specific traffic the rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule. Each condition type has its own tab in the rule editor. For more information, see QoS Rule Conditions, on page 470.

Comments

Each time you save changes to a rule you can add comments. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change.

In the policy editor, the system displays how many comments a rule has. In the rule editor, use the Comments tab to view existing comments and add new ones.

QoS Rule Conditions

Conditions specify the specific traffic the rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule. Each condition type has its own tab in the rule editor. You can rate limit traffic using:

See one of the following sections for more information.

Interface Rule Conditions

Interface rule conditions control traffic by its source and destination interfaces.

Depending on the rule type and the devices in your deployment, you can use predefined *interface objects* called *security zones* or *interface groups* to build interface conditions. Interface objects segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices; see Interface, on page 875.

Tip Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

Just as all interfaces in an interface object must be of the same type (all inline, passive, switched, routed, or ASA FirePOWER), all interface objects used in an interface condition must be of the same type. Because devices deployed passively do not transmit traffic, in passive deployments you cannot constrain rules by destination interface.

Network Rule Conditions

Networks control or decrypt traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Note You *cannot* use FDQN network objects in identity rules.

User Rule Conditions

Matches traffic based the user who initiates the connection, or the group to which the user belongs. For example, you could configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

You can configure user rule conditions for users in Microsoft Active Directory realms only.

In addition to configuring users and groups for configured realms, you can set policies for the following Special Identities users:

- Failed Authentication: User that failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified; for example, users that are not downloaded by a configured realm.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in Associating Other Policies with Access Control, on page 1177.

Application Rule Conditions

When the system analyzes IP traffic, it can identify and classify the commonly used applications on your network. This discovery-based *application awareness* is the basis for *application control*—the ability to control application traffic.

System-provided *application filters* help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. You can create reuseable user-defined filters based on combinations of the system-provided filters, or on custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled for an application, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application. For more information about application detectors, see Application Detector Fundamentals, on page 1850.

You can use both application filters and individually specified applications to ensure complete coverage. However, understand the following note before you order your access control rules.

Benefits of Application Filters

Application filters help you quickly configure application control. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

Table 31: Application Characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email clients are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged `high bandwidth` and `displays ads`.

Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like FTD, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

Port, Protocol, and ICMP Code Rule Conditions

Port conditions match traffic based on the source and destination ports. Depending on the rule type, “port” can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—You can control traffic using other protocols that do not use ports.

Minimize the number of matching criteria whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against *every* combination of the contents of the criteria you specify.

Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic. Note that application filtering is not available in prefilter rules.

Application filtering is also recommended for applications, like FTP, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match non-TCP traffic, there are some restrictions:

- Access control rules—For Classic devices, you can match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, you can add only network-based conditions: zone, IP address, port, and VLAN tag. Also, the system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For FTD devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- SSL rules—These rules support TCP port conditions only.
- IMCP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies sent in response to ICMP echo requests are ignored. For a rule to match on any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

URL Rule Conditions

Use URL conditions to control the websites that users on your network can access.

For complete information, see URL Filtering, on page 1211.

Custom SGT Rule Conditions

If you do not configure ISE/ISE-PIC as an identity source, you can control traffic using Security Group Tags (SGTs) that were **not** assigned by ISE. SGTs specify the privileges of traffic sources within a trusted network.

Custom SGT rule conditions use manually created SGT objects to filter traffic, rather than ISE SGTs obtained from the system's connection to an ISE server. These manually created SGT objects correspond to the SGT attributes on the traffic you want to control. Controlling traffic using custom SGTs is not considered user control.

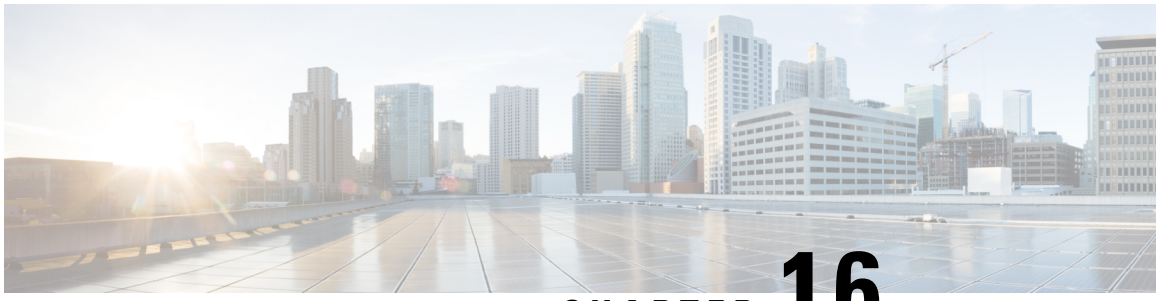
ISE SGT vs Custom SGT Rule Conditions

Some rules allow you to control traffic based on assigned SGT. Depending on the rule type and your identity source configuration, you can use either ISE-assigned SGTs or custom SGTs to match traffic with assigned SGT attributes.

Note If you use ISE SGTs to match traffic, even if a packet does not have an assigned SGT attribute, the packet still matches an ISE SGT rule if the SGT associated with the packet's source IP address is known in ISE.

Condition Type	Requires	SGTs Listed in Rule Editor
ISE SGT	ISE identity source	SGTs obtained by querying the ISE server, with automatically updated metadata
Custom SGT	No ISE/ISE-PIC identity source	Static SGT objects you create

Autotransition from Custom SGTs to ISE SGTs



If you create rules that match custom SGTs, then configure ISE/ISE-PIC as an identity source, the system:

- Disables **Security Group Tag** options in the object manager. Although the system retains existing SGT objects, you cannot modify them or add new ones.
- Retains existing rules with custom SGT conditions. However, these rules do not match traffic. You also cannot add additional custom SGT criteria to existing rules, or create new rules with custom SGT conditions.

If you configure ISE, Cisco recommends that you delete or disable existing rules with custom SGT conditions. Instead, use ISE attribute conditions to match traffic with SGT attributes.

History for QoS

Feature	Minimum FMC	Minimum FTD	Details
Ability to specify handling of URLs having unknown reputation.	6.7.0	Any	For details, see History for URL Filtering, on page 1236. New/modified screens: QoS rule editor
Rate limit increased.	6.2.1	Any	Raised the maximum rate limit from 1,000 Mbps to 100,000 Mbps. New/modified screens: QoS rule editor
Custom SGT and original client network filtering.	6.2.1	Any	Rate limit traffic using custom Security Group Tags (SGTs) and original client network information (XFF, True-Client-IP, or custom-defined HTTP headers). New/modified screens: QoS rule editor
QoS (rate limiting) introduced.	6.1.0	Any	FTD can rate limit (police) network traffic that is allowed or trusted by access control. New/modified screens: **Devices** > **QoS**

CHAPTER 16

Platform Settings

Platform settings for FTD devices configure a range of unrelated features whose values you might want to share among several devices. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

- Introduction to Platform Settings, on page 477

- Time Zone, on page 530
- UCAPL/CC Compliance, on page 531
- History for Platform Settings, on page 532

Introduction to Platform Settings

A platform settings policy is a shared set of features or parameters that define the aspects of a managed device that are likely to be similar to other managed devices in your deployment, such as time settings and external authentication.

A shared policy makes it possible to configure multiple managed devices at once, which provides consistency in your deployment and streamlines your management efforts. Any changes to a platform settings policy affects all the managed devices where you applied the policy. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

For example, your organization's security policies may require that your appliances have a "No Unauthorized Use" message when a user logs in. With platform settings, you can set the login banner once in a platform settings policy.

You can also benefit from having multiple platform settings policies on a single FMC. For example, if you have different mail relay hosts that you use under different circumstances or if you want to test different access lists, you can create several platform settings policies and switch between them, rather than editing a single policy.

Requirements and Prerequisites for Platform Settings Policies

Supported Domains

Any

User Roles

Admin

Access Admin

Network Admin

Manage Platform Settings Policies

Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** ( ), **Edit** ( ), or **Delete** ( ) the policy.

Caution
You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose a device type from the drop-down list:

- **Firepower Settings** to create a shared policy for managed Classic devices.
- **Threat Defense Settings** to create a shared policy for managed FTD devices.

b) Enter a **Name** for the new policy and optionally, a **Description**.

c) Optionally, choose the **Available Devices** where you want to apply the policy and click **Add** (or drag and drop) to add the selected devices. You can enter a search string in the **Search** field to narrow the list of devices.

d) Click **Save**.

The system creates the policy and opens it for editing.

Step 4 To change the target devices for a policy, click **Edit** ( ) next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.

b) To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add**. You can also drag and drop.

c) To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

d) Click **OK**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

ARP Inspection

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the FTD device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the FTD device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the FTD device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Diagnostic interface never floods packets even if this parameter is set to flood.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **ARP Inspection**.

Step 3 Add entries to the ARP inspection table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the desired options.

- **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.
- **Flood Enabled**—Whether to flood ARP requests that do not match static ARP entries out all interfaces other than the originating interface or the dedicated management interface. This is the default behavior.

  If you do not elect to flood ARP requests, then only those requests that exactly match static ARP entries are allowed.
- **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Add static ARP entries according to Add a Static ARP Entry, on page 426.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Banner

You can configure messages to show users when they connect to the device command line interface (CLI).

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Banner**.

Step 3 Configure the banner.

Following are some tips and requirements for banners.

- Only ASCII characters are allowed. You can use line returns (press Enter), but you cannot use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables **$(hostname)** or **$(domain)**.

- Although there is no absolute length restriction on banners, Telnet or SSH sessions will close if there is not enough system memory available to process the banner messages.
- From a security perspective, it is important that your banner discourage unauthorized access. Do not use the words "welcome" or "please," as they appear to invite intruders in. The following banner sets the correct tone for unauthorized access:

```
You have logged in to a secure device.
If you are not authorized to access this device,
log out immediately or risk criminal charges.
```

Step 4 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

DNS

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. There are two DNS server settings that apply to different types of traffic: data and special management traffic. Data traffic includes any services that use FQDNs for which a DNS lookup is necessary, such as access control rules and remote access VPN. Special management traffic includes traffic originating on the Management interface such as configuration and database updates. This procedure only applies to *data* DNS servers. For *management* DNS settings, see the CLI **configure network dns servers** and **configure network dns searchdomains** commands.

To determine the correct interface for DNS server communications, the managed device uses a routing lookup, but which routing table is used depends on the interfaces for which you enable DNS. See the interface settings below for more information.

You can configure trusted DNS services for DNS snooping using the Trusted DNS Servers tab. DNS snooping is used to map the application domains to IPs in order to detect the application on the first packet. Apart from configuring the trusted DNS servers, you can include the already configured servers in DNS group, DHCP pool, DHCP relay and DHCP client as trusted DNS servers.

Note For an application-based PBR, you must configure trusted DNS servers. You must also ensure that the DNS traffic passes through FTD in a clear-text format (encrypted DNS is not supported) so that domains can be resolved to detect applications.

Before you begin

- Ensure you have created a DNS server group. For more information, see Creating DNS Server Group Objects, on page 867.
- Ensure you have created interface objects to connect to the DNS servers.
- Ensure that the managed device has appropriate static or dynamic routes to access the DNS servers.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit a Threat Defense policy.

Step 2 Click **DNS**.

Step 3 Click the **DNS Settings** tab.

Step 4 Check **Enable DNS name resolution by device**.

Step 5 Choose the **DNS Server Group** that you have already created.

Step 6 (Optional) Enter the **Expiry Entry Timer** and **Poll Timer** values in minutes.

These options apply to FQDNs that are specified in network objects only. These do not apply to FQDNs used in other features.

- **Expire Entry Timer** specifies the minimum time-to-live (TTL) for the DNS entry, in minutes. If the expiration timer is longer than the entry's TTL, the TTL is increased to the expire entry time value. If the TTL is longer than the expiration timer, the expire entry time value is ignored: no additional time is added to the TTL in this case. Upon expiration, the entry is removed from the DNS lookup table. Removing an entry requires that the table be recompiled, so frequent removals can increase the processing load on the device. Because some DNS entries can have very short TTL (as short as three seconds), you can use this setting to virtually extend the TTL. The default is 1 minute (that is, the minimum TTL for all resolutions is 1 minute). The range is 1 to 65535 minutes.

  Note that for systems running 7.0 or earlier, the expiration time is actually added to the TTL: it does not specify a minimum value.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN that was defined in a network object. An FQDN is resolved periodically either when the poll timer has expired, or when the TTL of the resolved IP entry has expired, whichever occurs first.

Step 7 Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used.

Note that enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The FTD always uses a route lookup to determine the source interface.

- No interfaces selected—Enables DNS lookups on all interfaces, including Management and management-only interfaces. The FTD checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Specific interfaces selected but not the **Enable DNS Lookup via diagnostic interface also** option—Enables DNS lookups on the specified interfaces. The FTD checks the data routing table only.
- Specific interfaces selected plus the **Enable DNS Lookup via diagnostic interface also** option—Enables DNS lookups on the specified interfaces and the Diagnostic interface. The FTD checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Only the **Enable DNS Lookup via diagnostic interface also** option—Enables DNS lookups on Diagnostic. The FTD checks only the management-only routing table. Be sure to configure an IP address for the Diagnostic interface on the **Devices** > **Device Management** > **edit device** > **Interfaces** page.

Step 8 To configure the trusted DNS servers, click the **Trusted DNS Servers** tab.

Step 9 By default, the existing DNS servers that are configured in DHCP pool, DHCP relay, DHCP client, or DNS server group are included as trusted DNS servers. If you want to exclude any of them, uncheck the appropriate check boxes.

Step 10 To add trusted DNS servers, under **Specify DNS Servers**, click **Edit**.

Step 11 In the **Select DNS Servers** dialog box, either choose a host object as the trusted DNS server or directly specify the IP address of the trusted DNS server:

a) To choose existing host objects, under **Available Host Objects**, select the required host object and click **Add** to include it to **Selected DNS Servers**. For information on adding the host objects, see Creating Network Objects, on page 880.

b) To directly provide the IP address(IPv4 or IPv6) of the trusted DNS server, enter the address in the given text field, and click **Add** to include it to **Selected DNS Servers**.

c) Click **Save**. The added DNS servers are displayed in the **Trusted DNS Servers** page.

Note
You can configure a maximum of 12 DNS servers per policy.

Step 12 (Optional) To search for a DNS server that was added, using either the host name or the IP address, use the search field under **Specify DNS Servers**.

Step 13 Click **Save**.

What to do next

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions see, Creating Network Objects, on page 880.

External Authentication

Note You must have administrator privileges to perform this task.

When you enable external authentication for management users, the FTD verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

Sharing External Authentication Objects

External authentication objects can be used by the FMC and FTD devices. You can share the same object between the FMC and devices, or create separate objects. Note that the FTD supports defining users on the RADIUS server, while the FMC requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the FTD, but if you want to define users on the RADIUS server, you must create separate objects for the FTD and the FMC.

Note The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the FTD external authentication configuration will not work.

Assigning External Authentication Objects to Devices

For the FMC, enable the external authentication objects directly on **System** > **Users** > **External Authentication**; this setting only affects FMC usage, and it does not need to be enabled for managed device usage. For FTD devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access. Be sure that both the FTD and the FMC can reach the LDAP server, even if you are not sharing the object. The FMC is essential to retrieving the user list and downloading it to the device.

FTD Supported Fields

Only a subset of fields in the external authentication object are used for FTD SSH access. If you fill in additional fields, they are ignored. If you also use this object for the FMC, those fields will be used. This procedure only covers the supported fields for the FTD. For other fields, see *Configure External Authentication for the FMC* in the Firepower Management Center Administration Guide.

Usernames

Usernames must be Linux-valid usernames and be lower-case only, using alphanumeric characters plus period (.) or hyphen (-). Other special characters such as at sign (@) and slash (/) are not supported. You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the FMC; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the FMC.

If you previously configured the same username for an internal user using the **configure user add** command, the FTD first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Privilege Level

LDAP users always have Config privileges. RADIUS users can be defined as either Config or Basic users.

Before you begin

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see Secure Shell, on page 492. SSH is not supported to the Diagnostic interface.
- Inform RADIUS users of the following behavior to set their expectations appropriately:
  - The first time an external user logs in, FTD creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start the session. The user will see a message similar to the following: "New external username identified. Please log in again to start a session."
  - If the user's Service-Type attribute is not defined or incorrectly configured in the RADIUS server, and when using the RADIUS-defined users for authentication, the user will see a message similar to the following: "Your username is not defined with a service type that is valid for this system. You are not authorized to access the system?.

    In some cases, the SSH clients close the CLI window on an unsuccessful SSH connection, even before displaying the failure message. Hence, ensure that the user's Service-Type attribute is correctly defined in the RADIUS server.

- Similarly, if the user's Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to the following: "Your authorization privilege has changed. Please log in again to start a session."

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **External Authentication**.

Step 3 Click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System** > **Users** > **External Authentication**.

Step 4 Configure an LDAP Authentication Object.

a) Click **Add External Authentication Object**.
b) Set the **Authentication Method** to **LDAP**
c) Enter a **Name** and optional **Description**.
d) Choose a **Server Type** from the drop-down list.
e) For the **Primary Server**, enter a **Host Name/IP Address**.

Note
If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

f) (Optional) Change the **Port** from the default.
g) (Optional) Enter the **Backup Sever** parameters.
h) Enter **LDAP-Specific Parameters**.

- **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
- (Optional) **Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
- **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
- **Password** and **Confirm Password**—Enter and confirm the password for the user.
- (Optional) **Show Advanced Options**—Configure the following advanced options.
  - **Encryption**—Click **None**, **TLS**, or **SSL**.

Note

If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.

- **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.
- (Not Used) **User Name Template**—Not used by the FTD.
- **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

Note
The timeout range is different for the FTD and the FMC, so if you share an object, be sure not to exceed the FTD's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the FTD external authentication configuration will not work.

i) (Optional) Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.

j) Set the **CLI Access Filter**.

Choose one of the following methods:

- To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

k) Click **Save**.

Step 5 For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

a) Choose **System** > **Users** > **External Authentication**.

b) Click **Refresh** ( ) next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Theat Defense Platform Settings will also show that it is "Out-of-Date on *x* targeted devices."

c) Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Step 6 Configure a RADIUS Authentication Object.

a) Define users on the RADIUS server using the Service-Type attribute.

The following are supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step 6.j, on page 487). To use the same RADIUS server for the FTD and FMC while using the Service-Type attribute method for the FTD, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the FMC), and the other object leaves the **CLI Access Filter** empty (for use with FTDs).

b) In FMC, click **Add External Authentication Object**.
c) Set the **Authentication Method** to **RADIUS**.
d) Enter a **Name** and optional **Description**.
e) For the **Primary Server**, enter a **Host Name/IP Address**.

Note
If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

f) (Optional) Change the **Port** from the default.
g) Enter a **RADIUS Secret Key**.
h) (Optional) Enter the **Backup Sever** parameters.
i) Enter **RADIUS-Specific Parameters**.

- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
- **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.

j) (Optional) Instead of using RADIUS-defined users, under **CLI Access Filter**, enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter **`jchrichton, aerynsun, rygel`**.

You may want to use the **CLI Access Filter** method for FTD so you can use the same external authentication object with FTD and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note
If you want to only define users on the RADIUS server, you must leave this section empty.

k) Click **Save**.

Step 7 Return to **Devices** > > **Platform Settings** > **External Authentication**.

Step 8 Click **Refresh** ( ) to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

Step 9 Click **Slider enabled** ( ) next to the External Authentication object you want to use. You can only enable one object.

Step 10 Click **Save**.

Step 11 Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Fragment Settings

By default, the FTD device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments by setting **Chain** to 1. Fragmented packets are often used as Denial of Service (DoS) attacks.

Note These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced** > **Security Configuration**. Select **Devices** > **Device Management**, edit a FTD device, and select **Interfaces** to edit interface properties..

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Fragment Settings**.

Step 3 Configure the following options. Click **Reset to Defaults** if you want to use the default settings.

- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default is 200 fragments.
- **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to 1 to disallow fragments.
- **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is 5 seconds. If all fragments are not received within this time, all fragments are discarded.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

HTTP

You can enable the HTTPS server to provide a health check mechanism for a cloud load balancer, for example, for the FTDv on AWS using an Application Load Balancer.

Other uses for HTTPs on the FTD are not supported; for example, the FTD does not have a web interface for configuration in this management mode.

This configuration only applies to data interfaces, including any you have configured as management-only. It does not apply to the dedicated Management interface. The physical management interface is shared between the Diagnostic logical interface and the Management logical interface; this configuration applies only to the Diagnostic logical interface, if used, or to other data interfaces. The Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the FMC. It has a separate IP address and static routing.

To use HTTPS, you do not need an access rule allowing the host IP address. You only need to configure HTTPS access according to this section.

You can only use HTTPS to a reachable interface; if your HTTPS host is located on the outside interface, you can only initiate a management connection directly to the outside interface.

Before you begin

- You cannot configure both HTTPS and AnyConnect Remote Access SSL VPN on the same interface for the same TCP port. For example, if you configure remote access SSL VPN on the outside interface, you cannot also open the outside interface for HTTPS connections on port 443. If you must configure both features on the same interface, use different ports. For example, open HTTPS on port 4443.
- You need network objects that define the hosts or networks you will allow to make HTTPS connections to the device. You can add objects as part of the procedure, but if you want to use object groups to identify a group of IP addresses, ensure that the groups needed in the rules already exist. Select **Objects** > **Object Management** to configure objects.

Note You cannot use the system-provided **any** network object group. Instead, use **any-ipv4** or **any-ipv6**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **HTTP**.

Step 3 Check the **Enable HTTP Server** check box to enable the HTTP server.

Step 4 (Optional) Change the HTTP port. The default is 443.

Step 5 Identify the interfaces and IP addresses that allow HTTP connections.

Use this table to limit which interfaces will accept HTTP connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make HTTP connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Security Zones**—Add the zones that contain the interfaces to which you will allow HTTP connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Security Zones** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

ICMP

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The FTD does not respond to ICMP echo requests directed to a broadcast address.
- The FTD only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

Before you begin

Ensure that the objects needed in the rules already exist. Select **Objects** > **Object Management** to configure objects. You need network objects or groups that define the desired hosts or networks, and port objects that define the ICMP message types you want to control.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **ICMP**.

Step 3 Configure ICMP rules.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **Action**—Whether to permit (allow) or deny (drop) matching traffic.
- **ICMP Service**—The port object that identifies the ICMP message type.
- **Network**—The network object or group that identifies the hosts or networks whose access you are controlling.
- **Security Zones**—Add the zones that contain the interfaces that you are protecting. For interfaces not in a zone, you can type the interface name into the field below the **Selected Security Zones** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 4 (Optional.) Set rate limits on ICMPv4 Unreachable messages.

- **Rate Limit**—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
- **Burst Size**—Sets the burst rate, between 1 and 10. The system sends this number of replies, but subsequent replies are not sent until the rate limit is reached.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Secure Shell

If you enabled FMC access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more *data* interfaces on the FTD. SSH is not supported to the Diagnostic logical interface.

The FTD uses the CiscoSSH stack, which is based on OpenSSH. CiscoSSH supports FIPS compliance and regular updates, including updates from Cisco and the open source community.

Note SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the FMC. SSH for data interfaces shares the internal and external user list with SSH for the Management interface. Other settings are configured separately: for data interfaces, enable SSH and access lists using this screen; SSH traffic for data interfaces uses the regular routing configuration, and not any static routes configured at setup or at the CLI.

For the Management interface, to configure an SSH access list, see the **configure ssh-access-list** command in the Cisco Secure Firewall Threat Defense Command Reference. To configure a static route, see the **configure network static-routes** command. By default, you configure the default route through the Management interface at initial setup.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

You can SSH only to a reachable interface; if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface.

SSH supports the following ciphers and key exchange:

- Encryption—aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr
- Integrity—hmac-sha2-256
- Key exchange—dh-group14-sha256

Note After you make three consecutive failed attempts to log into the CLI using SSH, the device terminates the SSH connection.

Before you begin

- You can configure SSH internal users at the CLI using the **configure user add** command; see Add an Internal User at the CLI, on page 91. By default, there is an **admin** user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring **External Authentication** in platform settings. See External Authentication, on page 483.
- You need network objects that define the hosts or networks you will allow to make SSH connections to the device. You can add objects as part of the procedure, but if you want to use object groups to identify

a group of IP addresses, ensure that the groups needed in the rules already exist. Select **Objects** > **Object Management** to configure objects.

Note You cannot use the system-provided **any** network object. Instead, use **any-ipv4** or **any-ipv6**.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Secure Shell**.

Step 3 Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Security Zones**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Security Zones** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

SMTP Server

You must identity an SMTP server if you configure email alerts in the Syslog settings. The source email address you configure for Syslog must be a valid account on the SMTP servers.

Before you begin

Ensure that the network objects that define the host address of the primary and secondary SMTP servers exist. Select **Objects** > **Object Management** to define the objects. Alternatively, you can create the objects while editing the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **SMTP Server**.

Step 3 Select the network objects that identify the **Primary Server IP Address** and optionally, the **Secondary Server IP Address**.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

SNMP

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

The Simple Network Management Protocol (SNMP) enables monitoring of network devices from a central location. Cisco security appliances support network monitoring using SNMP versions 1, 2c, and 3, as well as traps and SNMP read access; SNMP write access is not supported.

SNMPv3 supports read-only users and encryption with DES (deprecated), 3DES, AES256, AES192, and AES128.

Note The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.6 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your FMC manages any FTDs running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those FTDs will fail.

Note SNMP configuration supports Routed and Diagnostic interface only.

Note To create an alert to an external SNMP server, access **Policies** > **Action** > **Alerts**

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **SNMP**.

Step 3 Enable SNMP and configure basic options.

- **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
- **Read Community String**, **Confirm**—Enter the password used by a SNMP management station when sending requests to the FTD device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. The security device uses the password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.
- **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Location**—Enter the location of this security device (for example, Building 42,Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Port**—Enter the UDP port on which incoming requests will be accepted. The default is 161.

Step 4 (SNMPv3 only.) Add SNMPv3 Users, on page 501.

Step 5 Add SNMP Hosts, on page 504.

Step 6 Configure SNMP Traps, on page 505.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

About SNMP

SNMP is an application-layer protocol that facilitates the exchange of management information between network devices and is part of the TCP/IP protocol suite. FTD provides support for network monitoring using SNMP Versions 1, 2c, and 3, and support the use of all three versions simultaneously. The SNMP agent running on the FTD interface lets you monitor the network devices through network management systems (NMSes), such as HP OpenView. FTD supports SNMP read-only access through issuance of a GET request. SNMP write access is not allowed, so you cannot make changes with SNMP. In addition, the SNMP SET request is not supported.

You can configure the FTD to send traps, which are unsolicited messages from the managed device to the management station for certain events (event notifications) to an NMS, or you can use the NMS to browse the Management Information Bases (MIBs) on the security devices. MIBs are a collection of definitions, and the FTD maintain a database of values for each definition. Browsing a MIB means issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the NMS to determine values.

An SNMP agent notifies the designated management stations if events occur that are predefined to require a notification, for example, when a link in the network goes up or down. The notification it sends includes an

SNMP OID, which identifies itself to the management stations. The agent also replies when a management station asks for information.

SNMP Terminology

The following table lists the terms that are commonly used when working with SNMP.

Table 32: SNMP Terminology

Term	Description
Agent	The SNMP server running on the Firepower Threat Defense. The SNMP agent has the following features: • Responds to requests for information and actions from the network management station. • Controls access to its Management Information Base, the collection of objects that the SNMP manager can view or change. • Does not allow SET operations.
Browsing	Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.
Management Information Bases (MIBs)	Standardized data structures for collecting information about packets, connections, buffers, failovers, and so on. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur.
Network management stations (NMSs)	The PCs or workstations set up to monitor SNMP events and manage devices.
Object identifier (OID)	The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.
Trap	Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as linkup, linkdown, coldstart, warmstart, authentication, or syslog messages. **coldStart**—The coldStart trap occurs when the SNMP agent starts after the SNMP configuration. This trap also occurs when the agent starts after a system reboot. **Note** For cluster and HA nodes, post a reload, if the interfaces reboot time exceeds 5 minutes (preset threshold), the trap is dropped. When the cluster and HA nodes have rebooted sucessfully, all other traps are sent as expected. The **snmp-server enable traps snmp coldstart** command is used to enable and disable transmission of these traps.

MIBs and Traps

MIBs are either standard or enterprise-specific. Standard MIBs are created by the IETF and documented in various RFCs. A trap reports significant events occurring on a network device, most often errors or failures. SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. SNMP traps are compiled into the ASA software.

If needed, you can also download RFCs, standard MIBs, and standard traps from the following locations:

http://www.ietf.org/

Browse the SNMP Object Navigator to look up Cisco MIBs, traps, and OIDs from the following location:

https://snmp.cloudapps.cisco.com/Support/SNMP/do/BrowseOID.do?local=en

In addition, download Cisco OIDs by FTP from the following location:

ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz

Supported Tables and Objects in MIBs

The following sections list the supported tables and objects for the specified MIBs.

Remote Access VPN Polling

Table 33: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
Active Sessions	crasNumSessions (1.3.6.1.4.1.9.9.392.1.3.1)	The number of currently active sessions.
Users	crasNumUsers (1.3.6.1.4.1.9.9.392.1.3.3)	The number of users who have active sessions.
Peak Sessions	crasNumPeakSessions (1.3.6.1.4.1.9.9.392.1.3.41)	The number of peak RA sessions since system up.

Site-to-Site VPN Tunnel Polling

Table 34: CISCO-REMOTE-ACCESS-MONITOR-MIB

Counter	OID	Description
LAN to LAN Sessions	crasL2LNumSessions (1.3.6.1.4.1.9.9.392.1.3.29)	The number of currently active LAN to LAN sessions.
Peak LAN to LAN Sessions	crasL2LPeakConcurrentSessions (1.3.6.1.4.1.9.9.392.1.3.31)	The number of peak concurrent LAN to LAN sessions since the system is up.

Connection Polling

Table 35: CISCO-FIREWALL-MIB

Counter	OID	Description
Active Connections	cfwConnectionActive (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.6)	The number of connections currently in use by the entire firewall.
Peak Connections	cfwConnectionPeak (1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.7)	The highest number of connections in use at any one time since system startup.
Connections Per Second	cfwConnectionPerSecond (1.3.6.1.4.1.9.9.147.1.2.2.3)	The current connections per second rate on the firewall.
Peak Connections Per Second	cfwConnectionPerSecondPeak (1.3.6.1.4.1.9.9.147.1.2.2.4)	The highest number of connections per second on the firewall since system startup.

NAT Translation Polling

Table 36: CISCO-NAT-EXT-MIB

Counter	OID	Description
Active Translations	cneAddrTranslationNumActive (1.3.6.1.4.1.9.9.532.1.1.1.1)	The total number of address translation entries that are currently available in the NAT device. This indicates the aggregate of the translation entries created from both the static and dynamic address translation mechanisms.

Counter	OID	Description
Peak Active Translations	cneAddrTranslationNumPeak (1.3.6.1.4.1.9.9.532.1.1.1.2)	The maximum number of address translation entries that are active at any one time since the system startup. This indicates the high watermark of address translation entries that are active at any one time since the system startup. This object includes the translation entries created from both the static and dynamic address translation mechanisms.

Routing Table Entries Polling

Table 37: IP-FORWARD-MIB

Counter	OID	Description
Active Translations	inetCidrRouteNumber (1.3.6.1.2.1.4.24.6)	The total number of current inetCidrRouteTable entries that valid.

Interface Duplex Status Polling

Table 38: CISCO-IF-EXTENSION-MIB

Counter	OID	Description
Duplex Status	cieIfDuplexCfgStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.20)	This object specifies the configured duplex status on the given interface.
Detected Duplex Status	cieIfDuplexDetectStatus (1.3.6.1.4.1.9.9.276.1.1.2.1.21)	This object specifies the detected duplex status on the given interface.

Snort 3 Intrusion Event Rate Polling

Table 39: CISCO-UNIFIED-FIREWALL-MIB

Counter	OID	Description
Snort 3 Intrusion Event Rate	cufwAaicIntrusionEvtRate (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The rate at which intrusion events were recorded by Snort on this firewall averaged over the last 300 seconds.

BGP Peer-Flap Trap Notification

Table 40: BGP4-MIB

Counter	OID	Description
BGP Peer-flap	bgpBackwardTransition (1.3.6.1.4.1.9.9.491.1.5.3.2.1)	The BGPBackwardTransition Event is generated when the BGP FSM moves from a higher numbered state to a lower numbered state.

CPU Utilization Polling

Table 41: CISCO-PROCESS-MIB

Counter	OID	Description
CPU Total Utilization	cpmCPUTotal1minRev (1.3.6.1.4.1.9.9.109.1.1.1.1.7.1)	Total system CPU utilization for the last one minute.

Counter	OID	Description
Individual CPU Core Utilization	Associated parameters and values of cpmCPUTotal1minRev 1.3.6.1.4.1.9.9.109.1.1.1.1.7.2 to 1.3.6.1.4.1.9.9.109.1.1.1.1.7.(n+1)	Individual CPU core utilization values for the last one minute, where 'n' represents the number of cores. Examples: • 3.6.1.4.1.99.109.1.1.1.1.7.(n+2) - Aggregate system CPU utilization % (This value is same as the system cpu usage from .3.6.1.4.1.99.109.1.1.1.1.7.1 in single context mode). • 3.6.1.4.1.99.109.1.1.1.1.7.(n+3) - Snort average CPU utilization % (total aggregate value of all snort instances) • 3.6.1.4.1.99.109.1.1.1.1.7.(n+4) - System process average % (average of "Sysproc" cores)

Note The SNMP OIDs 1.3.6.1.2.1.25.3.3 and 1.3.6.1.2.1.25.3.4 pertaining to CPU monitoring (hrProcessorTable and hrNetworkTable) were removed on ASA FirePOWER. You can view and monitor the CPU health details of the device only through its device manager.

Add SNMPv3 Users

Note You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note that SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

Note When using SNMPv3 with clustering or High Availability, if you add a new cluster unit after the initial cluster formation or you replace a High Availability unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.

Authentication algorithm options

The authentication algorithm options are MD5 (deprecated, pre-6.5 only), SHA, SHA224, SHA256, and SHA384.

Note The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

The encryption algorithm options are DES (deprecated, pre-6.5 only), 3DES, AES256, AES192, and AES128.

Note The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **SNMP** > **Users**.

Step 3 Click **Add**.

Step 4 Select the security level for the user from the **Security Level** drop-down list.

- **Auth**—Authentication but No Privacy, which means that messages are authenticated.
- **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.
- **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.

Step 5 Enter the name of the SNMP user in the **Username** field. Usernames must be 32 characters or less.

Step 6 Select the type of password, you want to use in the **Encryption Password Type** drop-down list.

- **Clear text**—The FTD device will still encrypt the password when deploying to the device.
- **Encrypted**—The FTD device will directly deploy the encrypted password.

Step 7 In the **Auth Algorithm Type** drop-down list, select the type of authentication you want to use: SHA, SHA224, SHA256, or SHA384.

Note
The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your FMC manages any FTDs running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those FTDs will fail.

Step 8 In the **Authentication Password** field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

Note
The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

Step 9 In the **Encryption Type** drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

Note
To use AES or 3DES encryption, you must have the appropriate license installed on the device.

Note
The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your FMC manages any FTDs running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those FTDs will fail.

Step 10 Enter the password to use for encryption in the **Encryption Password** field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows (where each xx is one octal):

- AES 128 requires 16 octals
- AES 192 requires 24 octals
- AES 256 requires 32 octals
- 3DES requires 32 octals
- DES can be any size

Note
For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

Step 11 Click **OK**.

Step 12 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add SNMP Hosts

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the FTD device.

You can add up to 4000 hosts. However, only 128 of this number can be for traps.

Before you begin

Ensure that the network objects that define the SNMP management stations exist. Select **Device** > **Object Management** to configure network objects.

Note The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **SNMP** > **Hosts**.

Step 3 Click **Add**.

Step 4 In the **IP Address** field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.

The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.

Step 5 Select the appropriate SNMP version from the **SNMP version** drop-down list.

Step 6 (SNMPv3 only.) Select the username of the SNMP user that you configured from the **User Name** drop-down list.

Note
You can associate up to 23 SNMP users per SNMP host.

Step 7 (SNMPv1, 2c only.) In the **Read Community String** field, enter the community string that you have already configured, for read access to the device. Re-enter the string to confirm it.

Note
This string is required, only if the string used with this SNMP station is different from the one already defined in the **Enable SNMP Server** section.

Step 8 Select the type of communication between the device and the SNMP management station. You can select both types.

- **Poll**—The management station periodically requests information from the device.

- **Trap**—The device sends trap events to the management station as they occur.

Note
When the SNMP host IP address is either an IPv4 range or an IPv4 subnet, you can configure either **Poll** or **Trap**, not both.

Step 9 In the **Port** field, enter a UDP port number for the SNMP host. The default value is 162. The valid range is 1 to 65535.

Step 10 Select the interface type for communication between the device and the SNMP management station under the **Reachable By** options. You can select either the device's Management interface or an available security zone/named interface.

- **Device Management Interface**—Communication between the device and the SNMP management station occurs over the Management interface.
  - When you choose this interface for SNMPv3 polling, all configured SNMPv3 users are allowed to poll and are not restricted to the user chosen in Step 6, on page 504. Here, SNMPv1 and SNMPv2c are not allowed from an SNMPv3 host.
  - When you choose this interface for SNMPv1 and SNMPv2c polling, the polling is not restricted at all to the version selected in Step 5, on page 504.
- **Security Zones or Named Interface**—Communication between the device and the SNMP management station occurs over a security zone or interface.
  - Search for zones in the **Available Zones** field.
  - Add the zones that contain the interfaces through which the device communicates with the management station to the **Selected Zone/Interface** field. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. The host will be configured on a device only if the device includes the selected interfaces or zones.

Step 11 Click **OK**.

Step 12 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure SNMP Traps

Use SNMP Traps to configure SNMP traps (event notifications) for the FTD device. Traps are different from browsing; they are unsolicited "comments" from the FTD device to the management station for certain events, such as linkup, linkdown, and syslog event generated. An SNMP object ID (OID) for the device appears in SNMP event traps sent from the device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy to one of these models. For example, not all models have field-replaceable units, so the **Field Replaceable Unit Insert/Delete** trap will not be configured on those models.

SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. SNMP traps are compiled into the FTD software.

If needed, you can download RFCs, standard MIBs, and standard traps from the following location:

http://www.ietf.org/

Browse the complete list of Cisco MIBs, traps, and OIDs from the following location:

SNMP Object Navigator

In addition, download Cisco OIDs by FTP from the following location:

ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **SNMP** > **SNMP Traps** to configure SNMP traps (event notifications) for the FTD device.

Step 3 Select the appropriate Enable Traps options. You can select either or both options.

a) Check **Enable All SNMP Traps** to quickly select all traps in the subsequent four sections.

b) Check **Enable All Syslog Traps** to enable transmission of trap-related syslog messages.

Note
SNMP traps are of higher priority than other notification messages from the FTD as they are expected to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process to consume excess resources in the agent and in the network, causing the system to hang. If you notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog traps. You can also limit the rate at which syslog messages are generated by severity level or message ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP class; see Limit the Rate of Syslog Message Generation, on page 523.

Step 4 The event-notification traps in the **Standard** section are enabled by default for an existing policy:

- **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string.
- **Link Up** – One of the device's communication links has become available (it has "come up"), as indicated in the notification.
- **Link Down** – One of the device's communication links has failed, as indicated in the notification.
- **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered.
- **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.

Step 5 Select the desired event-notification traps in the **Entity MIB** section:

- **Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.)
- **Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification
- **Configuration Change** – There has been a hardware change, as indicated in the notification

Step 6 Select the desired event-notification traps in the **Resource** section:

- **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached.

Step 7 Select the desired event-notification traps in the **Other** section:

- **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold.
- **CPU Rising Threshold** – This notification is generated when rising CPU utilization exceeds a predefined threshold for a configured period of time. Check this option to enable CPU rising threshold notifications:
  - **Percentage** – The default value is 70 percent for the high threshold notification; the range is between 10 and 94 percent. The critical threshold is hardcoded at 95 percent.
  - **Period** – The default monitoring period is 1 minute; the range is between 1 and 60 minutes.
- **Memory Rising Threshold** – This notification is generated when rising memory utilization exceeds a predefined threshold, thus reducing available memory. Check this option to enable memory rising threshold notifications:
  - **Percentage** – The default value is 70 percent for the high threshold notification; the range is between 50 and 95 percent.
- **Failover** – This notification is generated when there is a change in the failover state as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Cluster** – This notification is generated when there is a change in the cluster health as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Peer Flap** – This notification is generated when there is BGP route flapping, a situation in which BGP systems send an excessive number of update messages to advertise network reachability information.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

SSL

Note You must have administrator privileges and be in a leaf domain to perform this task.

You must make sure that you are running a fully licensed version of the Firepower Management Center. The SSL Settings will be disabled if you are running Firepower Management Center in evaluation mode. Additionally, the SSL Settings will be disabled when the licensed Firepower Management Center version does not meet the export-compliance criteria. If you are using Remote Access VPN with SSL, your Smart Account must have the strong-crypto features enabled. For more information, see *License Types and Restrictions* in the Firepower Management Center Administration Guide.

Procedure

Step 1 Select **Devices > Platform Settings** and create or edit a FTD policy.

Step 2 Select **SSL**.

Step 3 Add entries to the **Add SSL Configuration** table.

a) Click **Add** to create a new entry, or click **Edit** if the entry already exists.

b) Select the required security configurations from the drop-down list .

- **Protocol Version**—Specifies the TLS protocols to be used while establishing remote access VPN sessions.
- **Security Level**—Indicates the kind of security positioning you would like to set up for the SSL.

Step 4 Select the **Available Algorithms** based on the protocol version that you select and click **Add** to include them for the selected protocol. For more information, see About SSL Settings, on page 508.

The algorithms are listed based on the protocol version that you select. Each security protocol identifies unique algorithm for setting up the security level.

Step 5 Click **OK** to save the changes.

What to do next

Select **Deploy** > **Deployment** and click **Deploy** to deploy the policy to the assigned devices.

About SSL Settings

The FTD device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. The SSL Settings window lets you configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL.

Configure the SSL Settings at the following location:

Devices > Platform Settings > SSL

Fields

Minimum SSL Version as Server—Specify the minimum SSL/TLS protocol version that the FTD device uses when acting as a server. For example, when it functions as a Remote Access VPN Gateway.

TLS Version—Select one of the following TLS versions from the drop-down list:

TLS V1	Accepts SSLv2 client hellos and negotiates TLSv1 (or greater).
TLSV1.1	Accepts SSLv2 client hellos and negotiates TLSv1.1 (or greater).
TLSV1.2	Accepts SSLv2 client hellos and negotiates TLSv1.2 (or greater).

DTLS Version—Select the DTLS versions from the drop-down list, based on the selected TLS version. By default, DTLSv1 is configured on FTD devices, you can choose the DTLS version as per your requirement.

Note Ensure that the TLS protocol version is higher than or equal to the DTLS protocol version selected. TLS protocol versions support the following DTLS versions:

TLS V1	DTLSv1
TLSV1.1	DTLSv1
TLSV1.2	DTLSv1, DTLSv1.2

Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group1 - 768-bit modulus, Group2 - 1024-bit modulus, Group5 - 1536-bit modulus, Group14 - 2048-bit modulus, 224-bit prime order, and Group24 - 2048-bit modulus, 256-bit prime order. The default is Group1.

Elliptical Curve Diffie-Hellman Group—Choose a group from the drop-down list. Available options are Group19 - 256-bit EC, Group20 - 384-bit EC, and Group21 - 521-bit EC. The default value is Group19.

TLSv1.2 adds support for the following ciphers:

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256

Note ECDSA and DHE ciphers are the highest priority.

The SSL configuration table can be used to specify the protocol version, security level, and Cipher algorithms that you want to support on the Firepower Threat Defense devices.

Protocol Version—Lists the protocol version that the Firepower Threat Defense device supports and uses for SSL connections. Available protocol versions are:

- Default
- TLSV1

- TLSV1.1
- TLSV1.2
- DTLSv1
- DTLSv1.2

Security Level—Lists the cipher security levels that FTD device supports and uses for SSL connections.

If you have FTD devices with evaluation license, the security level is Low by default. With FTD smart license, the default security level is High. You can choose one of the following options to configure the required security level:

- **All** includes all ciphers, including NULL-SHA.
- **Low** includes all ciphers, except NULL-SHA.
- **Medium** includes all ciphers, except NULL-SHA, DES-CBC-SHA, RC4-SHA, and RC4-MD5 (this is the default).
- **Fips** includes all FIPS-compliant ciphers, except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA.
- **High** includes only AES-256 with SHA-2 ciphers and applies to TLS version 1.2 and the *default* version.
- **Custom** includes one or more ciphers that you specify in the Cipher algorithms/custom string box. This option provides you with full control of the cipher suite using OpenSSL cipher definition strings.

Cipher Algorithms/Custom String—Lists the cipher algorithms that the FTD device supports and uses for SSL connections. For more information about ciphers using OpenSSL, see https://www.openssl.org/docs/apps/ciphers.html

The FTD device specifies the order of priority for supported ciphers as:

Ciphers supported by TLSv1.2 only

ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-RSA-AES256-GCM-SHA384
DHE-RSA-AES256-GCM-SHA384
AES256-GCM-SHA384
ECDHE-ECDSA-AES256-SHA384
ECDHE-RSA-AES256-SHA384
DHE-RSA-AES256-SHA256
AES256-SHA256
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-RSA-AES128-GCM-SHA256
DHE-RSA-AES128-GCM-SHA256

AES128-GCM-SHA256
ECDHE-ECDSA-AES128-SHA256
ECDHE-RSA-AES128-SHA256
DHE-RSA-AES128-SHA256
AES128-SHA256

Ciphers not supported by TLSv1.1 or TLSv1.2

RC4-SHA
RC4-MD5
DES-CBC-SHA
NULL-SHA

Syslog

You can enable system logging (syslog) for FTD devices. Logging information can help you identify and isolate network or device configuration problems. You can also send some security events to a syslog server. The following topics explain logging and how to configure it.

About Syslog

System logging is a method of collecting messages from devices to a server running a syslog daemon. Logging to a central syslog server helps in aggregation of logs and alerts. Cisco devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and stores them in files, or prints them according to a simple configuration file. This form of logging provides protected long-term storage for logs. Logs are useful both in routine troubleshooting and in incident handling.

Table 42: System Logs for Firepower Threat Defense

Logs Related To	Details	Configure In
Device and system health, network configuration	This syslog configuration generates messages for features running on the data plane, that is, features that are defined in the CLI configuration that you can view with the **show running-config** command. This includes features such as routing, VPN, data interfaces, DHCP server, NAT, and so forth. Data plane syslog messages are numbered, and they are the same as those generated by devices running ASA software. However, Firepower Threat Defense does not necessarily generate every message type that is available for ASA Software. For information on these messages, see *Cisco Firepower Threat Defense Syslog Messages* at https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html. This configuration is explained in the following topics.	**Platform Settings**

Logs Related To	Details	Configure In
Security events	This syslog configuration generates alerts for file and malware, connection, Security Intelligence, and intrusion events. For details, see *About Sending Syslog Messages for Security Events* and subtopics in the Firepower Management Center Administration Guide.	**Platform Settings** and the **Logging** in an access control policy
(All devices) Policies, rules, and events	This syslog configuration generates alerts for access control rules, intrusion rules, and other advanced services as described in *Configurations Supporting Alert Responses* in the Firepower Management Center Administration Guide. These messages are not numbered. For information on configuring this type of syslog, see *Creating a Syslog Alert Response* in the Firepower Management Center Administration Guide.	**Alert Responses** and the **Logging** in an access control policy

You can configure more than one syslog server, and control the messages and events sent to each server. You can also configure different destinations, such as console, email, internal buffer, and so forth.

Severity Levels

The following table lists the syslog message severity levels.

Table 43: Syslog Message Severity Levels

Level Number	Severity Level	Description
0	**emergencies**	System is unusable.
1	**alert**	Immediate action is needed.
2	**critical**	Critical conditions.
3	**error**	Error conditions.
4	**warning**	Warning conditions.
5	**notification**	Normal but significant conditions.
6	**informational**	Informational messages only.
7	**debugging**	Debugging messages only. Log at this level only temporarily, when debugging issues. This log level can potentially generate so many messages that system performance can be affected.

Note ASA and FTD do not generate syslog messages with a severity level of zero (emergencies).

Syslog Message Filtering

You can filter generated syslog messages so that only certain syslog messages are sent to a particular output destination. For example, you could configure the FTD device to send all syslog messages to one output destination and to send a subset of those syslog messages to a different output destination.

Specifically, you can direct syslog messages to an output destination according to the following criteria:

- Syslog message ID number

  (This does not apply to syslog messages for security events such as connection and intrusion events.)

- Syslog message severity level
- Syslog message class (equivalent to a functional area)

  (This does not apply to syslog messages for security events such as connection and intrusion events.)

You customize these criteria by creating a message list that you can specify when you set the output destination. Alternatively, you can configure the FTD device to send a particular message class to each type of output destination independently of the message list.

(Message lists do not apply to syslog messages for security events such as connection and intrusion events.)

Syslog Message Classes

Note This topic does not apply to messages for security events (connection, intrusion, etc.)

You can use syslog message classes in two ways:

- Specify an output location for an entire category of syslog messages.
- Create a message list that specifies the message class.

The syslog message class provides a method of categorizing syslog messages by type, equivalent to a feature or function of the device. For example, the rip class denotes RIP routing.

All syslog messages in a particular class share the same initial three digits in their syslog message ID numbers. For example, all syslog message IDs that begin with the digits 611 are associated with the vpnc (VPN client) class. Syslog messages associated with the VPN client feature range from 611101 to 611323.

In addition, most of the ISAKMP syslog messages have a common set of prepended objects to help identify the tunnel. These objects precede the descriptive text of a syslog message when available. If the object is not known at the time that the syslog message is generated, the specific heading = value combination does not appear.

The objects are prefixed as follows:

Group = *groupname*, Username = *user*, IP = *IP_address*

Where the group is the tunnel-group, the username is the username from the local database or AAA server, and the IP address is the public IP address of the remote access client or Layer 2 peer.

The following table lists the message classes and the range of message IDs in each class.

Table 44: Syslog Message Classes and Associated Message ID Numbers

Class	Definition	Syslog Message ID Numbers
auth	User Authentication	109, 113
—	Access Lists	106
—	Application Firewall	415
—	Botnet Traffic Filtering	338
bridge	Transparent Firewall	110, 220
ca	PKI Certification Authority	717
citrix	Citrix Client	723
—	Clustering	747
—	Card Management	323
config	Command Interface	111, 112, 208, 308
csd	Secure Desktop	724
cts	Cisco TrustSec	776
dap	Dynamic Access Policies	734
eap, eapoudp	EAP or EAPoUDP for Network Admission Control	333, 334
eigrp	EIGRP Routing	336
email	E-mail Proxy	719
—	Environment Monitoring	735
ha	Failover	101, 102, 103, 104, 105, 210, 311, 709
—	Identity-based Firewall	746
ids	Intrusion Detection System	400, 733
—	IKEv2 Toolkit	750, 751, 752

Guidelines for Logging

This section includes guidelines and limitations that you should review before configuring logging.

IPv6 Guidelines

- IPv6 is supported. Syslogs can be sent using TCP or UDP.
- Ensure that the interface configured for sending syslogs is enabled, IPv6 capable, and the syslog server is reachable through the designated interface.
- Secure logging over IPv6 is not supported.

Additional Guidelines

- Do not configure FMC as a primary syslog server. The FMC can log some syslogs. However, it does not have adequate storage provision to accommodate voluminous information from connection events for every sensor, especially when multiple sensors are used and all send syslogs.
- The syslog server must run a server program called syslogd. Windows provides a syslog server as part of its operating system.
- The syslog server operates based on the syslog-ng process of the firewall system. Do not use external configuration files, like the *scwx.conf* file from SecureWorks. Such files are not compatible with the device. Using them will lead to parsing error and eventually the syslog-ng process will fail.
- To view logs generated by the FTD device, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the FTD device generates messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately.
- If you use TCP as the transport protocol, the system opens 4 connections to the syslog server to ensure that messages are not lost. If you are using the syslog server to collect messages from a very large number of devices, and the combined connection overhead is too much for the server, use UDP instead.

- It is not possible to have two different lists or classes being assigned to different syslog servers or same locations.
- You can configure up to 16 syslog servers.
- The syslog server should be reachable through the FTD device. You should configure the device to deny ICMP unreachable messages on the interface through which the syslog server is reachable and to send syslogs to the same server. Make sure that you have enabled logging for all severity levels. To prevent the syslog server from crashing, suppress the generation of syslogs 313001, 313004, and 313005.
- The number of UDP connections for syslog is directly related to the number of CPUs on the hardware platform and the number of syslog servers you configure. At any point in time, there can be as many UDP syslog connections as there are CPUs times the number of configured syslog servers. This is the expected behavior. Note that the global UDP connection idle timeout applies to these sessions, and the default is 2 minutes. You can adjust that setting if you want to close these session more quickly, but the timeout applies to all UDP connections, not just syslog.
- When the FTD device sends syslogs via TCP, the connection takes about one minute to initiate after the syslogd service restarts.

Configure Syslog Logging for FTD Devices

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

To configure syslog settings, perform the following steps:

Before you begin

See requirements in Guidelines for Logging, on page 516.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **Syslog** from the table of contents.

Step 3 Click **Logging Setup** to enable logging, specify FTP Server settings, and specify Flash usage. For more information, see Enable Logging and Configure Basic Settings, on page 518

Step 4 Click **Logging Destinations** to enable logging to specific destinations and to specify filtering on message severity level, event class, or on a custom event list. For more information, see Enable Logging Destinations, on page 520

You must enable a logging destination to see messages at that destination.

Step 5 Click **E-mail Setup** to specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages. For more information, see Send Syslog Messages to an E-mail Address, on page 521

Step 6 Click **Events List** to define a custom event list that includes an event class, a severity level, and an event ID. For more information, see Create a Custom Event List, on page 522

Step 7 Click **Rate Limit** to specify the volume of messages being sent to all configured destinations and define the message severity level to which you want to assign rate limits. For more information, see Limit the Rate of Syslog Message Generation, on page 523

Step 8 Click **Syslog Settings** to specify the logging facility, enable the inclusion of a time stamp, and enable other settings to set up a server as a syslog destination. For more information, see Configure Syslog Settings, on page 524

Step 9 Click **Syslog Servers** to specify the IP address, protocol used, format, and security zone for the syslog server that is designated as a logging destination. For more information, see Configure a Syslog Server, on page 525

FTD Platform Settings That Apply to Security Event Syslog Messages

"Security events" include connection, Security Intelligence, intrusion, and file and malware events.

Some of the syslog settings on the **Devices > Platform Settings > Threat Defense Settings > Syslog** page and its tabs apply to syslog messages for security events, but most apply only to messages for events related to system health and networking.

The following settings apply to syslog messages for security events:

- **Logging Setup** tab:
  - **Send syslogs in EMBLEM format**
- **Syslog Settings** tab:
  - **Enable Timestamp on Syslog Messages**
  - **Timestamp Format**
  - **Enable Syslog Device ID**
- **Syslog Servers** tab:
  - All options on the **Add Syslog Server** form (and the list of configured servers).

Enable Logging and Configure Basic Settings

Enable logging and configure the basic settings for the system to generate syslog messages for data plane events. You can also set up archiving on flash or an FTP server as a storage location when the local buffer becomes full. You can manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

The following procedure explains some of the basic syslog settings.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Logging Setup**.

Step 3 Enable logging and configure basic logging settings.

- **Enable Logging**—Turns on the data plane system logging for the FTD device.
- **Enable Logging on the Failover Standby Unit**—Turns on logging for the standby for the FTD device, if available.
- **Send syslogs in EMBLEM format**—Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages; EMBLEM is not compatible with TCP.

  Note
  Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in FMC, if you want to display the PRI value in the syslog messages of the managed FTD device, ensure to enable the EMBLEM format. Also, the device ID does not appear in EMBLEM-formatted syslog messages. For more information on PRI, see RFC5424.

- **Send debug messages as syslogs**—Redirects all the debug trace output to the syslog. The syslog message does not appear in the console if this option is enabled. Therefore, to see debug messages, you must enable logging at the console and configure it as the destination for the debug syslog message number and logging level. The syslog message number used is 711001. The default logging level for this syslog is debug.
- **Memory Size of Internal Buffer**—Specify the size of the internal buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 52428800.

Step 4 (Optional) Configure the syslog message logging to the FMC.

a) Enable VPN logging by checking the **Enable Logging to FMC** check box.

b) Choose the syslog severity level for the logging messages from the **Logging Level** drop-down list.

- The logging level for the VPN messages is set to **errors** by default.

  VPN troubleshooting syslogs can add excessive load on the FMC. Hence, enable this option with caution. Also, when you configure a device with site-to-site or remote access VPN, it automatically enables sending VPN syslogs to the management center by default. We recommend that you limit the logging level to **error** and above to restrict the excessive flow of syslogs to the FMC, especially in case of RAVPN, where multiple devices are involved.

For information on the levels, see Severity Levels, on page 512.

Step 5 (Optional) Configure an FTP server if you want to save log buffer contents to the server before the buffer is overwritten. Specify the FTP Server information.

- **FTP Server Buffer Wrap**—To save the buffer contents to the FTP server before it is overwritten, check this box and enter the necessary destination information in the following fields. To remove the FTP configuration, deselect this option.
- **IP Address**—Select the host network object that contains the IP address of the FTP server.
- **User Name**—Enter the username to use when connecting to the FTP server.

- **Path**—Enter the path, relative to the FTP root, where the buffer contents should be saved.
- **Password/ Confirm**—Enter and confirm the password used to authenticate the username to the FTP server.

Step 6 (Optional) Specify Flash size if you want to save log buffer contents to flash before the buffer is overwritten.

- **Flash**—To save the buffer contents to the flash memory before it is overwritten, check this box.
- **Maximum flash to be used by logging (KB)**—Specify the maximum space to be used in the flash memory for logging (in kilobytes). The range is 4-8044176 kilobytes.
- **Minimum free space to be preserved (KB)**—Specifies the minimum free space to be preserved in flash memory (in KB). The range is 0-8044176 kilobytes.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Enable Logging Destinations

You must enable a logging destination to see messages at that destination. When enabling a destination, you must also specify the message filter for the destination.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Logging Destinations**.

Step 3 Click **Add** to enable a destination and apply a logging filter, or edit an existing destination.

Step 4 In the **Logging Destinations** dialog box, select a destination and configure the filter to use for a destination:

a) Choose the destination you are enabling in the **Logging Destination** drop-down list. You can create one filter per destination: Console, E-Mail, Internal buffer, SNMP trap, SSH Sessions, and Syslog servers.

Note
Console and SSH session logging works in the diagnostic CLI only. Enter **system support diagnostic-cli**.

b) In **Event Class**, choose the filter that will apply to all classes not listed in the table.

You can configure these filters:

- **Filter on severity** —Select the severity level. Messages at this level or higher are sent to the destination
- **Use Event List** —Select the event list that defines the filter. You create these lists on the **Event Lists** page.

- **Disable Logging** —Prevents messages from being sent to this destination.

c) If you want to create filters per event class, click **Add** to create a new filter, or edit an existing filter, and select the event class and severity level to limit messages in that class. Click **OK** to save the filter.

For an explanation of the event classes, see Syslog Message Classes, on page 513.

d) Click **OK** .

Step 5 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Send Syslog Messages to an E-mail Address

You can set up a list of recipients for syslog messages to be sent as e-mails.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

Before you begin

- Configure an SMTP server on the SMTP Server platform settings page
- Enable Logging and Configure Basic Settings, on page 518
- Enable Logging Destinations

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Email Setup**.

Step 3 Specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

Step 4 Click **Add** to enter a new e-mail address recipient of the specified syslog messages.

Step 5 Choose the severity level of the syslog messages that are sent to the recipient from the drop-down list.

The syslog message severity filter used for the destination e-mail address causes messages of the specified severity level and higher to be sent. For information on the levels, see Severity Levels, on page 512.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Create a Custom Event List

An event list is a custom filter you can apply to a logging destination to control which messages are sent to the destination. Normally, you filter messages for a destination based on severity only, but you can use an event list to fine-tune which messages are sent based on a combination of event class, severity, and message identifier (ID).

Creating a custom event list is a two-step process. You create a custom list in the **Event Lists**, and then use the event list to define the logging filter for the various types of destination, in the **Logging Destinations**.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Events List**.

Step 3 Configure an event list.

a) Click **Add** to add a new list, or edit an existing list.

b) Enter a name for the event list in the **Name** field. Spaces are not allowed.

c) To identify messages based on severity or event class, select the **Severity/Event Class** tab and add or edit entries.

For information on the available classes see Syslog Message Classes, on page 513.

For information on the levels, see Severity Levels, on page 512.

Certain event classes are not applicable for the device in transparent mode. If such options are configured then they will be bypassed and not deployed.

d) To identify messages specifically by message ID, select the **Message ID** and add or edit the IDs.

You can enter a range of IDs using a hyphen, for example, 100000-200000. IDs are six digits. For information on how the initial three digits map to features, see Syslog Message Classes, on page 513.

For specific message numbers, see Cisco ASA Series Syslog Messages.

e) Click **OK** to save the event list.

Step 4 Click **Logging Destinations** and add or edit the destination that should use the filter.

See Enable Logging Destinations, on page 520.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Limit the Rate of Syslog Message Generation

You can limit the rate at which syslog messages are generated by severity level or message ID. You can specify individual limits for each logging level and each Syslog message ID. If the settings conflict, the Syslog message ID limits take precedence.

Tip If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most FTD platform settings do not apply to these messages. See FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Rate Limit**.

Step 3 To limit message generation by severity level, click **Logging Level** > **Add** and configure the following options:

- **Logging Level**—The severity level you are rate limiting. For information on the levels, see Severity Levels, on page 512.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

Step 4 Click **OK**.

Step 5 To limit message generation by syslog message ID, click **Syslog Level** > **Add** and configure the following options:

- **Syslog ID**—The syslog message ID you are rate limiting. For specific message numbers, see Cisco ASA Series Syslog Messages.
- **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
- **Interval**—The number of seconds before the rate limit counter resets.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Syslog Settings

You can configure general syslog settings to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), some settings on this page do not apply to these messages. See *Threat Defense Platform Settings That Apply to Security Event Syslog Messages* in the Firepower Management Center Administration Guide.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Syslog Settings**.

Step 3 Select a system log facility for syslog servers to use as a basis to file messages in the **Facility** drop-down list.

The default is LOCAL4(20), which is what most UNIX systems expect. However, because your network devices share available facilities, you might need to change this value for system logs.

Facility values are not typically relevant for security events. If you need to include Facility values in messages, see *Facility in Security Event Syslog Messages* in the Firepower Management Center Administration Guide.

Step 4 Select the **Enable timestamp on each syslog message** check box to include the date and time a message was generated in the syslog message.

Step 5 Select the **Timestamp Format** for the syslog message:

- The Legacy (MMM dd yyyy HH:mm:ss) format is the default format for syslog messages.

  When this timestamp format is selected, the messages do not indicate the time zone, which is always UTC.

- RFC 5424 (yyyy-MM-ddTHH:mm:ssZ) uses the ISO 8601 timestamp format as specified in the RFC 5424 syslog format.

  If you select the RFC 5424 format, a “Z” is appended to the end of each timestamp to indicate that the timestamp uses the UTC time zone.

Step 6 If you want to add a device identifier to syslog messages (which is placed at the beginning of the message), check the **Enable Syslog Device ID** check box and then select the type of ID.

- **Interface**—To use the IP address of the selected interface, regardless of the interface through which the appliance sends the message. Select the security zone that identifies the interface. The zone must map to a single interface.
- **User Defined ID**—To use a text string (up to 16 characters) of your choice.
- **Host Name**—To use the hostname of the device.

Step 7 Use the Syslog Message table to alter the default settings for specific syslog messages. You need to configure rules in this table only if you want to change the default settings. You can change the severity assigned to a message, or you can disable the generation of a message.

By default, Netflow is enabled and the entries are shown in the table.

a) To suppress syslog messages that are redundant because of Netflow, select **Netflow Equivalent Syslogs**.

This adds the messages to the table as suppressed messages.

Note
If any of these syslog equivalents are already in the table, your existing rules are not overwritten.

b) To add a rule, click **Add**.
c) You select the message number whose configuration you want to change, from the **Syslog ID** drop down list and then select the new severity level from the **Logging Level** drop down list, or select **Suppressed** to disable the generation of the message. Typically, you would not change the severity level and disable the message, but you can make changes to both fields if desired.
d) Click **OK** to add the rule to the table.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Configure a Syslog Server

To configure a syslog server to handle messages generated from your system, perform the following steps.

If you want this syslog server to receive security events such as connection and intrusion events, see also FTD Platform Settings That Apply to Security Event Syslog Messages, on page 518.

Before you begin

- See requirements in Guidelines for Logging, on page 516.
- Make sure your devices can reach your syslog collector on the network.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Syslog** > **Syslog Server**.

Step 3 Check the **Allow user traffic to pass when TCP syslog server is down (Recommended)** check box, to allow traffic if any syslog server that is using the TCP protocol is down.

Note
- This option is enabled by default. Unless required, we recommend that you allow connections through the FTD device when the external TCP syslog server is unreachable by the device.
- When the **Allow user traffic to pass when TCP syslog server is down** option is disabled in FMC version 6.2.x or earlier, it persist to be in the Disable state even after upgrading to version 6.3 or later. Ensure that you manually enable it.

- With this option disabled, and when more than one TCP syslog server configured in the device, the user traffic is allowed to pass if atleast one of the servers is reacheable by the FTD device. Thus, the disabled option is applied only when none of the TCP syslog servers configured in the device are reachable. The device generates the following syslog that describes the root cause of the denied traffic through the device:

  ```
  %FTD-3-414003: TCP Syslog Server intf : IP_Address /port not responding. New connections
  are denied based on logging permit-hostdown policy
  ```

Step 4 In the **Message queue size (messages)** field, enter a size of the queue for storing syslog messages on the security appliance when syslog server is busy. The minimum is 1 message. The default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).

When the messages exceed the configured queue size, they are dropped and result in missing syslog. To determine the ideal queue size, you need to identify the available block memory. Use the **show blocks** command to know the current memory utilization. For more information on the command and its attributes, see *Cisco Secure Firewall ASA Series Command Reference Guide*. For further assistance, contact Cisco TAC.

Step 5 Click **Add** to add a new syslog server.

a) In the **IP Address** drop-down list, select a network host object that contains the IP address of the syslog server.

b) Choose the protocol (either TCP or UDP) and enter the port number for communications between the FTD device and the syslog server.

UDP is faster and uses less resources on the device than TCP.

The default port for UDP is 514. You must manually configure port 1470 for TCP. Valid non-default port values for either protocol are 1025 through 65535.

c) Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

Note
Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in FMC, only when you enable logging in Cisco EMBLEM format, the PRI value in the syslog messages of the managed FTD is displayed. Also, the device ID does not appear in EMBLEM-formatted syslog messages. For more information on PRI, see RFC5424.

d) Check the **Enable Secure Syslog** check box to encrypt the connection between the device and server using SSL/TLS over TCP.

Note
You must select TCP as the protocol and its port value ranging between 1025 and 65535 to use this option. You must also upload the certificate required to communicate with the syslog server on the **Devices** > **Certificates** page. Finally, upload the certificate from the FTD device to the syslog server to complete the secure relationship and allow it to decrypt the traffic. The **Enable Secure Syslog** option is not supported on the device Management interface.

e) Select **Device Management Interface** or **Security Zones or Named Interfaces** to communicate with the syslog server.

- **Device Management Interface**: Send syslogs out of the Management interface. We recommend that you use this option when configuring syslog on Snort events.

  Note

The **Device Management Interface** option does not support the **Enable Secure Syslog** option.

- **Security Zones or Named Interfaces**: Select the interfaces from the list of **Available Zones** and click **Add**.

  Important
  The FTD data plane (Lina) syslog messages cannot be sent out through the diagnostic interface. Configure other interfaces or the Management interface (Br1/Management0) to send out the data plane syslog messages.

f) Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Timeouts

You can set the global idle timeout durations for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool.

You can also set a time out for console sessions with the device.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Timeouts**.

Step 3 Configure the timeouts you want to change.

For any given setting, select **Custom** to define your own value, **Default** to return to the system default value. In most cases, the maximum timeout is 1193 hours.

You can disable some timeouts by selecting **Disable**.

- **Console Timeout**—The idle time until a connection to the console is closed, range is 0 or 5 to 1440 minutes. The default is 0, which means the session does not time out. If you change the value, existing console sessions use the old timeout value. The new value applies to new connections only.
- **Translation Slot (xlate)**—The idle time until a NAT translation slot is freed. This duration must be at least 1 minute. The default is 3 hours.
- **Connection (Conn)**—The idle time until a connection slot is freed. This duration must be at least 5 minutes. The default is 1 hour.

- **Half-Closed**—The idle time until a TCP half-closed connection closes. A connection is considered half-closed if both the FIN and FIN-ACK have been seen. If only the FIN has been seen, the regular connection timeout applies. The minimum is 30 seconds. The default is 10 minutes.
- **UDP**—The idle time until a UDP connection closes. This duration must be at least 1 minute. The default is 2 minutes.
- **ICMP**—The idle time after which general ICMP states are closed. The default (and minimum) is 2 seconds.
- **RPC/Sun RPC**—The idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes.

  In a Sun RPC-based connection, when the parent connection is deleted or timed-out, a new child connection may not be considered as a part of the parent-child connection, and thereby the new connection could be evaluated as per the policy or rules set in the system. After the parent connection has timed-out the existing child connections are valid only until the timeout value set is reached.
- **H.225**—The idle time until an H.225 signaling connection closes. The default is 1 hour. To close a connection immediately after all calls are cleared, a timeout of 1 second (0:0:1) is recommended.
- **H.323**—The idle time after which H.245 (TCP) and H.323 (UDP) media connections close. The default (and minimum) is 5 minutes. Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.
- **SIP**—The idle time until a SIP signaling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.
- **SIP Media**—The idle time until a SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes. The SIP media timer is used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.
- **SIP Disconnect**—The idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 0:10:0. The default is 2 minutes (0:2:0).
- **SIP Invite**—The idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 00:30:0. The default is 3 minutes (0:3:0).
- **SIP Provisional Media**—The timeout value for SIP provisional media connections, between 1 and 30 minutes. The default is 2 minutes.
- **Floating Connection**—When multiple routes exist to a network with different metrics, the system uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To make it possible to use better routes, set the timeout to a value between 0:0:30 and 1193:0:0. This timer does not apply to connections through virtual tunnel interfaces (VTI). If a connection through a VTI gets stuck, you must manually clear it.
- **Xlate PAT**—The idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.
- **TCP Proxy Reassembly**—The idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).

- **ARP Timeout**—The number of seconds between ARP table rebuilds, from 60 to 4294967. The default is 14,400 seconds (4 hours).

Step 4 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Time Synchronization

Use a Network Time Protocol (NTP) server to synchronize the clock settings on your devices. We recommend you configure all FTDs managed by a FMC to use the same NTP server as the FMC. The FTD gets its time directly from the configured NTP server. If the FTD's configured NTP servers are not reachable for any reason, it synchronizes its time with the FMC.

The device supports NTPv4.

Note If you are deploying FTD on the Firepower 4100/9300 chassis, you must configure NTP on the Firepower 4100/9300 chassis so that Smart Licensing will work properly and to ensure proper timestamps on device registrations. You should use the same NTP server for the Firepower 4100/9300 chassis and the FMC.

Before you begin

- If your organization has one or more NTP servers that your FTD can reach, use the same NTP server or servers for your devices that you have configured for Time Synchronization on the **System > Configuration** page on your FMC.
- If you selected **Use the authenticated NTP server only** when configuring NTP server or servers for the FMC, for your devices use only the NTP server or servers that are configured to authenticate with the FMC. (The managed devices will use the same NTP servers as the FMC, but their NTP connections will not use authentication.)
- If your device cannot reach an NTP server or your organization does not have one, you must use the **Via NTP from Defense Center** option as discussed in the following procedure.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Select **Time Synchronization**.

Step 3 Configure one of the following clock options:

- **Via NTP from Defense Center**—(Default). The managed device gets time from the NTP servers you configured for the FMC (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of the following are true, the managed device synchronizes time from the FMC:

- The FMC's NTP servers are not reachable by the device.
- The FMC has no unauthenticated servers.

- **Via NTP from**—If your FMC is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as ntp.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in **System > Configuration > Time Synchronization**. If the NTP servers are not reachable, the FMC acts as an NTP server.

When multiple NTP servers are configured, the device uses the NTP server that is deemed appropriate based on the criteria defined in RFC. Thus, the status of "Being used" for a specific NTP server indicates that the server is currently used by the device.

Step 4 Click **Save**.

What to do next

- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

Time Zone

By default, the system uses the UTC time zone. To designate a different time zone for a device, use this procedure.

The time zone you specify will be used only for time-based policy application in policies that support this functionality.

Note Time-based ACLs is supported in Snort 3 also from FMC 7.0 onwards.

Procedure

Step 1 Select **Devices** > **Platform Settings** and create or edit an FTD policy.

You can also create time zone objects from the **Objects > Object Management > Time Zone** page.

Step 2 Create a new time zone object by clicking **+**.

Step 3 Select the time zone.

Step 4 Click **Save**.

What to do next

- Create time range objects, select applicable time ranges in access control and prefilter rules, and assign the parent policies to devices associated with the correct time zone.
- Deploy configuration changes; see Deploy Configuration Changes, on page 121.

UCAPL/CC Compliance

For more information about this setting and how to enable it for the FMC, see the Firepower Management Center Administration Guide.

Caution After you enable this setting, you cannot disable it. If you need to take the appliance out of CC or UCAPL mode, you must reimage.

Before you begin

- Firepower Threat Defense devices cannot use an evaluation license; your Smart Software Manager account must be enabled for export-controlled features.
- Firepower Threat Defense devices must be deployed in routed mode.
- You must be an Admin user to perform this task.
- Security certifications compliance mode cannot be changed if the FTD device is in high availability. Modify the security certifications compliance mode before forming the high availability pair.

Procedure

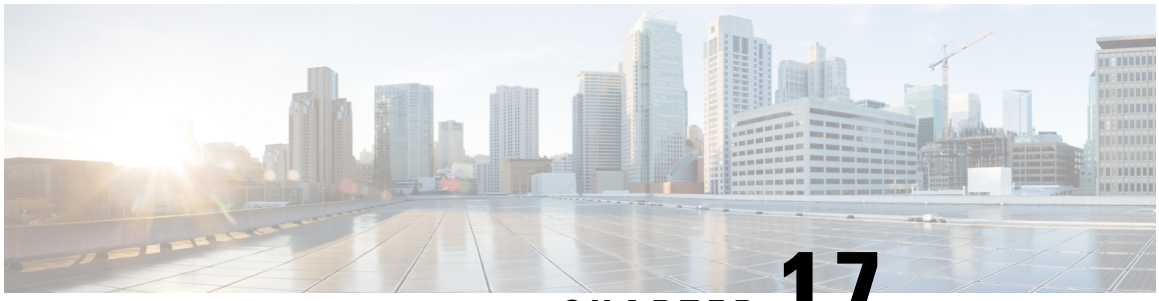
Step 1 Choose **Devices** > **Platform Settings** and create or edit the FTD policy.

Step 2 Click **UCAPL/CC Compliance**.

Step 3 To *permanently* enable security certifications compliance on the appliance, you have two choices:

- To enable security certifications compliance in Common Criteria mode, choose **CC** from the drop-down list.
- To enable security certifications compliance in Unified Capabilities Approved Products List mode, choose **UCAPL** from the drop-down list.

Step 4 Click **Save**.



You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

History for Platform Settings

Feature	Minimum FMC	Minimum FTD	Details
Network object support for HTTP, ICMP, and SSH platform settings.	7.1.0	7.1.0	You can now use network object groups that contain network objects for hosts or networks when configuring the IP addresses in the Threat Defense Platform Settings policy. Supported platforms: FTD
Support to specify trusted DNS servers.	7.1.0	7.1.0	The option to specify DNS servers that you can trust for address resolution while using direct internet access was introduced. We added a tab for configuring the trusted DNS servers when configuring direct internet access: **Devices** > **Platform Settings** > **DNS** > **Trusted DNS Servers**. Supported platforms: FTD
Platform settings using the MD5 authentication algorithm or DES encryption for SNMPv3 users can not be deployed to FTD devices running Versions 7.0+.	7.0.0	7.0.0	The MD5 authentication algorithm and DES encryption for SNMPv3 users on FTD were deprecated in Version 6.5. If your deployment includes SNMPv3 users using the MD5 authentication algorithm or DES encryption that were created using Version 6.4 or earlier, you can continue to use those users for FTD devices running Version 6.7 or earlier. However, you cannot edit those users and retain the MD5 or DES settings, and you cannot create new users with the MD5 or DES settings. If your FMC manages any FTDs running Versions 7.0+, deploying a platform settings policy with SNMP v3 users using the MD5 authentication algorithm or DES encryption to those FTDs will fail. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Hosts** Supported platforms: FTD
Specify SHA224 or SHA384 for SNMPv3 users' authorization algorithm.	7.0.0	7.0.0	You can now select SHA224 or SHA384 for SNMPv3 users' authorization algorithm. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users** Supported platforms: FTD
Specify time zone for device.	6.6.0	6.6.0	Specify a local time zone for a managed device, for use in time-based policy application. New/modified screens: **Devices** > **Platform Settings** > **Time Zone** Supported platforms: FTD
Specify the Management interface for SNMP communication.	6.6.0	6.6.0	You can now select the Management interface for communication between the device and the SNMP management station. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Hosts** Supported platforms: FTD

Feature	Minimum FMC	Minimum FTD	Details
Specify SHA256 for SNMPv3 users' authorization algorithm.	6.6.0	6.6.0	You can now select SHA256 for SNMPv3 users' authorization algorithm. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users** Supported platforms: FTD
DES encryption and the MD5 authentication algorithm for SNMPv3 users on FTD have been deprecated.	6.5.0	Any	We recommend that you not use the MD5 authentication algorithm or DES encryption for SNMPv3 users on FTD devices, as these options have been deprecated. If your deployment includes SNMPv3 users using the MD5 authentication algorithm or DES encryption that were created using a Version 6.4 or earlier, you can continue to use those users. However, you cannot edit those users and retain the MD5 or DES settings, and you cannot create new users with the MD5 or DES settings. New/modified screens: **Devices** > **Platform Settings** > **SNMP** > **Users** Supported platforms: FTD
Allow user traffic to pass when TCP syslog server is down.	6.3.0	6.3.0	We recommend that you allow connections through the FTD device when the external TCP syslog server is unreachable by the device. The **Allow user traffic to pass when TCP syslog server is down (Recommended to be enabled)** option in the Platform Settings is Enabled by default.
Limit number of SSH login failures.	6.3.0	6.3.0	When a user accesses any device via SSH and fails three successive login attempts, the device terminates the SSH session.
External authentication added for SSH.	6.2.3	6.2.3	You can now configure external authentication for SSH access to the FTD using LDAP or RADIUS. New/modified screens: **Devices** > **Platform Settings** > **External Authentication** Supported platforms: FTD
Support for UC/APPL compliance mode.	6.2.1	6.2.1	You can enable security certifications compliance in CC mode or UCAPL mode. Enabling security certifications compliance does not guarantee strict compliance with all requirements of the security mode selected. For more information on hardening procedures, refer to the guidelines for this product provided by the certifying entity. New/modified screens: **Devices** > **Platform Settings** > **UC/APPL Compliance** Supported platforms: Any device
SSL settings for remote access VPN.	6.2.1	6.2.1	The FTD device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. You can configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL. New/modified screens: **Devices** > **Platform Settings** > **SSL** Supported platforms: FTD

Feature	Minimum FMC	Minimum FTD	Details
External authentication for SSH and HTML removed.	6.1.0	6.1.0	Due to changes to support converged management access, only local users are supported for SSH and HTML to data interfaces. Also, you can no longer SSH to the logical Diagnostic interface; instead you can SSH to the logical Management interface (which shares the same physical port). Previously, only external authentication was supported for SSH and HTML access to Diagnostic and data interfaces, while only local users were supported to the Management interface. New/modified screens: **Devices** > **Platform Settings** > **External Authentication** Supported platforms: FTD
Firepower Threat Defense support.	6.0.1	6.0.1	This feature was introduced. New/modified screens: **Devices** > **Platform Settings** Supported platforms: FTD

CHAPTER 17

Network Address Translation

The following topics explain Network Address Translation (NAT) and how to configure it on FTD devices.

- Why Use NAT?, on page 535
- NAT Basics, on page 536
- Requirements and Prerequisites for NAT Policies, on page 544
- Guidelines for NAT, on page 544
- Manage NAT Policies, on page 550
- Configure NAT for Threat Defense, on page 552
- Translating IPv6 Networks, on page 590
- Monitoring NAT, on page 603
- Examples for NAT, on page 604
- History for FTD NAT, on page 656

Why Use NAT?

Each computer and device within an IP network is assigned a unique IP address that identifies the host. Because of a shortage of public IPv4 addresses, most of these IP addresses are private, not routable anywhere outside of the private company network. RFC 1918 defines the private IP addresses you can use internally that should not be advertised:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses because it can be configured to advertise at a minimum only one public address for the entire network to the outside world.

Other functions of NAT include:

- Security—Keeping internal IP addresses hidden discourages direct attacks.
- IP routing solutions—Overlapping IP addresses are not a problem when you use NAT.

- Flexibility—You can change internal IP addressing schemes without affecting the public addresses available externally; for example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.
- Translating between IPv4 and IPv6 (Routed mode only) —If you want to connect an IPv6 network to an IPv4 network, NAT lets you translate between the two types of addresses.

Note NAT is not required. If you do not configure NAT for a given set of traffic, that traffic will not be translated, but will have all of the security policies applied as normal.

NAT Basics

The following topics explain some of the basics of NAT.

NAT Terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the "real" network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, "real" can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the "mapped" network.

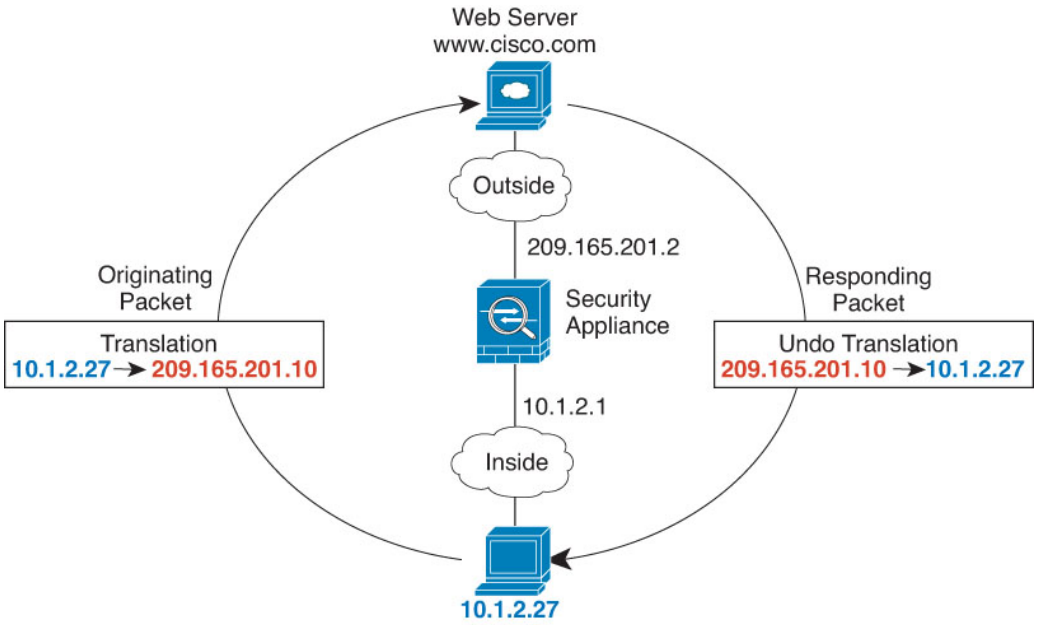
Note During address translation, IP addresses configured for the device interfaces are not translated.

- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that "source" and "destination" are used in commands and descriptions throughout this guide even though a given connection might originate at the "destination" address.

NAT Types

You can implement NAT using the following methods:

- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See Dynamic NAT, on page 557.
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See Dynamic PAT, on page 562.
- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See Static NAT, on page 572.
- Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See Identity NAT, on page 580.



NAT in Routed and Transparent Mode

You can configure NAT in both routed and transparent firewall mode. You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. The following sections describe typical usage for each firewall mode.

NAT in Routed Mode

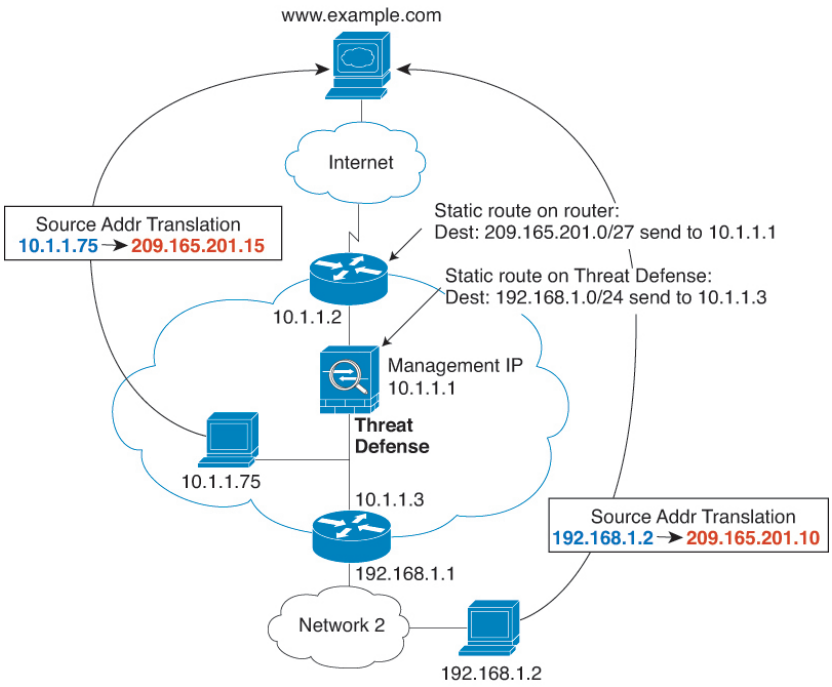
The following figure shows a typical NAT example in routed mode, with a private network on the inside.

Figure 150: NAT Example: Routed Mode

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the FTD device receives the packet because the FTD device performs proxy ARP to claim the packet.

3. The FTD device then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

NAT in Transparent Mode or Within a Bridge Group



Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. It can perform a similar function within a bridge group in routed mode.

NAT in transparent mode, or in routed mode between members of the same bridge group, has the following requirements and limitations:

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the FTD sends an ARP request to a host on the other side of the FTD, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

The following figure shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

Figure 151: NAT Example: Transparent Mode

1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.

2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the FTD receives the packet because the upstream router includes this mapped network in a static route directed to the FTD management IP address.
3. The FTD then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the FTD sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except for returning traffic, the FTD looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the FTD static route for 192.168.1.0/24.

Auto NAT and Manual NAT

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)

Auto NAT

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

Manual NAT

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

Note For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Comparing Auto NAT and Manual NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that manual NAT is more scalable.
- How source and destination NAT is implemented.
  - Auto NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.
- Order of NAT Rules.
  - Auto NAT—Automatically ordered in the NAT table.
  - Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

NAT Rule Order

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.

Note There is also a Section 0, which contains any NAT rules that the system creates for its own use. These rules have priority over all others. The system automatically creates these rules and clears xlates as needed. You cannot add, edit, or modify rules in Section 0.

Table 45: NAT Rule Table

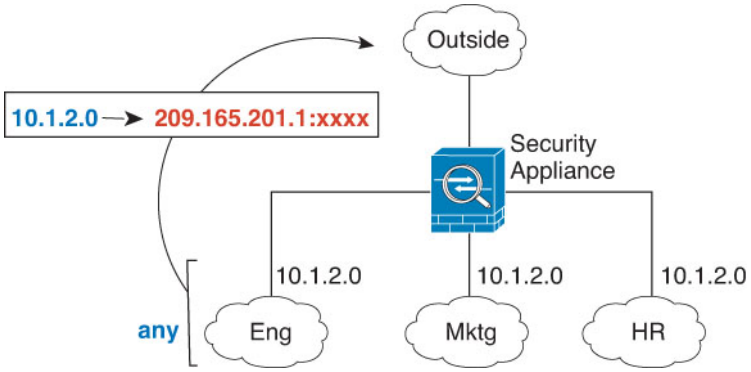
Table Section	Rule Type	Order of Rules within the Section
Section 1	Manual NAT	Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1. By "specific rules first," we mean: • Static rules should come before dynamic rules. • Rules that include destination translation should come before rules with source translation only. If you cannot eliminate overlapping rules, where more than one rule might apply based on the source or destination address, be especially careful to follow these recommendations.
Section 2	Auto NAT	If a match in section 1 is not found, section 2 rules are applied in the following order: **1.** Static rules. **2.** Dynamic rules. **Within each rule type, the following ordering guidelines are used:** **1.** Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses. **2.** For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0. **3.** If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.
Section 3	Manual NAT	If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply.

For section 2 rules, for example, you have the following IP addresses defined within network objects:

- 192.168.1.0/24 (static)
- 192.168.1.0/24 (dynamic)
- 10.1.1.0/24 (static)

- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:



- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

NAT Interfaces

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.

Figure 152: Specifying Any Interface

However, the concept of "any" interface does not apply to bridge group member interfaces. When you specify "any" interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. When specifying interfaces, you do so indirectly by selecting the interface object that contains the interface.

Configuring Routing for NAT

The FTD device needs to be the destination for any packets sent to the translated (mapped) address.

When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

Addresses on the Same Network as the Mapped Interface

If you use addresses on the same network as the destination (mapped) interface, the FTD device uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the FTD device does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

Note If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address. Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur. Configure the ARP table in the ingress interface's **Advanced** settings.

Addresses on a Unique Network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the FTD device.

Alternatively for routed mode, you can configure a static route on the FTD device for the mapped addresses using any IP address on the destination network as the gateway, and then redistribute the route using your routing protocol. For example, if you use NAT for the inside network (10.1.1.0/24) and use the mapped IP address 209.165.201.5, then you can configure a static route for 209.165.201.5 255.255.255.255 (host address) to the 10.1.1.99 gateway that can be redistributed.

For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the FTD device: specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

The Same Address as the Real Address (Identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The FTD device will then proxy ARP for the address, even though the packet is not actually destined for the FTD device. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the FTD device ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the FTD device.

Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

Firewall Mode Guidelines for NAT

NAT is supported in routed and transparent firewall mode.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Group Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.
- When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.
- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported. However, you can do NAT64/46 between members of different bridge groups, or between a bridge group member (source) and standard routed interface (destination).

Note You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes.

IPv6 NAT Guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.
- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.
- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

IPv6 NAT Best Practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-to-net, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.
- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

NAT Support for Inspected Protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

- Pinhole creation—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.
- NAT rewrite— Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.
- Protocol enforcement—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.

The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.

Note NAT rewrite is supported on the listed ports only. For some of these protocols, you can extend inspection to other ports using Network Analysis Policies, but NAT rewrite is not extended to those ports. This includes DCERPC, DNS, FTP, and Sun RPC inspection. If you use these protocols on non-standard ports, do not use NAT on the connections.

Table 46: NAT Supported Application Inspection

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
DCERPC	TCP/135	No NAT64.	Yes
DNS over UDP	UDP/53	No NAT support is available for name resolution through WINS.	No
ESMTP	TCP/25	No NAT64.	No
FTP	TCP/21	(Clustering) No static PAT.	Yes
H.323 H.225 (Call signaling) H.323 RAS	TCP/1720 UDP/1718 For RAS, UDP/1718-1719	(Clustering) No static PAT. No extended PAT. No NAT64.	Yes
ICMP ICMP Error	ICMP (ICMP traffic directed to a device interface is never inspected.)	No limitations.	No
IP Options	RSVP	No NAT64.	No

Application	Inspected Protocol, Port	NAT Limitations	Pinholes Created
NetBIOS Name Server over IP	UDP/137, 138 (Source ports)	No extended PAT. No NAT64.	No
RSH	TCP/514	No PAT. No NAT64. (Clustering) No static PAT.	Yes
RTSP	TCP/554 (No handling for HTTP cloaking.)	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
SIP	TCP/5060 UDP/5060	No extended PAT. No NAT64 or NAT46. (Clustering) No static PAT.	Yes
Skinny (SCCP)	TCP/2000	No extended PAT. No NAT64, NAT46, or NAT66. (Clustering) No static PAT.	Yes
SQL*Net (versions 1, 2)	TCP/1521	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes
Sun RPC	TCP/111 UDP/111	No extended PAT. No NAT64.	Yes
TFTP	UDP/69	No NAT64. (Clustering) No static PAT. Payload IP addresses are not translated.	Yes
XDMCP	UDP/177	No extended PAT. No NAT64. (Clustering) No static PAT.	Yes

FQDN Destination Guidelines

You can specify the translated (mapped) destination in a manual NAT rule using a fully-qualified domain name (FQDN) network object instead of an IP address. For example, you can create a rule based on traffic that is destined for the www.example.com web server.

When using an FQDN, the system obtains the DNS resolution and writes the NAT rule based on the returned address. If more than one address is obtained from the DNS server, the address used is based on the following:

- If there is an address on the same subnet as the specified interface, that address is used. If there isn't one on the same subnet, the first address returned is used.
- The IP type for the translated source and translated destination must match. For example, if the translated source address is IPv6, the FQDN object must specify IPv6 as the address type. If the translated source is IPv4, the FQDN object can specify IPv4 or both IPv4 and IPv6. In this case, an IPv4 address is selected.

You cannot include an FQDN object in a network group that is used for manual NAT destination. In NAT, an FQDN object must be used alone, as only a single destination host makes sense for this type of NAT rule.

If the FQDN cannot be resolved to an IP address, the rule is not functional until a DNS resolution is obtained.

Additional Guidelines for NAT

- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.
- You cannot write NAT rules for a Virtual Tunnel Interface (VTI), which are used in site-to-site VPN. Writing rules for the VTI's source interface will not apply NAT to the VPN tunnel. To write NAT rules that will apply to VPN traffic tunneled on a VTI, you must use "any" as the interface; you cannot explicitly specify interface names.
- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.
- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.
- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the **clear xlate** command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

  If you create a new NAT rule that should apply to an existing connection (such as a VPN tunnel), you need to use **clear conn** to end the connection. Then, the attempt to re-establish the connection should hit the NAT rule and the connection should be NAT'ed correctly.

Note If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** or **clear conn** commands. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.

- A network object used in NAT cannot include more than 131,838 IP addresses, either explicitly or implied in a range of addresses or a subnet. Break up the address space into smaller ranges and write separate rules for the smaller objects.
- (Manual NAT only.) When using **any** as the source address in a NAT rule, the definition of "any" traffic (IPv4 vs. IPv6) depends on the rule. Before the FTD device performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the FTD device can determine the value of **any** in a NAT rule. For example, if you configure a rule from "any" to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means "any IPv6 traffic." If you configure a rule from "any" to "any," and you map the source to the interface IPv4 address, then **any** means "any IPv4 traffic" because the mapped interface address implies that the destination is also IPv4.
- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify "any" interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  - The failover interface IP address.
  - (Transparent mode.) The management IP address.
  - (Dynamic NAT.) The standby interface IP address when VPN is enabled.
- Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.
- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.
- If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.
- If you use PAT on Sun RPC traffic, which is used to connect to NFS servers, be aware that the NFS server might reject connections if the PAT'ed port is above 1024. The default configuration of NFS servers is to reject connections from ports higher than 1024. The error is typically "Permission Denied." Mapping ports above 1024 happens if you do not select the option to include the reserved ports (1-1023) in the port range of a PAT pool. You can avoid this problem by changing the NFS server configuration to allow all port numbers.
- NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.
- Do not name a network object or group pat-pool, using any combination of upper- or lower-case letters.
- The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.
- You cannot use NAT on the internal payload of Protocol Independent Multicast (PIM) registers.
- (Manual NAT) When writing NAT rules for a dual ISP interface setup (primary and backup interfaces using service level agreements in the routing configuration), do not specify destination criteria in the rule. Ensure the rule for the primary interface comes before the rule for the backup interface. This allows

the device to choose the correct NAT destination interface based on the current routing state when the primary ISP is unavailable. If you specify destination objects, the NAT rule will always select the primary interface for the otherwise duplicate rules.

- If you get the ASP drop reason nat-no-xlate-to-pat-pool for traffic that should not match the NAT rules defined for the interface, configure identity NAT rules for the affected traffic so the traffic can pass untranslated.
- If you configure NAT for GRE tunnel endpoints, you must disable keepalives on the endpoints or the tunnel cannot be established. The endpoints send keepalives to the original addresses.
- DHCP and BOOTP share ports UDP/67-68. Because BOOTP is obsolete, writing NAT rules for the bootps port can cause port allocation problems when also running DHCP. Consider using DHCP relay instead for transmitting DHCP requests between network segments.

Manage NAT Policies

Network Address Translation (NAT) converts the IP address of an incoming packet to a different address in the outgoing packet. One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into routable addresses that can be used on the public Internet. NAT keeps track of the translations, also known as xlates, to ensure that return traffic is directed to the correct untranslated host address.

Procedure

Step 1 Choose **Devices** > **NAT** .

Step 2 Manage your NAT policies:

- Create—Click **New Policy** and select **Threat Defense NAT**. See Creating NAT Policies, on page 551.
- Copy—Click **Copy** ( ) next to the policy you want to copy. You are prompted to give the copy a new, unique name. The copy includes all policy rules and configurations, but does not include device assignments.
- Report—Click **Report** ( ) for the policy. You are prompted to save the PDF report, which includes policy attributes, device assignments, rules, and object usage information.
- Edit—Click **Edit** ( ) next to the policy you want to edit. See Configure NAT for Threat Defense, on page 552.
- Delete—Click **Delete** ( ) next to the policy you want to delete, then click **OK**. When prompted whether to continue, you are also informed if another user has unsaved changes in the policy.

  Caution
  After you have deployed a NAT policy to a managed device, you cannot delete the policy from the device. Instead, you must deploy a NAT policy with no rules to remove the NAT rules already present on the managed device. You also cannot delete a policy that is the last deployed policy on any of its target

devices, even if it is out of date. Before you can delete the policy completely, you must deploy a different policy to those targets.

Creating NAT Policies

When you create a new NAT policy you must, at minimum, give it a unique name. Although you are not required to identify policy targets at policy creation time, you must perform this step before you can deploy the policy. If you apply a NAT policy with no rules to a device, the system removes all NAT rules from that device.

Procedure

Step 1 Choose **Devices** > **NAT** .

Step 2 Click **New Policy** and from the drop-down list, choose **Threat Defense NAT** for FTD devices.

Firepower NAT is for older devices that are not covered in this document.

Step 3 Enter a unique **Name**.

Step 4 Optionally, enter a **Description**.

Step 5 Choose the devices where you want to deploy the policy:

- Choose a device in the **Available Devices** list, and click **Add to Policy**.
- Click and drag a device from the **Available Devices** list to the **Selected Devices** list.
- Remove a device from the **Selected Devices** list by clicking **Delete** ( ) next to the device.

Step 6 Click **Save**.

Configuring NAT Policy Targets

You can identify the managed devices you want to target with your policy while creating or editing a policy. You can search a list of available devices and high-availability pairs, and add them to a list of selected devices.

Procedure

Step 1 Choose **Devices** > **NAT** .

Step 2 Click **Edit** ( ) next to the NAT policy you want to modify.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 3 Click **Policy Assignments**.

Step 4 Do any of the following:

- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add to Policy**. You can also drag and drop.
- To remove a device assignment, click **Delete** ( ) next to a device, high-availability pair, or device group in the **Selected Devices** list.

Step 5 Click **OK**.

Configure NAT for Threat Defense

Network address translation can be very complex. We recommend that you keep your rules as simple as possible to avoid translation problems and difficult troubleshooting situations. Careful planning before you implement NAT is critical. The following procedure provides the basic approach.

The NAT policy is a shared policy. You assign the policy to devices that should have similar NAT rules.

Whether a given rule in the policy applies to an assigned device is determined by the interface objects (security zones or interface groups) used in the rule. If the interface objects include one or more interface for the device, the rule is deployed to the device. Thus, you can configure rules that apply to subsets of devices within a single shared policy by carefully designing your interface objects. Rules that apply to "any" interface object are deployed to all devices.

If you change the type of an interface to a type that is not valid for use with a NAT policy that targets a device with that interface, the policy labels the interface as deleted. Click **Save** in the NAT policy to automatically remove the interface from the policy.

You can configure multiple NAT policies if groups of your devices require significantly different rules.

Procedure

Step 1 Select **Devices** > **NAT**.

- Click **New Policy** > **Threat Defense NAT** to create a new policy. Give the policy a name, optionally assign devices to it, and click **Save**.

  You can change device assignments later by editing the policy and clicking **Policy Assignments**.

- Click **Edit** ( ) to edit an existing threat defense NAT policy. Note that the page also shows Firepower NAT policies, which are not used by FTD devices.

  If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Decide what kinds of rules you need.

You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, see NAT Types, on page 536.

Step 3 Decide which rules should be implemented as manual or auto NAT.

For a comparison of these two implementation options, see Auto NAT and Manual NAT, on page 539.

Step 4 Decide which rules should be custom per device.

Because you can assign a NAT policy to multiple devices, you can configure a single rule on many devices. However, you might have rules that should be interpreted differently by each device, or some rules that should apply to a subset of devices only.

Use interface objects to control on which devices a rule is configured. Then, use object overrides on network objects to customize the addresses used per device.

For detailed information, see Customizing NAT Rules for Multiple Devices, on page 554.

Step 5 Create the rules as explained in the following sections.

- Dynamic NAT, on page 557
- Dynamic PAT, on page 562
- Static NAT, on page 572
- Identity NAT, on page 580

Step 6 Manage the NAT policy and rules.

You can do the following to manage the policy and its rules.

- To edit the policy name or description, click in those fields, type in your changes, and click outside the fields.
- To view only those rules that apply to a specific device, click **Filter by Device** and select the desired device. A rule applies to a device if it uses an interface object that includes an interface on the device.
- To view any warnings or errors in the policy, click **Show Warnings**, then choose a **Device**. Warnings and errors mark configurations that could adversely affect traffic flow or prevent the policy from deploying.
- To change the devices to which the policy is assigned, click the **Policy Assignments** link and modify the selected devices list as desired.
- To change whether a rule is enabled or disabled, right click the rule and select the desired option from the **State** command. You can temporarily disable a rule without deleting it using these controls.
- To add a rule, click the **Add Rule** button.
- To edit a rule, click **Edit** ( ) for the rule.
- To delete a rule, click **Delete** ( ) for the rule.
- To change the number of rules displayed on the page, use the **Rows Per Page** drop-down list.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Customizing NAT Rules for Multiple Devices

Because the NAT policy is shared, you can assign a given policy to more than one device. However, you can configure at most one auto NAT rule for a given object. Thus, if you want to configure different translations for an object based on the specific device doing the translation, you need to carefully configure the interface objects (security zones or interface groups) and define network object overrides for the translated address.

The interface objects determine on which devices a rule gets configured. The network object overrides determine what IP addresses are used by a given device for that object.

Consider the following scenario:

- FTD-A and FTD-B have inside networks 192.168.1.0/24 attached to the interface named “inside.”
- On FTD-A, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.100.10.10 - 10.100.10.200 range when going to the “outside” interface.
- On FTD-B, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.200.10.10 - 10.200.10.200 range when going to the “outside” interface.

To accomplish the above, you would do the following. Although this example rule is for dynamic auto NAT, you can generalize the technique for any type of NAT rule.

Procedure

Step 1 Create the security zones for the inside and outside interfaces.

a) Choose **Objects** > **Object Management**.
b) Select **Interface Objects** from the table of contents and click **Add** > **Security Zone**. (You can use interface groups instead of zones.)
c) Configure the inside zone properties.
   - **Name**—Enter a name, for example, **inside-zone**.
   - **Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
   - **Selected Interfaces**—Add the FTD-A/inside and FTD-B/inside interfaces to the selected list.
d) Click **Save**.
e) Click **Add** > **Security Zone** and define the outside zone properties.
   - **Name**—Enter a name, for example, **outside-zone**.
   - **Interface Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
   - **Selected Interfaces**—Add the FTD-A/outside and FTD-B/outside interfaces to the selected list.
f) Click **Save**.

Step 2 Create the network object for the original inside network on the Object Management page.

a) Select **Network** from the table of contents and click **Add Network** > **Add Object**.
b) Configure the inside network properties.
   - **Name**—Enter a name, for example, **inside-network**.

- **Network**—Enter the network address, for example, **192.168.1.0/24**.

c) Click **Save**.

Step 3 Create the network object for the translated NAT pool and define overrides.

a) Click **Add Network** > **Add Object**.
b) Configure the NAT pool properties for FTD-A.

- **Name**—Enter a name, for example, **NAT-pool**.
- **Network**—Enter the range of addresses to include in the pool for FTD-A, for example, **10.100.10.10-10.100.10.200**.

c) Select **Allow Overrides**.
d) Click the **Overrides** heading to open the list of object overrides.
e) Click **Add** to open the Add Object Override dialog box.
f) Select FTD-B and **Add** it to the Selected Devices list.
g) Click **Override** and change **Network** to **10.200.10.10-10.200.10.200**
h) Click **Add** to add the override to the device.

By defining an override for FTD-B, whenever the system configures this object on FTD-B, it will use the override value instead of the value defined in the original object.

i) Click **Save**.

Step 4 Configure the NAT rule.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-zone.
- **Destination Interface Objects** = outside-zone.

Note
The interface objects control on which devices the rule is configured. Because in this example the zones contain interfaces for FTD-A and FTD-B only, even if the NAT policy were assigned to additional devices, the rule would be deployed to those 2 devices only.

e) On **Translation**, configure the following:

- **Original Source** = inside-network object.
- **Translated Source** > **Address**= NAT-pool object.

f) Click **Save**.

You now have a single rule that will be interpreted differently for FTD-A and FTD-B, providing unique translations for the inside networks protected by each firewall.

Searching and Filtering the NAT Rule Table

You can search and filter the NAT rule table to help you find rules that you need to modify or view. When you filter the table, only matching rules are shown. Note that although the rule numbers change to be sequentially 1, 2, and so forth, filtering does not change the actual rule number or the rule's location in the table relative to hidden rules. Filtering simply changes what you can see to help you locate rules that interest you.

When editing the NAT policy, you can use the fields above the table to do the following types of search/filter:

- **Filter by Device**—Click **Filter by Device**, then select the devices whose rules you want to see and click **OK**. Whether a rule applies to a device is determined by the rule's interface constraints. If you specify a security zone or interface group for either the source or destination interface, the rule applies to a device if at least one interface for the device is in the zone or group. If a NAT rule applies to any source and any destination interface, then it applies to all devices.

  If you also do a text or multiple-attribute search, the results are constrained to the selected devices.

  To remove this filter, click **Filter by Device** and deselect the devices, or select **All**, and click **OK**.

- **Simple Text Search**—In the **Filter** box, type a string and press Enter. The string is compared to all values in the rules. For example, if you enter "network-object-1," which is the name of a network object, you would get rules that use the object in source, destination, and PAT pool attributes.

  For network and port objects, the string is also compared to the contents of the objects used in the rule. For example, if a PAT pool object includes the range 10.100.10.3-10.100.10.100, searching on either 10.100.10.3 or 10.100.10.100 (or a partial 10.100.10) will include rules that use that PAT pool object. However, the match must be exact: searching on 10.100.10.5 will not match this PAT pool object, even though the IP address is within the object's IP address range.

  To remove the filter, click the **x** on the right side of the Filter box.

- **Multiple-Attribute Search**—If a simple text search gives you too many hits, you can configure multiple values for the search. Click in the **Filter** box to open the list of attributes, then select or enter strings for the attributes you intend to search and click the **Filter** button. These attributes are the same as the ones you would configure within a NAT rule. The attributes are AND'ed, so filtered results include only those rules that match all attributes you configured.

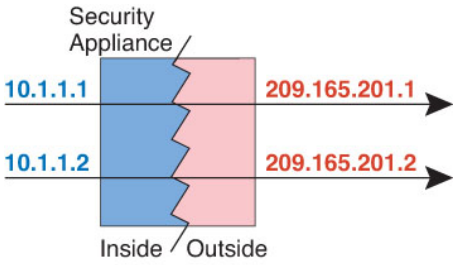
  - For binary attributes, such as the rule state (enabled/disabled), whether a PAT pool is configured (enabled/disabled), the direction of the rule (uni/bi), or rule type (static/dynamic), simply check or uncheck the boxes as appropriate. Select both boxes if you do not care about the attribute value. If you deselect both boxes, no rules will match the filter.

  - For string attributes, type a full or partial string relevant to that attribute. These will be object names, either for security zones/interface groups, network objects, or port objects. It can also be the network or port object contents, which are matched the same way they are for simple text searches.

  To remove the filter, click the **x** on the right side of the Filter box, or click in the Filter box to open the drop-down list, and click the Clear button.

Dynamic NAT

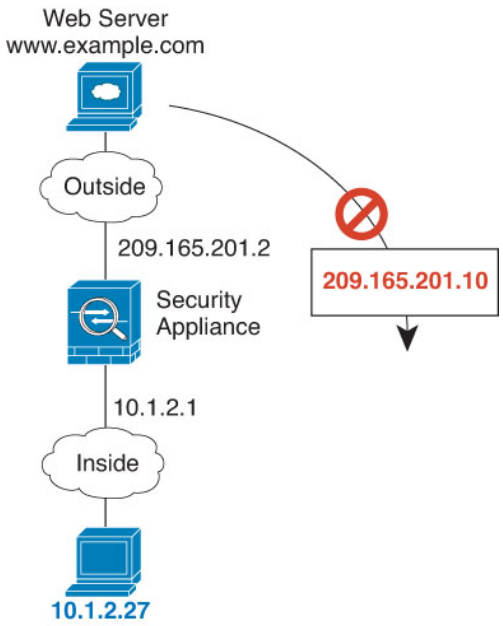
The following topics explain dynamic NAT and how to configure it.



About Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule. A successful connection from a remote host can reset the idle timer for the connection.



The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

Figure 153: Dynamic NAT

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.

Figure 154: Remote Host Attempts to Initiate a Connection to a Mapped Address

Dynamic NAT Disadvantages and Advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

Configure Dynamic Auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.

- **Translated Source**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The network object or group that contains the mapped addresses.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 642.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure Dynamic Manual NAT

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—This can be a network object or group, but it cannot include a subnet. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

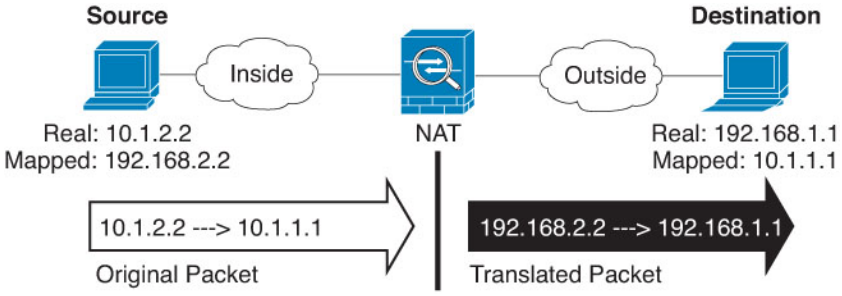
Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The network object or group that contains the mapped addresses.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 (Optional.) On **Advanced**, select the desired options:

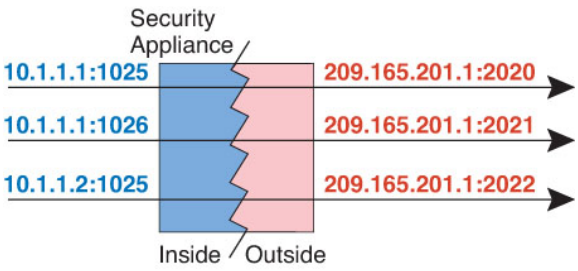
- (For source translation only.) **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 642.
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

Dynamic PAT

The following topics describe dynamic PAT.



About Dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

Figure 155: Dynamic PAT

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

Note We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.

Dynamic PAT Disadvantages and Advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the FTD device interface IP address as the PAT address.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see NAT Support for Inspected Protocols, on page 546.

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

PAT Pool Object Guidelines

When creating network objects for a PAT pool, follow these guidelines.

For a PAT pool

- Ports are mapped to an available port in the 1024 to 65535 range. You can optionally include the reserved ports, those below 1024, to make the entire port range available for translations.

  When operating in a cluster, blocks of 512 ports per address are allocated to the members of the cluster, and mappings are made within these port blocks. If you also enable block allocation, the ports are distributed according to the block allocation size, whose default is also 512. If you change the cluster unit limit (the size of the cluster), ensure that you clear xlates or reboot the devices so that PAT pools can be appropriately reallocated to the cluster units.

- If you enable block allocation for a PAT pool, port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host.

- If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT, then the other rule must also specify extended PAT.

- If a host has an existing connection, then subsequent connections from that host use the same PAT IP address. If no ports are available, this can prevent the connection. Use the round robin option to avoid this problem.

- For best performance, limit the number of IP addresses within a PAT pool to 10,000.

For extended PAT for a PAT pool

- Many application inspections do not support extended PAT.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.
- You cannot use extended PAT on units in a cluster.
- Extended PAT increases memory usage on the device.

For round robin for a PAT pool

- If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. However, this “stickiness” does not survive a failover. If the device fails over, then subsequent connections from a host might not use the initial IP address.
- IP address “stickiness” is also impacted if you mix PAT pool/round robin rules with interface PAT rules on the same interface. For any given interface, choose either a PAT pool or interface PAT; do not create competing PAT rules.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

Configure Dynamic Auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Dynamic**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty.

Step 6 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information.

Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the FTD devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 7 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address or PAT pool.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 8 Click **Save** to add the rule.

Step 9 Click **Save** on the NAT page to save your changes.

Configure Dynamic Manual PAT

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

Procedure

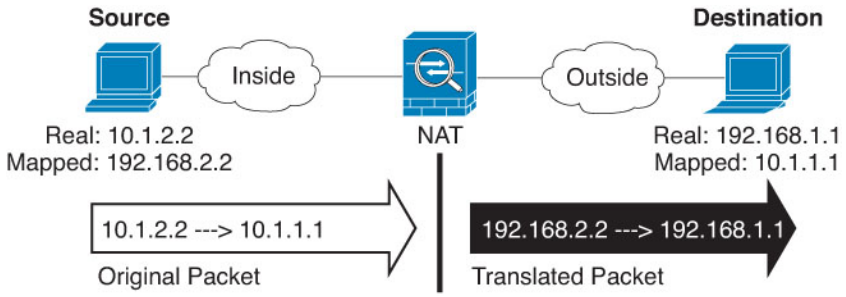
Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

Step 8 If you are using a PAT pool, select the **PAT Pool** page and do the following:

a) Select **Enable PAT pool**.

b) Select the network object group that contains the addresses for the pool in the **PAT** > **Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range**, **Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the FTD devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Step 9 (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

Step 10 Click **Save** to add the rule.

Step 11 Click **Save** on the NAT page to save your changes.

Configure PAT with Port Block Allocation

For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). If you allocate a block of ports, subsequent connections from the host use new randomly-selected ports within the block. If necessary, additional blocks are allocated

if the host has active connections for all ports in the original block. Blocks are freed when the last xlate that uses a port in the block is removed.

The main reason for allocating port blocks is reduced logging. The port block allocation is logged, connections are logged, but xlates created within the port block are not logged. On the other hand, this makes log analysis more difficult.

Port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host. You can create a separate NAT rule that does not use block allocation for applications that use low port numbers; for twice NAT, ensure the rule comes before the block allocation rule.

Before you begin

Usage notes for NAT rules:

- You can include the **Use Round Robin Allocation** option, but you cannot include the options for extending PAT uniqueness, using a flat range, including the reserved ports, or falling through to interface PAT. Other source/destination address and port information is also allowed.
- As with all NAT changes, if you replace an existing rule, you must clear xlates related to the replaced rule to have the new rule take effect. You can clear them explicitly or simply wait for them to time out. When operating in a cluster, you must clear xlates globally across the cluster.

Note If you are switching between a regular PAT and block allocation PAT rule, for object NAT, you must first delete the rule, then clear xlates. You can then create the new object NAT rule. Otherwise, you will see pat-port-block-state-mismatch drops in the **show asp drop** output.

- For a given PAT pool, you must specify (or not specify) block allocation for all rules that use the pool. You cannot allocate blocks in one rule and not in another. PAT pools that overlap also cannot mix block allocation settings. You also cannot overlap static NAT with port translation rules with the pool.

Procedure

Step 1 (Optional.) Configure global PAT port block allocation settings.

There are a few global settings that control port block allocation. If you want to change the defaults for these options, you must configure a FlexConfig object and add it to your FlexConfig policy.

a) Select **Objects** > **Object Management** > **FlexConfig** > **FlexConfig Object** and create a new object.
b) Configure the block allocation size, which is the number of ports in each block.

xlate block-allocation size *value*

The range is 32-4096. The default is 512. Use the “no” form to return to the default.

If you do not use the default, ensure that the size you choose divides evenly into 64,512 (the number of ports in the 1024-65535 range). Otherwise, there will be ports that cannot be used. For example, if you specify 100, there will be 12 unused ports.

c) Configure the maximum blocks that can be allocated per host.

xlate block-allocation maximum-per-host *number*

The limit is per protocol, so a limit of 4 means at most 4 UDP blocks, 4 TCP blocks, and 4 ICMP blocks per host. The range is 1-8, the default is 4. Use the "no" form to return to the default.

d) (Optional.) Enable interim syslog generation.

xlate block-allocation pba-interim-logging *seconds*

By default, the system generates syslog messages during port block creation and deletion. If you enable interim logging, the system generates the following message at the interval you specify. The messages report all active port blocks allocated at that time, including the protocol (ICMP, TCP, UDP) and source and destination interface and IP address, and the port block. You can specify an interval from 21600-604800 seconds (6 hours to 7 days).

%ASA-6-305017: Pba-interim-logging: Active *protocol* block of ports for translation from *real_interface*:*real_host_ip* to *mapped_interface*:*mapped_ip_address*/*start_port_num-end_port_num*

Example:

The following example sets the block allocation size to 64, the per-host maximum to 8, and enables interim logging every 6 hours.

```
xlate block-allocation size 64
xlate block-allocation maximum-per-host 8
xlate block-allocation pba-interim-logging 21600
```

e) Select the following options in the FlexConfig object:

- **Deployment** = **Everytime**
- **Type** = **Append**

f) Click **Save** to create the FlexConfig object.
g) Select **Devices** > **FlexConfig**, and create or edit the FlexConfig policy that is assigned to the devices that need to have these settings adjusted.
h) Select your object in the available objects list and click **>** to move it to the selected objects list.
i) Click **Save**.

You can click **Preview Config**, select one of the target devices, and verify that the xlate commands appear correctly.

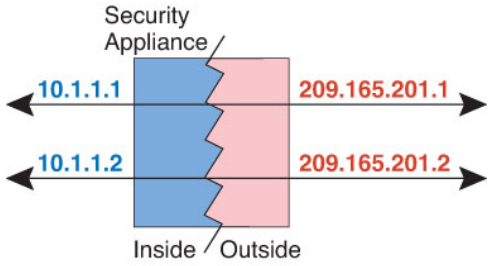
Step 2 Add NAT rules that use PAT pool port block allocation.

a) Select **Devices** > **NAT** and add or edit the threat defense NAT policy.
b) Add or edit a NAT rule and configure at least the following options.

- **Type** = **Dynamic**
- In **Translation** > **Original Source**, select the object that defines the source address.
- On **PAT Pool**, configure the following options:
  - Select **Enable PAT Pool**
  - In **PAT** > **Address**, select a network object or group that defines the pat pool.
  - Select the **Block Allocation** option.

c) Save your changes to the rule and to the NAT policy.

Static NAT



The following topics explain static NAT and how to implement it.

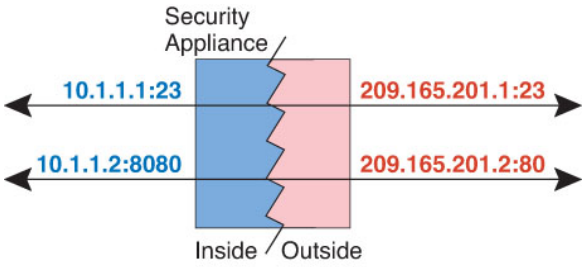
About Static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

Figure 156: Static NAT

Note You can disable bidirectionality if desired.



Static NAT with Port Translation

Static NAT with port translation lets you specify a real and mapped protocol and port.

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 157: Typical Static NAT with Port Translation Scenario

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.

Note For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

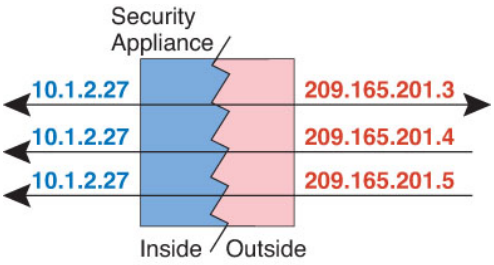
Static NAT with Identity Port Translation

You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

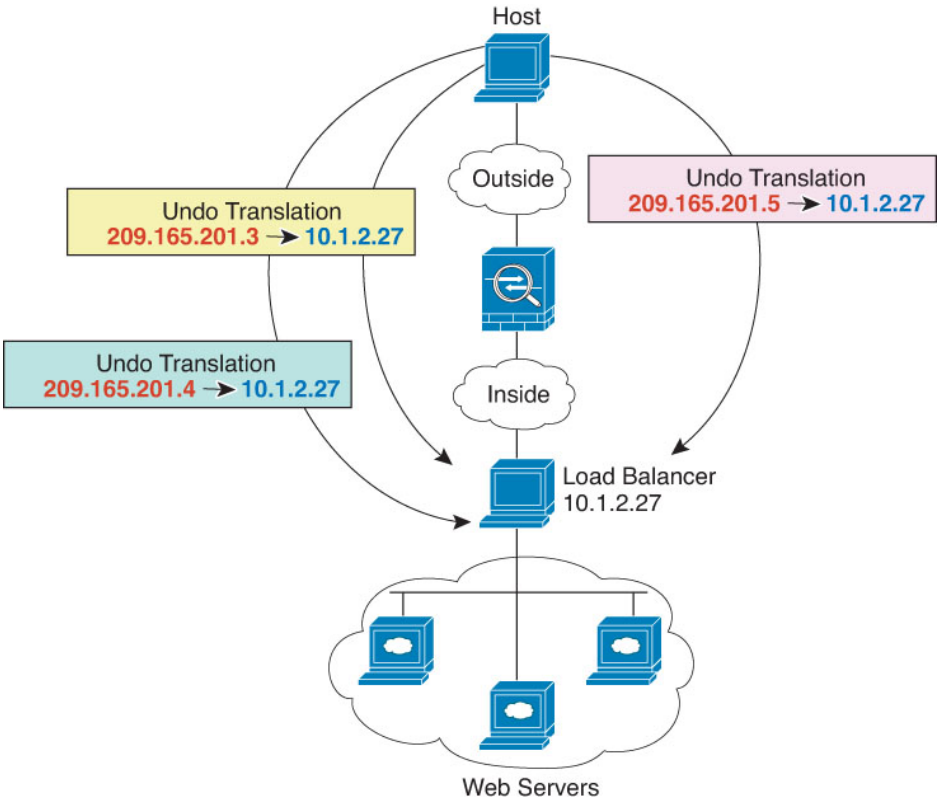
Static Interface NAT with Port Translation



You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

One-to-Many Static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

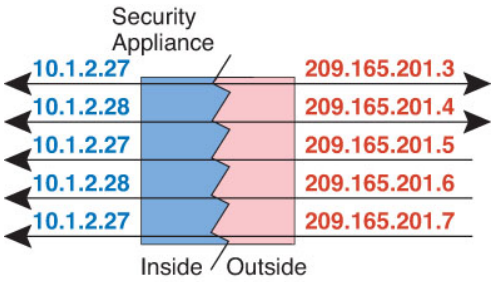


The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

Figure 158: One-to-Many Static NAT

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 159: One-to-Many Static NAT Example



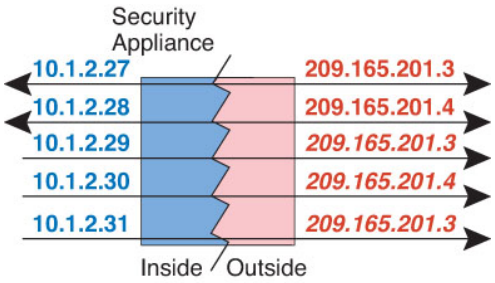
Other Mapping Scenarios (Not Recommended)

NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated *to* the real host, but all traffic *from* the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.

Figure 160: Few-to-Many Static NAT



For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

Note Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

Figure 161: Many-to-Few Static NAT

Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

Configure Static Auto NAT

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, ranges, or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:

- To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
- (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

- (Optional.) **Original Port**, **Translated Port**—If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 642. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure Static Manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, range, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

Procedure

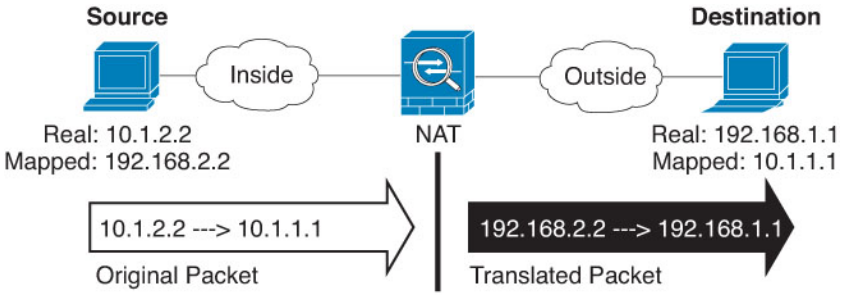
Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

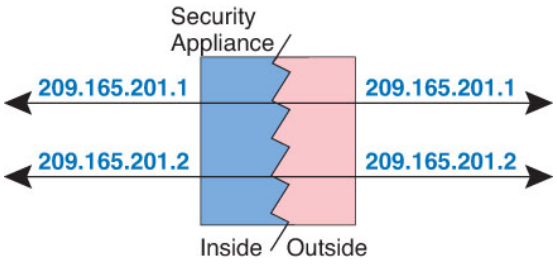
NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 642. This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.



Step 10 Click **Save** on the NAT page to save your changes.

Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate an address to itself.

The following figure shows a typical identity NAT scenario.

Figure 162: Identity NAT

The following topics explain how to configure identity NAT.

Configure Identity Auto NAT

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—A network object or group with the exact same contents as the original source object. You can use the same object.

Procedure

Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Do not configure the **Original Port** and **Translated Port** options for identity NAT.

Step 6 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Do not configure this option for identity NAT.
- **Net to Net Mapping**—Do not configure this option for identity NAT.

- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Step 7 Click **Save** to add the rule.

Step 8 Click **Save** on the NAT page to save your changes.

Configure Identity Manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.

Procedure

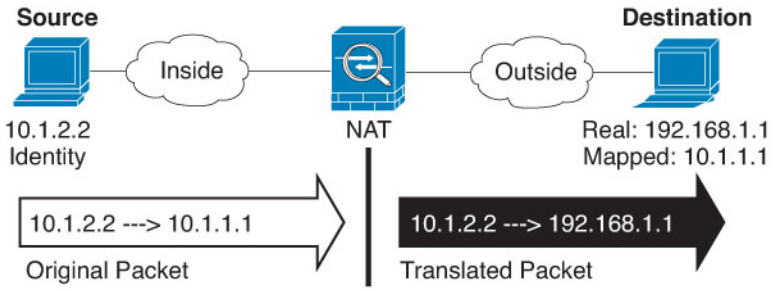
Step 1 Select **Devices** > **NAT** and create or edit the FTD NAT policy.

Step 2 Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** ( ) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

Step 3 Configure the basic rule options:



- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Step 4 On **Interface Objects**, configure the following options:

- **Source Interface Objects**, **Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Step 5 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

  You can select **Interface Object** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

Step 7 (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port**, **Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port**, **Translated Destination Port**—Defines a port translation for the destination address.

Step 8 (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Step 9 Click **Save** to add the rule.

Step 10 Click **Save** on the NAT page to save your changes.

NAT Rule Properties for FTD

Use Network Address Translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publicly routable addresses. The translation can be from one address to another, or you can use Port Address Translation (PAT) to translate many addresses to one or a few addresses, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

NAT Type

Whether you want to configure a **Manual NAT Rule** or an **Auto NAT Rule**. Auto NAT translates the source address only, and you cannot make different translations based on the destination address. Because auto NAT is more simple to configure, use it unless you need the added features of manual NAT. For more information on the differences, see Auto NAT and Manual NAT, on page 539.

Type

Whether the translation rule is **Dynamic** or **Static**. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

Enable (Manual NAT only.)

Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page. You cannot disable auto NAT rules.

Insert (Manual NAT only.)

Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

Description (Optional. Manual NAT only.)

A description of the purpose of the rule.

The following topics describe the tabs for the NAT rules properties.

Interface Objects NAT Properties

Interface objects (security zones or interface groups) define the interfaces to which a NAT rule applies. In routed mode, you can use the default "any" for both source and destination to apply to all interfaces of all assigned devices. However, you typically want to select specific source and destination interfaces.

Notes

- The concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

  If you select interface objects, a NAT rule will be configured on an assigned device only if the device has interfaces included in all selected objects. For example, if you select both source and destination security zones, both zones must contain one or more interface for a given device.

- If more than one interface in an interface object exists on a given device, identical rules are created for each interface. This can become an issue for static NAT rules that include destination translation. Because NAT rules are applied based on first hit rule, only the rule created for the first interface configured for the object matches traffic. When configuring static NAT with destination translation, use interface objects that include at most one interface per device assigned to the NAT policy to ensure you are getting the desired results.

Source Interface Objects, Destination Interface Objects

(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped

interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

Translation Properties for Auto NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

Original Source (Always required.)

The network object that contains the addresses you are translating. This must be a network object (not a group), and it can be a host, range, or subnet.

You cannot create auto NAT rules for the system-defined any-ipv4 or any-ipv6 objects.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary. Do not configure these options for identity NAT.

Translation Properties for Manual NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

Original Source (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can specify **Any** in the rule.

Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Original Destination

The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a

static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

Translated Destination

The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

You can use a network object that specifies a fully-qualified domain name as the translated destination; for more information, see FQDN Destination Guidelines, on page 547.

Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port

The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

- (Dynamic NAT or PAT.) You cannot do translation on the **Original Source Port** and **Translated Source Port**. You can do translation on the destination port only.
- NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

PAT Pool NAT Properties

When you configure dynamic NAT, you can define a pool of addresses to use for Port Address Translation using the properties on the **PAT Pool** tab.

Enable PAT Pool

Select this option to configure a pool of addresses for PAT.

PAT

The addresses to use for the PAT pool, one of the following:

- **Address**—The object that defines the PAT pool addresses, either a network object that includes a range, or a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.
- **Destination Interface IP**—Indicates that you want to use the destination interface as the PAT address. For this option, you must select a specific **Destination Interface Object**; you cannot use **Any** as the destination interface. This is another way to implement interface PAT.

Round Robin

To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

Extended PAT Table

To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going

to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

Flat Port Range; Include Reserved Ports

To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the FTD devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

Block Allocation

To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

Advanced NAT Properties

When you configure NAT, you can configure properties that provide specialized services in the **Advanced** options. All of these properties are optional: configure them only if you need the service.

Translate DNS replies that match this rule

Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see Rewriting DNS Queries and Responses Using NAT, on page 642. This option is not available if you are doing port translation in a static NAT rule.

Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address. You also cannot select the option if you configure a PAT pool.

IPv6

Whether to use the IPv6 address of the destination interface for interface PAT.

Net to Net Mapping (Static NAT only.)

For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.

Do not proxy ARP on Destination Interface (Static NAT only.)

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

Unidirectional (Manual NAT only, static NAT only.)

Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

Translating IPv6 Networks

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:

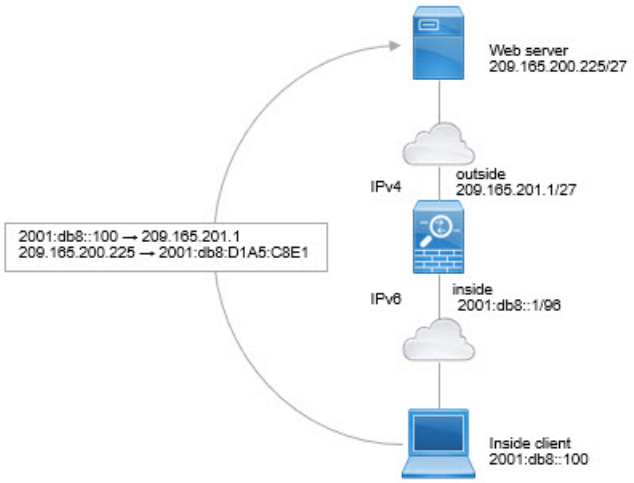
- NAT64, NAT46—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

Note NAT46 supports static mappings only.

- NAT66—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Note NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

NAT64/46: Translating IPv6 Addresses to IPv4



When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.

- The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.
- The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

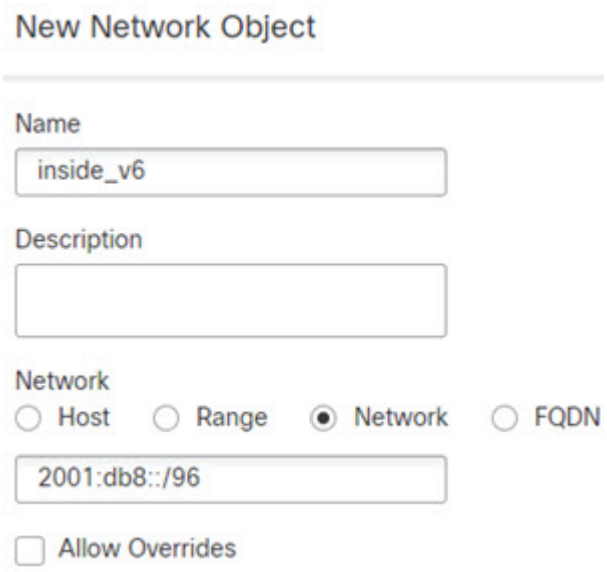
You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.

Procedure



Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

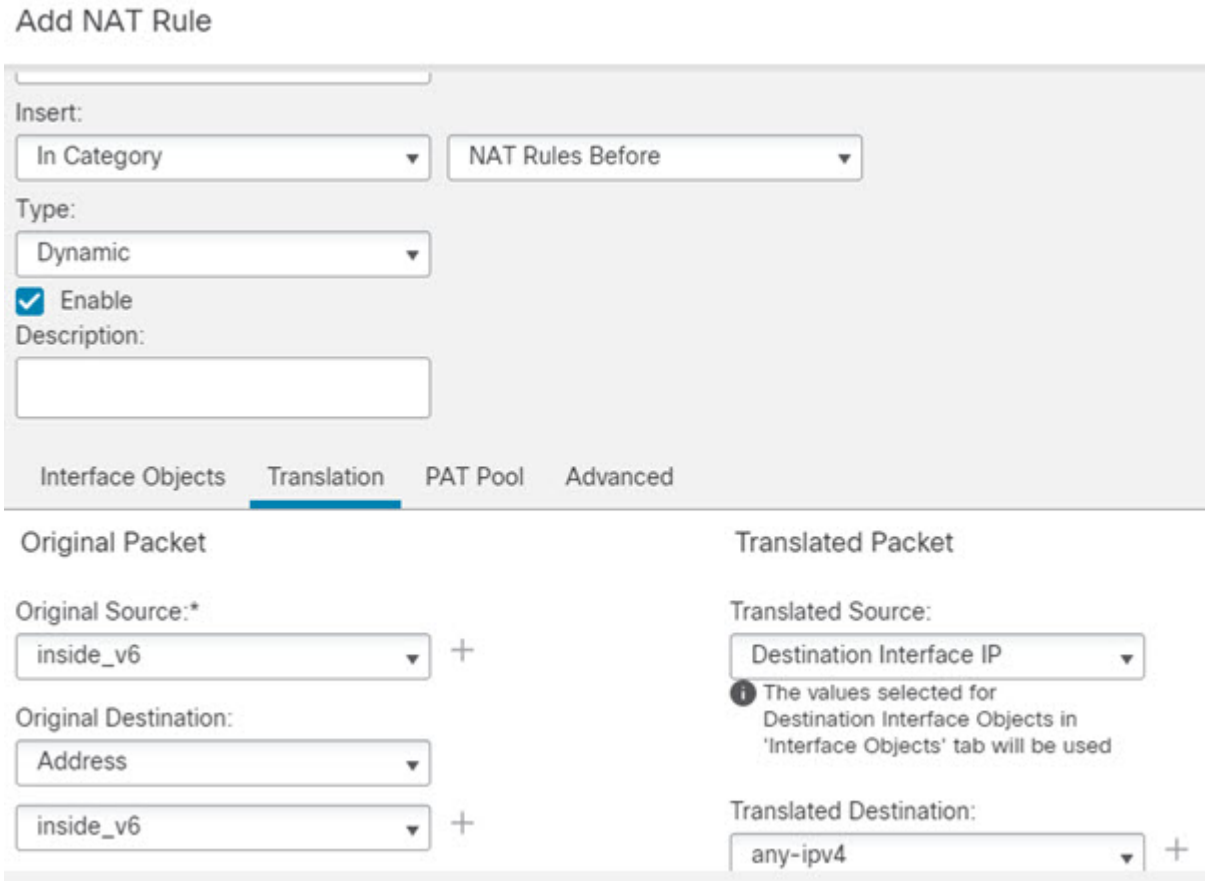
d) Click **Save**.

Step 2 Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



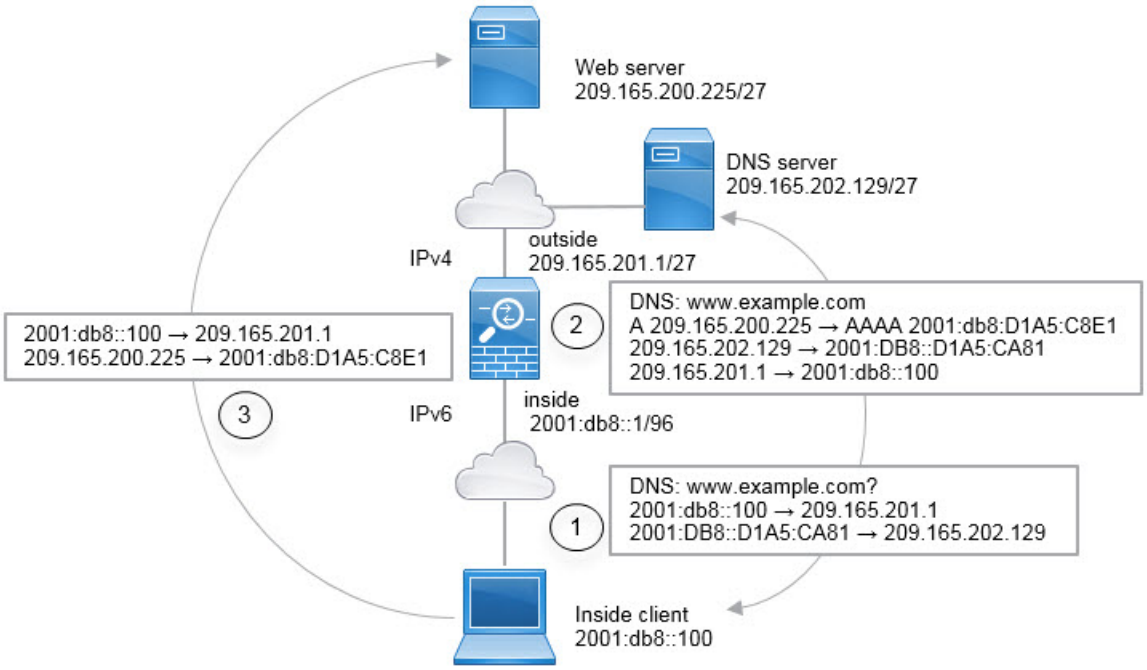
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.
- **Original Destination** = inside_v6 network object.
- **Translated Destination** = any-ipv4 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

g) Click **Save** on the NAT rules page.

NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

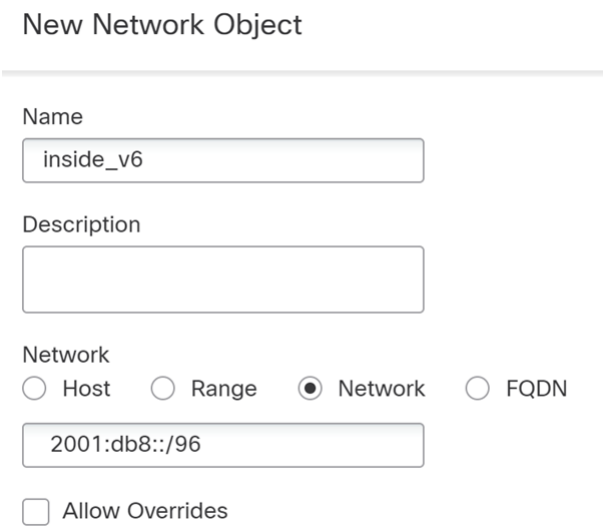
1. The client's computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
   - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
   - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)
2. The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
   - 209.165.202.129 to 2001:DB8::D1A5:CA81
   - 209.165.201.1 to 2001:db8::100
3. The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
   - 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
   - 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)

The following procedure explains how to configure this example.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

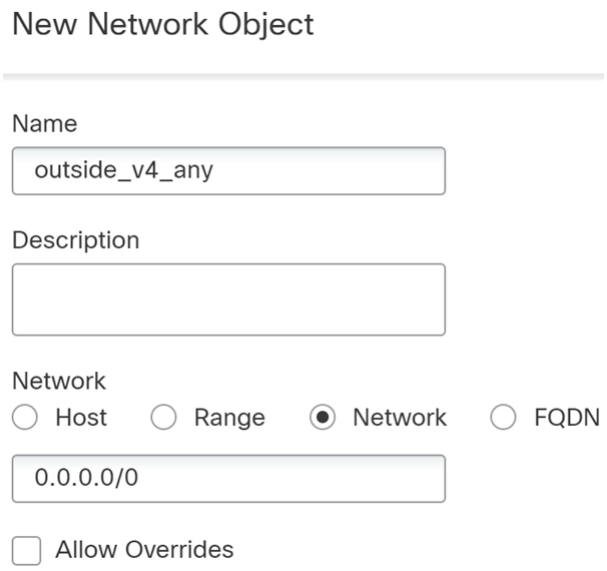


Step 1 Create the network objects that define the inside IPv6 and outside IPv4 networks.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8::/96.

d) Click **Save**.

e) Click **Add Network** > **Add Object** and define the outside IPv4 network.

Name the network object (for example, outside_v4_any) and enter the network address 0.0.0.0/0.

f) Click **Save**.

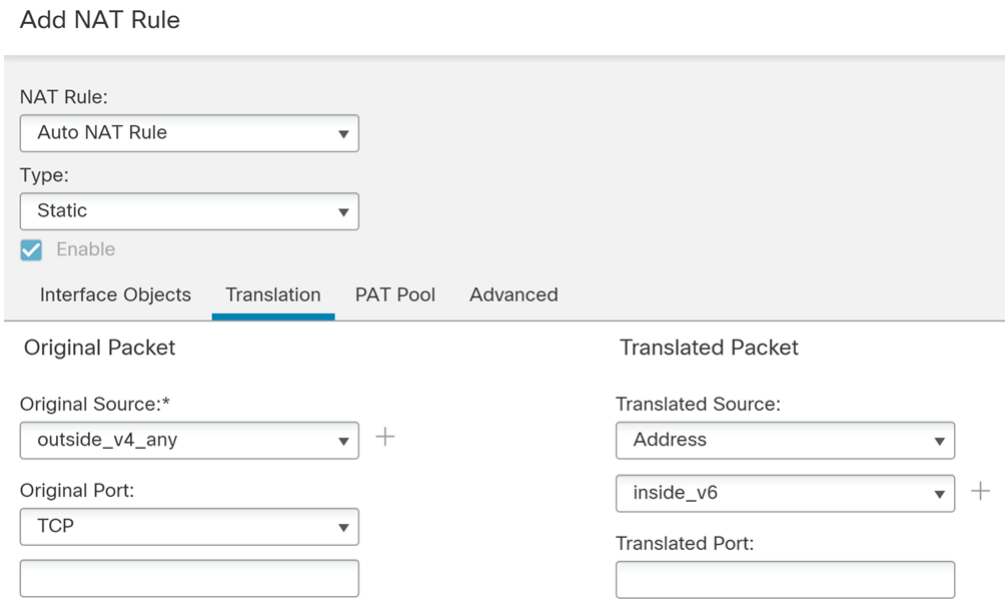
Step 2 Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

Step 3 Configure the static NAT46 rule for the outside IPv4 network.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

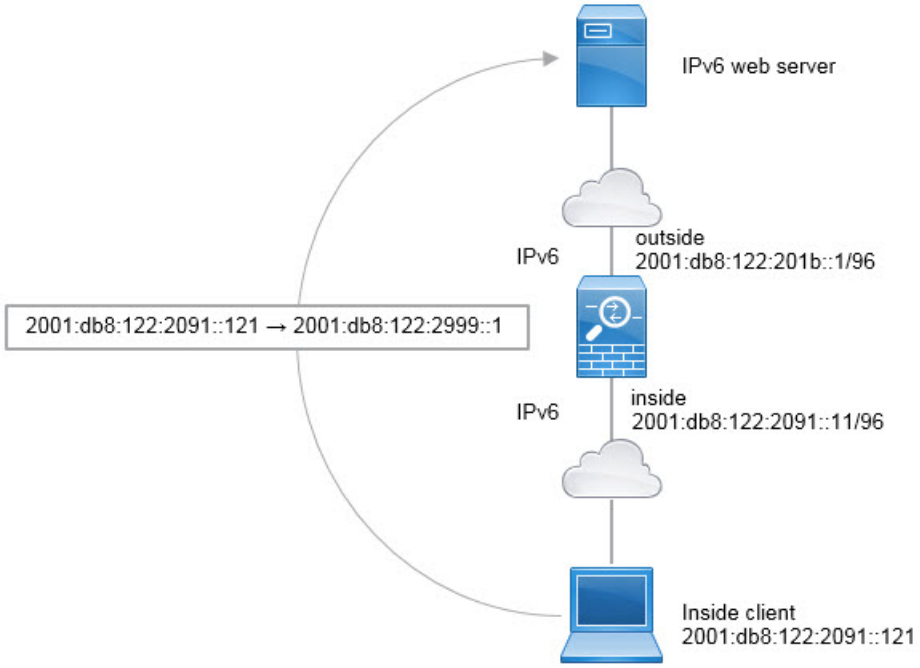
d) On **Translation**, configure the following:

- **Original Source** = outside_v4_any network object.
- **Translated Source** > **Address** = inside_v6 network object.

e) On **Advanced**, select **Translate DNS replies that match this rule**.

f) Click **OK**.

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.



NAT66: Translating IPv6 Addresses to Different IPv6 Addresses

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

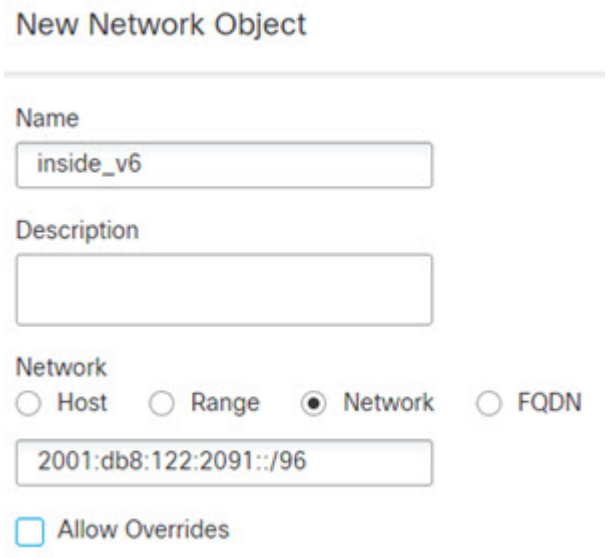
NAT66 Example, Static Translation between Networks

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

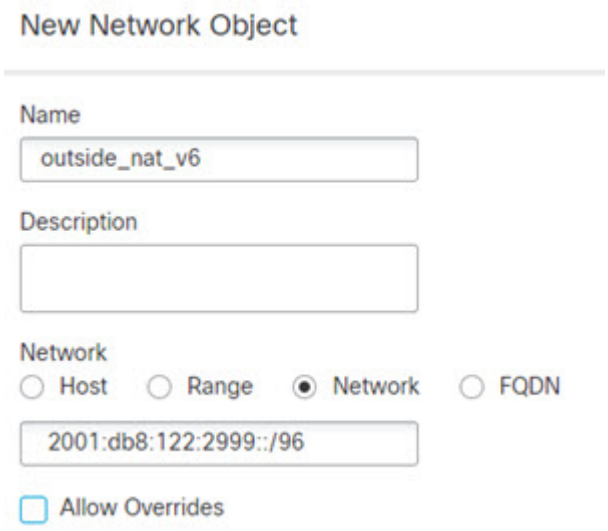


Step 1 Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the inside IPv6 network.



Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.

d) Click **Save**.

e) Click **Add Network** > **Add Object** and define the outside IPv6 NAT network.

Name the network object (for example, outside_nat_v6) and enter the network address 2001:db8:122:2999::/96.

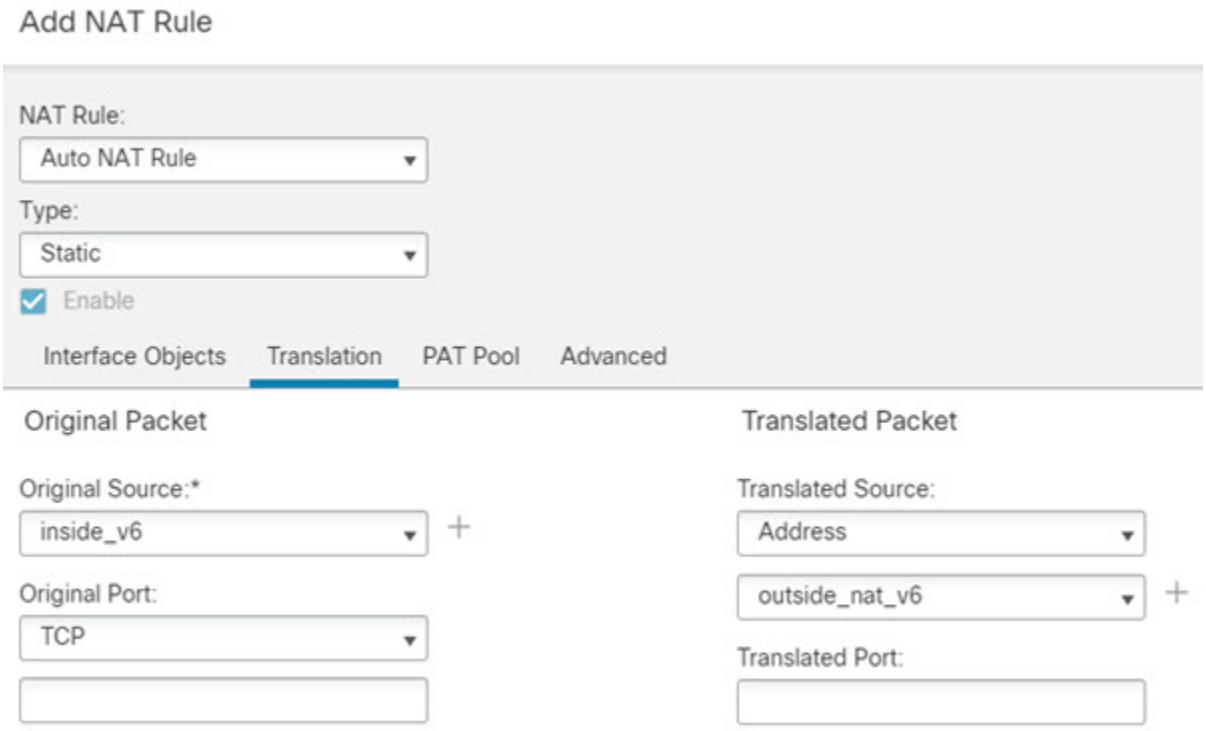
f) Click **Save**.

Step 2 Configure the static NAT rule for the inside IPv6 network.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



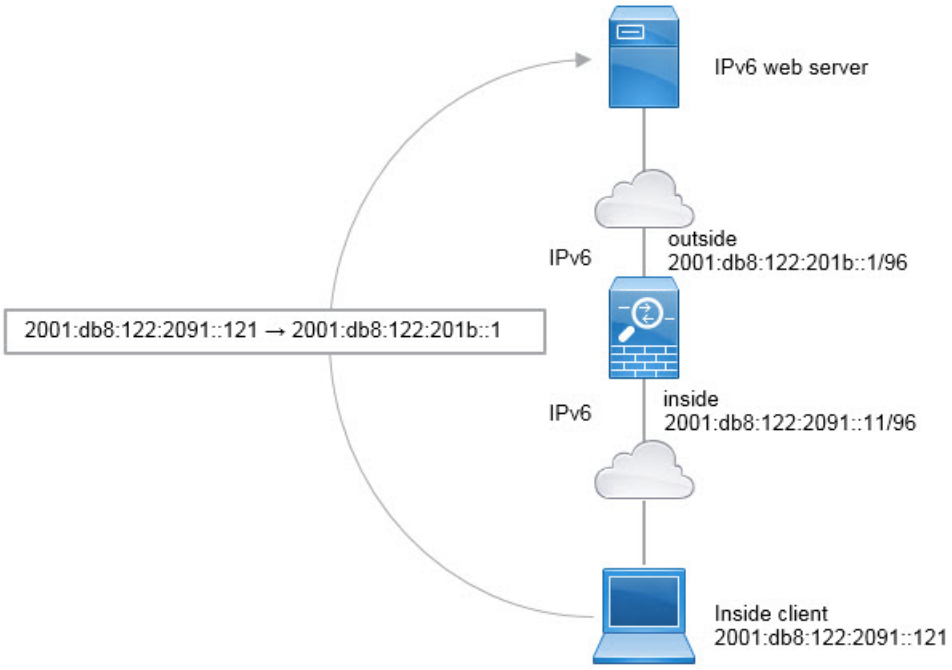
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = outside_nat_v6 network object.



f) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

NAT66 Example, Simple IPv6 Interface PAT

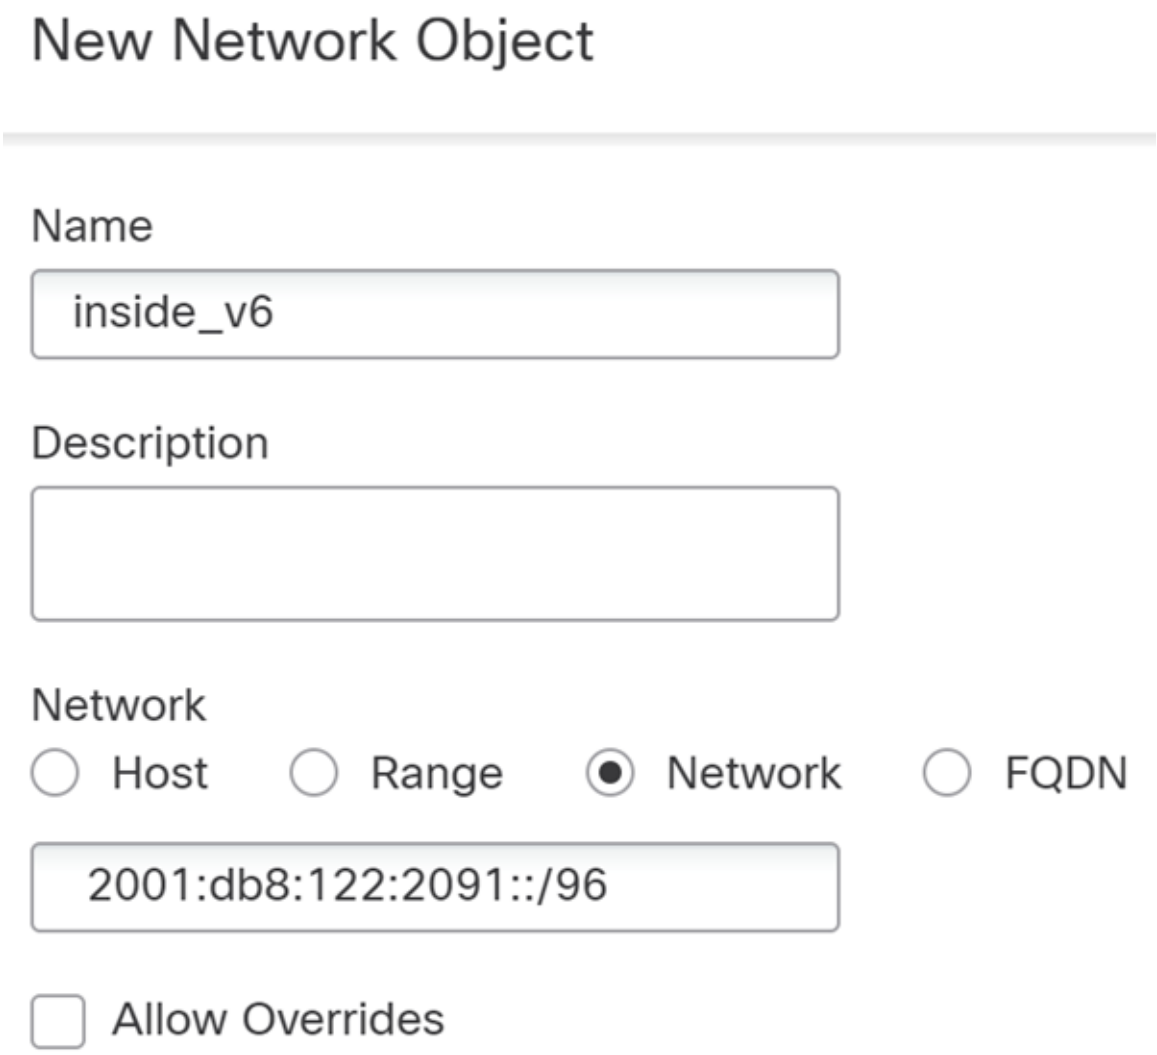
A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

When you configure an interface PAT rule for NAT66, all the global addresses that are configured on that interface are used for PAT mapping. Link-local or site-local addresses for the interface are not used for PAT.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure



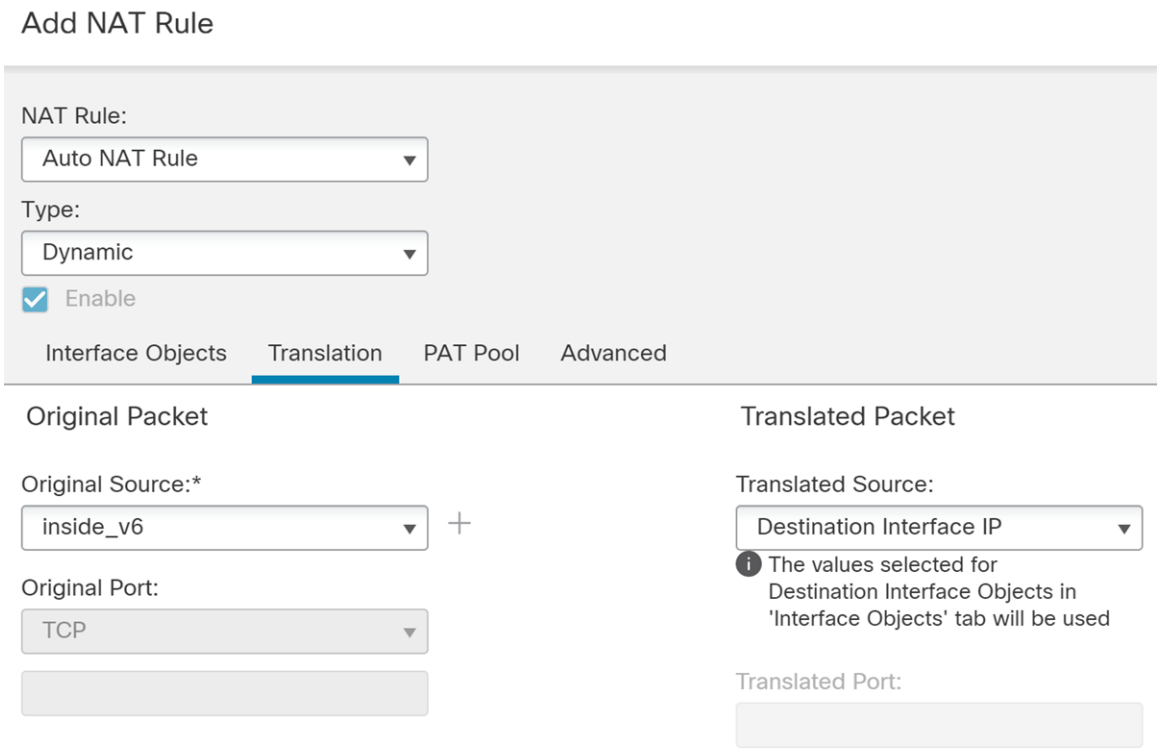
Step 1 Create the network object that defines the inside IPv6 network.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:db8:122:2091::/96.



d) Click **Save**.

Step 2 Configure the dynamic PAT rule for the inside IPv6 network.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Dynamic.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.
e) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** = **Destination Interface IP**.

f) On **Advanced**, select **IPv6**, which indicates that the IPv6 address of the destination interface should be used.

g) Click **OK**.

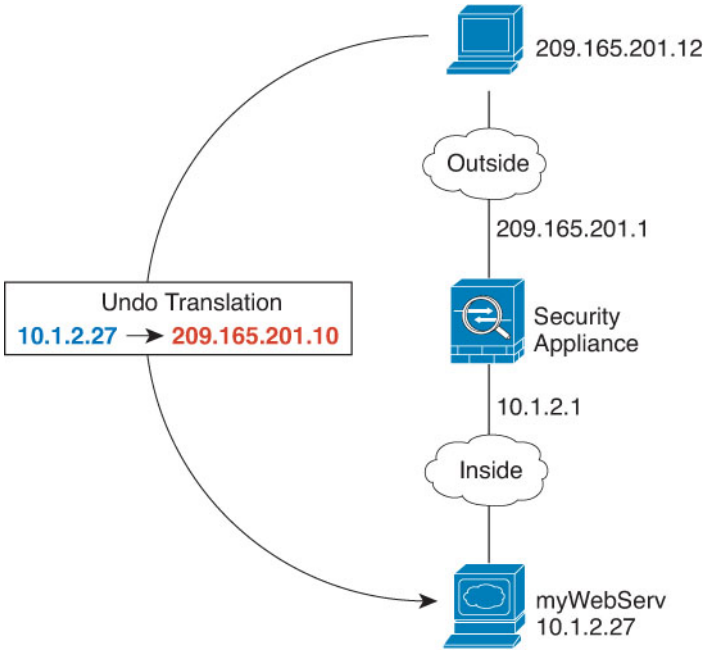
With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a NAT66 PAT translation to one of the IPv6 global addresses configured for the outside interface.

Monitoring NAT

To monitor and troubleshoot NAT connections, log into the device CLI and use the following commands.

- **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.
- **show xlate** displays the actual NAT translations that are currently active.
- **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the

connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules.



Examples for NAT

The following topics provide examples for configuring NAT on Threat Defense devices.

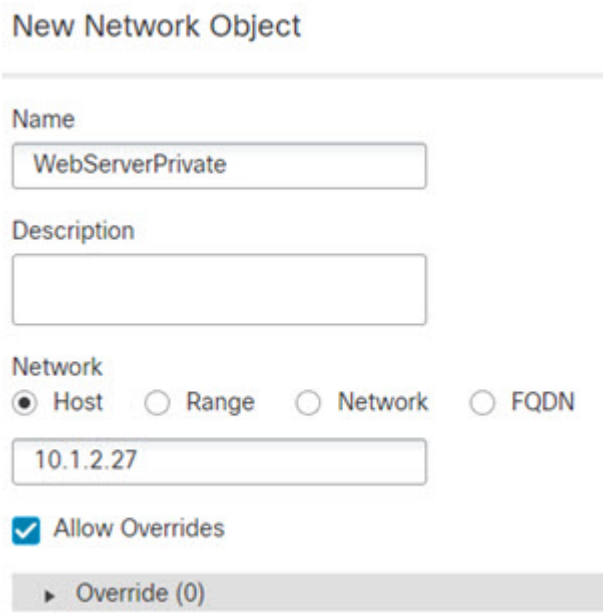
Providing Access to an Inside Web Server (Static Auto NAT)

The following example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

Figure 163: Static NAT for an Inside Web Server

Before you begin

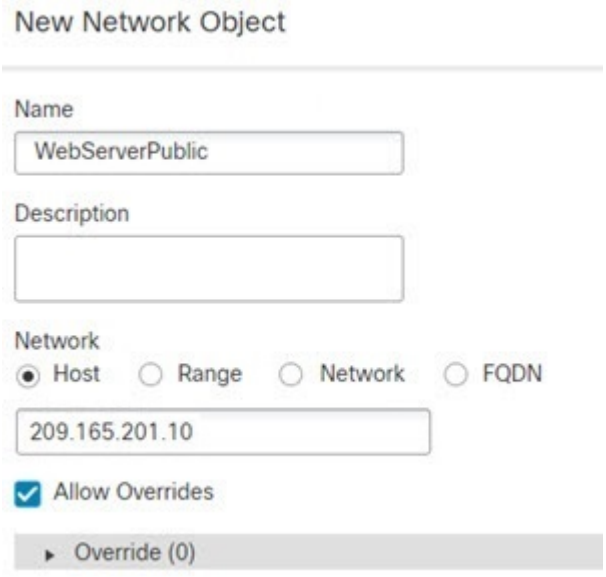
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.



Procedure

Step 1 Create the network objects that define the server's private and public host addresses.

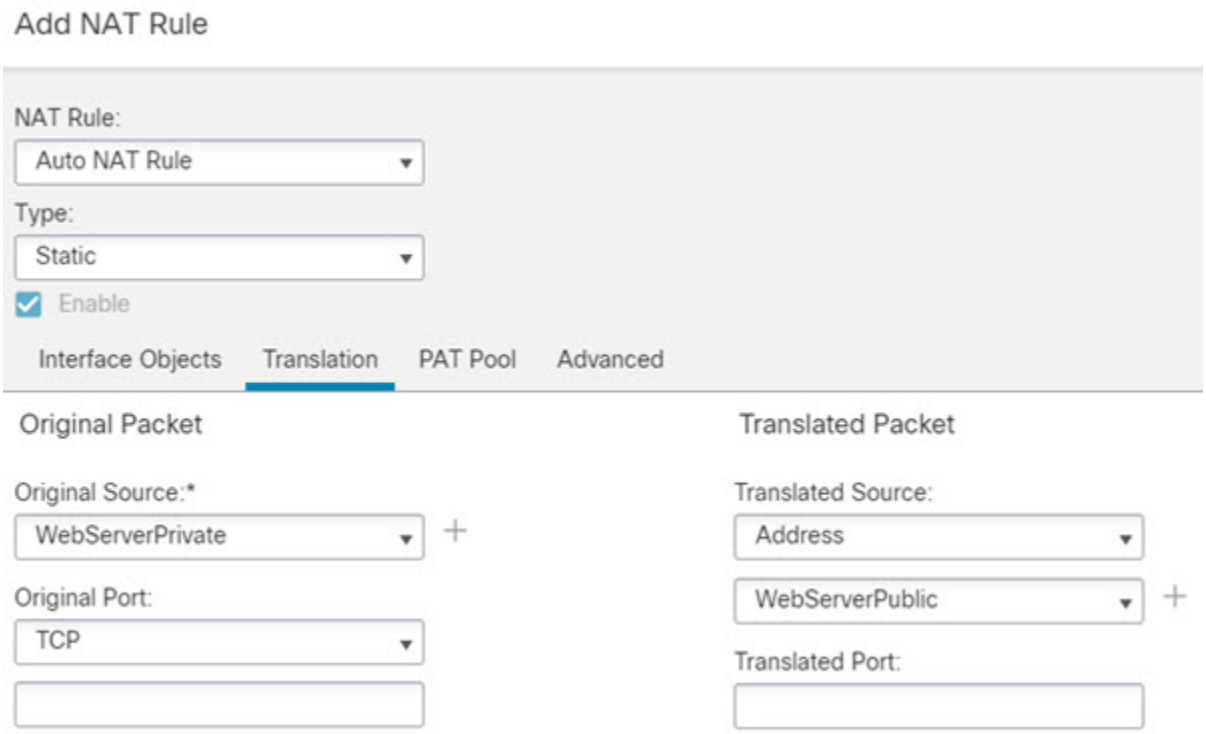
a) Choose **Objects** > **Object Management**.



b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.
c) Define the web server's private address.

Name the network object (for example, WebServerPrivate) and enter the real host IP address, 10.1.2.27.

d) Click **Save**.
e) Click **Add Network** > **Add Object** and define the public address.

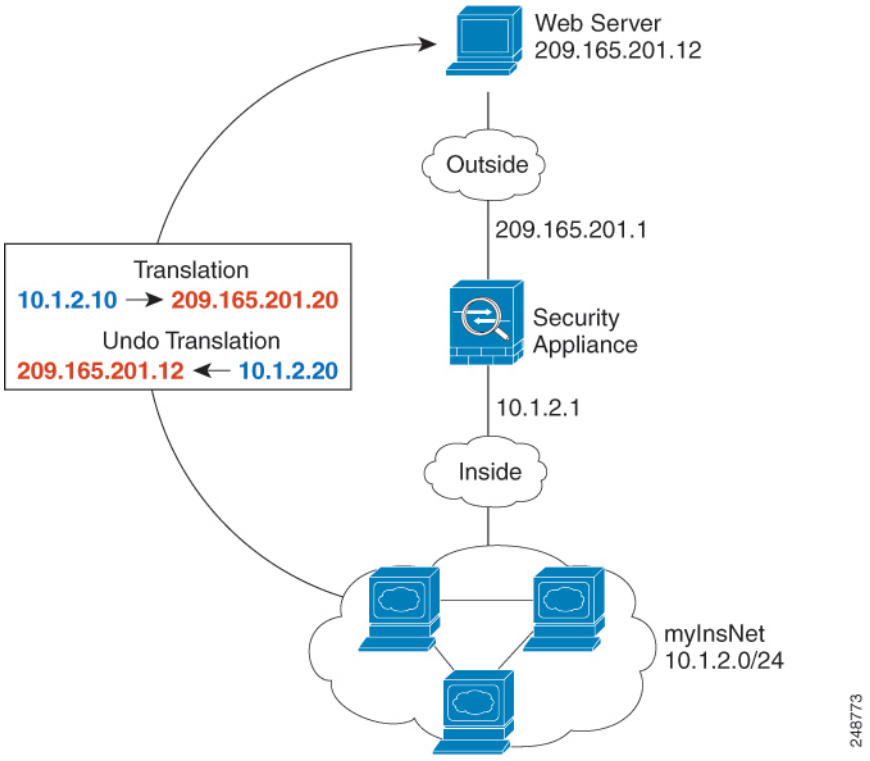


Name the network object (for example, WebServerPublic) and enter the host address 209.165.201.10.

f) Click **Save**.

Step 2 Configure static NAT for the object.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.
e) On **Translation**, configure the following:
   - **Original Source** = WebServerPrivate network object.
   - **Translated Source** > **Address**= WebServerPublic network object.



f) Click **Save**.

Step 3 Click **Save** on the NAT rule page.

Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server

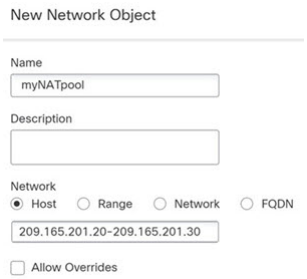
The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network.

Figure 164: Dynamic NAT for Inside, Static NAT for Outside Web Server

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure



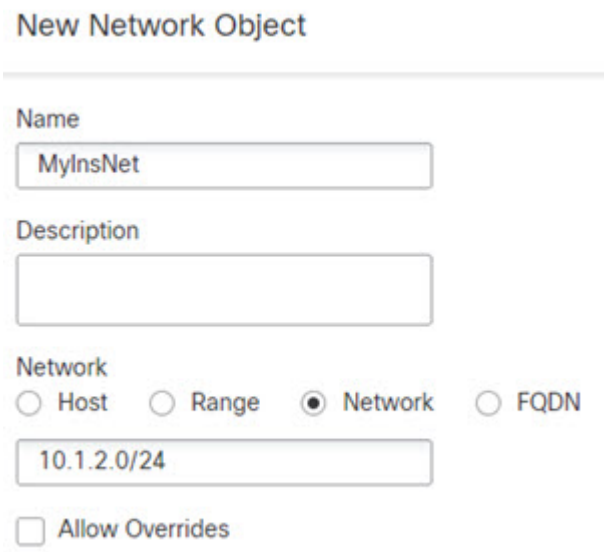
Step 1 Create a network object for the dynamic NAT pool to which you want to translate the inside addresses.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the dynamic NAT pool.

Name the network object (for example, myNATpool) and enter the network range 209.165.201.20-209.165.201.30.

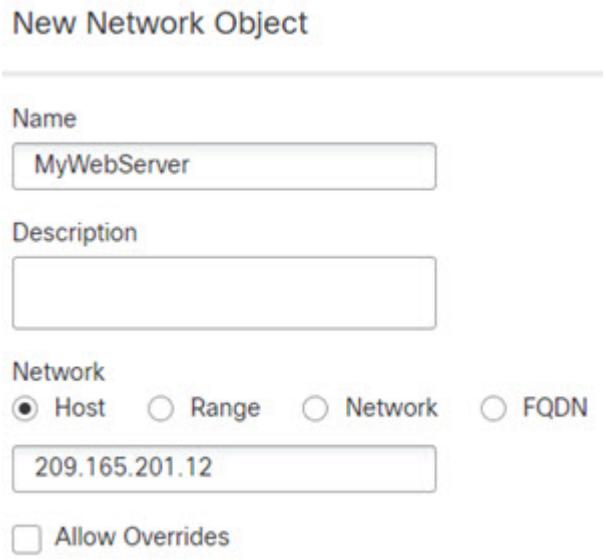


d) Click **Save**.

Step 2 Create a network object for the inside network.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyInsNet) and enter the network address 10.1.2.0/24.

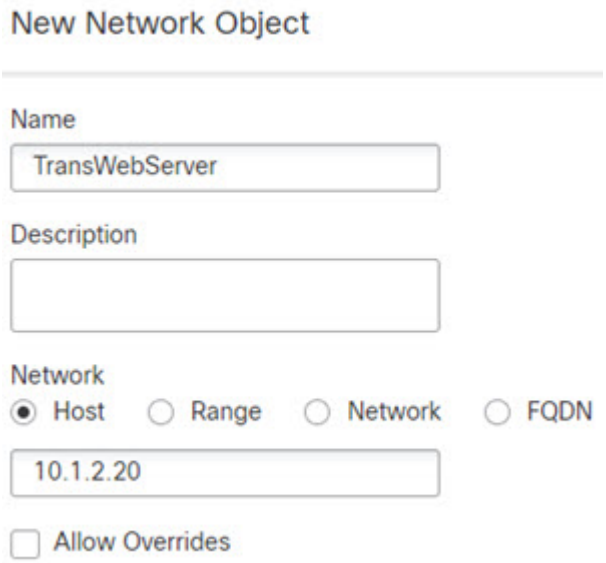


c) Click **Save**.

Step 3 Create a network object for the outside web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, MyWebServer) and enter the host address 209.165.201.12.



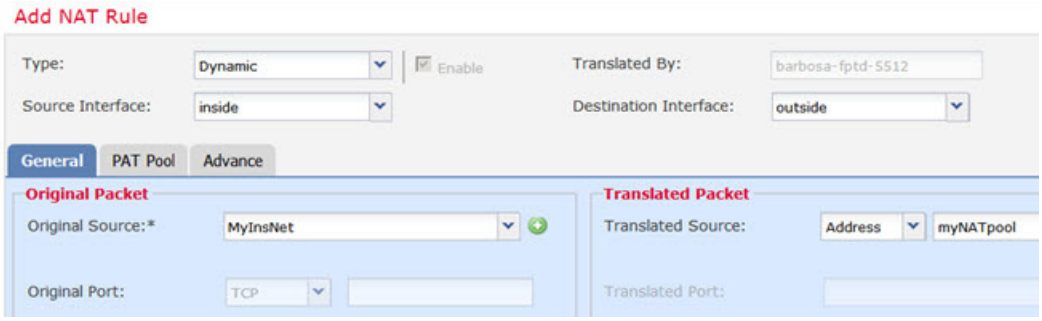
c) Click **Save**.

Step 4 Create a network object for the translated web server address.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TransWebServer) and enter the host address 10.1.2.20.

c) Click **Save**.



Step 5 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

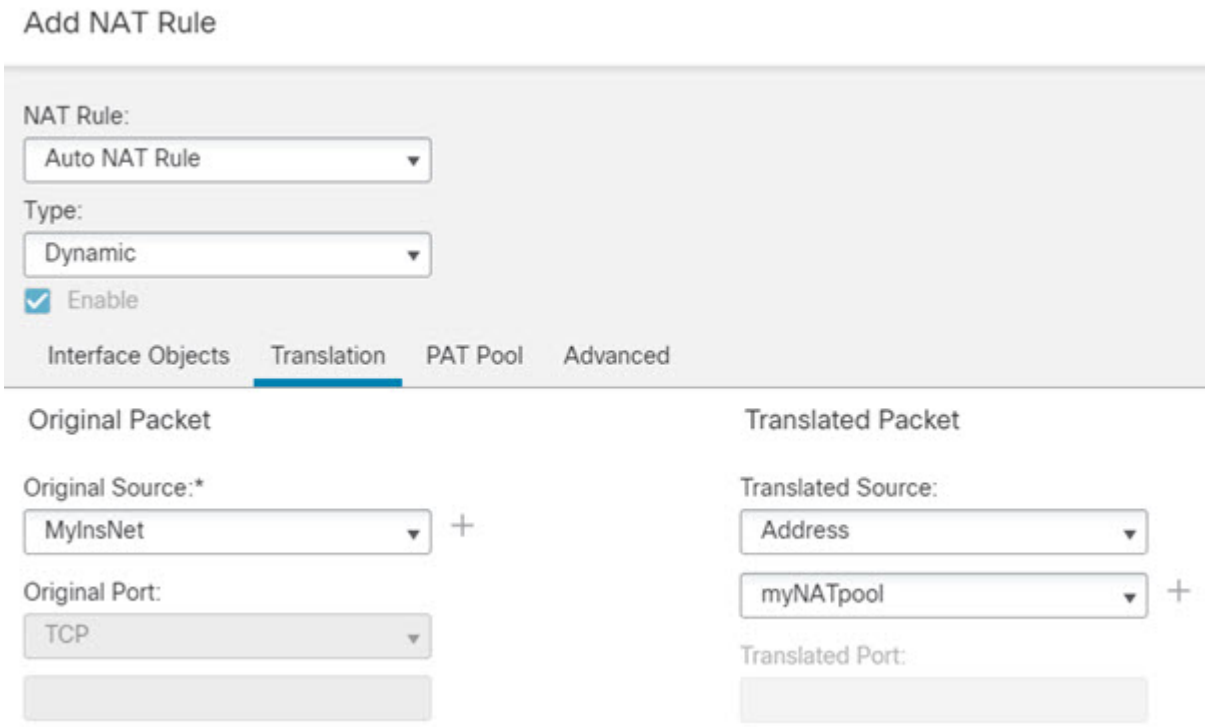
b) Click **Add NAT Rule** > **Add Auto NAT**.
c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

d) Click **Save**.

Step 6 Configure dynamic NAT for the inside network using the dynamic NAT pool object.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:



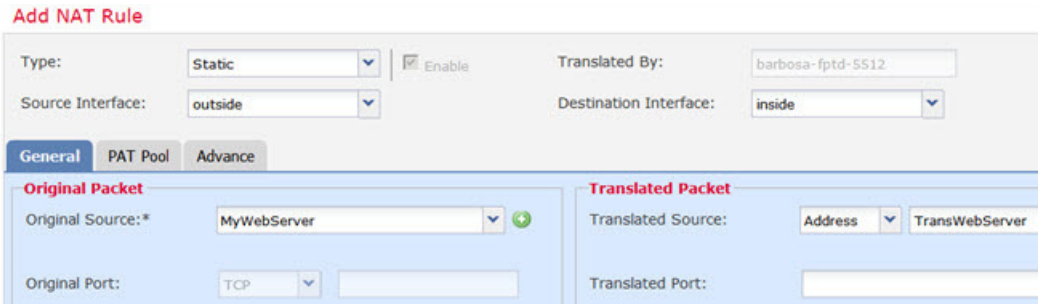
- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myInsNet network object.
- **Translated Source** > **Address**= myNATpool network group.

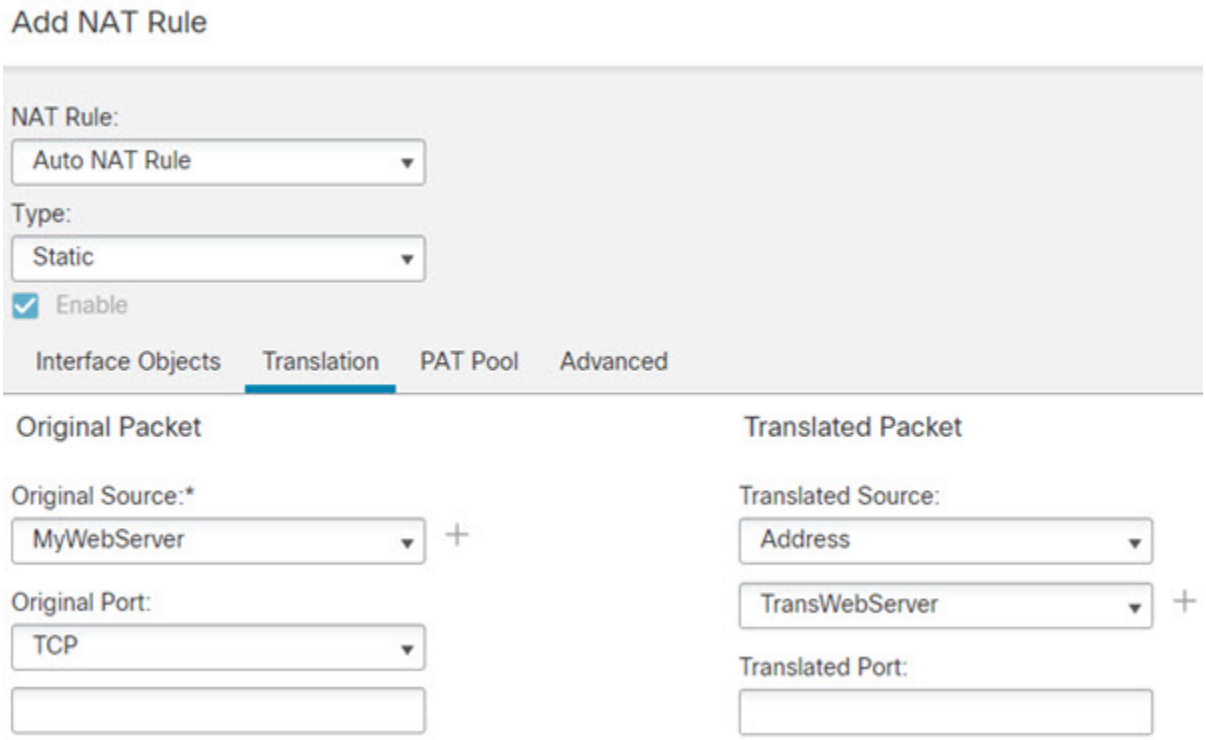


f) Click **Save**.

Step 7 Configure static NAT for the web server.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

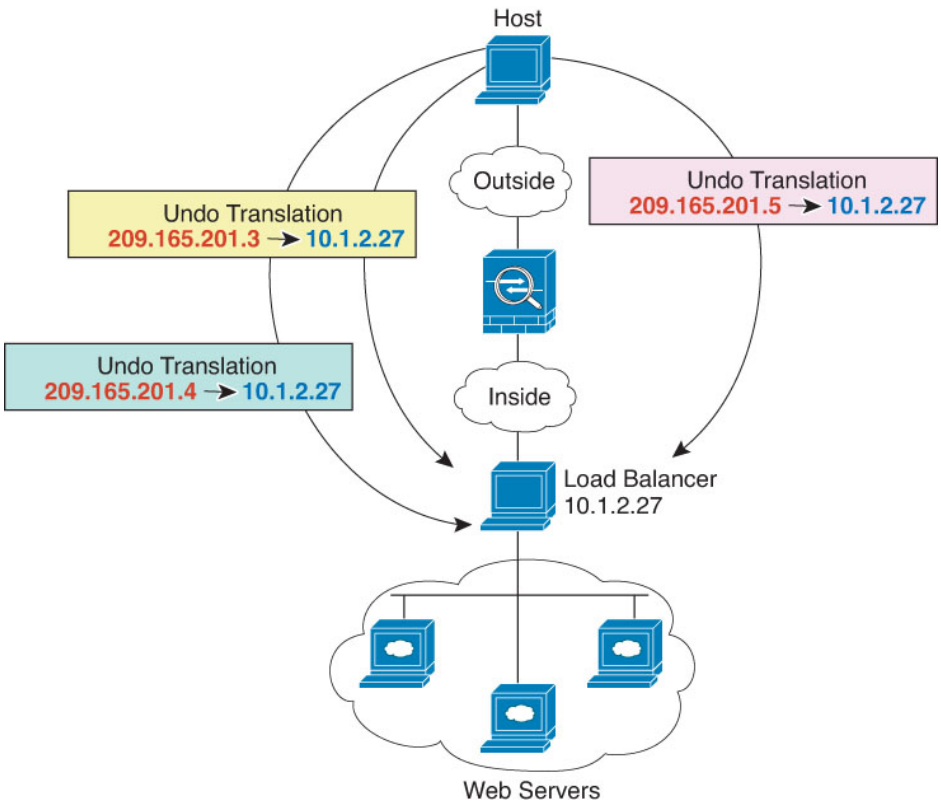


- **Type** = Static.
- **Source Interface** = outside.
- **Destination Interface** = inside.
- **Original Source** = myWebServer network object.
- **Translated Source** > **Address**= TransWebServer network object.

c) Click **Save**.

Step 8 Configure static NAT for the web server.

a) Click **Add Rule**.
b) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.
c) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = outside.
   - **Destination Interface Objects** = inside.
d) On **Translation**, configure the following:
   - **Original Source** = myWebServer network object.
   - **Translated Source** > **Address**= TransWebServer network object.



e) Click **Save**.

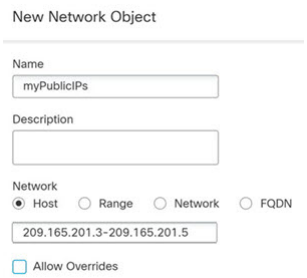
Step 9 Click **Save** on the NAT rule page.

Inside Load Balancer with Multiple Mapped Addresses (Static Auto NAT, One-to-Many)

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 165: Static NAT with One-to-Many for an Inside Load Balancer

Before you begin



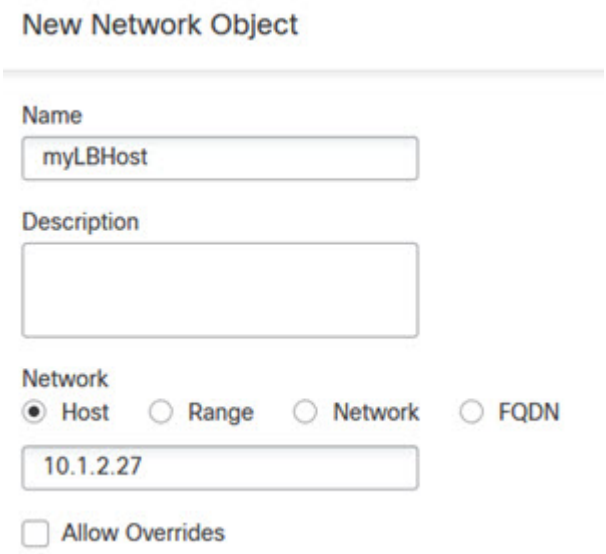
Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

Step 1 Create a network object for the addresses to which you want to map the load balancer.

a) Choose **Objects** > **Object Management**.
b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.
c) Define the addresses.

Name the network object (for example, myPublicIPs) and enter the network range 209.165.201.3-209.165.201.5.



d) Click **Save**.

Step 2 Create a network object for the load balancer.

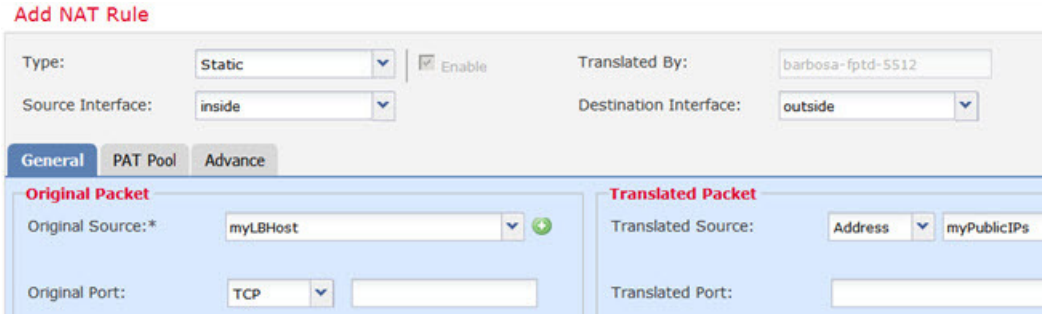
a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, myLBHost), enter the host address 10.1.2.27.

c) Click **Save**.

Step 3 Configure static NAT for the load balancer.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

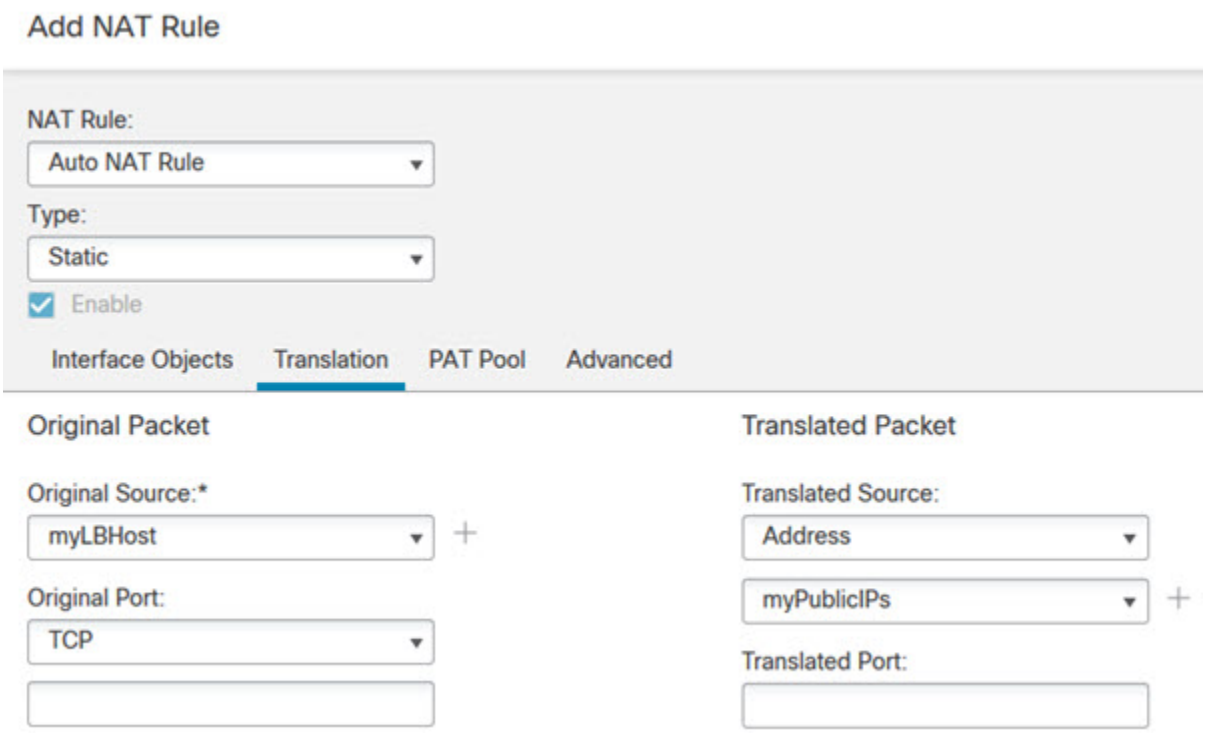


Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

b) Click **Add NAT Rule** > **Add Auto NAT**.

c) Configure the following properties:

- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.

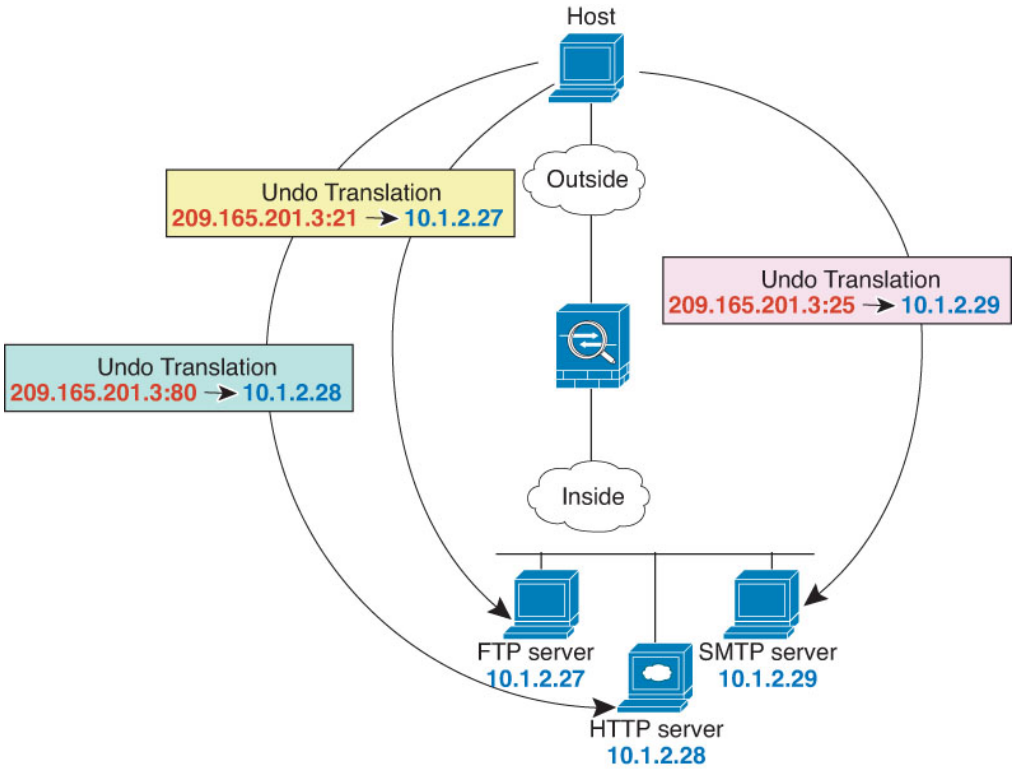


- **Original Source** = myLBHost network object.
- **Translated Source** > **Address**= myPublicIPs network group.

d) Click **Save**.

Step 4 Configure static NAT for the load balancer.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Auto NAT Rule.
   - **Type** = Static.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = outside.
e) On **Translation**, configure the following:
   - **Original Source** = myLBHost network object.
   - **Translated Source** > **Address**= myPublicIPs network group.



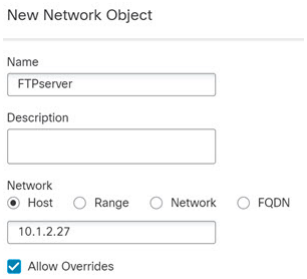
f) Click **Save**.

Step 5 Click **Save** on the NAT rule page.

Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.

Figure 166: Static NAT-with-Port-Translation



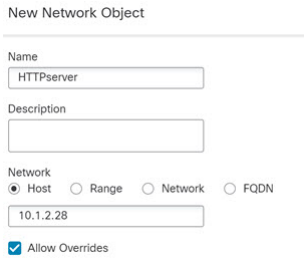
Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

Step 1 Create a network object for the FTP server.

a) Choose **Objects** > **Object Management**.
b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.
c) Name the network object (for example, FTPserver), and enter the real IP address for the FTP server, 10.1.2.27.

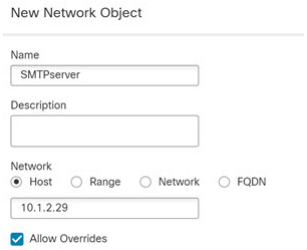


d) Click **Save**.

Step 2 Create a network object for the HTTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, HTTPserver), enter the host address 10.1.2.28.

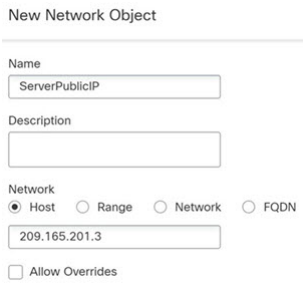


c) Click **Save**.

Step 3 Create a network object for the SMTP server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, SMTPserver), enter the host address 10.1.2.29.



c) Click **Save**.

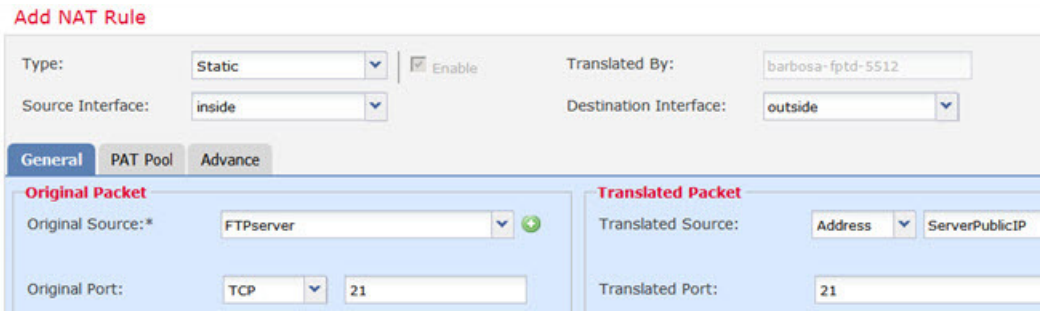
Step 4 Create a network object for the public IP address used for the three servers.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, ServerPublicIP) and enter the host address 209.165.201.3.

c) Click **Save**.

Step 5 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.



a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.

Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

b) Click **Add NAT Rule** > **Add Auto NAT**.

c) Configure the following properties:

- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.

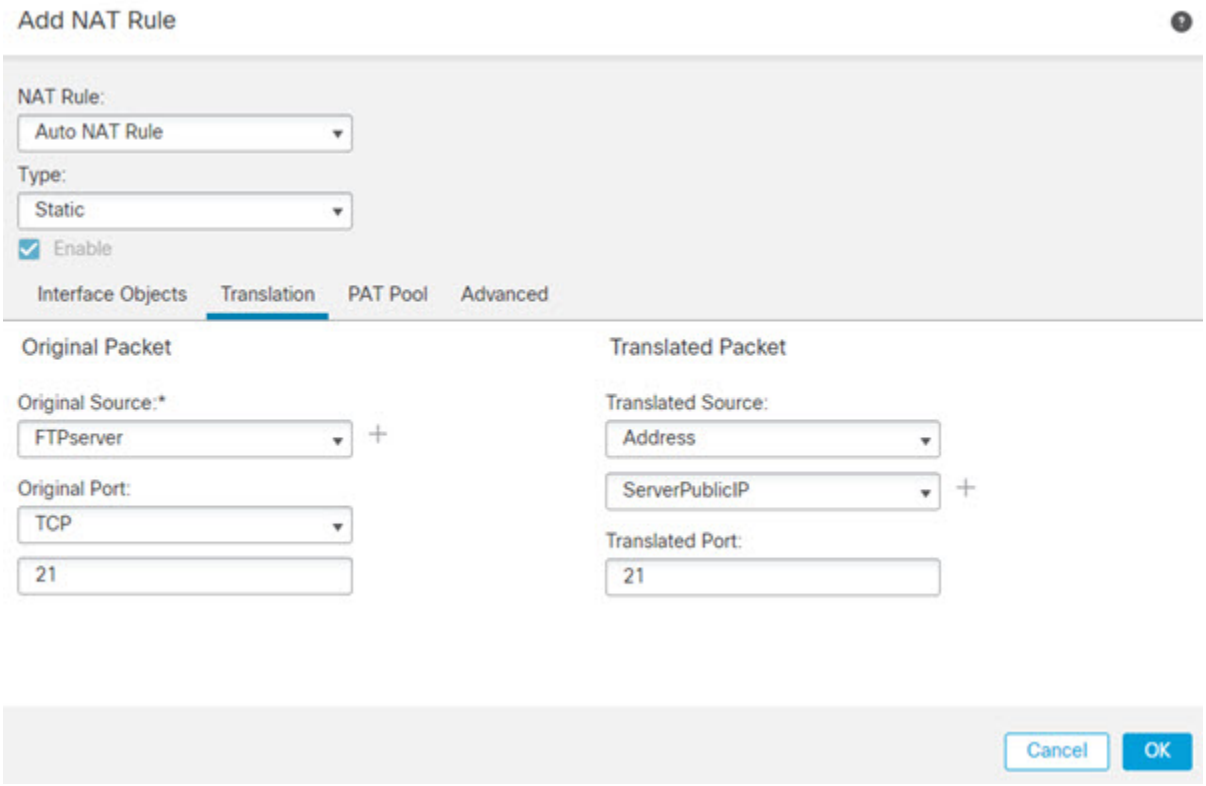
d) Click **Save**.

Step 6 Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

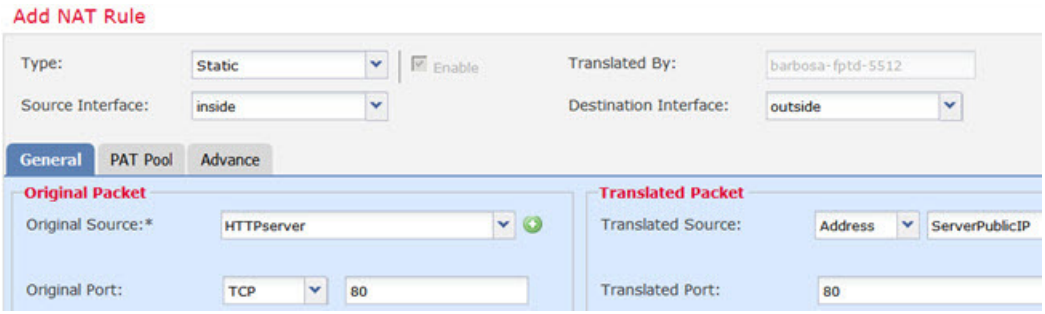
d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = FTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 21.
- **Translated Port** = 21.

f) Click **Save**.



Step 7 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = HTTPserver network object.

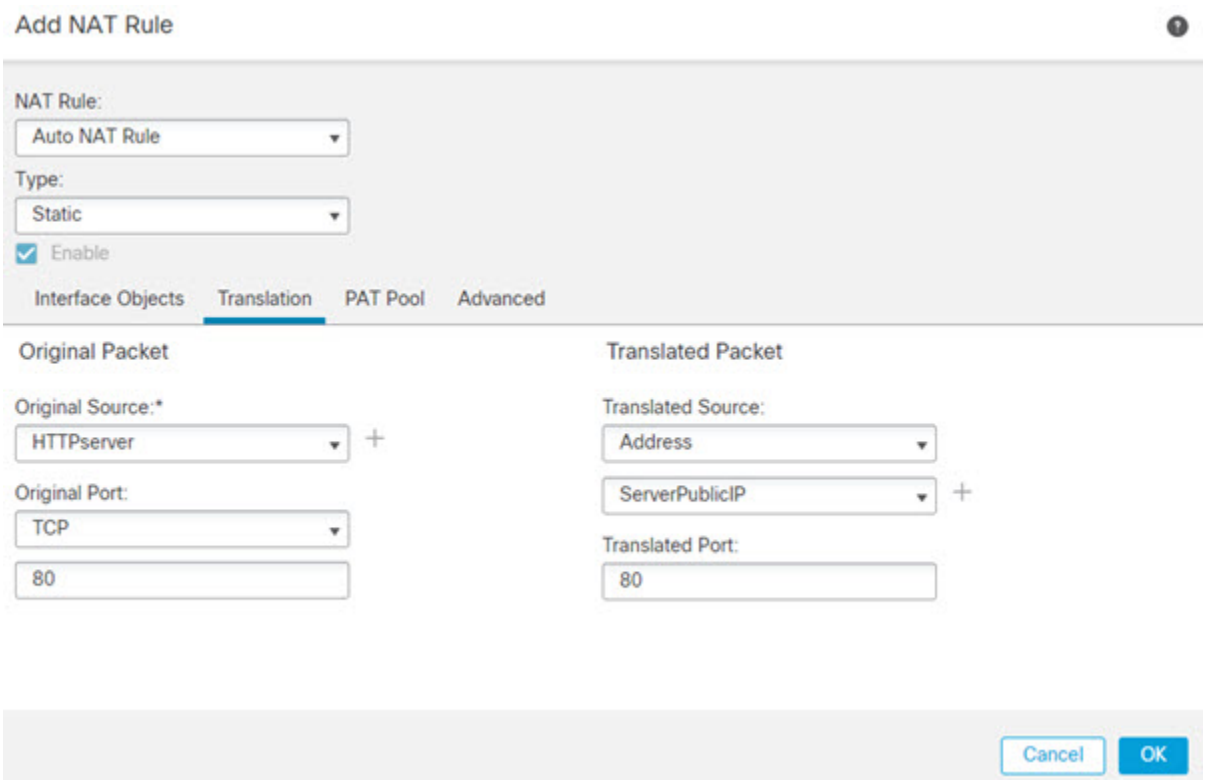
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.

c) Click **Save**.

Step 8 Configure static NAT with port translation for the HTTP server, mapping the HTTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



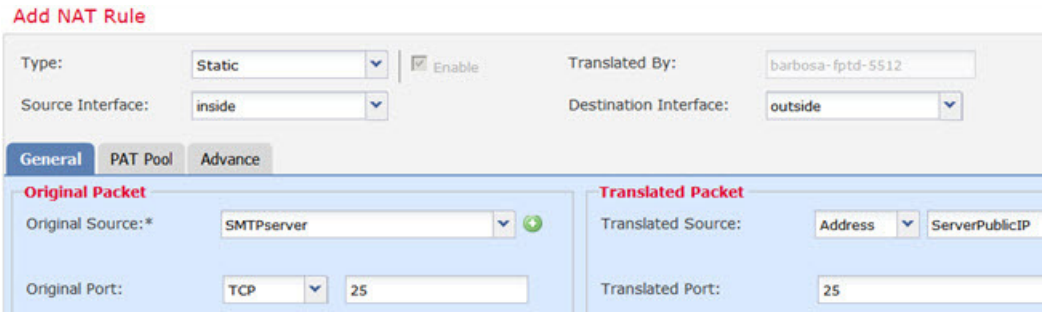
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = HTTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 80.
- **Translated Port** = 80.



e) Click **Save**.

Step 9 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add NAT Rule** > **Add Auto NAT**.

b) Configure the following properties:

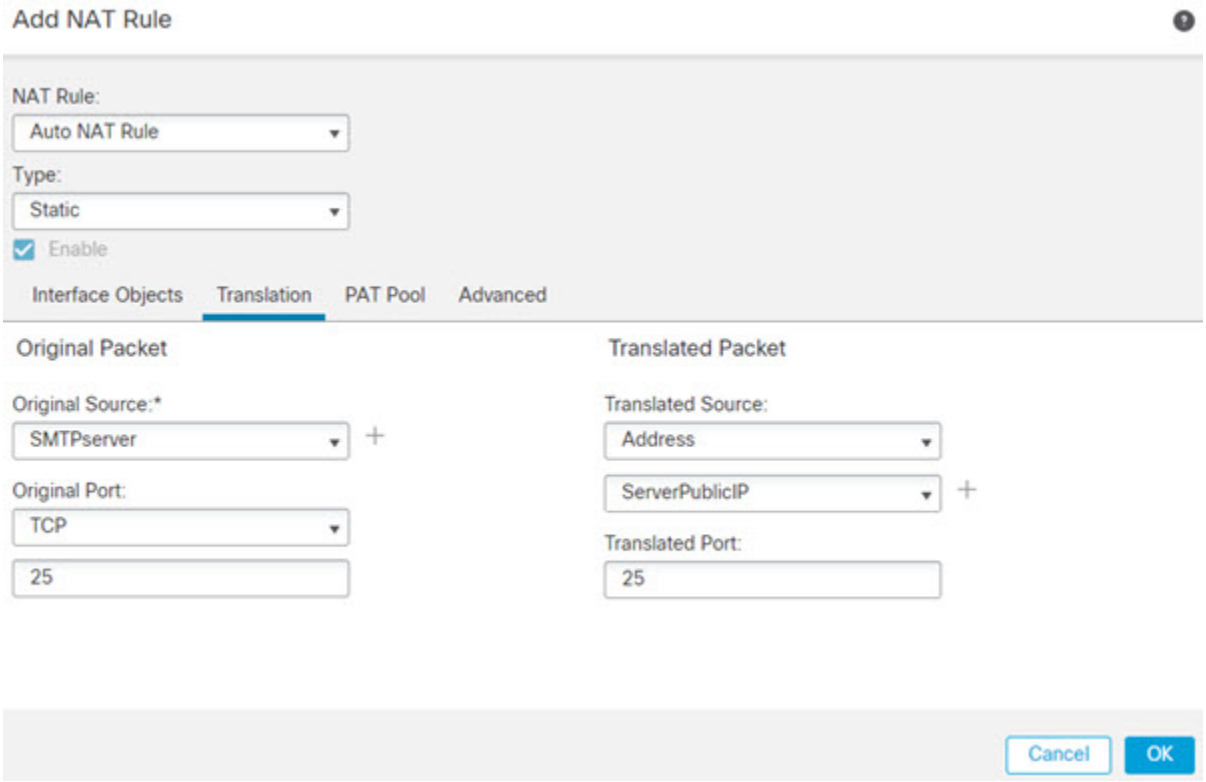
- **Type** = Static.
- **Source Interface** = inside.
- **Destination Interface** = outside.
- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.

c) Click **Save**.

Step 10 Configure static NAT with port translation for the SMTP server, mapping the SMTP port to itself.

a) Click **Add Rule**.

b) Configure the following properties:



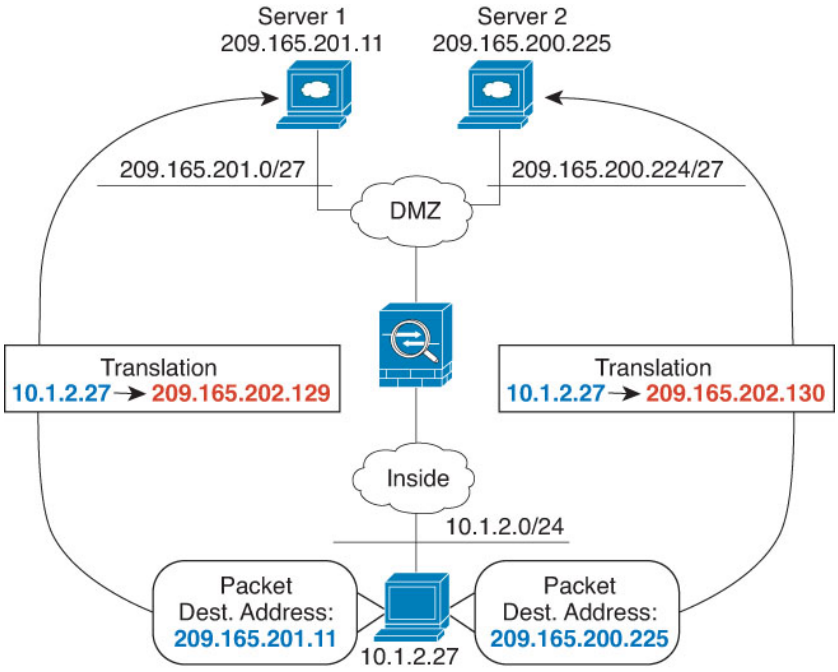
- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

d) On **Translation**, configure the following:

- **Original Source** = SMTPserver network object.
- **Translated Source** > **Address**= ServerPublicIP network object.
- **Original Port** > **TCP** = 25.
- **Translated Port** = 25.



e) Click **Save**.

Step 11 Click **Save** on the NAT rule page.

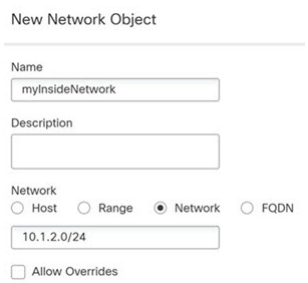
Different Translation Depending on the Destination (Dynamic Manual PAT)

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:*port*. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:*port*.

Figure 167: Manual NAT with Different Destination Addresses

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.



Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Name the network object (for example, myInsideNetwork), and enter the real network address, 10.1.2.0/24.

d) Click **Save**.

Step 2 Create a network object for the DMZ network 1.

a) Click **Add Network** > **Add Object**.
b) Name the network object (for example, DMZnetwork1) and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

c) Click **Save**.

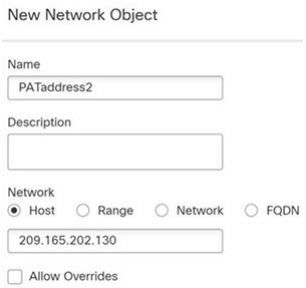
Step 3 Create a network object for the PAT address for DMZ network 1.

a) Click **Add Network** > **Add Object**.
b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.

c) Click **Save**.

Step 4 Create a network object for the DMZ network 2.

a) Click **Add Network** > **Add Object**.
b) Name the network object (for example, DMZnetwork2) and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).



c) Click **Save**.

Step 5 Create a network object for the PAT address for DMZ network 2.

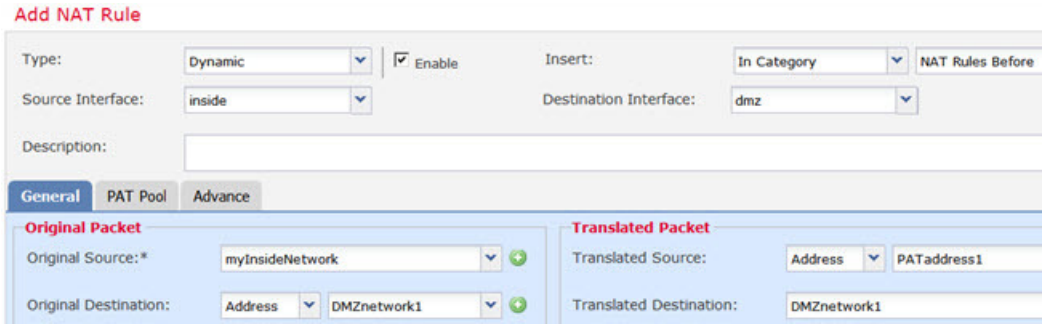
a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

Step 6 Configure dynamic manual PAT for DMZ network 1.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.



Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

b) Click **Add NAT Rule** > **Add Manual NAT**.

c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

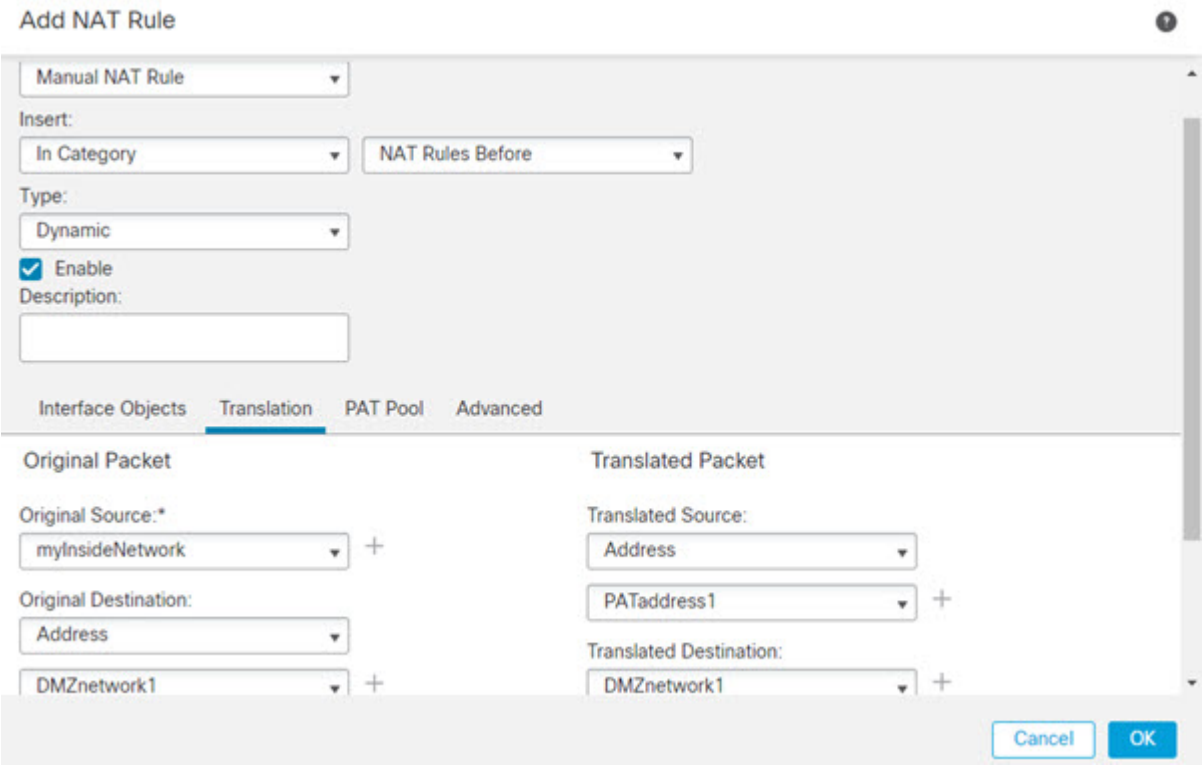
Note
Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.

d) Click **Save**.

Step 7 Configure dynamic manual PAT for DMZ network 1.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.



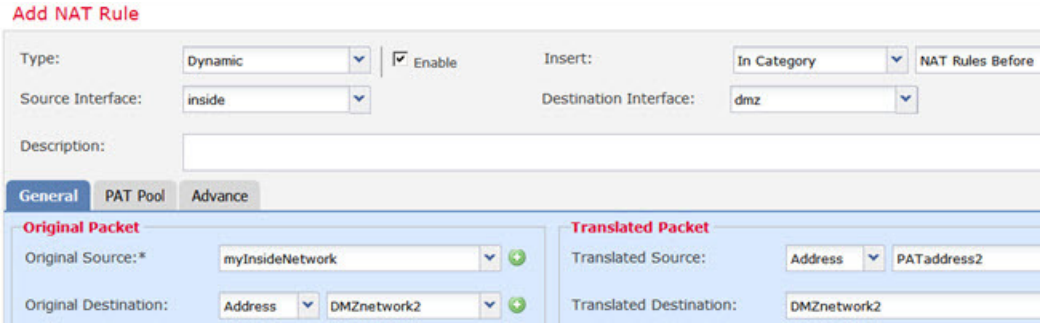
d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

Note
Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.



f) Click **Save**.

Step 8 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add NAT Rule** > **Add Manual NAT**.

b) Configure the following properties:

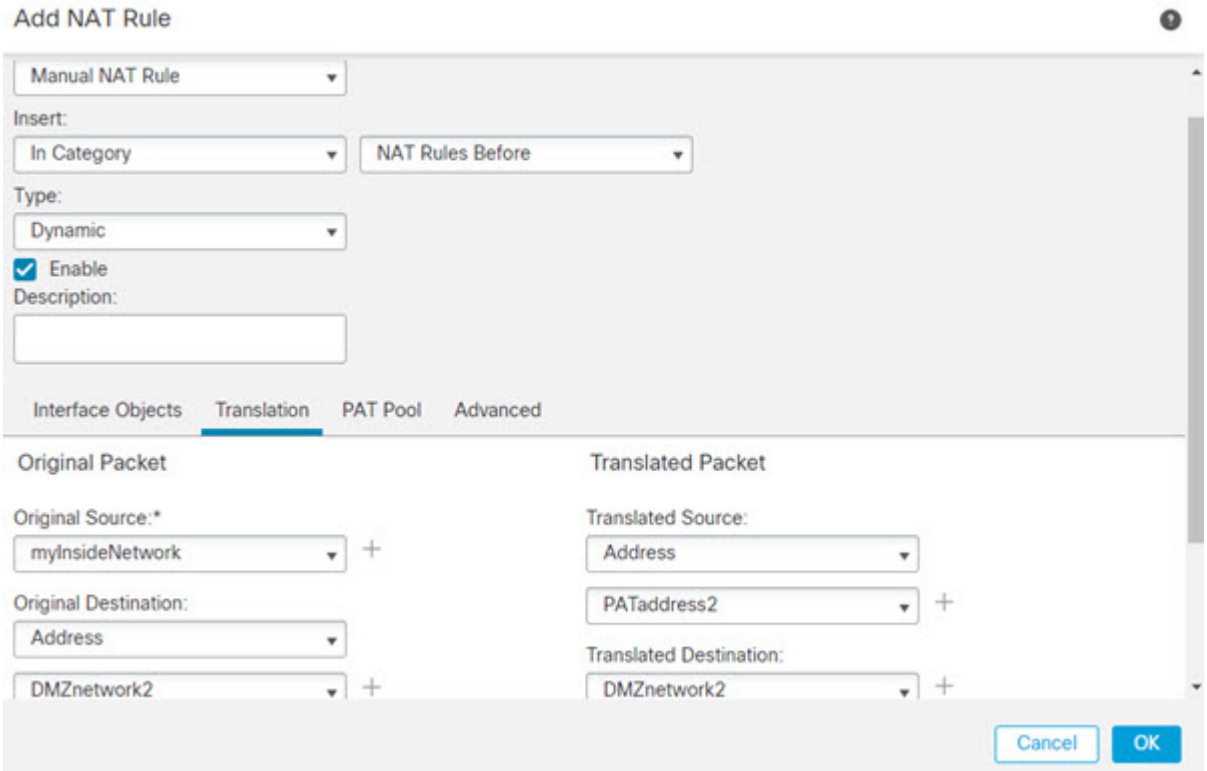
- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.

c) Click **Save**.

Step 9 Configure dynamic manual PAT for DMZ network 2.

a) Click **Add Rule**.

b) Configure the following properties:



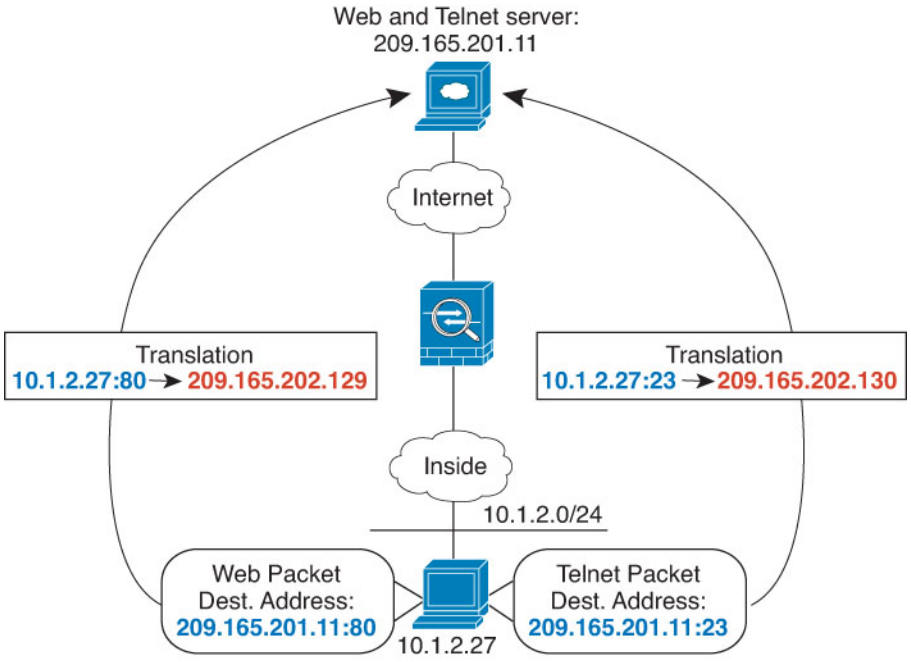
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = DMZnetwork2 network object.
- **Translated Destination** = DMZnetwork2 network object.



e) Click **Save**.

Step 10 Click **Save** on the NAT rule page.

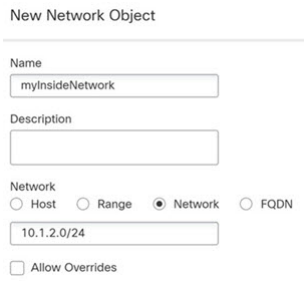
Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT)

The following figure shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129:*port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130:*port*.

Figure 168: Manual NAT with Different Destination Ports

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.



Procedure

Step 1 Create a network object for the inside network.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Name the network object (for example, myInsideNetwork) and enter the real network address, 10.1.2.0/24.

d) Click **Save**.

Step 2 Create a network object for the Telnet/Web server.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, TelnetWebServer) and enter the host address 209.165.201.11.

c) Click **Save**.

Step 3 Create a network object for the PAT address when using Telnet.

a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress1) and enter the host address 209.165.202.129.

c) Click **Save**.

Step 4 Create a network object for the PAT address when using HTTP.

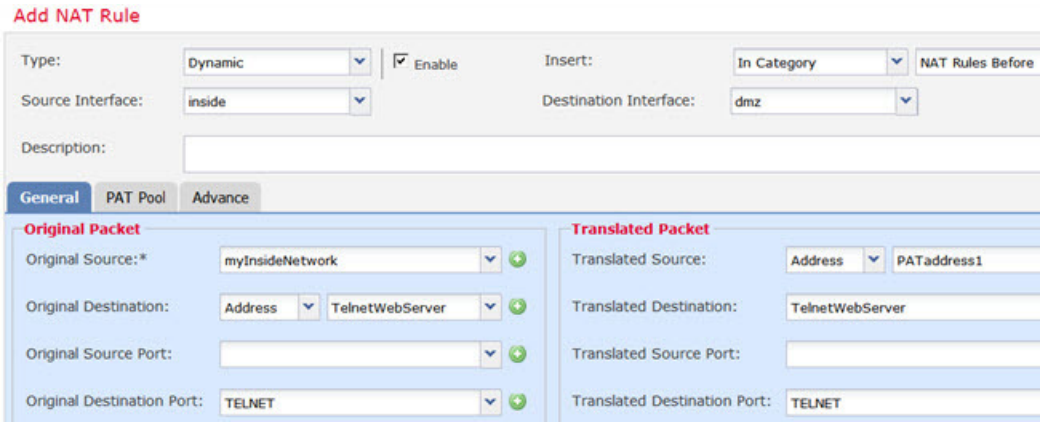
a) Click **Add Network** > **Add Object**.

b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

c) Click **Save**.

Step 5 Configure dynamic manual PAT for Telnet access.

a) Select **Devices** > **Device Management** and edit the Threat Defense device on which you are defining the rule. Select **NAT**.



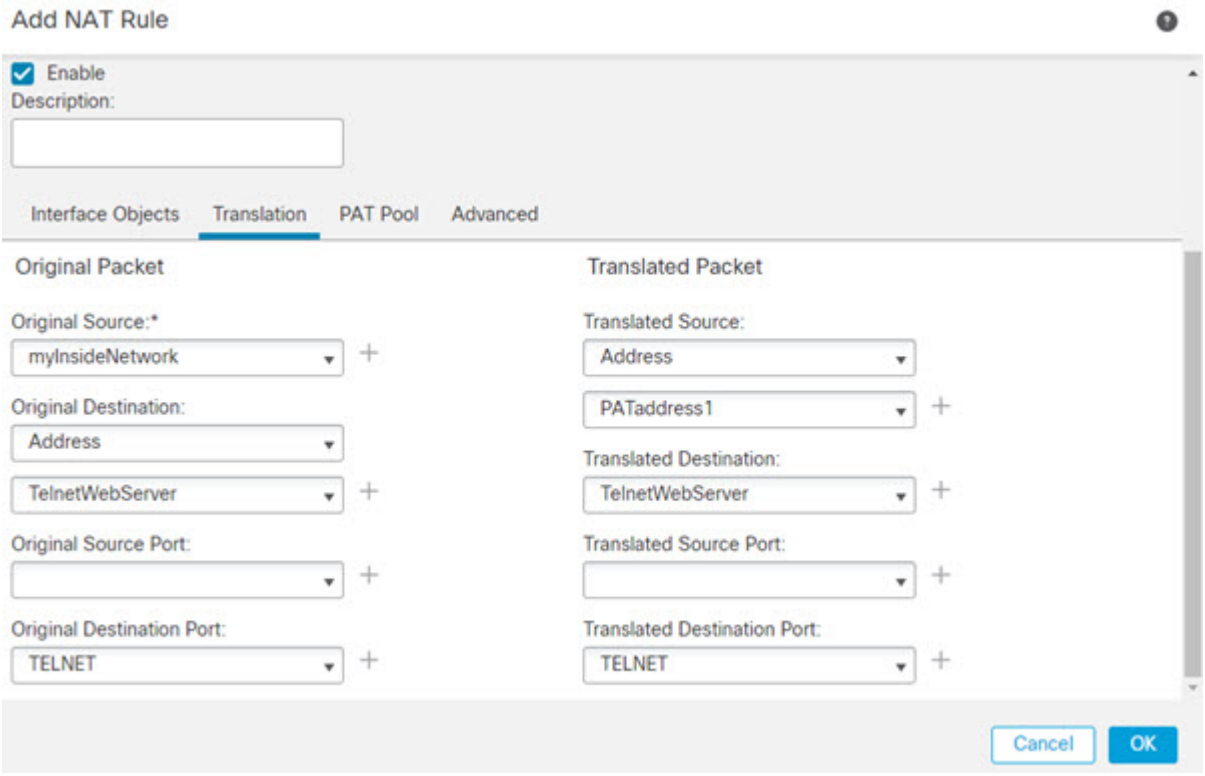
Ensure that you are currently in the same leaf domain that includes the device, if you are using domains.

b) Click **Add NAT Rule** > **Add Manual NAT**.

c) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

Note
Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.



d) Click **Save**.

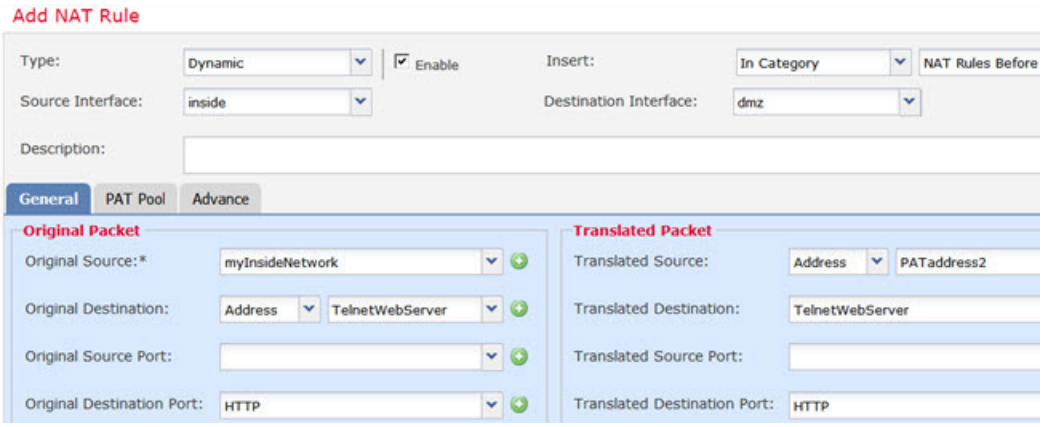
Step 6 Configure dynamic manual PAT for Telnet access.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.
b) Click **Add Rule**.
c) Configure the following properties:
   - **NAT Rule** = Manual NAT Rule.
   - **Type** = Dynamic.
d) On **Interface Objects**, configure the following:
   - **Source Interface Objects** = inside.
   - **Destination Interface Objects** = dmz.
e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress1 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = TELNET port object (system-defined).
- **Translated Destination Port** = TELNET port object (system-defined).

Note
Because you do not want to translate the destination address or port, you need to configure identity NAT for them by specifying the same address for the original and translated destination addresses, and the same port for the original and translated port.

f) Click **Save**.



Step 7 Configure dynamic manual PAT for web access.

a) Click **Add NAT Rule** > **Add Manual NAT**.

b) Configure the following properties:

- **Type** = Dynamic.
- **Source Interface** = inside.
- **Destination Interface** = dmz.
- **Original Source** = myInsideNetwork network object.

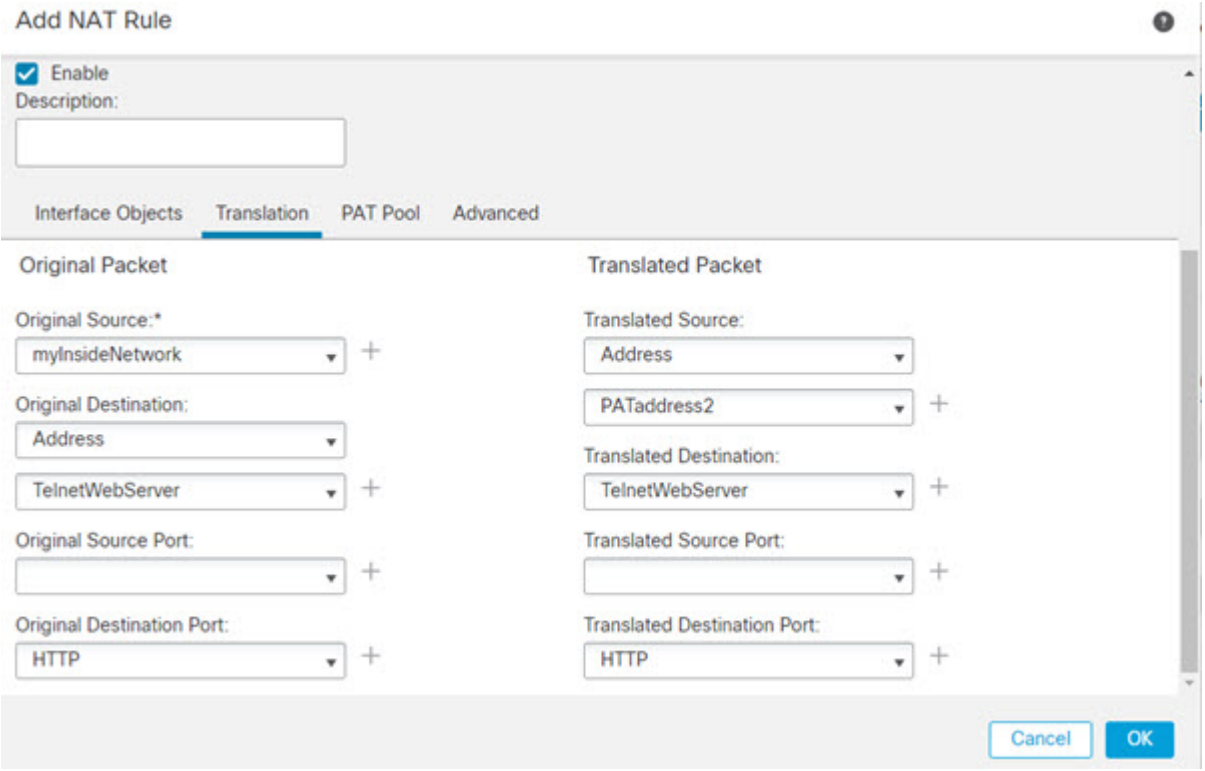
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).

c) Click **Save**.

Step 8 Configure dynamic manual PAT for web access.

a) Click **Add Rule**.

b) Configure the following properties:



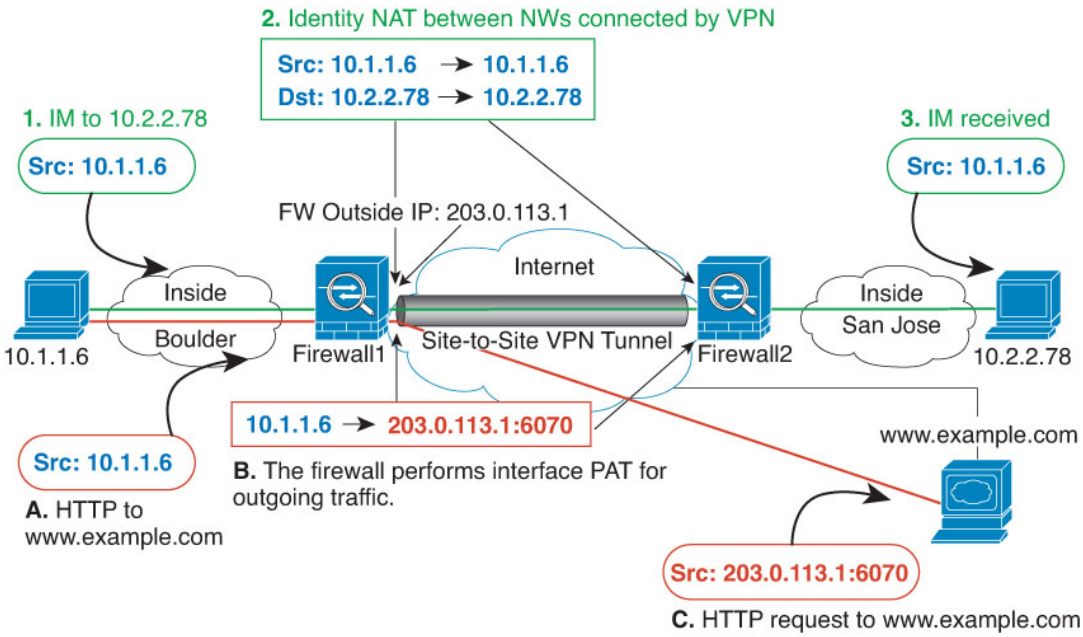
- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

d) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source** > **Address**= PATaddress2 network object.
- **Original Destination** > **Address** = TelnetWebServer network object.
- **Translated Destination** = TelnetWebServer network object.
- **Original Destination Port** = HTTP port object (system-defined).
- **Translated Destination Port** = HTTP port object (system-defined).



e) Click **Save**.

Step 9 Click **Save** on the NAT rule page.

NAT and Site-to-Site VPN

The following figure shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

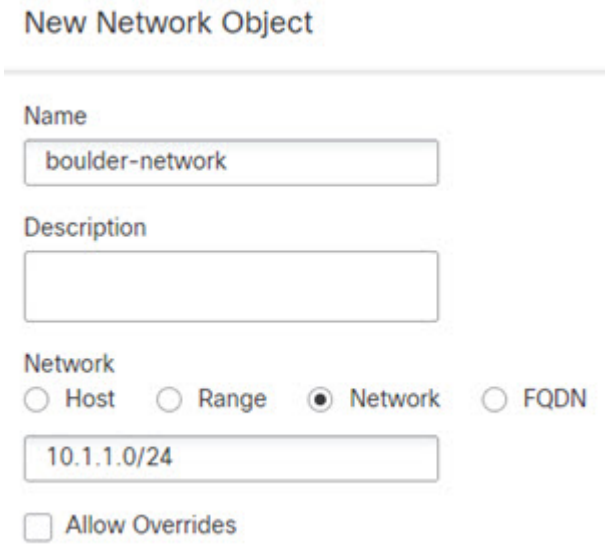
Figure 169: Interface PAT and Identity NAT for Site-to-Site VPN

The following example explains the configuration for Firewall1 (Boulder).

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the devices in the VPN. In this example, we will assume the interface objects are security zones named **inside-boulder** and **outside-boulder** for the Firewall1 (Boulder) interfaces. To configure interface objects, select **Objects** > **Object Management**, then select **Interfaces**.

Procedure

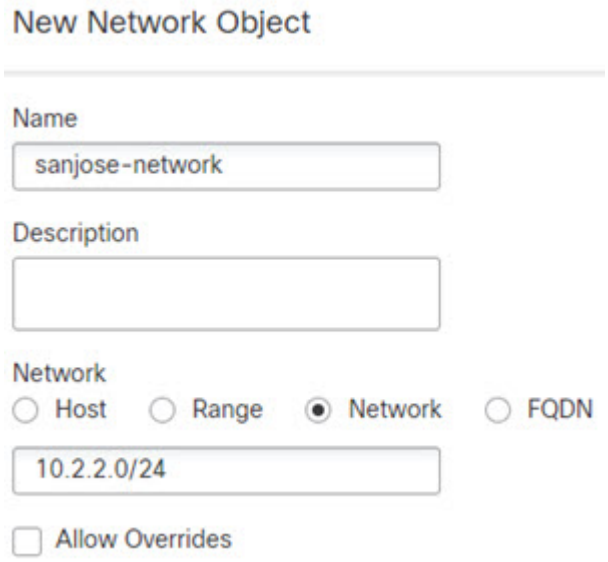


Step 1 Create the objects to define the various networks.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Identify the Boulder inside network.



Name the network object (for example, boulder-network) and enter the network address, 10.1.1.0/24.

d) Click **Save**.

e) Click **Add Network** > **Add Object** and define the inside San Jose network.

Name the network object (for example, sanjose-network) and enter the network address 10.2.2.0/24.

f) Click **Save**.

Step 2 Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

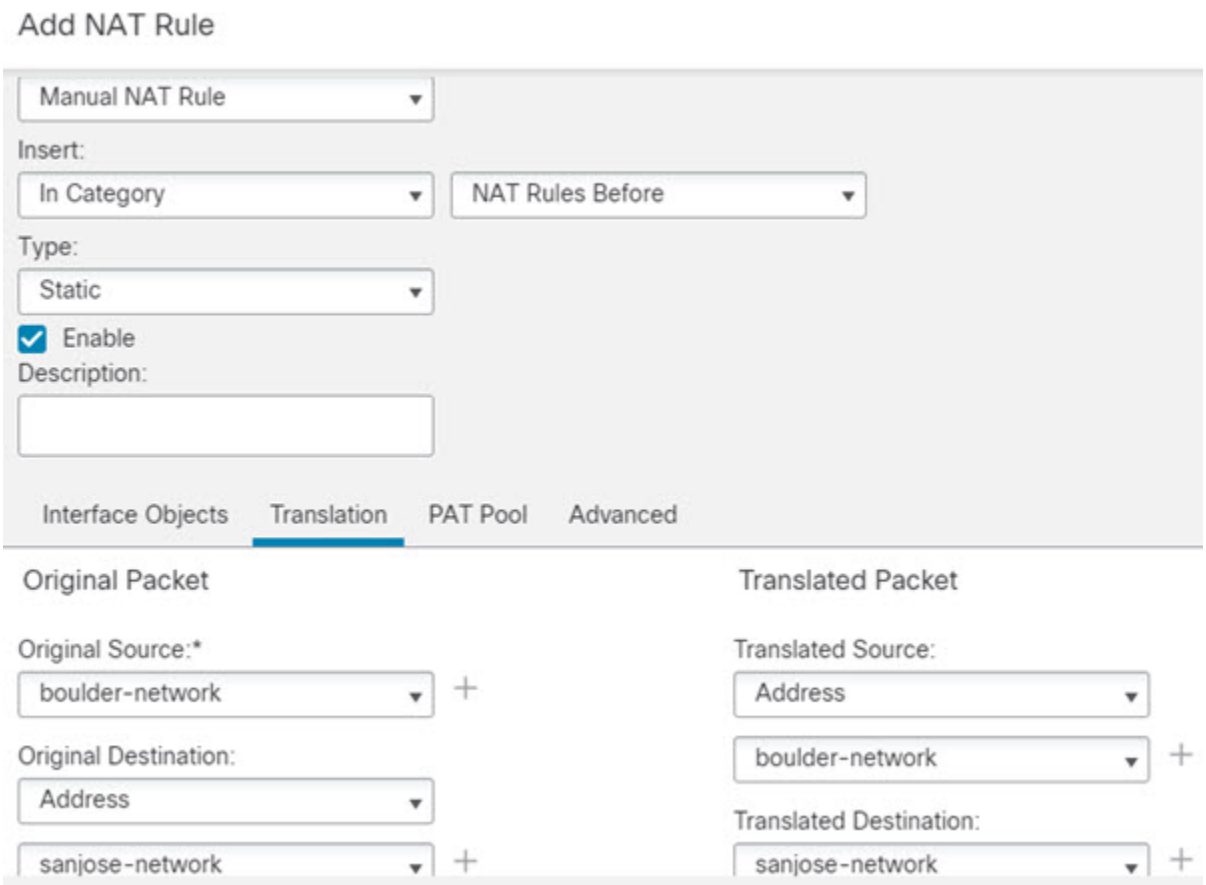
b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.

- **Type** = Static.

d) On **Interface Objects**, configure the following:



- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

e) On **Translation**, configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** > **Address** = boulder-network object.
- **Original Destination** > **Address** = sanjose-network object.
- **Translated Destination** = sanjose-network object.

Note
Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.

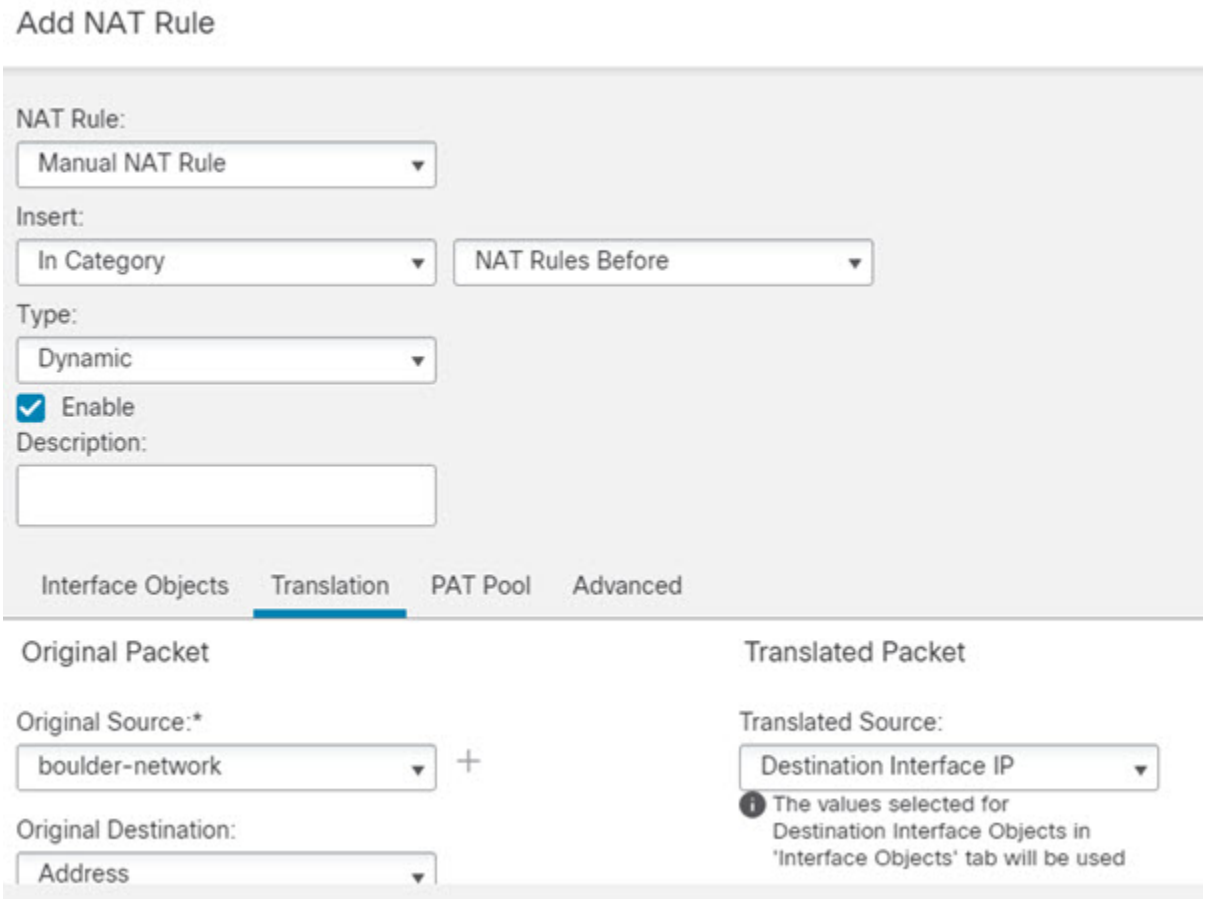
f) On **Advanced**, select **Do not proxy ARP on Destination interface**.

g) Click **Save**.

Step 3 Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

a) Click **Add Rule**.

b) Configure the following properties:



- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.
- **Insert Rule** = any position after the first rule. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside-boulder.
- **Destination Interface Objects** = outside-boulder.

d) On **Translation**, configure the following:

- **Original Source** = boulder-network object.
- **Translated Source** = **Destination Interface IP**. This option configures interface PAT using the interface contained in the destination interface object.
- **Original Destination** > **Address** = any (leave blank).
- **Translated Destination** = any (leave blank).

e) Click **Save**.

Step 4 If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

Rewriting DNS Queries and Responses Using NAT

You might need to configure the FTD device to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation rule. DNS modification is also known as DNS doctoring.

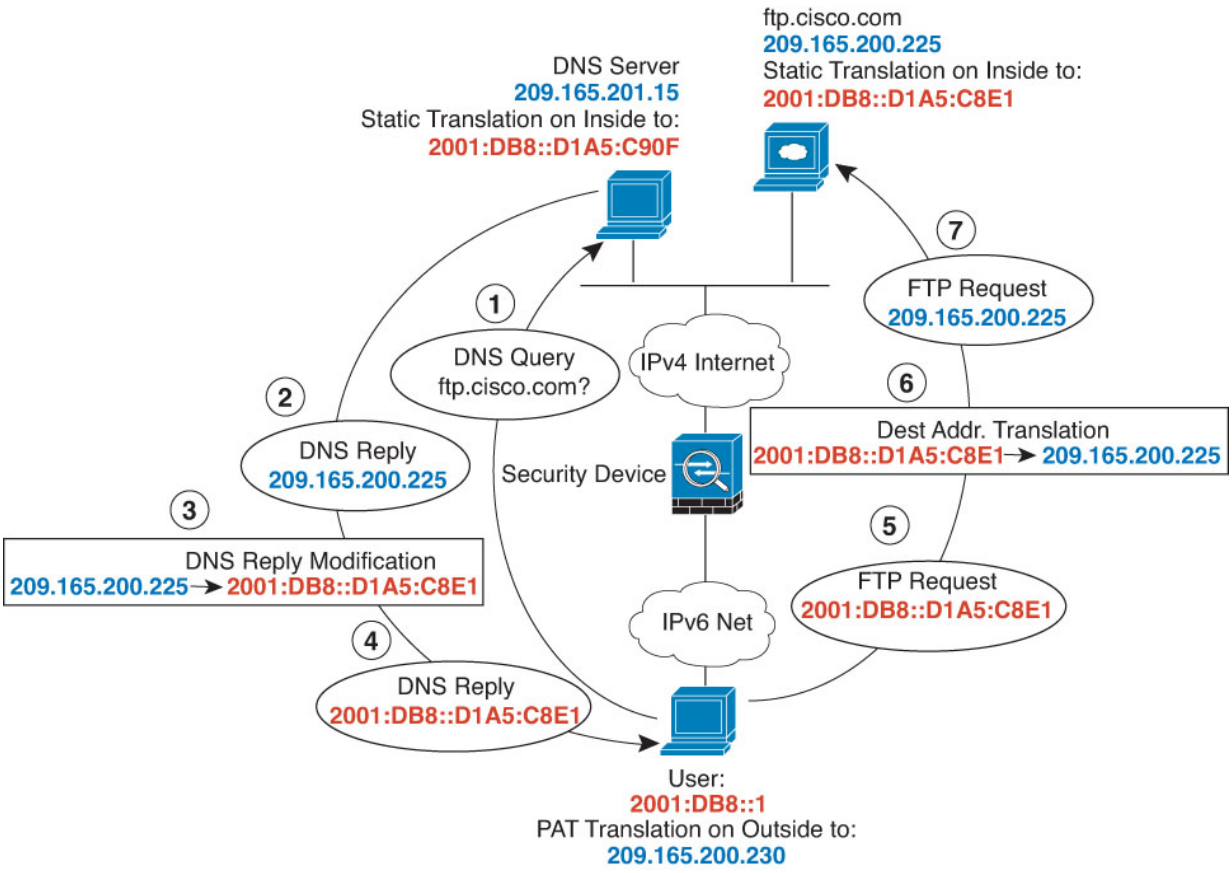
This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value. This feature works with NAT44,NAT 66, NAT46, and NAT64.

Following are the main circumstances when you would need to configure DNS rewrite on a NAT rule.

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

DNS Rewrite Limitations

Following are some limitations with DNS rewrite:



- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA record, and the PAT rule to use is ambiguous.
- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination address as well as the source address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the can not accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.
- You must enable DNS application inspection with DNS NAT rewrite enabled for NAT rules to rewrite DNS queries and responses. By default, DNS inspection with DNS NAT rewrite enabled is globally applied, so you probably do not need to change the inspection configuration.
- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.
- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

The following topics provide examples of DNS rewrite in NAT rules.

DNS64 Reply Modification

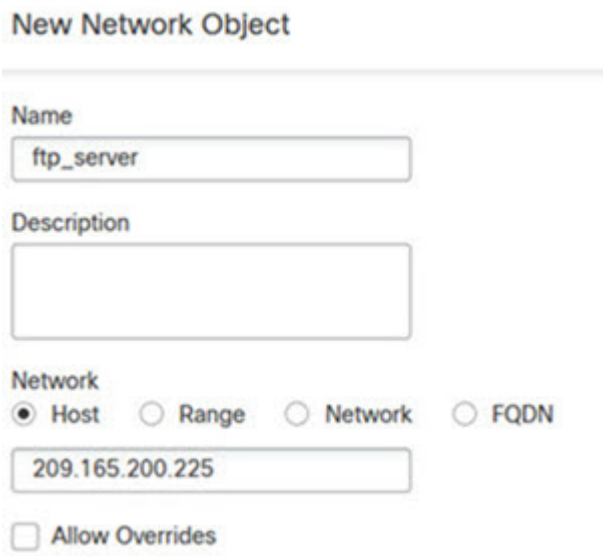
The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

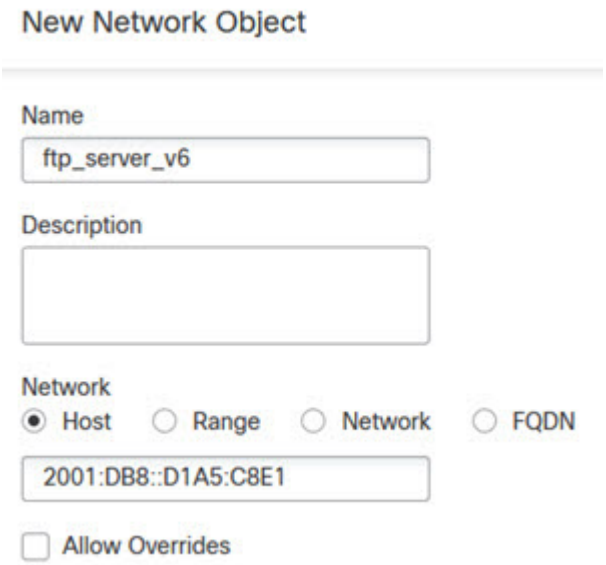


Step 1 Create the network objects for the FTP server, DNS server, inside network, and PAT pool.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

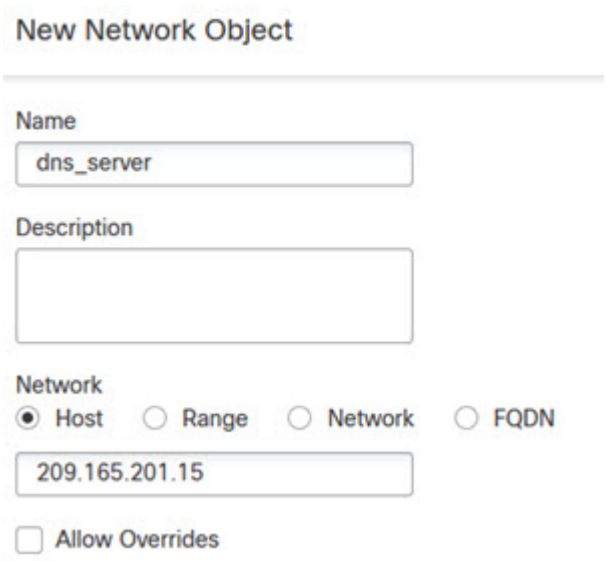
c) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 209.165.200.225.

d) Click **Save**.

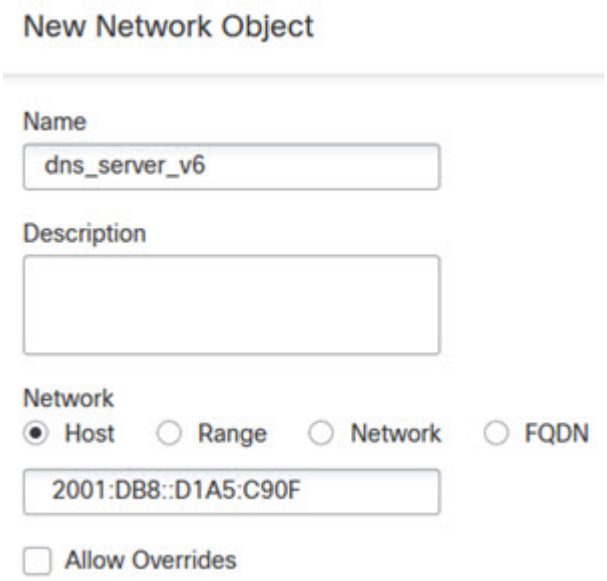
e) Click **Add Network** > **Add Object** and define the FTP server's translated IPv6 address.



Name the network object (for example, ftp_server_v6) and enter the host address, 2001:DB8::D1A5:C8E1.

f) Click **Save**.

g) Click **Add Network** > **Add Object** and define the DNS server's real address.



Name the network object (for example, dns_server) and enter the host address, 209.165.201.15.

h) Click **Save**.

i) Click **Add Network** > **Add Object** and define the DNS server's translated IPv6 address.

Name the network object (for example, dns_server_v6) and enter the host address, 2001:DB8::D1A5:C90F (where D1A5:C90F is the IPv6 equivalent of 209.165.201.15).

j) Click **Save**.

k) Click **Add Network** > **Add Object** and define the inside IPv6 network.

Name the network object (for example, inside_v6) and enter the network address, 2001:DB8::/96.

l) Click **Save**.

m) Click **Add Network** > **Add Object** and define the IPv4 PAT pool for the inside IPv6 network.

Name the network object (for example, ipv4_pool) and enter the range 209.165.200.230-209.165.200.235.

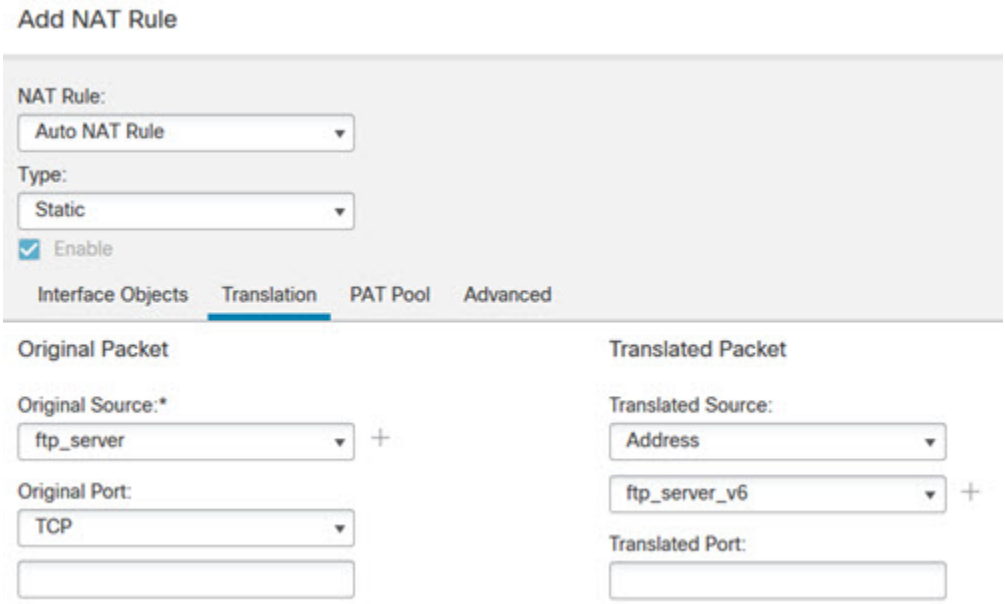
n) Click **Save**.

Step 2 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_v6 network object.

f) On **Advanced**, select the following options:

- **Translate DNS replies that match this rule**.
- **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

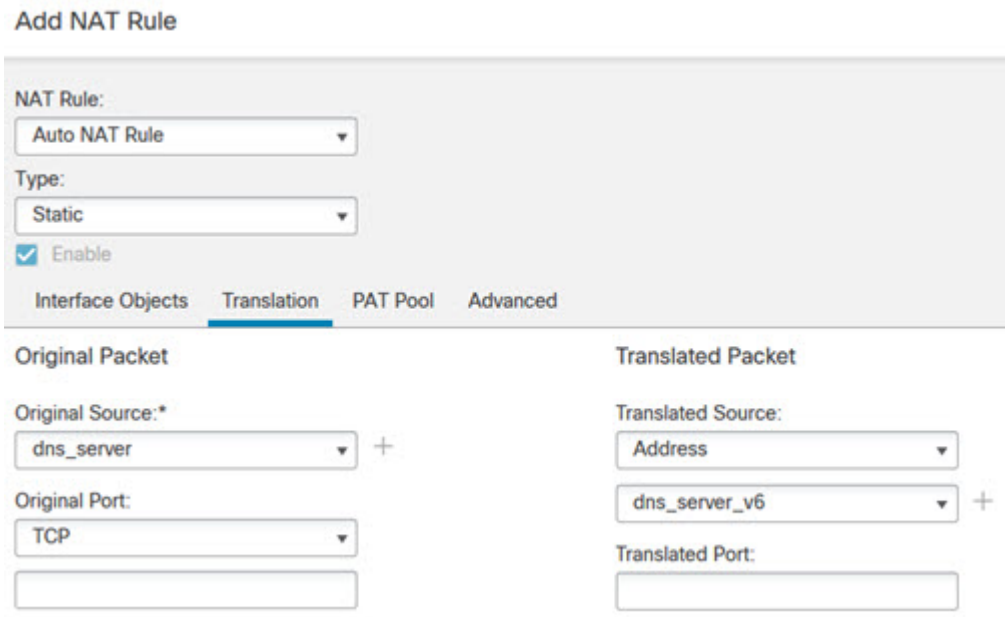
g) Click **OK**.

Step 3 Configure the static NAT rule for the DNS server.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:

- **Original Source** = dns_server network object.
- **Translated Source** > **Address** = dns_server_v6 network object.

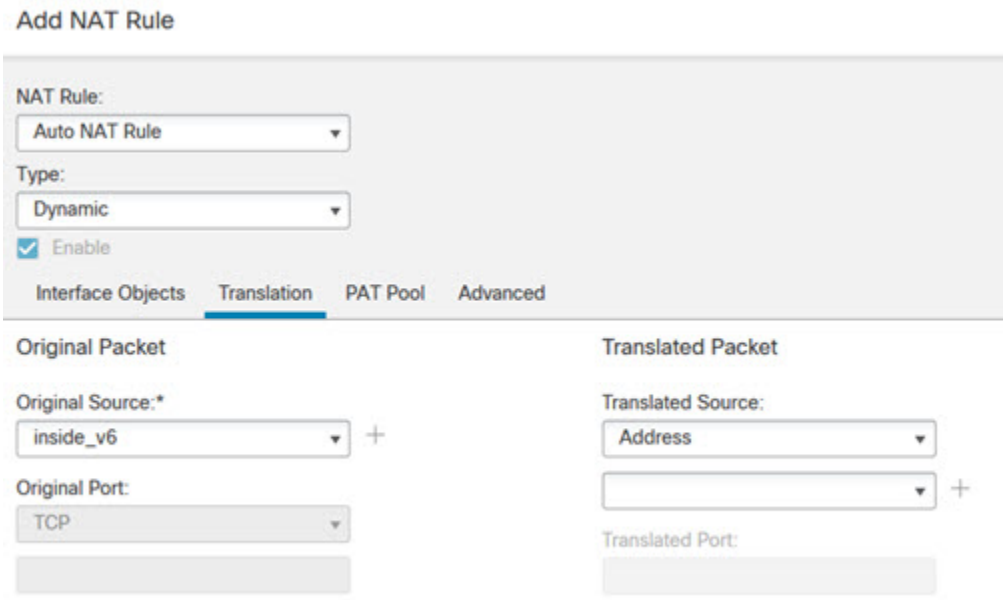
e) On **Advanced**, select **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

f) Click **OK**.

Step 4 Configure the dynamic NAT with a PAT pool rule for the inside IPv6 network.

a) Click **Add Rule**.

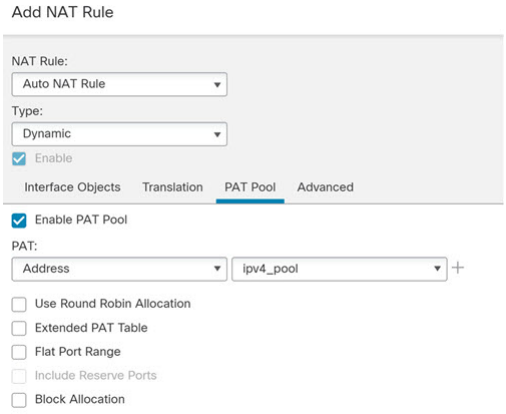
b) Configure the following properties:



- **NAT Rule** = Auto NAT Rule.
- **Type** = Dynamic.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

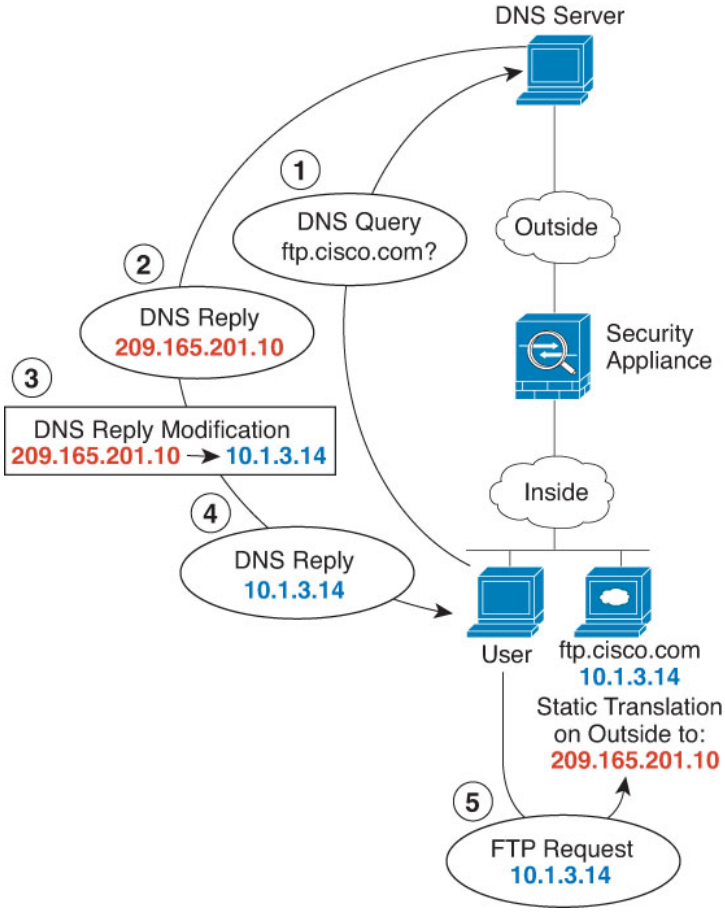


d) On **Translation**, configure the following:

- **Original Source** = inside_v6 network object.
- **Translated Source** > **Address** = leave this field empty.

e) On **PAT Pool**, configure the following:

- **Enable PAT Pool** = select this option.
- **Translated Source** > **Address** = ipv4_pool network object.



f) Click **OK**.

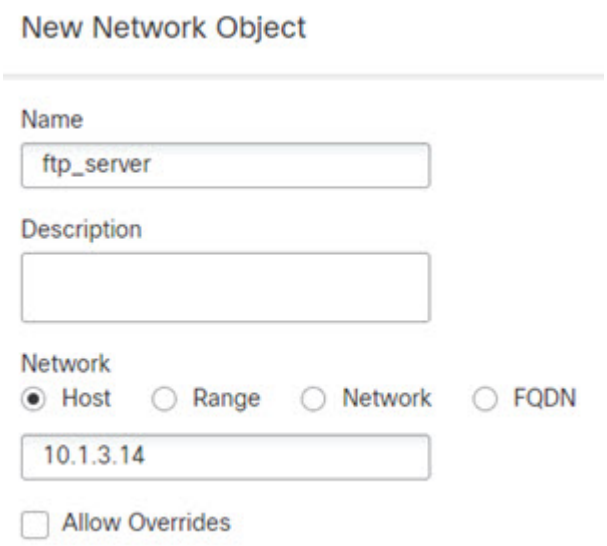
DNS Reply Modification, DNS Server on Outside

The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.

In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

Before you begin

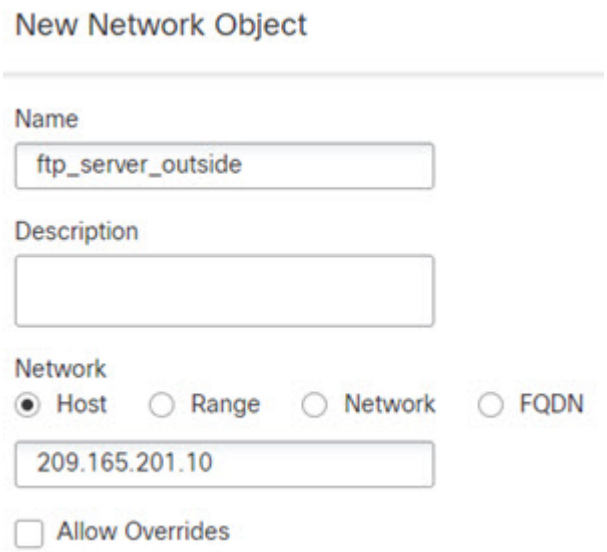


Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management**.
b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.
c) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 10.1.3.14.

d) Click **Save**.

e) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_outside) and enter the host address, 209.165.201.10.

f) Click **Save**.

Step 2 Configure the static NAT rule with DNS modification for the FTP server.

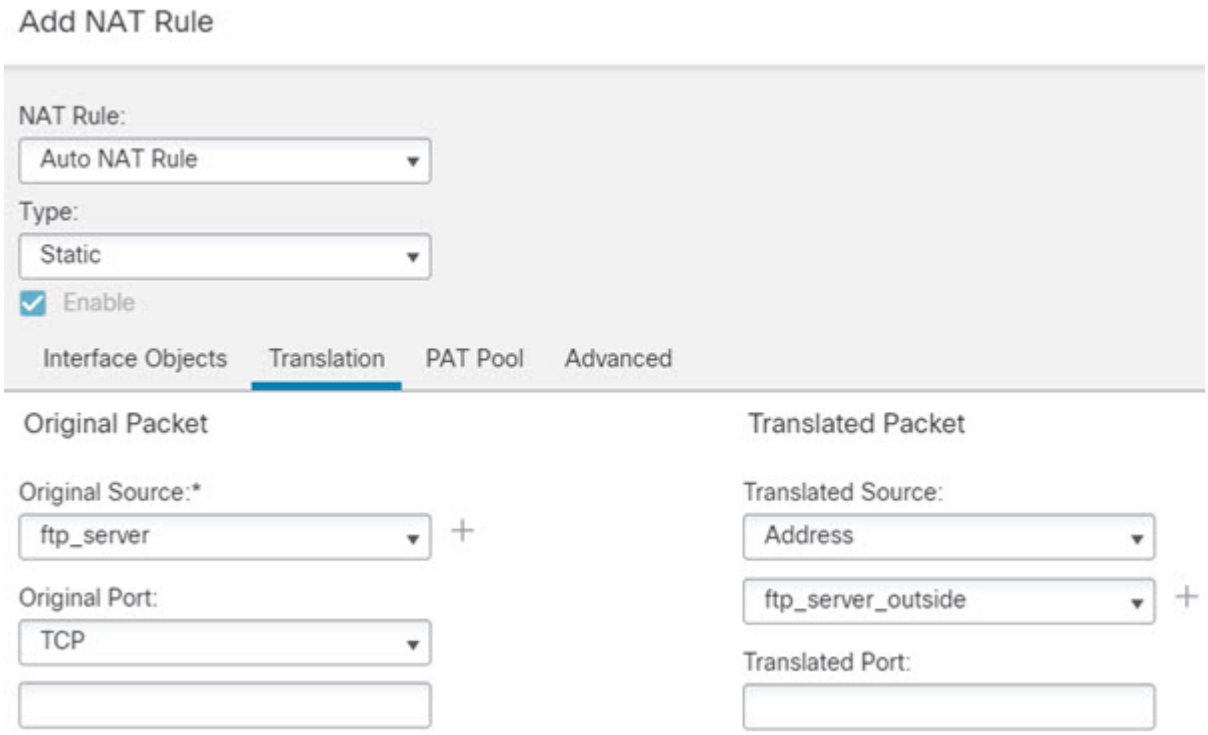
a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.

- **Type** = Static.

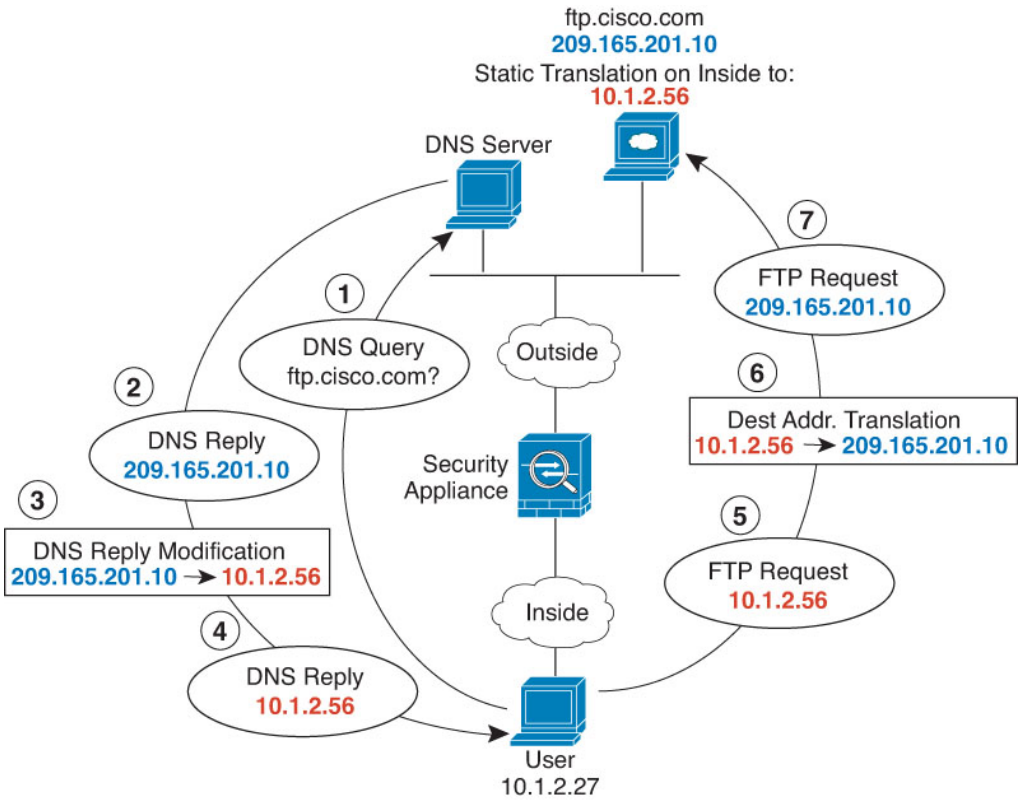


d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_outside network object.



f) On **Advanced**, select **Translate DNS replies that match this rule**.

g) Click **OK**.

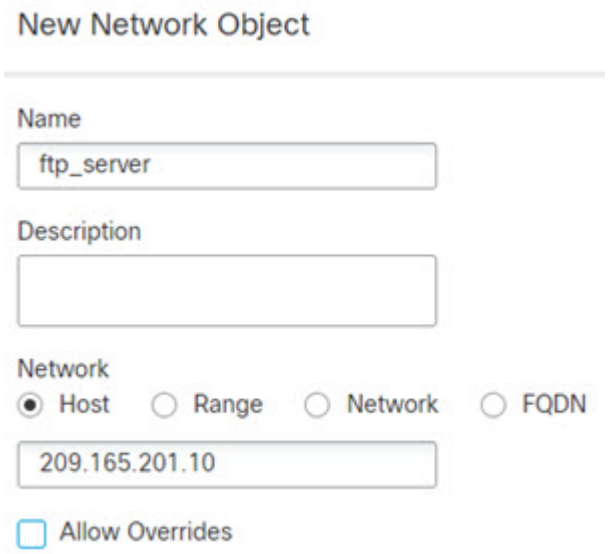
DNS Reply Modification, DNS Server on Host Network

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects** > **Object Management**, then select **Interface**.

Procedure

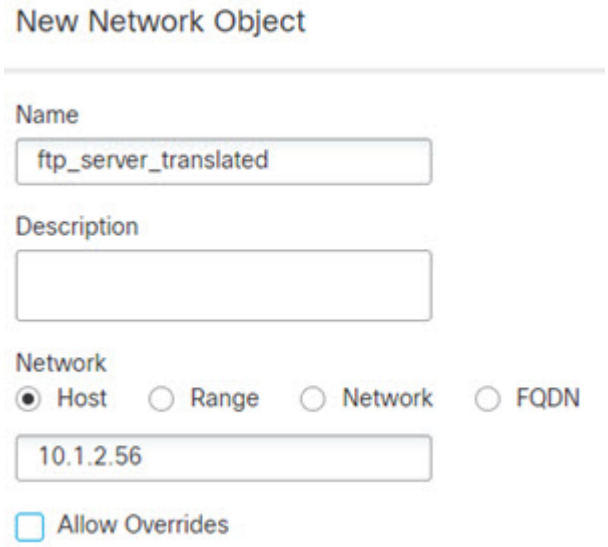


Step 1 Create the network objects for the FTP server.

a) Choose **Objects** > **Object Management**.

b) Select **Network** from the table of contents and click **Add Network** > **Add Object**.

c) Define the real FTP server address.



Name the network object (for example, ftp_server) and enter the host address, 209.165.201.10.

d) Click **Save**.

e) Click **Add Network** > **Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp_server_translated) and enter the host address, 10.1.2.56.

f) Click **Save**.

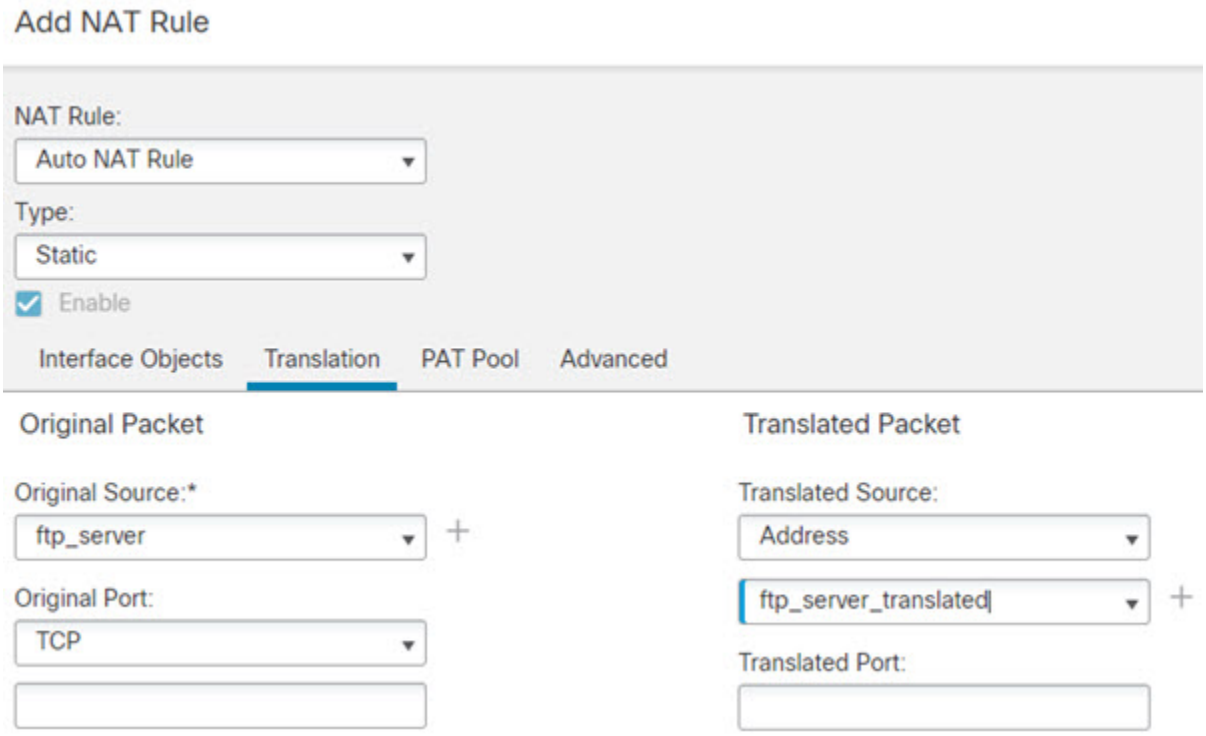
Step 2 Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices** > **NAT** and create or edit the FTD NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.



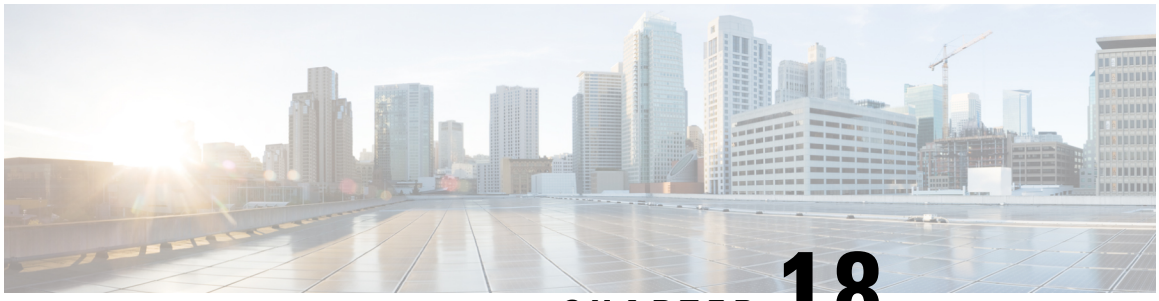
d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp_server network object.
- **Translated Source** > **Address** = ftp_server_translated network object.

f) On **Advanced**, select **Translate DNS replies that match this rule**.



g) Click **OK**.

History for FTD NAT

Feature	Minimum FMC	Minimum FTD	Details
Manual NAT support for fully-qualified domain name (FQDN) objects as the translated destination.	7.1	Any	You can use an FQDN network object, such as one specifying www.example.com, as the translated destination address in manual NAT rules. The system configures the rule based on the IP address returned from the DNS server.

Feature	Minimum FMC	Minimum FTD	Details
Changes to PAT address allocation in clustering. The PAT pool **Flat Port Range** option is now enabled by default and it is not configurable.	6.7	Any	The way PAT addresses are distributed to the members of a cluster is changed. Previously, addresses were distributed to the members of the cluster, so your PAT pool would need a minimum of one address per cluster member. Now, the control unit instead divides each PAT pool address into equal-sized port blocks and distributes them across cluster members. Each member has port blocks for the same PAT addresses. Thus, you can reduce the size of the PAT pool, even to as few as one IP address, depending on the amount of connections you typically need to PAT. Port blocks are allocated in 512-port blocks from the 1024-65535 range. You can optionally included the reserved ports, 1-1023, in this block allocation when you configure PAT pool rules. For example, in a 4-node cluster, each node gets 32 blocks with which it will be able to handle 16384 connections per PAT pool IP address compared to a single node handling all 65535 connections per PAT pool IP address. As part of this change, PAT pools for all systems, whether standalone or operating in a cluster, now use a flat port range of 1023 - 65535. Previously, you could optionally use a flat range by including the **Flat Port Range** option in a PAT pool rule. The **Flat Port Range** option is now ignored: the PAT pool is now always flat. You can optionally select the **Include Reserved Ports** option to include the 1 - 1023 port range within the PAT pool. Note that if you configure port block allocation (the **Block Allocation** PAT pool option), your block allocation size is used rather than the default 512-port block. In addition, you cannot configure extended PAT for a PAT pool for systems in a cluster.
Ability to search and filter the FTD NAT rule table.	6.7	Any	You can now search for rules in FTD NAT policies to help you find rules based on IP addresses, ports, object names, and so forth. Search results include partial matches. Searching on criteria filters the rule table so only matching rules are displayed. We added a search field above the rule table when you edit FTD NAT policies.
Carrier grade NAT enhancements.	6.5	Any	For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). New/modified screens: We added the **Block Allocation** option to the NAT PAT Pool tab for FTD NAT rules.
Support for network range objects in NAT for FTD.	6.1.0	Any	You can now use network range objects in FTD NAT rules where appropriate.
Network Address Translation (NAT) for FTD.	6.0.1	Any	The NAT policy for FTD was added. New/modified screens: Threat Defense was added as a type of NAT policy to the **Devices** > **NAT** page.

CHAPTER 18

Alarms for the Cisco ISA 3000

You can configure the alarm system on a Cisco ISA 3000 device to alert you when undesirable conditions occur.

- About Alarms, on page 659
- Defaults for Alarms, on page 661
- Requirements and Prerequisites for Alarms, on page 662
- Configure the Alarms for the ISA 3000, on page 662
- Monitoring Alarms, on page 670
- History for Alarms, on page 671

About Alarms

You can configure the ISA 3000 to issue alarms for a variety of conditions. If any conditions do not match the configured settings, the system triggers an alarm, which is reported by way of LEDs, syslog messages, SNMP traps, and through external devices connected to the alarm output interface. By default, triggered alarms issue syslog messages only.

You can configure the alarm system to monitor the following:

- Power supply.
- Primary and secondary temperature sensors.
- Alarm input interfaces.

The ISA 3000 has internal sensors plus two alarm input interfaces and one alarm output interface. You can connect external sensors, such as door sensors, to the alarm inputs. You can connect external alarm devices, such as buzzers or lights, to the alarm output interface.

The alarm output interface is a relay mechanism. Depending on the alarm conditions, the relay is either energized or de-energized. When it is energized, any device connected to the interface is activated. A de-energized relay results in the inactive state of any connected devices. The relay remains in an energized state as long as alarms are triggered.

For information about connecting external sensors and the alarm relay, see Cisco ISA 3000 Industrial Security Appliance Hardware Installation Guide.

Alarm Input Interfaces

You can connect the alarm input interfaces (or contacts) to external sensors, such as one that detects if a door is open.

Each alarm input interface has a corresponding LED. These LEDs convey the alarm status of each alarm input. You can configure the trigger and severity for each alarm input. In addition to the LED, you can configure the contact to trigger the output relay (to activate an external alarm), to send syslog messages, and to send SNMP traps.

The following table explains the statuses of the LEDs in response to alarm conditions for the alarm inputs. It also explains the behavior for the output relay, syslog messages, and SNMP traps, if you enable these responses to the alarm input.

Alarm Status	LED	Output Relay	Syslog	SNMP Trap
Alarm not configured	Off	—	—	—
No alarms triggered	Solid green	—	—	—
Alarm activated	Minor alarm—solid red Major alarm—flashing red	Relay energized	Syslog generated	SNMP trap sent
Alarm end	Solid green	Relay de-energized	Syslog generated	—

Alarm Output Interface

You can connect an external alarm, such as a buzzer or light, to the alarm output interface.

The alarm output interface functions as a relay and also has a corresponding LED, which conveys the alarm status of an external sensor connected to the input interface, and internal sensors such as the dual power supply and temperature sensors. You configure which alarms should activate the output relay, if any.

The following table explains the statuses of the LEDs and output relay in response to alarm conditions. It also explains the behavior for syslog messages, and SNMP traps, if you enable these responses to the alarm.

Alarm Status	LED	Output Relay	Syslog	SNMP Trap
Alarm not configured	Off	—	—	—
No alarms triggered	Solid green	—	—	—
Alarm activated	Solid red	Relay energized	Syslog generated	SNMP trap sent
Alarm end	Solid green	Relay de-energized	Syslog generated	—

Syslog Alarms

By default, the system sends syslog messages when any alarm is triggered. You can disable syslog messaging if you do not want the messages.

For syslog alarms to work, you must also enable diagnostic logging. Choose **Device** > **Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and configure destinations and settings on the **Syslog** page. For example, you can configure a syslog server, console logging, or internal buffer logging.

Without enabling a destination for diagnostic logging, the alarm system has nowhere to send syslog messages.

SNMP Alarms

You can optionally configure the alarms to send SNMP traps to your SNMP server. For SNMP trap alarms to work, you must also configure SNMP settings.

Choose **Device** > **Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and enable SNMP and configure settings on the **SNMP** page.

Defaults for Alarms

The following table specifies the defaults for alarm input interfaces (contacts), redundant power supply, and temperature.

	Alarm	Trigger	Severity	SNMP Trap	Output Relay	Syslog Message
Alarm Contact 1	Enabled	Closed State	Minor	Disabled	Disabled	Enabled
Alarm Contact 2	Enabled	Closed State	Minor	Disabled	Disabled	Enabled
Redundant Power Supply (when enabled)	Enabled	—	—	Disabled	Disabled	Enabled
Temperature	Enabled for the primary temperature alarm (default values of 92°C and -40°C for the high and low thresholds respectively) Disabled for the secondary alarm.	—	—	Enabled for primary temperature alarm	Enabled for primary temperature alarm	Enabled for primary temperature alarm

Admin

Configure the Alarms for the ISA 3000

You use FlexConfig to configure alarms for the ISA 3000. The following topics explain how to configure the different types of alarms.

Configure Alarm Input Contacts

If you connect the alarm input contacts (interfaces) to external sensors, you can configure the contacts to issue alarms based on the input from the sensor. In fact, the contacts are enabled by default to send syslog messages if the contact is closed, that is, if the electrical current stops flowing through the contact. You need to configure the contact only if the defaults do not meet your requirements.

The alarm contacts are numbered 1 and 2, so you need to understand how you have wired the physical pins to configure the correct settings. You configure the contacts separately.

Procedure

Step 1 Create the FlexConfig object to configure the alarm input contacts.

a) Choose **Objects** > **Object Management**.

b) Choose **FlexConfig** > **FlexConfig Object** from the table of contents.

c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Configure_Alarm_Contacts.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the alarm contacts. The following steps explain the commands.

d) Configure a description for the alarm contact.

alarm contact {**1** | **2**} **description** *string*

For example, to set the description of contact 1 to "Door Open," enter the following:

```
alarm contact 1 description Door Open
```

e) Configure the severity for the alarm contact.

alarm contact {**1** | **2** | **any**} **severity** {**major** | **minor** | **none**}

Instead of configuring one contact, you can specify **any** to change the severity for all contacts. The severity controls the behavior of the LED associated with the contact.

- **major**—The LED blinks red.
- **minor**—The LED is solid red. This is the default.
- **none**—The LED is off.

For example, to set the severity of contact 1 to Major, enter the following:

```
alarm contact 1 severity major
```

f) Configure the trigger for the alarm contact.

alarm contact {**1** | **2** | **any**} **trigger** {**open** | **closed**}

Instead of configuring one contact, you can specify **any** to change the trigger for all contacts. The trigger determines the electrical condition that signals an alert.

- **open**—The normal condition for the contact is closed, that is, the electrical current is running through the contact. An alert is triggered if the contact becomes open, that is, the electrical current stops flowing.
- **closed**—The normal condition for the contact is open, that is, the electrical current does not run through the contact. An alert is triggered if the contact becomes closed, that is, the electrical current starts running through the contact. This is the default.

For example, you connect a door sensor to alarm input contact 1, and its normal state has no electrical current flowing through the alarm contact (it is open). If the door is opened, the contact is closed and electrical current flows through the alarm contact. You would set the alarm trigger to closed so that the alarm goes off when the electrical current starts flowing.

```
alarm contact 1 trigger closed
```

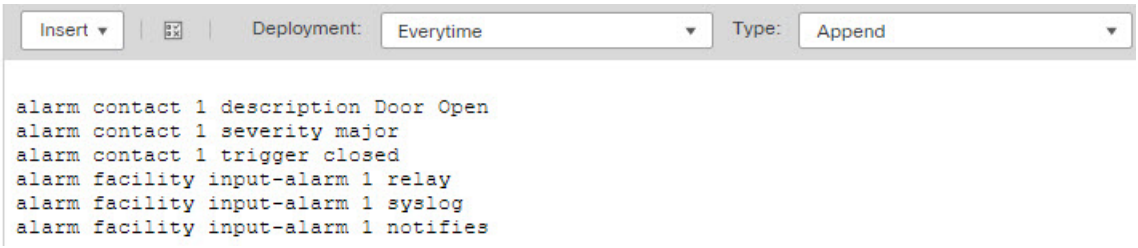
g) Configure the actions to take when the alarm contact is triggered.

alarm facility input-alarm {**1** | **2**} {**relay** | **syslog** | **notifies**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.

For example, to enable all actions for the alarm input contact 1, enter the following:



```
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

h) Verify that the object body contains the commands you want.

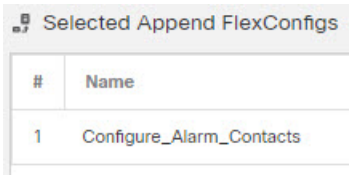
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

The object body should look similar to the following:

i) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the alarm contact FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the

preview. Note that you will also see commands generated from other changes you have made to managed features. For the alarm contact commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 1923.

Configure Power Supply Alarms

The ISA 3000 has two power supplies. By default, the system operates in single-power mode. However, you can configure the system to operate in dual mode, where the second power supply automatically provides power if the primary power supply fails. When you enable dual-mode, the power supply alarm is automatically enabled to send syslog alerts, but you can disable the alert altogether, or also enable SNMP traps or the alarm hardware relay.

The following procedure explains how to enable dual mode, and how to configure the power supply alarms.

Procedure

Step 1 Create the FlexConfig object to configure the power supply alarm.

a) Choose **Objects** > **Object Management**.

b) Choose **FlexConfig** > **FlexConfig Object** from the table of contents.

c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Power_Supply_Alarms.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the power supply alarms. The following steps explain the commands.

d) Enable dual power supply mode.

power-supply dual

For example:

```
power-supply dual
```

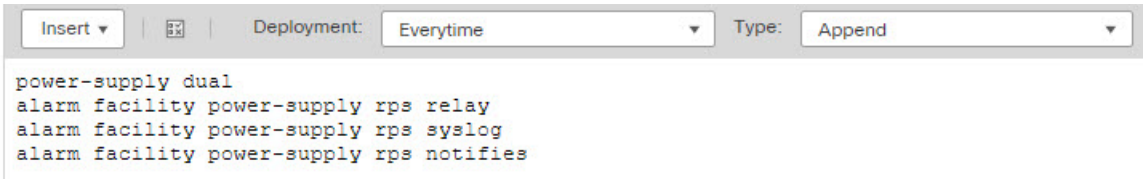
e) Configure the actions to take when the power supply alarm is triggered.

alarm facility power-supply rps {**relay** | **syslog** | **notifies** | **disable**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.
- **disable**—Disable the power supply alarm. Any other actions configured for the power supply alarm are inoperable.

For example, to enable all actions for the power supply alarm, enter the following:



```
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

f) Verify that the object body contains the commands you want.

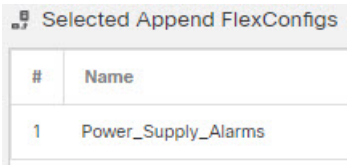
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

The object body should look similar to the following:

g) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the power supply alarm FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.
e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the power supply alarm commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 1923.

Configure Temperature Alarms

You can configure alarms based on the temperature of the CPU card in the device.

You can set a primary and secondary temperature range. If the temperature drops below the low threshold, or exceeds the high threshold, the alarm is triggered.

The primary temperature alarm is enabled by default for all alarm actions: output relay, syslog, and SNMP. The default settings for the primary temperature range is -40°C to 92°C.

The secondary temperature alarm is disabled by default. You can set the secondary temperature within the range -35°C to 85°C.

Because the secondary temperature range is more restrictive than the primary range, if you set either the secondary low or high temperature, that setting disables the corresponding primary setting, even if you configure non-default values for the primary setting. You cannot enable two separate high and two separate low temperature alarms.

Thus, in practice, you should configure the primary only, or the secondary only, setting for high and low.

Procedure

Step 1 Create the FlexConfig object to configure the temperature alarms.

a) Choose **Objects** > **Object Management**.

b) Choose **FlexConfig** > **FlexConfig Object** from the table of contents.

c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.

- **Name**—The object name. For example, Configure_Temperature_Alarms.
- **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
- **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
- **Object body**—In the object body, type the commands needed to configure the temperature alarms. The following steps explain the commands.

d) Configure the acceptable temperature range.

alarm facility temperature {**primary** | **secondary**} {**low** | **high**} *temperature*

The temperature is in Celsius. The allowed range for the primary alarm is -40 to 92, which is also the default range. The allowed range for the secondary alarm is -35 to 85. The low value must be lower than the high value.

For example, to set a more restrictive temperature range of -20 to 80, which falls within the allowed range for the secondary alarm, configure the secondary alarm as follows:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
```

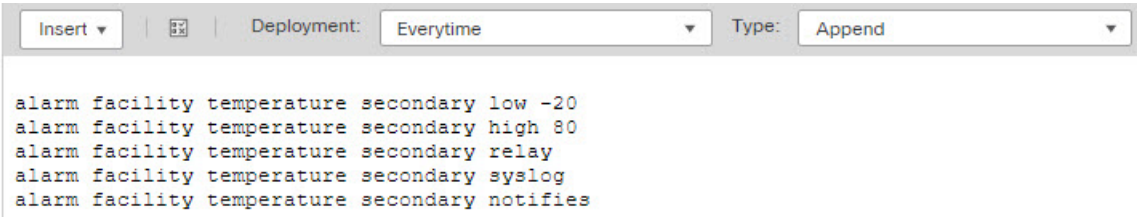
e) Configure the actions to take when the temperature alarm is triggered.

alarm facility temperature {**primary** | **secondary**} {**relay** | **syslog** | **notifies**}

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message.
- **notifies**—Send an SNMP trap.

For example, to enable all actions for the secondary temperature alarm, enter the following:



```
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

f) Verify that the object body contains the commands you want.

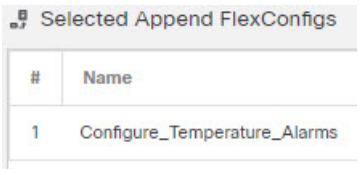
For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

The object body should look similar to the following:

g) Click **Save**.

Step 2 Create the FlexConfig policy and assign it to the devices.



a) Choose **Devices** > **FlexConfig**.

b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

c) Select the temperature alarms FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

d) Click **Save**.

e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.

f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the temperature alarms commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See Verify the Deployed Configuration, on page 1923.

Monitoring Alarms

The following topics explain how to monitor and manage alarms.

Monitoring Alarm Status

You can use the following commands in the CLI to monitor alarms.

- **show alarm settings**

  Shows the current configuration for each possible alarm.

- **show environment alarm-contact**

  Shows information about the physical status of the input alarm contacts.

- **show facility-alarm relay**

  Shows information about the alarms that have triggered the output relay.

- **show facility-alarm status** [**info** | **major** | **minor**]

  Shows information on all alarms that have been triggered. You can limit the view by filtering on **major** or **minor** status. The **info** keyword provides the same output as using no keyword.

Monitoring Syslog Messages for Alarms

Depending on the type of alarms you configure, you might see the following syslog messages.

Dual Power Supply Alarms

- %FTD-1-735005: Power Supply Unit Redundancy OK
- %FTD-1-735006: Power Supply Unit Redundancy Lost

Temperature Alarms

In these alarms, *Celsius* is replaced by the temperature detected on the device, in Celsius.

- %FTD-6-806001: Primary alarm CPU temperature is High *Celsius*
- %FTD-6-806002: Primary alarm for CPU high temperature is cleared
- %FTD-6-806003: Primary alarm CPU temperature is Low *Celsius*

- %FTD-6-806004: Primary alarm for CPU Low temperature is cleared
- %FTD-6-806005: Secondary alarm CPU temperature is High *Celsius*
- %FTD-6-806006: Secondary alarm for CPU high temperature is cleared
- %FTD-6-806007: Secondary alarm CPU temperature is Low *Celsius*
- %FTD-6-806008: Secondary alarm for CPU Low temperature is cleared

Alarm Input Contact Alarms

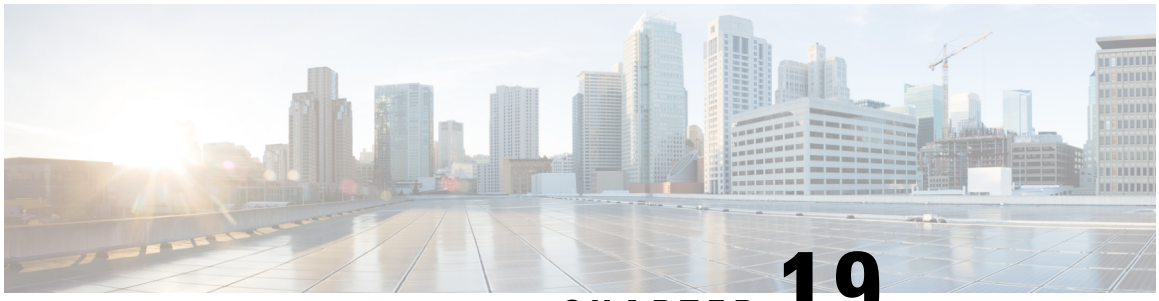
In these alarms, *description* is the description for the contact that you configured.

- %FTD-6-806009: Alarm asserted for ALARM_IN_1 *alarm_1_description*
- %FTD-6-806010: Alarm cleared for ALARM_IN_1 *alarm_1_description*
- %FTD-6-806011: Alarm asserted for ALARM_IN_2 *alarm_2_description*
- %FTD-6-806012: Alarm cleared for ALARM_IN_2 *alarm_2_description*

Turning Off the External Alarm

If you are using an external alarm that is attached to the alarm output, and the alarm is triggered, you can turn off the external alarm from the device CLI using the **clear facility-alarm output** command. This command de-energizes the output pin and also turns off the output LED.

History for Alarms



Feature	Minimum FMC	Minimum FTD	Description
Alarms for the Cisco ISA 3000 series.	6.7	Any	Configuring alarms for the Cisco ISA 3000 series was validated using FlexConfig. You should be able to configure the alarms in older releases that support FlexConfig, except for the dual power supply alarms. Supported platforms: Firepower Threat Defense on the ISA 3000.

CHAPTER 19

Static and Default Routes

This chapter describes how to configure static and default routes on the FTD.

- About Static and Default Routes, on page 675
- Requirements and Prerequisites for Static Routes, on page 677
- Guidelines for Static and Default Routes, on page 678
- Add a Static Route, on page 678
- Reference for Routing, on page 680

About Static and Default Routes

To route traffic to a non-connected host or network, you must define a route to the host or network, either using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, typically the next hop router.

Default Route

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the FTD device sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

You should always define a default route.

Because FTD uses separate routing tables for data traffic and for management traffic, you can optionally configure a default route for data traffic and another default route for management traffic. Note that from-the-device traffic uses either the management-only or data routing table by default depending on the type (see Routing Table for Management Traffic, on page 686), but will fall back to the other routing table if a route is not found. Default routes will always match traffic, and will prevent a fall back to the other routing table. In this case, you must specify the interface you want to use for egress traffic if that interface is not in the default routing table. The Diagnostic interface is included in the management-only table. The special Management interface uses a separate Linux routing table, and has its own default route. See the **configure network** commands.

Static Routes

You might want to use static routes in the following cases:

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the FTD device.
- You are using a feature that does not support dynamic routing protocols.
- Virtual routers use static routes to create route leaks. Route leaks enable flow of traffic from an interface of a virtual router to another interface in another virtual router. For more information, see Interconnecting Virtual Routers, on page 692.

Route to null0 Interface to Drop Unwanted Traffic

Access rules let you filter packets based on the information contained in their headers. A static route to the null0 interface is a complementary solution to access rules. You can use a null0 route to forward unwanted or undesirable traffic so the traffic is dropped.

Static null0 routes have a favorable performance profile. You can also use static null0 routes to prevent routing loops. BGP can leverage the static null0 route for Remotely Triggered Black Hole routing.

Route Priorities

- Routes that identify a specific destination take precedence over the default route.
- When multiple routes exist to the same destination (either static or dynamic), then the administrative distance for the route determines priority. Static routes are set to 1, so they typically are the highest priority routes.
- When you have multiple static routes to the same destination with the same administrative distance, see Equal-Cost Multi-Path (ECMP) Routing, on page 686.
- For traffic emerging from a tunnel with the Tunneled option, this route overrides any other configured or learned default routes.

Transparent Firewall Mode and Bridge Group Routes

For traffic that originates on the FTD device and is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the FTD device knows out of which bridge group member interface to send traffic. Traffic that originates on the FTD device might include communications to a syslog server or SNMP server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. For transparent mode, you cannot specify the BVI as the gateway interface; only member interfaces can be used. For bridge groups in routed mode, you must specify the BVI in a static route; you cannot specify a member interface. See MAC Address vs. Route Lookups, on page 148 for more information.

Static Route Tracking

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the FTD device goes down.

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

The FTD device implements static route tracking by associating a static route with a monitoring target host on the destination network that the FTD device monitors using ICMP echo requests. If an echo reply is not received within a specified time period, the host is considered down, and the associated route is removed from the routing table. An untracked backup route with a higher metric is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. The target can be any network object that you choose, but you should consider using the following:

- The ISP gateway (for dual ISP support) address
- The next hop gateway address (if you are concerned about the availability of the gateway)
- A server on the target network, such as a syslog server, that the FTD device needs to communicate with
- A persistent network object on the destination network

Note A PC that may be shut down at night is not a good choice.

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

Requirements and Prerequisites for Static Routes

Model Support

FTD

Supported Domains

Any

User Roles

Admin

Network Admin

Guidelines for Static and Default Routes

Firewall Mode and Bridge Groups

- In transparent mode, static routes must use the bridge group member interface as the gateway; you cannot specify the BVI.
- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- Static route tracking is not supported for bridge group member interfaces or on the BVI.

Supported Network Address

- Static route tracking is not supported for IPv6.
- The FTD does not support Class E routing, so a Class E network is not routable in static routes.

Clustering

- In clustering, static route tracking is only supported on the control node.

Network Object Group

You cannot use a range of network objects or a network object group having a range of IP addresses in a static route.

ASP and RIB Route Entries

All routes and its distance installed on the device are captured in the ASP routing table. This is common for all static and dynamic routing protocols. Only the best distance route is captured in the RIB table.

Add a Static Route

A static route defines where to send traffic for specific destination networks. You should at a minimum define a default route. A default route is simply a static route with 0.0.0.0/0 as the destination IP address.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (May be required) From the virtual routers drop-down list, select the virtual router for which you are configuring a static route.

Step 4 Select **Static Route**.

Step 5 Click **Add Routes**.

Step 6 Click **IPv4** or **IPv6** depending on the type of static route that you are adding.

Step 7 Choose the **Interface** to which this static route applies.

For transparent mode, choose a bridge group member interface name. For routed mode with bridge groups, you can choose either the bridge group member interface for the BVI name. To "black hole" unwanted traffic, choose the **Null0** interface.

For a device using virtual routing, you can select an interface that belongs to another virtual router. You can create such a static route if you want to leak traffic from this virtual router into the other virtual router. For more information, see Interconnecting Virtual Routers, on page 692.

Step 8 In the **Available Network** list, choose the destination network.

To define a default route, create an object with the address 0.0.0.0/0 and select it here.

Note
Although you can create and choose a Network Object Group containing a range of IP addresses, the FMC does not support using ranges in static routes.

Step 9 In the **Gateway** or **IPv6 Gateway** field, enter or choose the gateway router that is the next hop for this route. You can provide an IP address or a Networks/Hosts object.

When you are using static-route configuration for virtual routers to leak routes, do not specify the next hop gateway.

Step 10 In the **Metric** field, enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1.

The metric is a measurement of the "expense" of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. The metric is used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connected routes. The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static route takes precedence. Connected routes always take precedence over static or dynamically discovered routes.

Step 11 (Optional) For a default route, click the **Tunneled** checkbox to define a separate default route for VPN traffic.

You can define a separate default route for VPN traffic if you want your VPN traffic to use a different default route than your non VPN traffic. For example, traffic incoming from VPN connections can be easily directed towards internal networks, while traffic from internal networks can be directed towards the outside. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the device that cannot be routed using learned or static routes, is sent to this route. You can configure only one default tunneled gateway per device. ECMP for tunneled traffic is not supported.

Step 12 (IPv4 static route only) To monitor route availability, enter or choose the name of an SLA (service level agreement) Monitor object that defines the monitoring policy, in the **Route Tracking** field.

See SLA Monitor, on page 918.

Step 13 Click **Ok**.

Reference for Routing

This section describes underlying concepts of how routing behaves within the FTD.

Path Determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which include route information. Route information varies depending on the routing algorithm used.

Routing algorithms fill routing tables with a variety of information. Destination or next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the next hop on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can include other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

Supported Route Types

There are several route types that a router can use. The FTD device uses the following route types:

- Static Versus Dynamic
- Single-Path Versus Multipath
- Flat Versus Hierarchical
- Link-State Versus Distance Vector

Static Versus Dynamic

Static routing algorithms are actually table mappings established by the network administrator. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a default route for a router to which all unrouteable packets are sent), for example, can be designated to act as a repository for all unrouteable packets, ensuring that all messages are at least handled in some way.

Single-Path Versus Multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are substantially better throughput and reliability, which is generally called load sharing.

Flat Versus Hierarchical

Some routing algorithms operate in a flat space, while others use routing hierarchies. In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from non-backbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more non-backbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas. In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

Link-State Versus Distance Vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables. Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, link-state algorithms are used in conjunction with OSPF routing protocols.

Supported Internet Protocols for Routing

The FTD device supports several Internet protocols for routing. Each protocol is briefly described in this section.

- Enhanced Interior Gateway Routing Protocol (EIGRP)

  EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperation with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

- Open Shortest Path First (OSPF)

OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

- Routing Information Protocol (RIP)

  RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

- Border Gateway Protocol (BGP)

  BGP is an interautonomous system routing protocol. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP). Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

Routing Table

The FTD uses separate routing tables for data traffic (through-the-device) and for management traffic (from-the-device). This section describes how the routing tables work. For information about the management routing table, see also Routing Table for Management Traffic, on page 686.

How the Routing Table Is Populated

The FTD routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the FTD device can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner. When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

  For example, if the RIP and OSPF processes discovered the following routes:

  - RIP: 192.168.32.0/24
  - OSPF: 192.168.32.0/19

  Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the FTD device learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

  Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the

lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the FTD device learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the FTD device uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the FTD device.

Table 47: Default Administrative Distance for Supported Routing Protocols

Route Source	Default Administrative Distance
Connected interface	0
VPN route	1
Static route	1
EIGRP Summary Route	5
External BGP	20
Internal EIGRP	90
OSPF	110
IS-IS	115
RIP	120
EIGRP external route	170
Internal and local BGP	200
Unknown	255

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the FTD device receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the FTD device chooses the

OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

A VPN advertised route (V-Route/RRI)) is equivalent to a static route with the default administrative distance 1. But it has a higher preference as with the network mask 255.255.255.255.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the FTD device would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the FTD device on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

Backup Dynamic and Floating Static Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the FTD device. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

How Forwarding Decisions Are Made

Forwarding decisions are made as follows:

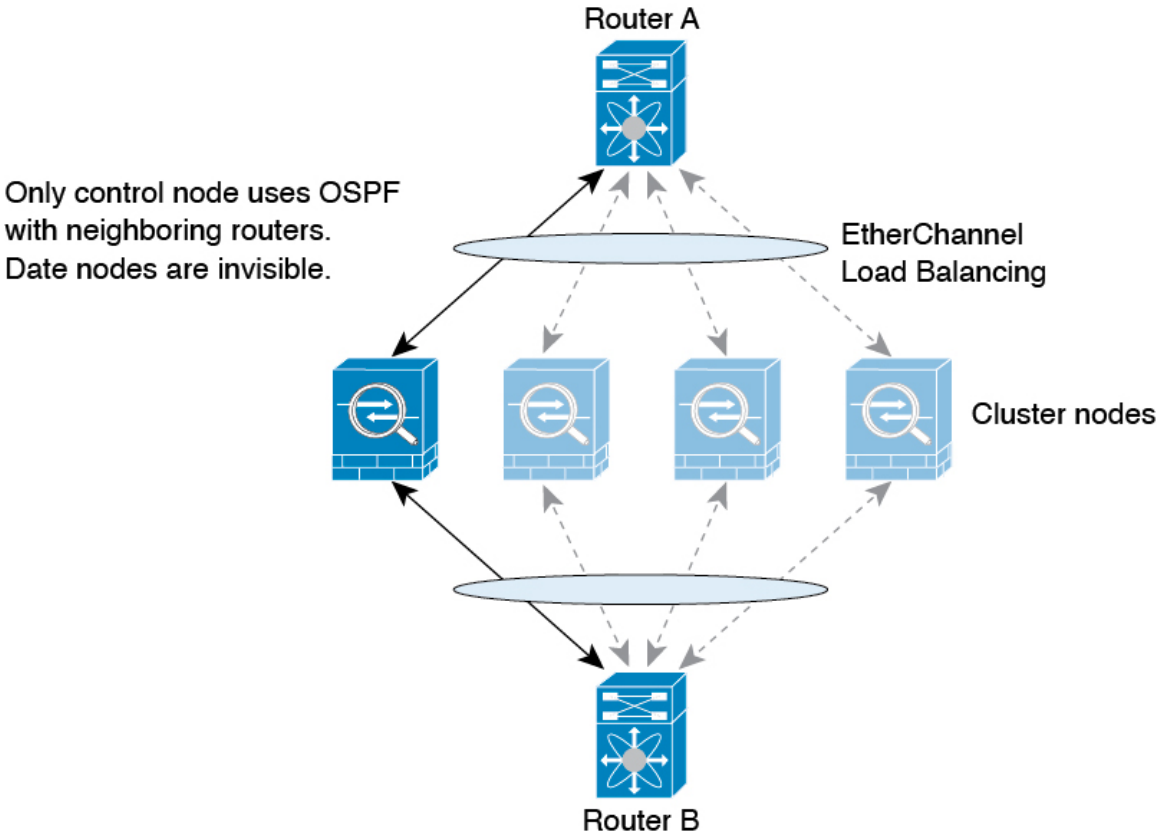
- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

For example, a packet destined for 192.168.32.1 arrives on an interface with the following routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits verses 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.

Note Existing connections continue to use their established interfaces even if a new similar connection would result in different behavior due to a change in routes.



Dynamic Routing and High Availability

Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit. This means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active in an active/standby ready High Availability pair, it will already have an identical routing table as that of the former active unit because routes are synchronized as a part of the High Availability bulk synchronization and continuous replication processes.

Dynamic Routing in Clustering

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 170: Dynamic Routing in Spanned EtherChannel Mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a

consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

Routing Table for Management Traffic

As a standard security practice, it is often necessary to segregate and isolate management (from-the-device) traffic from data traffic. To achieve this isolation, FTD uses a separate routing table for management-only traffic vs. data traffic. Separate routing tables means that you can create separate default routes for data and management as well.

Types of Traffic for Each Routing Table

Through-the-device traffic always uses the data routing table.

From-the-device traffic, depending on the type, uses either the management-only routing table or the data routing table by default. If a match is not found in the default routing table, it checks the other routing table.

- Management-only table from-the-device traffic includes AAA server communications.
- Data table from-the-device traffic includes DNS server lookups and DDNS. An exception is if you only specify the Diagnostic interface for DNS, then the FTD will only use the management-only table.

Interfaces Included in the Management-Only Routing Table

Management-only interfaces include any Diagnostic x/x interfaces as well as any interfaces that you have configured to be management-only.

Note The Management logical interface uses its own Linux routing table that is not part of the FTD route lookup. Traffic originating on the Management interface includes the FMC communication, licensing communication, and database updates. The Diagnostic logical interface, on the other hand, uses the management-only routing table described in this section.

Fallback to the Other Routing Table

If a match is not found in the default routing table, it checks the other routing table.

Using the Non-Default Routing Table

If you need from-the-box traffic to go out an interface that isn't in its default routing table, then you might need to specify that interface when you configure it, rather than relying on the fall back to the other table. The FTD device will only check routes for the specified interface. For example, if you need to communicate with a RADIUS server on a data interface, then specify that interface in the RADIUS configuration. Otherwise, if there is a default route in the management-only routing table, then it will match the default route and never fall back to the data routing table.

Dynamic Routing

The management-only routing table supports dynamic routing separate from the data interface routing table. A given dynamic routing process must run on either the management-only interface or the data interface; you cannot mix both types.

Equal-Cost Multi-Path (ECMP) Routing

The FTD device supports Equal-Cost Multi-Path (ECMP) routing.

You can have up to 8 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```

In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

ECMP Across Multiple Interfaces Using Traffic Zones

If you configure traffic zones to contain a group of interfaces, you can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Similarly, your dynamic routing protocol can automatically configure equal cost routes. The FTD device load-balances traffic across the interfaces with a more robust load balancing mechanism.

When a route is lost, the device seamlessly moves the flow to a different route.

About Route Maps

Route maps are used when redistributing routes into an OSPF, RIP, EIGRP or BGP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, and each has a permit or deny result. Evaluation of an ACL or a route map consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms. Criteria matches and match interpretation are dictated by the way that they are applied and the feature that uses them. The same route map applied to different features might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.
- Each ACL ends with an implicit deny statement, by design convention. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Route maps that are applied to *redistribution* behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained a deny statement at the end.

Permit and Deny Clauses

Route maps can have permit and deny clauses. The deny clause rejects route matches from redistribution. You can use an ACL as the matching criterion in the route map. Because ACLs also have permit and deny clauses, the following rules apply when a packet matches the ACL:

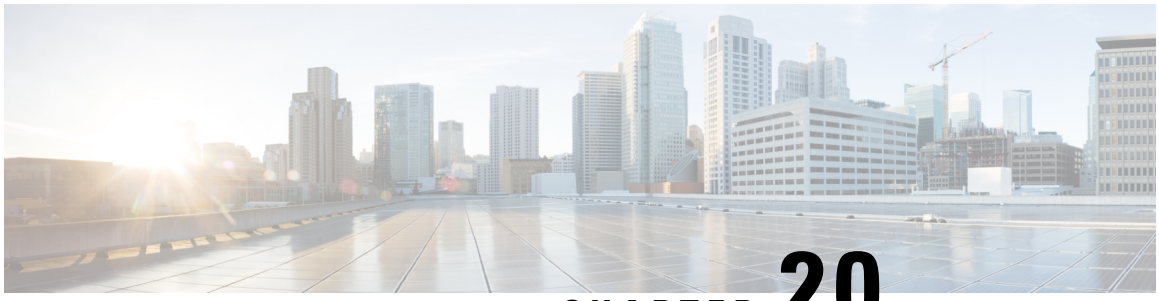
- ACL permit + route map permit: routes are redistributed.
- ACL permit + route map deny: routes are not redistributed.
- ACL deny + route map permit or deny: the route map clause is not matched, and the next route-map clause is evaluated.

Match and Set Clause Values

Each route map clause has two types of values:

- A match value selects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeeds, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the set commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found that matches the route or until the end of the route map is reached.



A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several match entries are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a match entry refers to several objects in one entry, either of them should match (the logical OR algorithm is applied).
- If a match entry is not present, all routes match the clause.
- If a set entry is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note Do not configure a set entry in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a match or set entry does perform an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

CHAPTER 20

Virtual Routers

This chapter describes underlying concepts about virtual routers and on how virtual routing behaves within the Firepower Threat Defense.

- History for Virtual Routers, on page 738

About Virtual Routers and Virtual Routing and Forwarding (VRF)

You can create multiple virtual routers to maintain separate routing tables for groups of interfaces. Because each virtual router has its own routing table, you can provide clean separation in the traffic flowing through the device.

Thus, you can provide support to two or more distinct customers over a common set of networking equipment. You can also use virtual routers to provide more separation for elements of your own network, for example, by isolating a development network from your general purpose corporate network.

Virtual routers implement the “light” version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP).

When you create a virtual router, you assign interfaces to the router. You can assign a given interface to one, and only one, virtual router. You would then define static routes, and configure routing protocols such as OSPF or BGP, for each virtual router. You would also configure separate routing processes over your entire network, so that routing tables on all participating devices are using the same per-virtual-router routing process and tables. Using virtual routers, you create logically-separated networks over the same physical network to ensure the privacy of the traffic that runs through each virtual router.

Because the routing tables are separate, you can use the same, or overlapping, address spaces across the virtual routers. For example, you could use the 192.168.1.0/24 address space for two separate virtual routers, supported by two separate physical interfaces.

Note that there are separate management and data routing tables per virtual router. For example, if you assign a management-only interface to a virtual router, then the routing table for that interface is separate from the data interfaces assigned to the virtual router.

Applications of Virtual Routers

You can use virtual routers to isolate network on shared resources and/or to isolate networks with common security policy. Thus, virtual routers help you to achieve:

- Traffic separation for customers through dedicated routing tables for each customer or for different departments.
- Common security policy management for different departments or networks.
- Shared internet access for different departments or network.

Global and User-Defined Virtual Routers

Global Virtual Routers

For a device with virtual routing capability, system creates a global virtual router by default. The system assigns all interfaces in your network to the global virtual router. A routed interface can belong to either a user-defined virtual router or a global virtual router. When you upgrade FTD to a version which has virtual router capability, all its existing routing configuration becomes part of the global virtual router.

User-Defined Virtual Routers

A user-defined virtual router is the one defined by you. You can create more than one virtual router on a device. However, anytime, an interface can be assigned to only one user-defined virtual router. While some of the device features are supported on user-defined virtual routers, few of the features are supported only on the global virtual routers. .

Supported Features and Monitoring Policies

You can configure the following features on the global virtual router only:

- OSPFv3
- RIP
- EIGRP
- IS-IS
- Multicast Routing
- Policy Based Routing (PBR)
- VPN

EIGRP, ISIS, and PBR are supported through Flex Config in FMC (see Predefined FlexConfig Objects, on page 1904). Configure only global virtual router interfaces for these features.

DHCP server auto-configuration uses WINS/DNS server that is learned from an interface. This interface can only be a global virtual router interface.

You can configure the following features separately for each user-defined virtual router:

- Static routes and their SLA monitors
- OSPFv2
- BGPv4/v6
- Integrated Routing and Bridging (IRB)
- SNMP

Following features are used by the system when querying or communicating with the remote system (from-the-box traffic). These features use interfaces in the global virtual router only. That means, if you configure an interface for the feature, it must belong to the global virtual router. As a rule, anytime, if the system must look up a route to reach an external server for its own management purposes, it does the route lookup in the global virtual router.

- DNS server when used to resolve fully qualified names used in access control rules, or for resolving names for the **ping** command. If you specify **any** as the interface for a DNS server, the system considers interfaces in the global virtual router only.
- AAA server or identity realm when used with VPN. You can configure VPN on interfaces in the global virtual router only. Thus, the external AAA servers that are used for VPN, such as Active Directory, must be reachable through an interface in the global virtual router.
- Syslog server.

Configuring Policies to be Virtual-Router-Aware

When you create a virtual router, the routing table for that virtual router is automatically separated from the global virtual router or any other virtual router. However, security policies are not automatically virtual-router-aware.

For example, if you write an access control rule that applies to “any” source or destination security zone, then the rule will apply to all interfaces across all virtual routers. This might in fact be exactly what you want. For example, all of your customers might want to block access to the same list of objectionable URL categories.

But, if you need to apply a policy to one of the virtual routers but not others, you need to create security zones that contain interfaces from that single virtual router only. Then, use the virtual-router-constrained security zones in the source and destination criteria of the security policy.

By using security zones whose memberships are constrained to the interfaces assigned to a single virtual router, you can write virtual-router-aware rules in the following policies:

- Access control policy.
- Intrusion and file policies.
- SSL decryption policy.
- Identity policy and user-to-IP address mappings. If you use overlapping address spaces in virtual routers, ensure that you create separate realms for each virtual router and apply them correctly in the identity policy rules.

If you use overlapping address spaces in your virtual routers, you should use security zones to ensure that the right policies get applied. For example, if you use the 192.168.1.0/24 address space in two separate virtual routers, an access control rule that simply specifies the 192.168.1.0/24 network will apply to traffic in both virtual routers. If that is not the desired outcome, you can limit the application of the rule by also specifying the source/destination security zones for just one of the virtual routers.

Interconnecting Virtual Routers

Static and Dynamic Route Leaking

You can configure the device to route traffic between virtual routers. This process of route leaking can be done manually by setting up static routes or dynamically through BGP settings.

Static Route Leaking

You can configure static routes to route traffic between virtual routers.

For example, if you have the outside interface in the global virtual router, you can set up static default routes in each of the other virtual routers to send traffic to the outside interface. Then, any traffic that cannot be routed within a given virtual router gets sent to the global router for subsequent routing.

Static routes between virtual routers are known as route leaks, because you are leaking traffic to a different virtual router. When you are leaking routes, say, VR1 routes to VR2, you can initiate connections from VR2 to VR1 only. For traffic to flow from VR1 to VR2, you must configure the reverse route. When you create a static route to an interface in another virtual router, you do not need to specify a gateway address. Simply select the destination interface.

For inter-virtual-router routes, the system does destination interface look-up in the source virtual router. Then, it looks up the MAC address of the next hop in the destination virtual router. Thus, the destination virtual router must have either a dynamic (learned) or static route for the selected interface for the destination address.

Configuring NAT rules that use source and destination interfaces in different virtual routers can also allow traffic to route between virtual routers. If you do not select the option for NAT to do a route lookup, the rule will simply send traffic out the destination interface with a NATed address whenever destination translation happens. However, the destination virtual router should have a route for the translated destination IP address so that next-hop lookup can succeed.

Though NAT rule leaks traffic from one virtual router to another, to ensure correct routing, we recommend that you configure a static route leak between these virtual routers for the translated traffic. Without the route leak, sometimes the rule may not match the traffic you expect it to match, and the translation may not be applied.

Virtual routing does not support a cascading or chain of route leaks. For example, assume that your FTD has VR1, VR2, and VR3 virtual routers; VR3 is directly connected to a network - 10.1.1.0/24. Now, assume you configure a route leak in VR1 for network 10.1.1.0/24 through interface in VR2 and in VR2 define a route leak for 10.1.1.0/24 through VR3. This chain of route leaks will not allow traffic to hop from VR1 to VR2 and then exit from VR3. In case of route leaks, the route lookups first determine egress interface from input Virtual Router’s routing table and then looks at the output of Virtual Router’s routing table for next hop lookup. From both the lookups, egress interface should match. In our example, the egress interfaces will not be the same and hence the traffic does not pass through.

Use static inter VRF route with caution when the destination network is not a direct-connected subnet of the upstream (outgoing) VR. For example, assume two VRs - VR1 and VR2. While VR1 handles the outgoing traffic which gets the default route from its external peer through BGP or any dynamic routing protocol, and

VR2 handles the incoming traffic which is configured with static inter VRF default route with VR1 as the next-hop. When VR1 loses the default route from its peer, VR2 will not able to detect that its upstream (outgoing) VR lost the default route and the traffic is still sent toward VR1 which will eventually get dropped without notifications. In this scenario, we recommend that you configure VR2 with dynamic route leak through BGP.

Dynamic Route Leaking Using BGP

You can implement an inter-virtual-router route leak by exporting routes from a source virtual router (say VR1) to the source BGP table using route target extended community and then importing the same route target extended community from the source BGP table into the destination BGP table, which in turn is used by the destination virtual router (say, VR2). You can use the route maps for filtering the routes. The routes of global virtual router can also be leaked to user-defined virtual routers and vice versa. The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

For details on configuring BGP route leaking, see Configure BGP Route Import/Export Settings, on page 794.

BGP Route Leaking Guidelines

- Ensure that all the routes required for recursion are imported and present in the routing table of the ingress virtual router.
- ECMP is supported per virtual router. Hence, do not configure an ECMP across different virtual routers. The overlapping prefixes imported from different virtual routers cannot form an ECMP. That is, when you attempt to import routes with overlapping addresses from two different virtual routers to other virtual routers (a global virtual router or an user-defined virtual router), only one route (as per BGP best path algorithm, the first route that was advertised) is imported to the respective virtual routing table. For example, if a network 10.10.0.0/24, connected to VR1 is advertised through BGP to a global virtual router first, and later another network with the same address 10.10.0.0/24, connected to VR2 is also advertised through BGP to global virtual router, only the VR1 network route is imported to the global virtual routing table.
- OSPFv3 is not supported on user-defined virtual routers. Hence, do not configure BGPv6 to leak OSPFv3 user-defined virtual routers to global virtual router. However, you can configure BGPv6 to leak OSPFv3 global virtual router routes to user-defined virtual router through redistribution.

Overlapping IP Addresses

Virtual router creates multiple instances of routing tables that are independent, thereby, the same or overlapping IP addresses can be used without conflicts. FTD allows the same network to be part of two or more virtual routers. This involves multiple policies to be applied at the interface or at the virtual router level.

Other than few exceptions, the routing functions and most of the NGFW and IPS capability does not get impacted by the overlapping IP addresses. The following section describes the features that have limitations with overlapping IP addresses and the suggestions or recommendations to overcome them.

Limitations with Overlapping IP Addresses

When using an overlapping IP address in multiple virtual routers, to ensure proper application of the policy, you have to modify policies or rules for some of the features. Such features require you to use more specific interface either by splitting existing security zone or using new interface group as the need be.

Following features need modification for its proper functioning with an overlapping IP address:

- Network Map—Modify the network discovery policy to exclude some overlapping IP segments to ensure that there is no overlapping IP address being mapped.
- Identity Policy—The identity feed source cannot differentiate among virtual routers; to overcome this limitation, map overlapping address spaces or virtual routers in different realms.

For the following features, you need to apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments:

- Access Policy
- Prefilter Policy
- QoS/Rate Limit
- SSL Policy

Unsupported Features with Overlapping IP Addresses

- ISE SGT-based Rule in AC Policy—The static security group tag (SGT) to IP address mappings downloaded from Cisco Identity Services Engine (ISE) are not virtual-router-aware. Set up separate ISE systems per virtual router if you need to create different SGT mappings per virtual router. This is not necessary if you intend to map the same IP addresses to the same SGT number in each virtual router.
- Overlapping DHCP server pools are not supported across virtual routers.
- Events and Analytics—Many of the FMC analytics are dependent on network map and identity mappings which cannot differentiate if the same IP address belongs to two different end hosts. Hence, these analytics are not accurate when there are overlapping IP segments existing in same device but different virtual routers.

Configuring SNMP on User-Defined Virtual Routers

In addition to supporting SNMP on the management interface and Global virtual router data interfaces, Firepower Threat Defense now allows you to configure SNMP host on user-defined virtual routers.

Configuring an SNMP host on user-defined virtual routers includes the following process:

1. Enable the Physical Interface and Configure Ethernet Settings
2. Create a Virtual Router
3. Add SNMP Hosts

Note SNMP is not virtual router-aware. Hence, while configuring SNMP server on the user-defined virtual router, ensure that the network address is not an Overlapping IP Addresses.

4. Deploy Configuration Changes. On successful deployment, the-SNMP polling and traps are sent to the Network Management Station through the virtual router interface.

Maximum Number of Virtual Routers By Device Model

The maximum number of virtual routers you can create depends on the device model. The following table provides the maximum limits. You can double-check on your system by entering the **show vrf counters** command, which shows the maximum number of user-defined virtual routers for that platform not including the global virtual router. The numbers in the table below include user and global routers. For the Firepower 4100/9300, these numbers apply to native mode.

For platforms that support multi-instance capability, such as the Firepower 4100/9300, determine the maximum number of virtual routers per container instance by dividing the maximum virtual routers by the number of cores on the device, and then multiplying by the number of cores assigned to the instance, rounding down to the nearest whole number. For example, if the platform supports a maximum of 100 virtual routers, and it has 70 cores, then each core would support a maximum of 1.43 virtual routers (rounded). Thus, an instance assigned 6 cores would support 8.58 virtual routers, which rounds down to 8, and an instance assigned 10 cores would support 14.3 virtual routers (rounding down, 14).

Device Model	Maximum Virtual Routers
Firepower 1010	Virtual routers are not supported on this model.
Firepower 1120	5
Firepower 1140	10
Firepower 1150	10
Firepower 2110	10
Firepower 2120	20
Firepower 2130	30
Firepower 2140	40
Secure Firewall 3110	15
Secure Firewall 3120	25
Secure Firewall 3130	50
Secure Firewall 3140	100
Firepower 4110	60
Firepower 4112	60
Firepower 4115	80
Firepower 4120	80
Firepower 4125	100
Firepower 4140	100

Device Model	Maximum Virtual Routers
Firepower 4145	100
Firepower 4150	100
Firepower 9300 appliance, all models	100
FTDv, all platforms	30
ISA 3000	10

Guidelines and Limitations for Virtual Routers

Firewall Mode Guidelines

Virtual routers are supported on routed firewall mode only.

Interface Guidelines

- You can assign an interface to only one virtual router.
- A virtual router can have any number of interfaces that are assigned to it.
- You can assign only routed interfaces with logical names to a user-defined virtual router.
- If you want to change a virtual router interface to a non-routed mode, remove the interface from the virtual router, and then change its mode.

- You can assign an interface to a virtual router, either from a global virtual router or from another user-defined virtual router.
- The following interfaces cannot be assigned to an user-defined virtual router:
  - Diagnostic interfaces.
  - Members of EtherChannel.
  - Members of Redundant interfaces.
  - Members of BVI.
  - Static VTIs.
- VTI is supported only in global virtual router. The tunnel source of VTI interface should also belong to the global virtual router.
- You cannot use interfaces that belong to user-defined virtual routers in policy-based site-to-site or remote access VPNs.
- If a route using the interface that is being moved or its virtual router is deleted, exist in source or destination virtual router table, remove the routes before the interface movement or virtual router deletion.
- As separate routing tables are maintained for each virtual router, when an interface is moved from one virtual router to another virtual router, be it global or user-defined, the system removes the IP address configured on the interface temporarily. All existing connections on the interface are terminated. Thus, moving interfaces between virtual routers have drastic effect on the network traffic. Hence take precautionary measures before you move interfaces.

Global Virtual Router Guidelines

- The interfaces which are named and not part of other virtual routers, are part of the global virtual router.
- You cannot remove routed interfaces from global virtual router.
- You cannot modify global virtual router.
- Generally, after configuring interfaces, if you un-register and register back to same or another FMC, interface configuration is imported back from device. With virtual router support, there is a restriction—the IP address for only global virtual router interfaces is retained.

Clustering Guidelines

- When the control unit link fails due to failure of its interfaces, the unit removes all leaked routes of its interfaces from the global routing table and propagates the inactive connected and static routes to other units of the cluster. This results in removal of those leaked routes from the routing table in other units. These removal takes place prior to another unit becoming a new control unit, which takes approximately 500 ms. When another unit becomes the new control unit, these routes are learned and added back to the routing tables through BGP convergence. Thus, till the convergence time, approximately one minute, the leaked routes are not available for the routing events to take place.
- When a control role change occurs in a cluster, the leaked routes learnt through BGP is updated with the best ECMP path. However, the non-best ECMP path is removed from the cluster routing table only after

the BGP reconvergence timer elapses, that is 210 seconds. Thus, till the BGP reconvergence timer elapse, the old, non-best ECMP path persist as preferred route for routing events.

Additional Guidelines

- While configuring BGP for virtual routers, you can redistribute the routes belonging to different protocols within the same virtual routers. For example, OSPF VR2 routes cannot be imported into BGP VR1. You can only redistribute OSPF VR2 into BGP VR2, and then configure a route leak between BGP VR2 and BGP VR1.
- You cannot use IPv6 ACL for filtering the routes in the route map. Only prefix list is supported.
- Security Intelligence Policy—The Security Intelligence policy is not virtual-router-aware. If you add an IP address, URL, or DNS name to the block list, it is blocked for all virtual routers. This limitation is applicable on the interface having security zones.
- NAT Rules—Do not mix interfaces in NAT rules. In virtual routing, if the specified source and destination interface objects (interface groups or security zones) have interfaces that belong to different virtual routers, the NAT rule diverts traffic from one virtual router through another virtual router. The NAT does the route lookup in the virtual router table for the inbound interface only. If necessary, define static routes in the source virtual router for the destination interface. If you leave the interface as **any**, the rule applies to all interfaces regardless of virtual router membership.
- DHCP Relay—Interconnecting virtual routers for DHCP relay is not supported. For example, if DHCP relay client is enabled on VR1 interface and DHCP relay server is enabled on VR2 interface, the DHCP requests will not be forwarded outside of VR2 interface.
- Recreating a deleted virtual router—When you recreate a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to recreate a deleted virtual router successively, use a different name for the new virtual router.

Modifications to the FMC Web Interface - Routing Page

Devices earlier to the FTD 6.6 and few device models are not supported with virtual routing capability. The FMC web interface displays the same Routing page of the FMC 6.5 or earlier version for such non supported devices. To know the supported devices and platform for virtual routing, see Maximum Number of Virtual Routers By Device Model.

You can configure virtual routers in the routing page of a supported device:

1. Navigate to **Devices** > **Device Management** and edit the virtual-router-aware device.
2. Click **Routing** to enter the virtual routers page.

For devices using virtual routing, the left pane of the Routing page displays the following:

- **Manage Virtual Routers**—allows you to create and manage virtual routers.
- List of virtual routing protocols—lists routing protocols that you can configure for the virtual routers.
- **General Settings**—allows you to configure BGP general settings that are applicable for all the virtual routers. Select the **Enable BGP** check box in order to define other BGP settings. To configure other BGP settings for a virtual router, navigate to **BGP** in the virtual routing protocols .

Manage Virtual Routers

When you click **Manage Virtual Routers** on the Virtual Routers pane, the Manage Virtual Routers page appears. This page displays the existing virtual routers on the device and the associated interfaces. In this page, you can **Add Virtual Router** (+) to the device. You can also **Edit** (✎) and **Delete** (🗑) user-defined virtual routers. You cannot edit or remove a global virtual router. You can only **View** (🔍) the details of a global virtual router.

Create a Virtual Router

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

Step 4 Click **Add Virtual Router** (+).

Step 5 In the Add Virtual Router box, enter a name and description for the virtual router.

Note
If you are creating a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to create a deleted virtual router successively, use a different name for the new virtual router.

Step 6 Click **Ok**.

The Routing page appears, displaying the newly created virtual router page.

What to do next

- Configure a Virtual Router.

Configure a Virtual Router

You can assign interfaces to a user-defined virtual router and configure the routing policies for the device. Though you cannot manually add or remove interfaces for a global virtual router, you can configure the routing policies for the device interfaces.

Before you begin

- To configure routing policies for a user-defined virtual router, add a router. See Create a Virtual Router, on page 699.

- All routing configuration settings of a non-virtual routing capable device are also available for a global virtual router. For information on the settings, see Reference for Routing.
- Only limited routing protocols are supported for a user-defined virtual router.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the virtual-router supported device. Navigate to **Routing**. For information on the modifications to the routing page, see Modifications to the FMC Web Interface - Routing Page, on page 698.

Step 2 From the drop-down list, select the desired virtual router.

Step 3 In the **Virtual Router Properties** page, you can modify the description.

Step 4 To add interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.

Remember the following:

- Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.
- Only interfaces of global virtual routers are available for assigning; the **Available Interfaces** box lists only interfaces that are not assigned to any other user-defined virtual routers. You can assign physical interfaces, subinterfaces, redundant interfaces, bridge groups, and EtherChannels to a virtual router, but not their member interfaces. Because the member interfaces cannot be named, they cannot be used in virtual routing.

  You can assign the diagnostic interface and VTIs to the global virtual router only. You must ensure that the tunnel source of the VTI interface should also belong to the global virtual router.

Step 5 To save the settings, click **Save**.

Step 6 To configure the routing policy for the virtual router, click the respective names to open the corresponding settings page:

- **OSPF**—Only OSPFv2 is supported on the user-defined virtual router. All other settings for OSPFv2 are as applicable as for a non-virtual-router-aware interface, except that **Interface** allows you to select only the interfaces of the virtual router that you are configuring. You can define the OSPFv3 and OSPFv2 routing policies for a global virtual router. For information on the OSPF settings, see OSPF, on page 751.
- **RIP**—You can configure RIP routing policies only for a global virtual router. For information on RIP settings, see RIP, on page 799.
- **BGP**—This page displays the BGP general settings that you have configured in **Settings**:
  - You cannot modify any of those general settings on this page, except for the router ID settings. You can override the router ID settings that were defined in the **Settings** page by editing them on this page.
  - To configure other BGP IPv4 or IPv6 settings, you must enable the BGP option in **BGP** page under **General Settings**.
  - BGP configuration for both IPv4 and IPv6 address family are supported for global router and the user-defined virtual router.

For information on configuring BGP settings, see BGP, on page 779.

- **Static Route**—Use this setting to define where to send traffic for a specific destination network. You can also use this setting to create an inter-virtual-router static route. You can create a leak of connected or static route by using the interfaces of user-defined or global virtual routers. **FMC prefixes** to an interface to indicate that it is belonging to another virtual router and can be used for a route leak. For the route leak to be successful, do not specify next hop gateway.

  The Static Route table displays the virtual router whose interface is used for a route leak in the **Leaked from Virtual Router** column. If it is not a route leak, the column displays N/A.

  Irrespective of which virtual router the static route belongs, a Null0 interface is listed along with the interfaces of the same virtual router to which the static route belongs.

  For information on static route settings, see Static and Default Routes, on page 675.

- **Multicast**—You can configure multicast routing policies only for a global virtual router. For information on multicast settings, see Multicast, on page 805.

Step 7 To save the settings, click **Save**.

What to do next

- Modify a Virtual Router.
- Remove Virtual Routers.

Modify a Virtual Router

You can modify the description and other routing policies of a virtual router.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the assigned interfaces are displayed in the **Virtual Routers** page.

Step 4 To modify a virtual router, click **Edit** ( ) against the desired virtual router.

Note
You cannot modify the general settings of the global virtual router. Hence, edit is not available for the global router; instead a **View** ( ) is provided to view the settings.

Step 5 To save the changes, click **Save**.

What to do next

- Remove Virtual Routers.

Remove Virtual Routers

Before you begin

- You cannot delete the Global virtual router. Hence, the delete option is not available for the Global virtual router.
- You can remove multiple virtual routers at a time.
- All the routing policies of the deleted virtual router are also deleted.
- All the interfaces of the deleted virtual router move to the global virtual router.
- If there are any restrictions on the movement of interfaces, such as overlapping IPs, route conflicts, and so on, you can remove the router only after resolving the conflicts.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 Click **Manage Virtual Routers**.

All virtual routers along with the mapped interfaces are displayed in the **Virtual Routers** page.

Step 4 To remove a virtual router, click **Delete** ( ) against the desired virtual router.

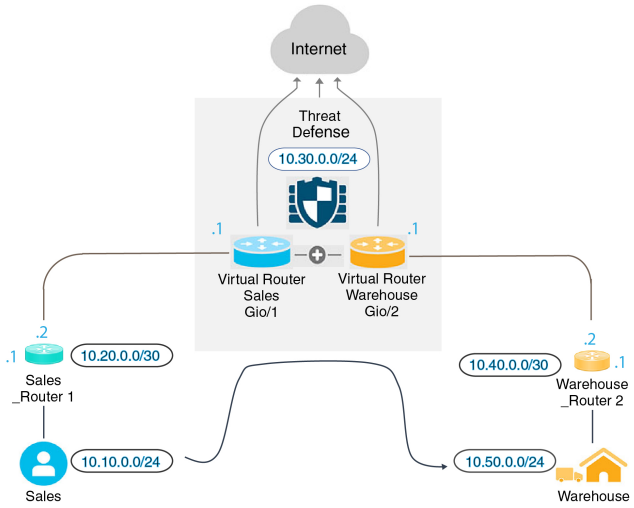
Step 5 To remove multiple routers, holding the CTRL key, click the virtual routers that you want to delete. Right-click, and then click **Delete**.

Step 6 To save the changes, click **Save**.

Monitoring Virtual Routers

To monitor and troubleshoot virtual routers, log into the device CLI and use the following commands:

- **show vrf**: Displays the details of the virtual routers and their associated interfaces.
- **show route vrf** <*vrf_name*>: Displays the routing details of a virtual router.
- **show run router bgp all**: Displays the BGP routing details of all virtual router.
- **show run router bgp vrf** <*vrf_name*>: Displays the BGP routing details of a virtual router.



Configuration Examples for Virtual Routers

How to Route to a Distant Server through Virtual Routers

In virtual routing, you can create multiple virtual routers to maintain separate routing tables for groups of interfaces, thereby achieve network separation. In some scenarios, you may need to access a server that is reachable only through a separate virtual router. This example provides the procedure that interconnects virtual routers to reach to a host that is multiple hops away.

Consider an example, where a member of the sales department of a garment company wants to look up at the stock maintained by the warehousing department of its factory unit. In a virtual routing environment, you need to leak route between virtual routers where destination (warehousing department) is multiple hops away from sales department. This route leaking is done by adding multihop route leak, where, you configure a static route in Sales virtual router(source) to an interface in Warehouse virtual router (destination). As the destination network is multi-hop away, you also need to configure the Warehouse virtual router with the route to the destination network, namely 10.50.0.0/24.

Figure 171: Interconnecting Two Virtual Routers - An Example

Before you begin

This example assumes that you have already configured Sales_Router1 to route traffic from 10.20.0.1/30 interface to 10.50.0.5/24.

Procedure

Step 1 Configure the inside interface (Gi0/1) of the device to be assigned to Sales virtual router:

a) Choose **Devices** > **Device Management** > **Interfaces**.

b) Edit the Gi0/1 interface:

- **Name**—For this example, VR-Sales.

- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.30.0.1/24.

c) Click **Ok**.
d) Click **Save**.

Step 2 Configure the inside interface (Gi0/2) of the device to be assigned to Warehouse virtual router:

a) Choose **Devices** > **Device Management** > **Interfaces**.
b) Edit the Gi0/2 interface:

- **Name**—For this example, VR-Warehouse.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address (10.30.0.1/24), as you are yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Create Sales and Warehouse virtual routers and assign their interfaces:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Choose **Routing** > **Manage Virtual Routers**.
c) Click **Add Virtual Router** and create Sales.
d) Click **Add Virtual Router** and create Warehouse.
e) Select Sales from virtual router drop-down, in **Virtual Router Properties**, add VR-Sales as **Selected Interface** and save.
f) Select Warehouse from virtual router drop-down, in **Virtual Router Properties**, add VR-Warehouse as **Selected Interface** and save.

Step 4 Revisit the VR-Warehouse interface configuration:

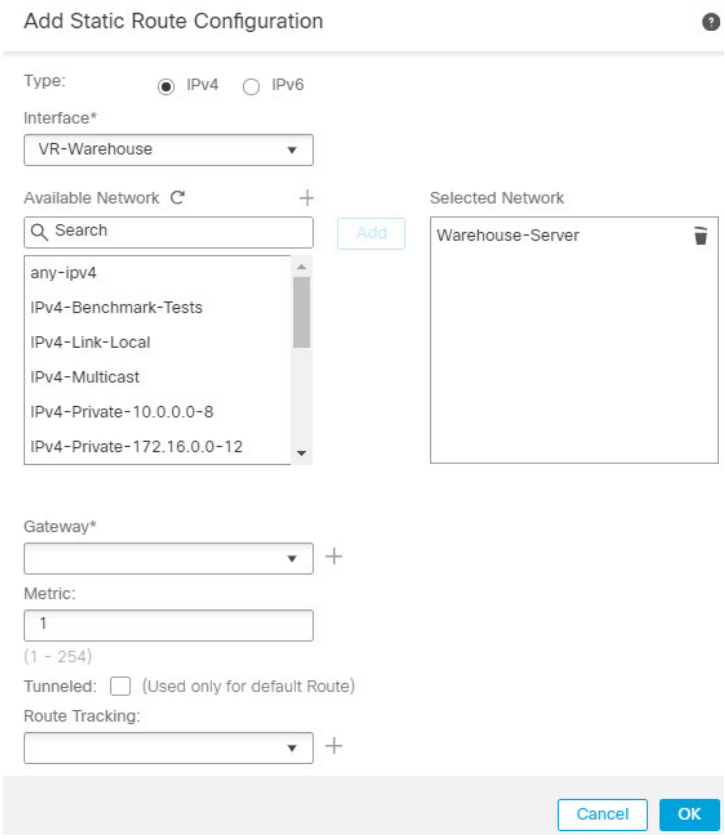
a) Choose **Devices** > **Device Management** > **Interfaces**.
b) Click **Edit** against VR-Warehouse interface. Specify the IP Address as 10.30.0.1/24. The system now allows you to configure with same IP address of VR-Sales, because the interfaces are seperately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 5 Create network objects for the warehouse server—10.50.0.0/24, and for the warehouse gateway— 10.40.0.2/30:

a) Choose **Object** > **Object Management**.
b) Choose **Add Network** > **Add Object**:

- **Name**—For this example, Warehouse-Server.
- **Network**—Click Network and enter 10.50.0.0/24.

c) Click **Save**.
d) Choose **Add Network** > **Add Object**:



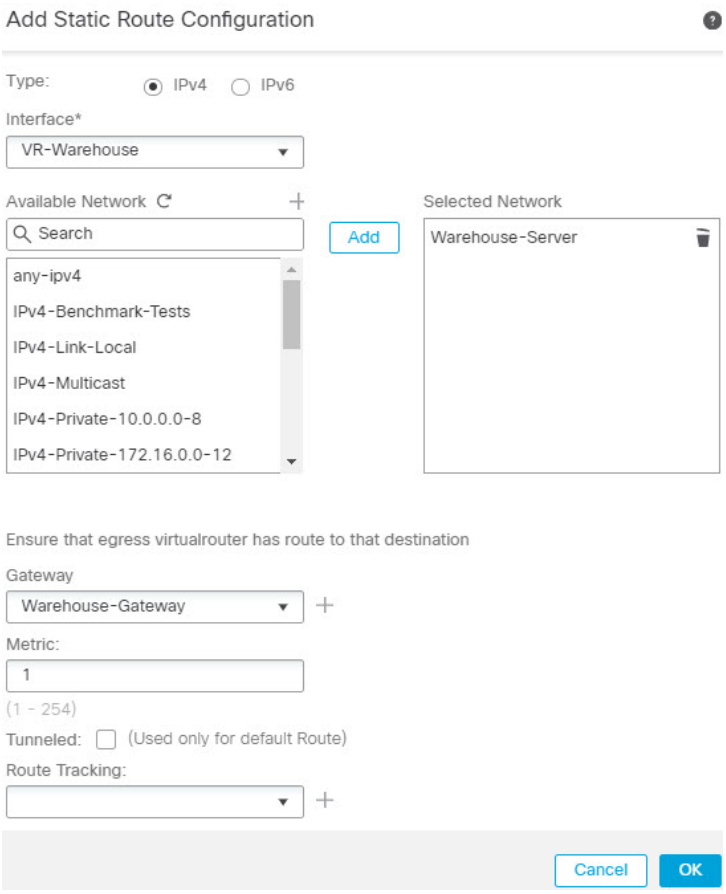
- **Name**—For this example, Warehouse-Gateway.
- **Network**—Click Host and enter 10.40.0.2.

e) Click **Save**.

Step 6 Define the route leak in Sales that points to the VR-Warehouse interface:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Choose **Routing**.
c) Choose Sales virtual router from the drop-down, and then click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.
- **Network**—Select the Warehouse-Server object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



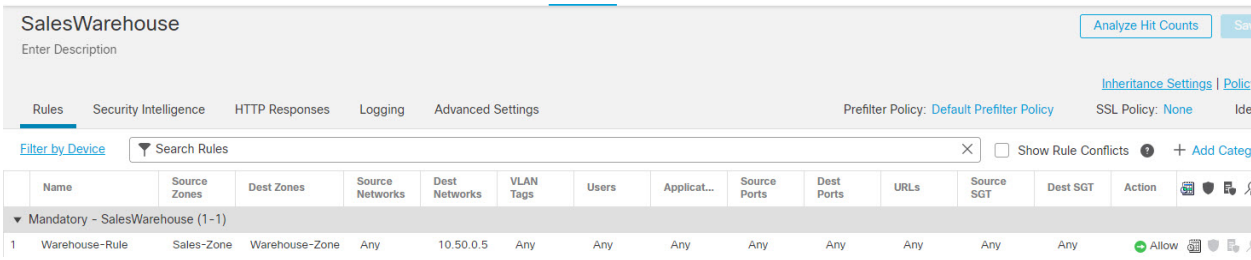
e) Click **Ok**.
f) Click **Save**.

Step 7 In the Warehouse virtual router, define the route that points to the Warehouse Router 2 gateway:

a) Choose Warehouse virtual router from the drop-down, and then click **Static Route**.
b) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select VR-Warehouse.

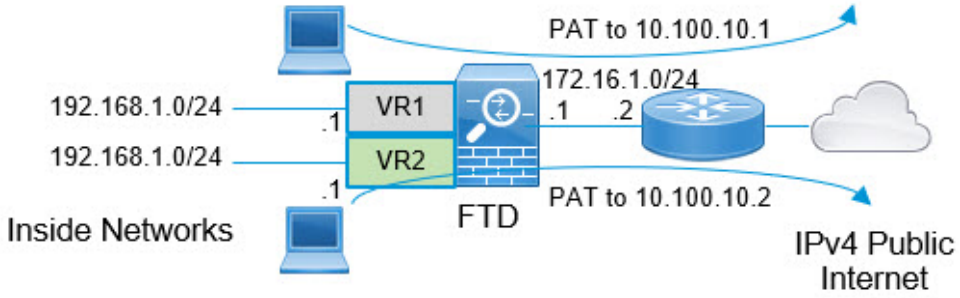
- **Network**—Select the Warehouse-Server object.
- **Gateway**—Select the Warehouse-Gateway object.



c) Click **Ok**.
d) Click **Save**.

Step 8 Configure access control rule that allows access to the warehouse server. For creating the access control rule, you need to create security zones. Use **Object** > **Object Management** > **Interface**. Choose **Add** > **Security Zone** and create security zones for VR-Sales and VR-Warehouse; for Warehouse-Server network object, create a Warehouse-Server interface group (Choose **Add** > **Interface Group**).

Step 9 Choose **Policies** > **Access Control** and configure an access control rule to allow traffic from the source interfaces in the Sales virtual router to the destination interfaces in the Warehouse virtual router for the destination Warehouse-Server network object.



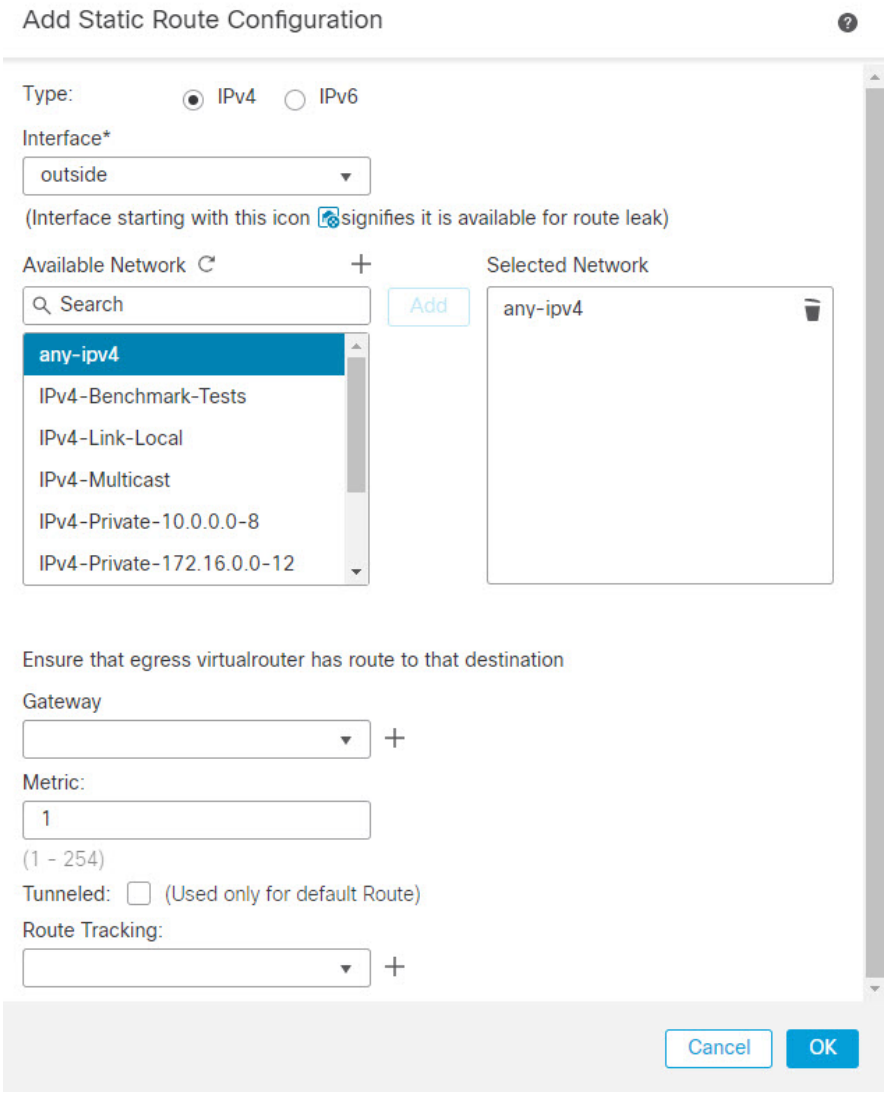
For example, if the interfaces in Sales are in the Sales-Zone security zone, and those in Warehouse are in the Warehouse-Zone security zone, the access control rule would look similar to the following:

How to Provide Internet Access with Overlapping Address Spaces

When using virtual routers, you can have the same network address for interfaces that reside in separate routers. However, because the IP addresses routed in these separate virtual routers are the same, apply NAT/PAT rules for each interface with separate NAT/PAT pools to ensure that return traffic goes to the correct destination. This example provides the procedure to configure the virtual routers and NAT/PAT rules to manage the overlapping address spaces.

For example, interfaces vr1-inside and vr2-inside on FTD is defined to use the IP address 192.168.1.1/24, managing endpoints on their segment in the 192.168.1.0/24 network. To allow Internet access from two virtual routers that use the same address space, you need to apply NAT rules separately to the interfaces within each virtual router, ideally using separate NAT or PAT pools. You could use PAT to translate the source addresses in VR1 to 10.100.10.1, and for those in VR2, to 10.100.10.2. The following illustration shows this setup, where the Internet-facing outside interface is part of the global router. You must define the NAT/PAT rules with the source interface (vr1-inside and vr2-inside) explicitly selected—using “any” as the source interface makes it impossible for the system to identify the correct source because the same IP address could exist on two different interfaces.

Note Even if you have some interfaces within virtual routers that does not use overlapping address spaces, define the NAT rule with the source interface to make troubleshooting easier, and to ensure a cleaner separation between traffic from the virtual routers that is Internet-bound.



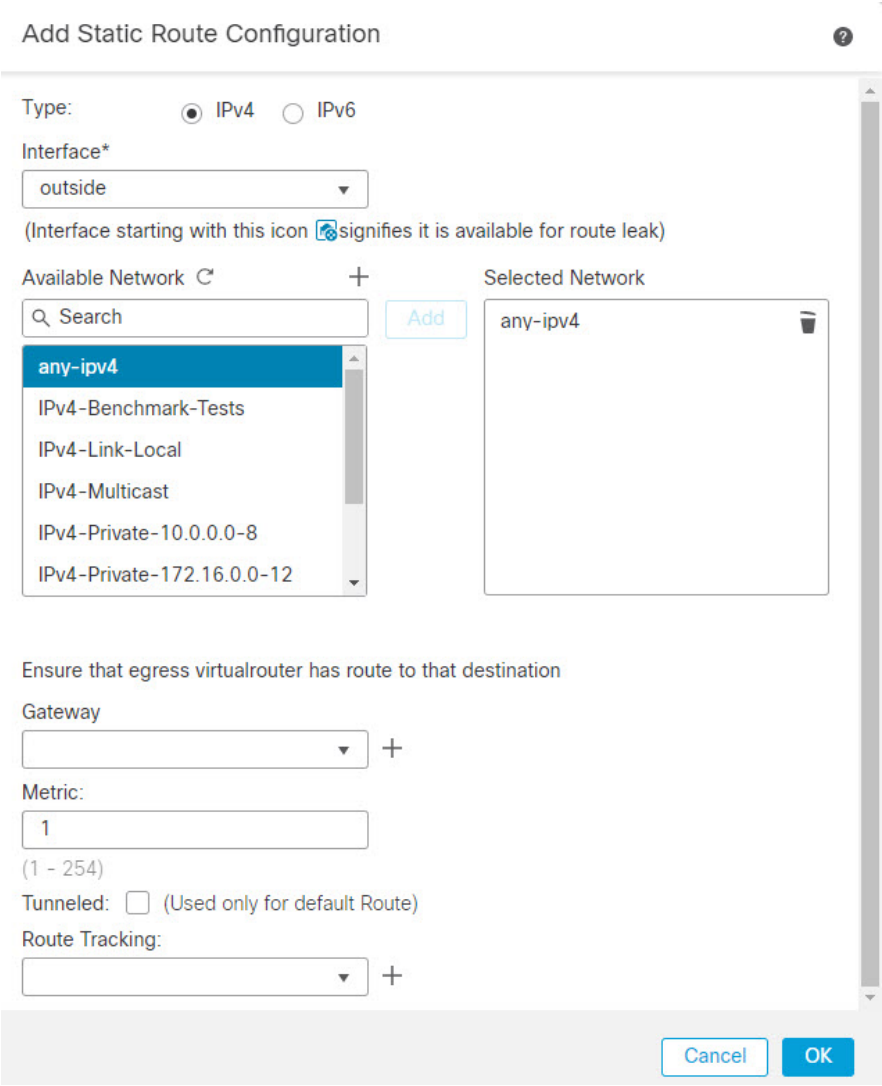
Procedure

Step 1 Configure the inside interface of the device for VR1:

a) Choose **Devices** > **Device Management** > **Interfaces**.
b) Edit the interfaces that you want to assign to VR1:
   - **Name**—For this example, vr1-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP**.
   - **IP Address**—Enter 192.168.1.1/24.
c) Click **Ok**.
d) Click **Save**.

Step 2 Configure the inside interface of the device for VR2:
a) Choose **Devices** > **Device Management** > **Interfaces**.
b) Edit the interfaces that you want to assign to VR2:
   - **Name**—For this example, vr2-inside.
   - Select the **Enabled** checkbox.
   - In **IPV4**, for **IP Type**, choose **Use Static IP**.
   - **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address, as you are yet to create user-defined virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 3 Configure VR1 and the static default route leak to the outside interface:
a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VR1.
c) For VR1, in **Virtual Router Properties**, assign vr1-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
   - **Interface**—Select the outside interface of the global router.
   - **Network**—Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR1.
   - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not provide a Gateway.



f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VR2 and the static default route leak to the outside interface:

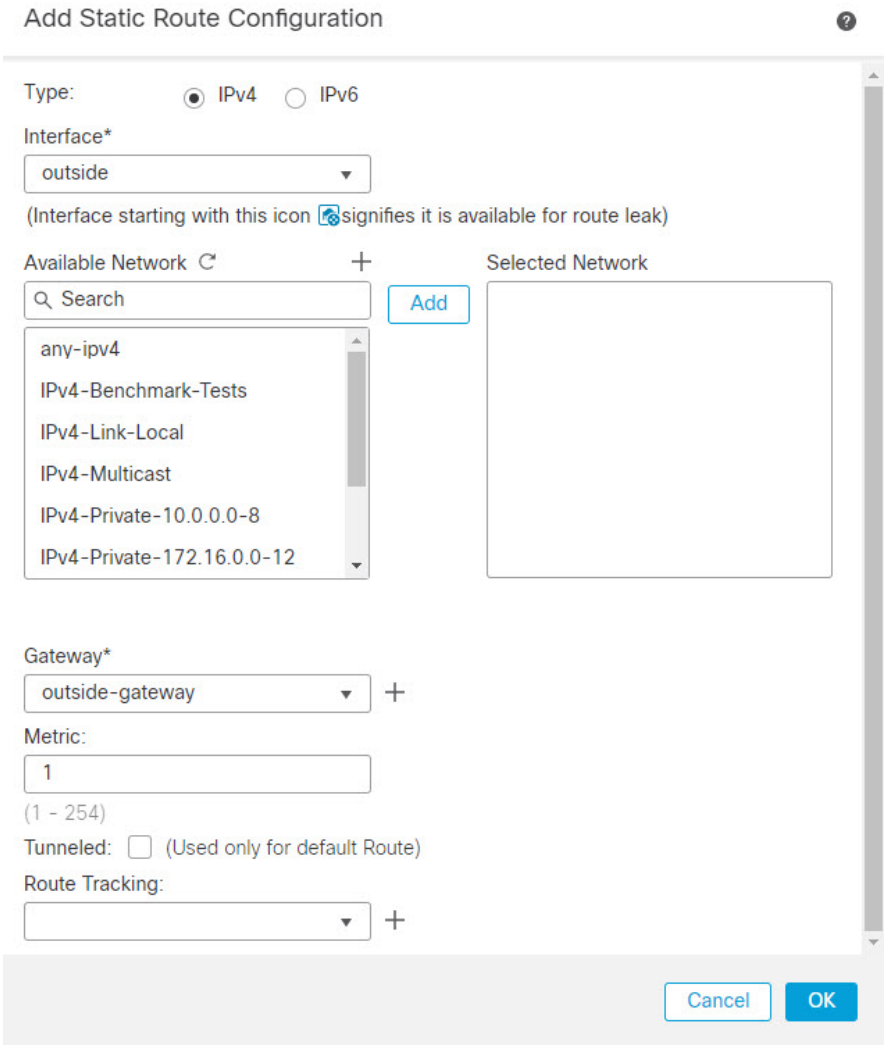
a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VR2.
c) For VR2, in **Virtual Router Properties**, assign vr2-inside and save.
d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR2.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the Gateway.

f) Click **Ok**.

g) Click **Save**.

Step 5 Configure IPv4 static default route, namely 172.16.1.2 on the outside interface of the global router:



a) Choose **Devices** > **Device Management**, and edit the FTD device.

b) Choose **Routing** and edit global router properties.

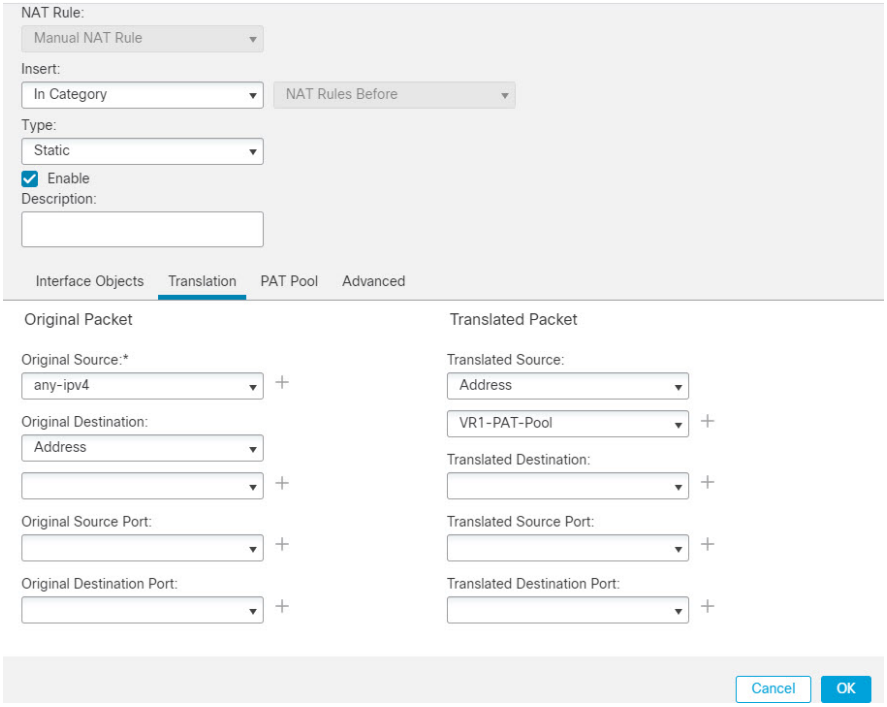
c) Click **Static Route**.

d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the any-ipv4 object. This will be the default route for any IPv4 traffic.
- **Gateway**—If already created, select the host name from the drop-down. If the object is not yet created, click **Add** and define the host object for the IP address of the gateway at the other end of the network link on the outside interface, in this example, 172.16.1.2. After you create the object, select it in the Gateway field.

e) Click **Ok**.
f) Click **Save**.

Step 6 Revisit the vr2-inside interface configuration:



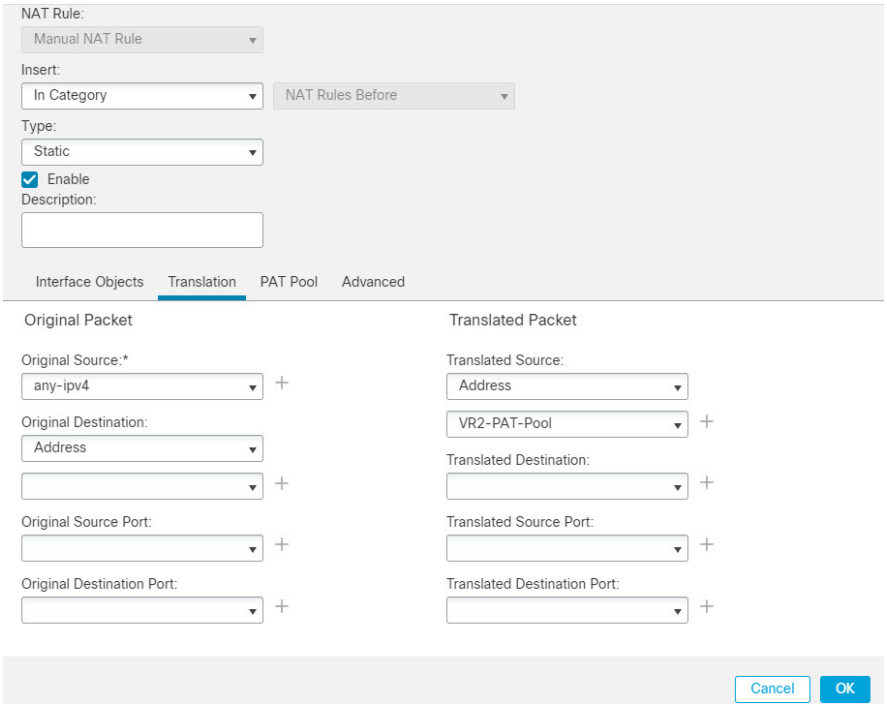
a) Choose **Devices** > **Device Management** > **Interfaces**.
b) Click **Edit** against vr2-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with same IP address of vr1-inside, because the interfaces are separately assigned to two different virtual routers.
c) Click **Ok**.
d) Click **Save**.

Step 7 Create the NAT rule to PAT inside to outside traffic of VR1 to 10.100.10.1.

a) Choose **Devices** > **NAT**.
b) Click **New Policy** > **Threat Defense NAT**.
c) Enter InsideOutsideNATRule as the NAT policy name, and select the FTD device. Click **Save**.
d) In InsideOutsideNATRule page, click **Add Rule** and define the following:

- **NAT Rule**—Select Manual NAT Rule.

- **Type**—Select Dynamic.
- **Insert**—Above, if any dynamic NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select vr1-interface object and click **Add to Source** (If the object is not available, create one in **Object** > **Object Management** > **Interface**), and select outside as **Add to Destination**.
- In **Translation**, for **Original Source**, select any-ipv4. For **Translated Source**, click **Add** and define host object VR1-PAT-Pool with 10.100.10.1. Select VR1-PAT-Pool as shown in the figure below:



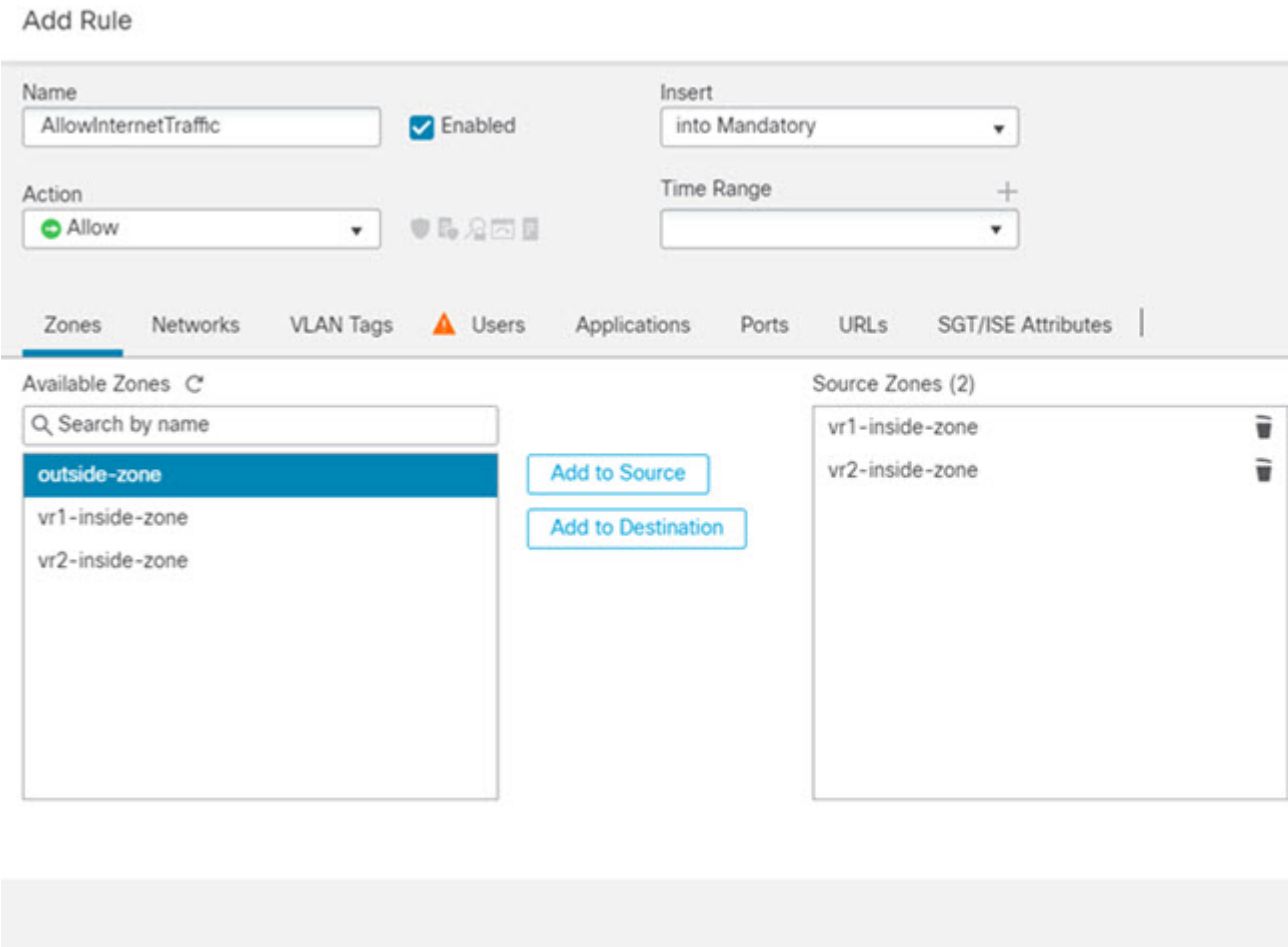
e) Click **Ok**.
f) Click **Save**.

Step 8 Add NAT rule to PAT inside to outside traffic of VR2 to 10.100.10.2.

a) Choose **Devices** > **NAT**.
b) Edit InsideOutsideNATRule to define the VR2 NAT rule:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Dynamic.
- **Insert**—Above, if any dynamic NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select vr2-interface object and click **Add to Source** (If the object is not available, create one in **Object** > **Object Management** > **Interface**), and select outside as **Add to Destination**.

- In **Translation**, for **Original Source**, select any-ipv4. For **Translated Source**, click **Add** and define host object VR2-PAT-Pool with 10.100.10.2. Select VR2-PAT-Pool as shown in the figure below:

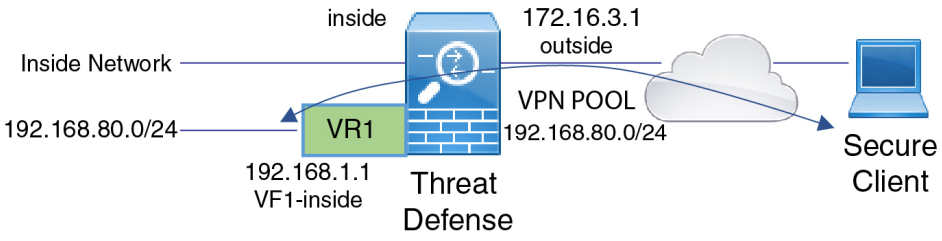


c) Click **Ok**.

d) Click **Save**.

Step 9 To configure the access control policy that allows traffic from the vr1-inside and vr2-inside interfaces to the outside interface, you need to create security zones. Use **Object** > **Object Management** > **Interface**. Choose **Add** > **Security Zone** and create security zones for vr1-inside, vr2-inside, and outside interfaces.

Step 10 Choose **Policies** > **Access Control** and configure an access control rule to allow traffic from vr1-inside-zone and vr2- inside-zone to outside-zone.



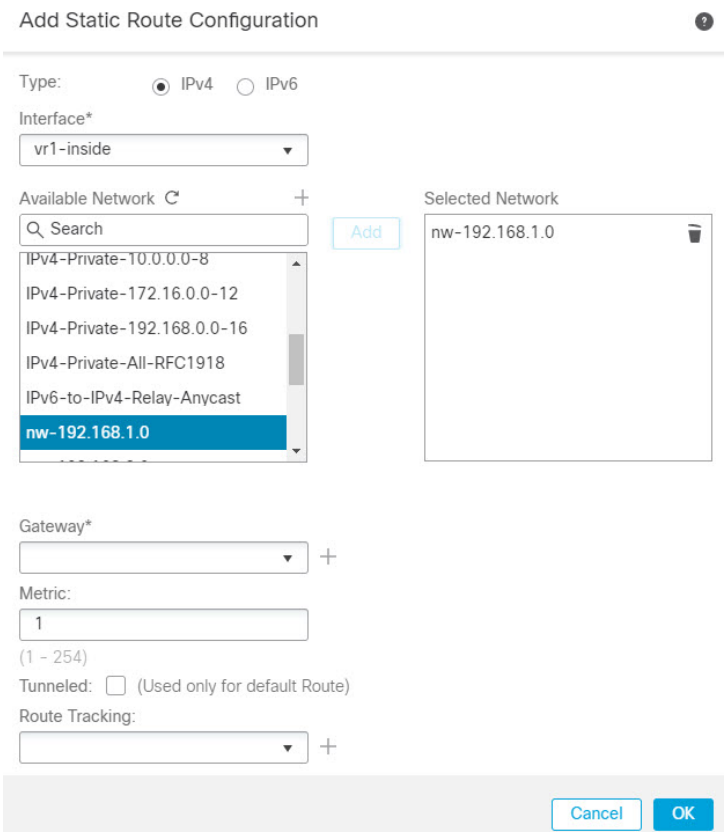
Assuming that you create zones named after the interfaces, a basic rule that allows all traffic to flow to the Internet will look like the following. You can apply other parameters to this access control policy:

How to Allow RA VPN Access to Internal Networks in Virtual Routing

On virtual routing-enabled devices, RA VPN is supported only on global virtual router interfaces. This example provides the procedure that allows your AnyConnect Client user to connect to user-defined virtual router networks.

In the following example, the RA VPN (AnyConnect Client) user connects to the outside interface of FTD at 172.16.3.1, and is given an IP address within the pool of 192.168.80.0/24. The user can access the inside network of only the global virtual router. To allow traffic flow through the network of the user-defined virtual router VR1, namely 192.168.1.0/24, leak the route by configuring the static routes on global and VR1.

Before you begin



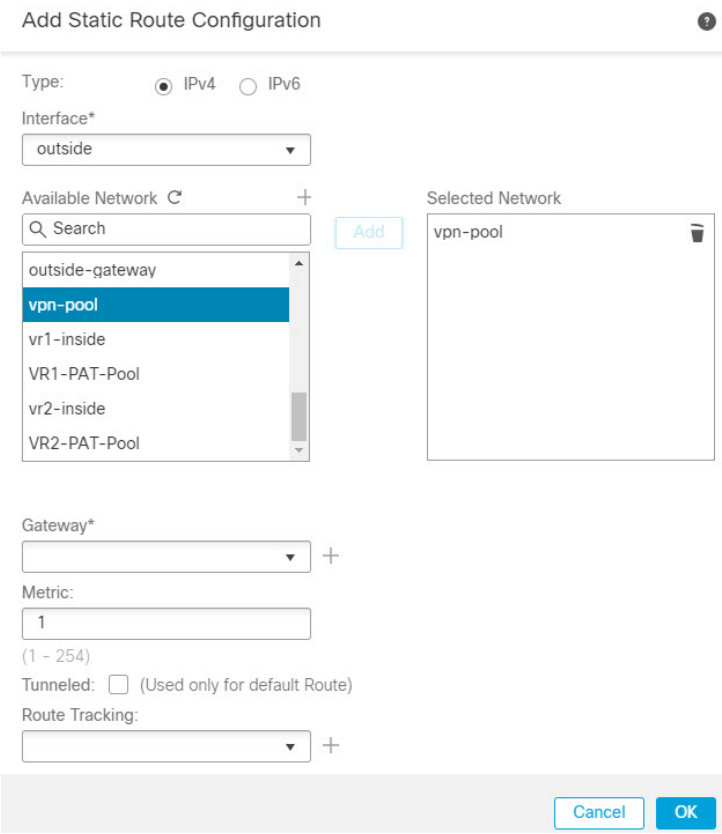
This example assumes that you have already configured the RA VPN, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

Procedure

Step 1 Configure route leak from Global virtual router to the user-defined VR1:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Click **Routing**. By default, the Global routing properties page appears.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.



The route leak allows AnyConnect Client assigned IP addresses in the VPN pool to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

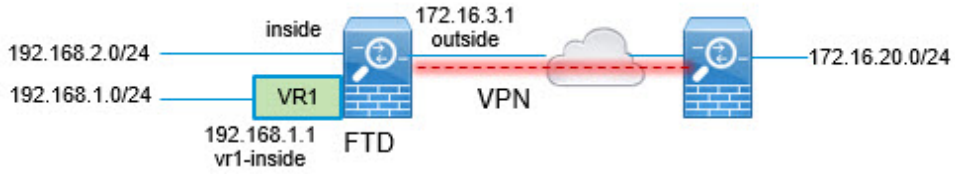
Step 2 Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

The configured static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections to AnyConnect Client assigned IP addresses in the VPN pool.

e) Click **Ok**.



What to do next

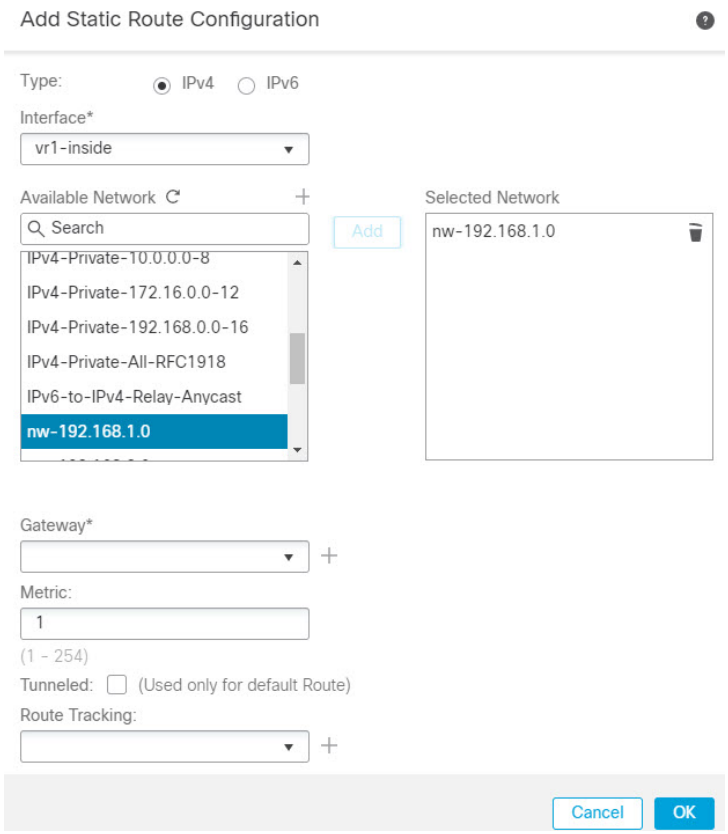
If RA VPN address pool and the IP addresses in the user-defined virtual router overlap, you must also use static NAT rules on the IP addresses to enable proper routing. Alternatively, you can change your RA VPN address pool so that there is no overlap.

How to Secure Traffic from Networks in Multiple Virtual Routers over a Site-to-Site VPN

On virtual routing-enabled devices, Site-to-Site VPN is supported only on global virtual router interfaces. You cannot configure it on an interface that belongs to a user-defined virtual router. This example provides the procedure that allows you to secure the connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN. You also need to update the site-to-site VPN connection to include the user-defined virtual routing networks.

Let us consider a scenario, where, a site-to-site VPN is configured between a branch office network to a company headquaters network; the FTD in the branch office having virtual routers. In this case, the site-to-site VPN is defined on the outside interface of the branch office at 172.16.3.1. This VPN includes the inside network 192.168.2.0/24 without extra configuration, because the inside interface is also part of the global virtual router. But, to provide site-to-site VPN services to the 192.168.1.0/24 network, which is part of the VR1 virtual router, you must leak the route by configuring the static routes on global and VR1, and add the VR1 network to the site-to-site VPN configuration.

Before you begin



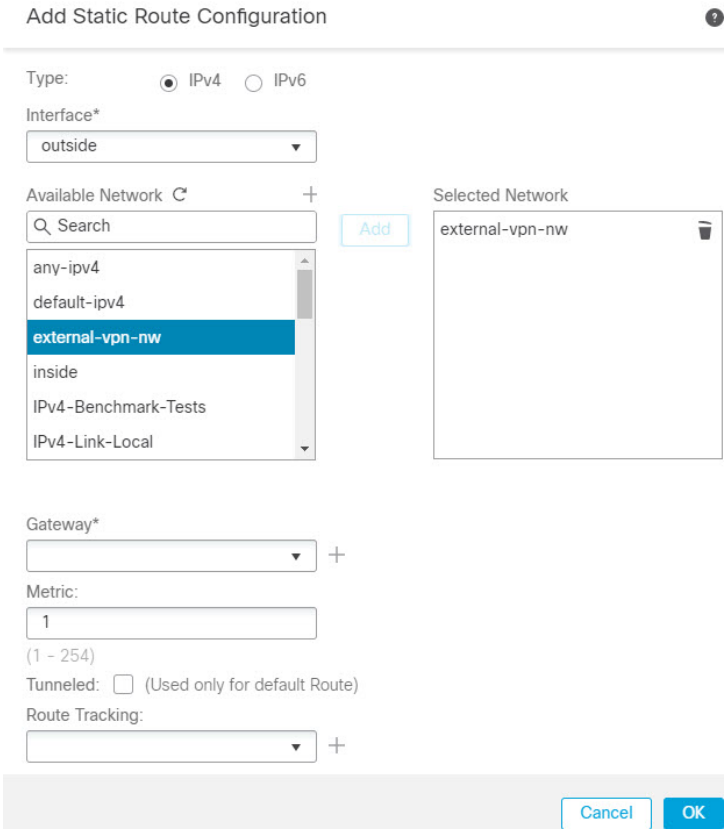
This example assumes that you have already configured the site-to-site VPN between the 192.168.2.0/24 local network and the 172.16.20.0/24 external network, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

Procedure

Step 1 Configure route leak from the Global virtual router to the user-defined VR1:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Click **Routing**. By default, the Global routing properties page appears.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the VR1 inside interface.
- **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.



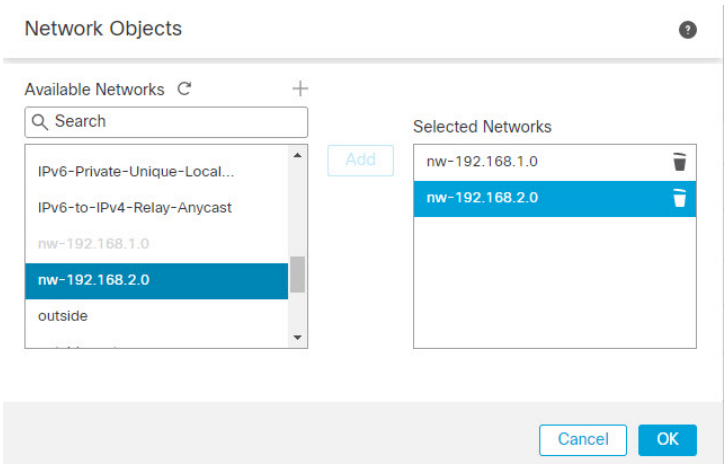
The route leak allows endpoints protected by the external (remote) end of the site-to-site VPN to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

Step 2 Configure the route leak from VR1 to the Global virtual router:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Click **Routing** and from the drop-down, select VR1.
c) Click **Static Route**.
d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the outside interface of the global router.
- **Network**—Select the global virtual router network object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

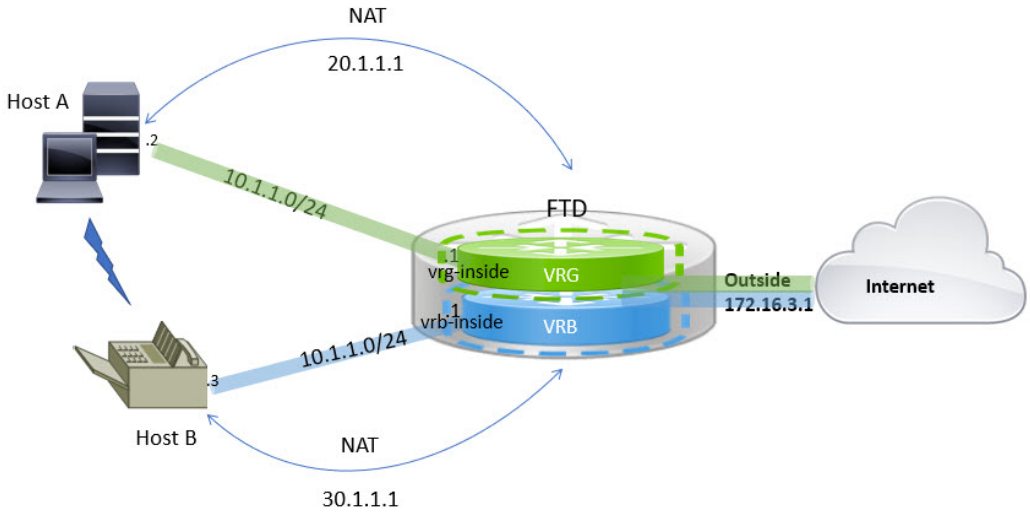


This static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections that will traverse the site-to-site VPN tunnel. For this example, the remote endpoint that is protecting the 172.16.20.0/24 network.

e) Click **Ok**.

Step 3 Add the 192.168.1.0/24 network to the site-to-site VPN connection profile:

a) Choose **Devices** > **VPN** > **Site To Site**, and edit the VPN Topology.
b) In **Endpoints**, edit Node A endpoint.
c) In **Edit Endpoint**, in the **Protected Networks** field, click **Add New Network Object**.
d) Add the VR1 network object with 192.168.1.0 network:



e) Click **Ok** and save the configuration.

How to Route Traffic between Two Overlapping Network Host in Virtual Routing

You can configure hosts on the virtual routers that have same network address. If the hosts want to communicate, you can configure twice NAT. This example provides the procedure to configure the NAT rules to manage the overlapping network host.

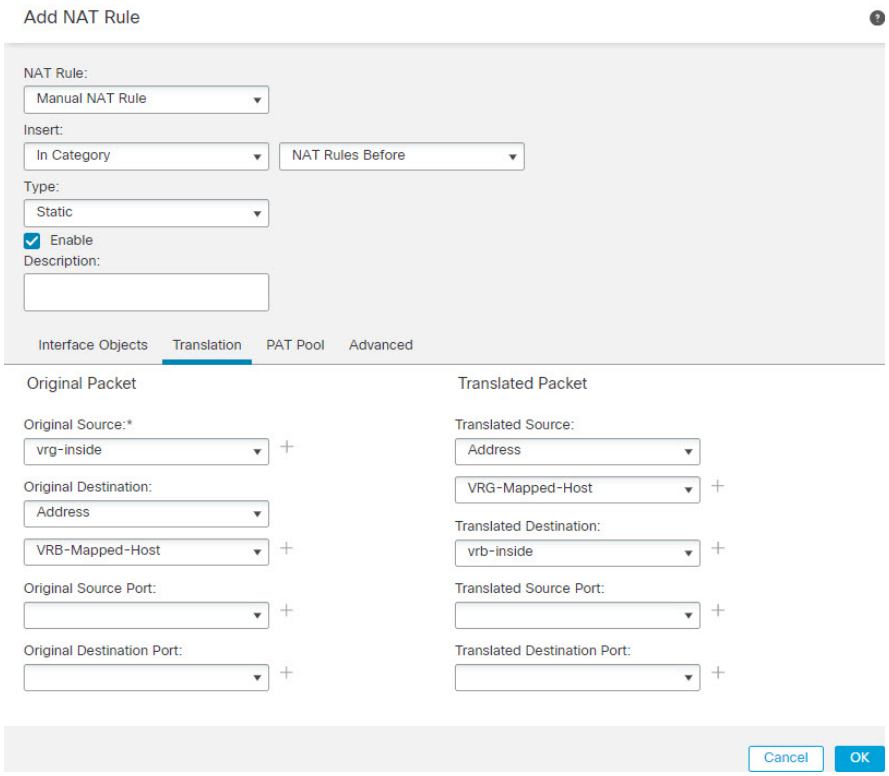
In the following example, two hosts Host A and Host B belong to different virtual routers: VRG (interface vrg-inside), VRB (interface vrb-inside) respectively with the same subnet 10.1.1.0/24. For both the hosts to communicate, create a NAT policy where, VRG-Host interface object would use a mapped NAT address - 20.1.1.1, and VRB-Host interface object would use a mapped NAT address - 30.1.1.1. Thus, Host A uses 30.1.1.1 to communicate to Host B; Host B uses 20.1.1.1 to reach Host A.

Before you begin

This example assumes that you have already configured:

- vrg-inside and vrb-inside interfaces are associated with virtual routers: VRG and VRB respectively and vrg-inside and vrb-inside interfaces configured with same subnet address (say, 10.1.1.0/24).
- Interfaces zones VRG-Inf, VRB-Inf created with vrg-inside and vrb-inside interfaces respectively.
- Host A in VRG with vrg-inside as default gateway; Host B in VRB with vrb-inside as default gateway.

Procedure



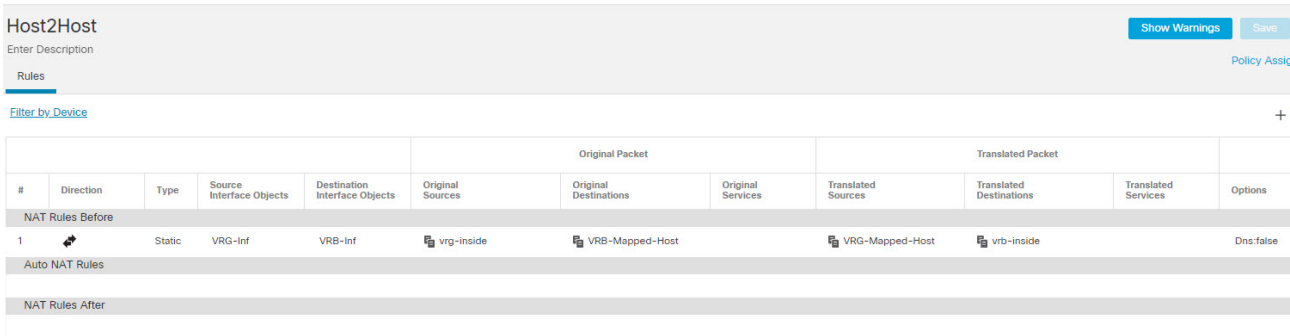
Step 1 Create the NAT rule to handle traffic from Host A to Host B. Choose **Devices** > **NAT**.

Step 2 Click **New Policy** > **Threat Defense NAT**.

Step 3 Enter a NAT policy name, and select the FTD device. Click **Save**.

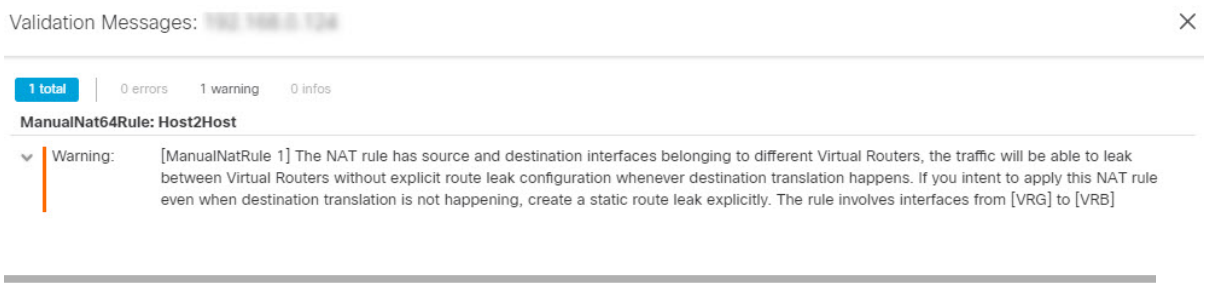
Step 4 In the NAT page, click **Add Rule** and define the following:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inf object and click **Add to Source** (If the object isn't available, create one in **Object** > **Object Management** > **Interface**), and select VRB-Inf object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select vrg-inside.
  - **Original Destination**, click **Add** and define object VRB-Mapped-Host with 30.1.1.1. Select VRB-Mapped-Host.
  - **Translated Source**, click **Add** and define object, VRG-Mapped-Host with 20.1.1.1. Select VRG-Mapped-Host.
  - **Translated Destination**, select vrb-inside as shown in the following figure:



When you run the **show nat detail** command on the FTD device, you will see an output similar to this:

```
firepower(config-service-object-group)# show nat detail
Manual NAT Policies (Section 1)
1 (2001) to (3001) source static vrg-inside VRG-MAPPED-HOST destination static VRB-MAPPED-HOST
 vrb-inside
translate_hits = 0, untranslate_hits = 0
Source - Origin: 10.1.1.1/24, Translated: 20.1.1.1/24
Destination - Origin: 30.1.1.1/24, Translated: 10.1.1.1/24
```

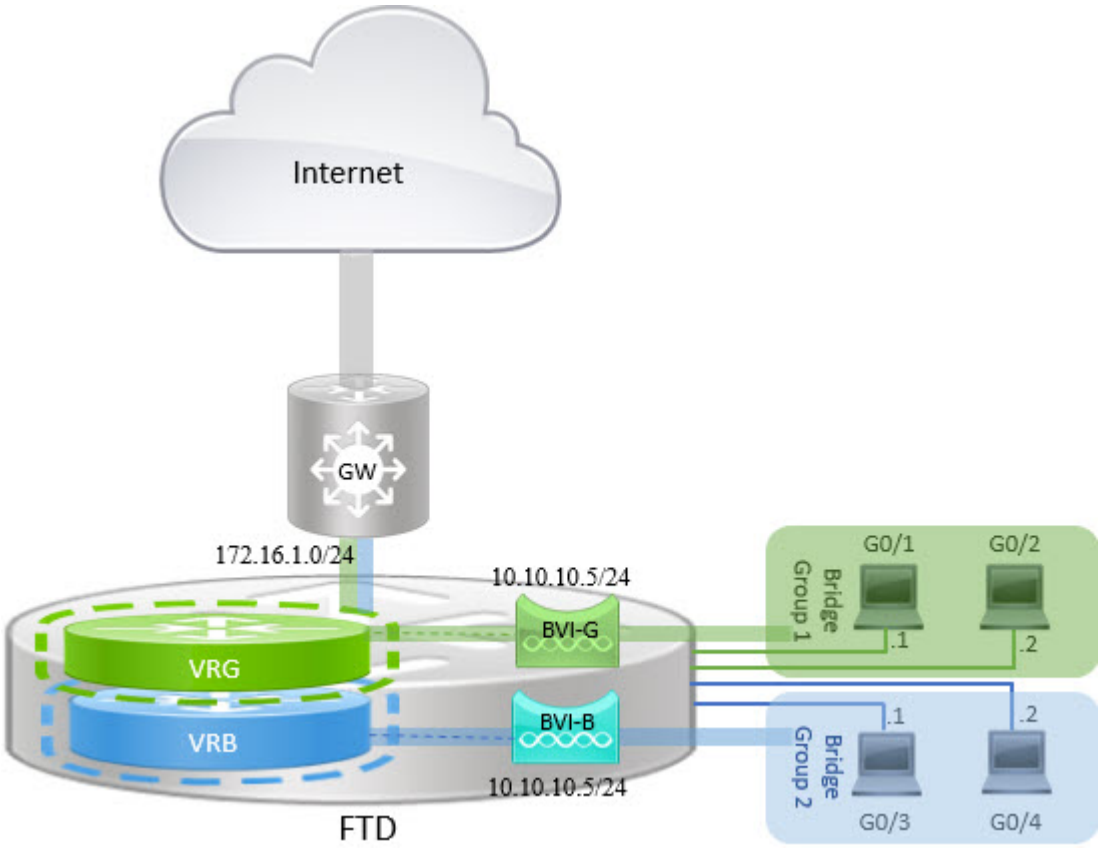


Step 5 Click **Ok**.

Step 6 Click **Save**.

The NAT rule looks like this:

When you deploy the configuration, a warning message appears:

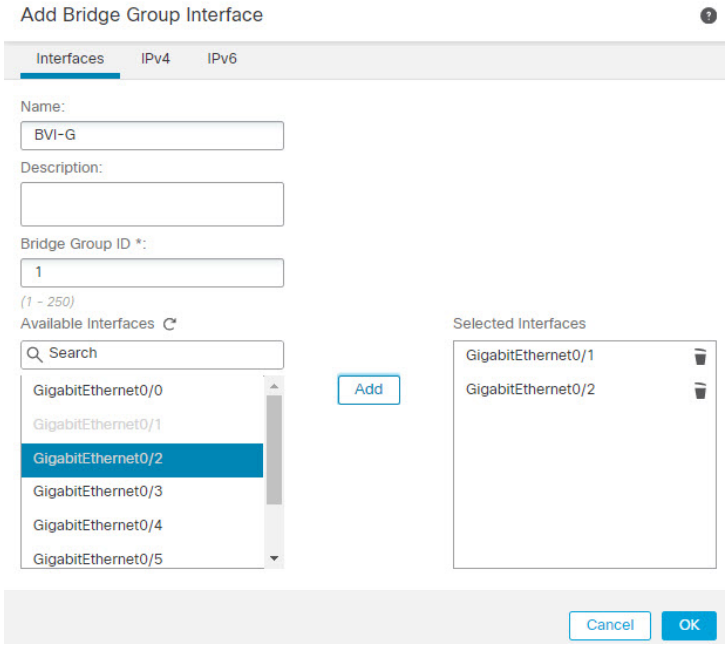


How to Manage Overlapping Segments in Routed Firewall Mode with BVI Interfaces

You can deploy single FTD between multiple overlapping networks transparently and/or deploy the firewall between the hosts of same network. To achieve this deployment, configure BVI per virtual router. The procedure to configure the BVIs in virtual router is explained here.

BVI is a virtual interface within a router that acts like a normal routed interface. It does not support bridging, but represents the comparable bridge group to routed interfaces within the router. All the packets coming in or going out of these bridged interfaces, pass through the BVI interface. The interface number of the BVI is the number of the bridge group that the virtual interface represents.

In the following example, BVI-G is configured in VRG and Bridge Group 1 is the routed interface for interfaces G0/1 and G0/2. Similarly, BVI-B is configured in VRB and Bridge Group 2 is the routed interface for interfaces G0/3 and G0/4. Consider that both BVIs have the same IP subnet address, say 10.10.10.5/24. Because of virtual routers, the network is isolated on the shared resources.



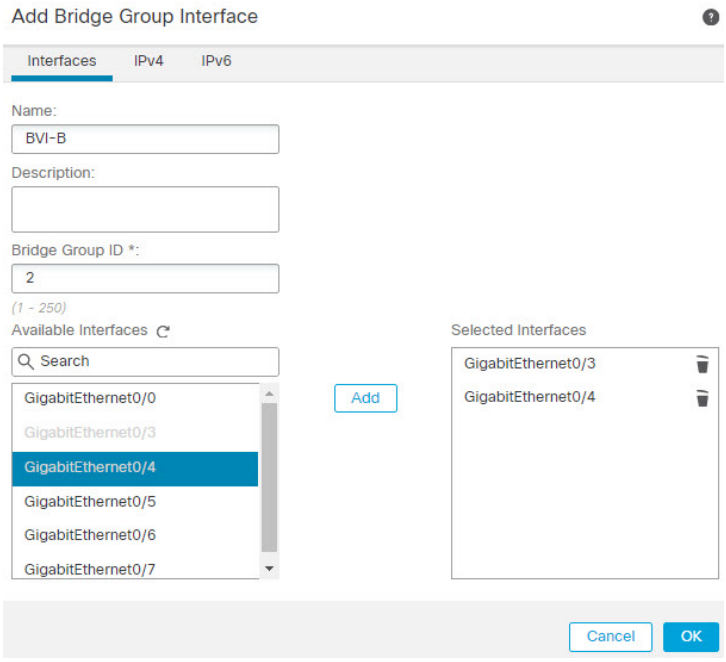
Procedure

Step 1 Choose **Devices** > **Device Management**. Edit the required device.

Step 2 In **Interfaces**, choose **Add Interfaces** > **Bridge Group Interface**.

a) Enter the following details for BVI-G:

- **Name**—For this example, BVI-G.
- **Bridge Group ID**—For this example, 1.
- **Available Interface**—Select the interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 10.10.10.5/24.



b) Click **Ok**.

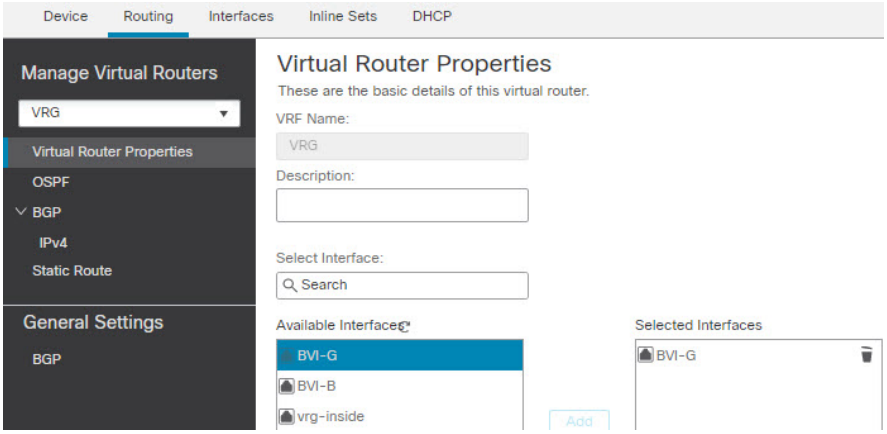
c) Click **Save**.

a) Enter the following details for BVI-B:

- **Name**—For this example, BVI-B.
- **Bridge Group ID**—For this example, 2.
- **Available Interface**—Select the sub interfaces.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave this field empty as the system does not allow two interfaces to have overlapping IP address. You can revisit the Bridge Group and provide the same IP address after aligning it under a virtual router.

b) Click **Ok**.

c) Click **Save**.



Step 3 Create virtual router, say VRG, and select BVI-G as its network:

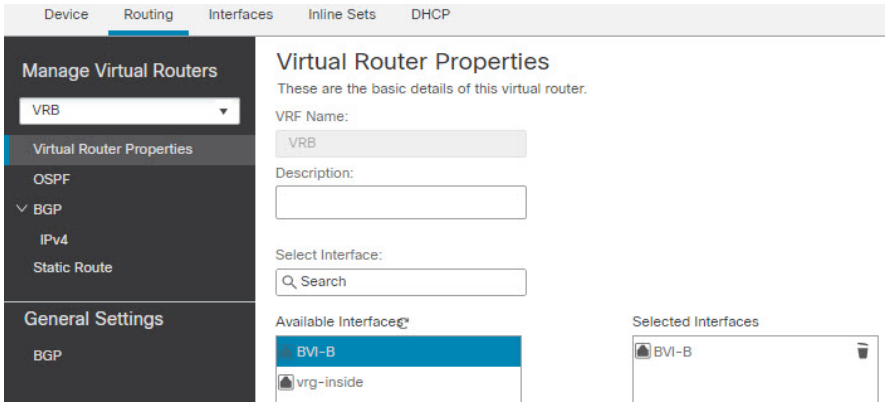
a) Choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

d) In **Virtual Routing Properties**, select **BVI-G** and click **Add**.

e) Click **Save**.



Step 4 Create virtual router, say VRB, and select BVI-B as its network:

a) Choose **Devices** > **Device Management**.

b) Edit the device, and choose **Routing** > **Manage Virtual Routers**.

c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

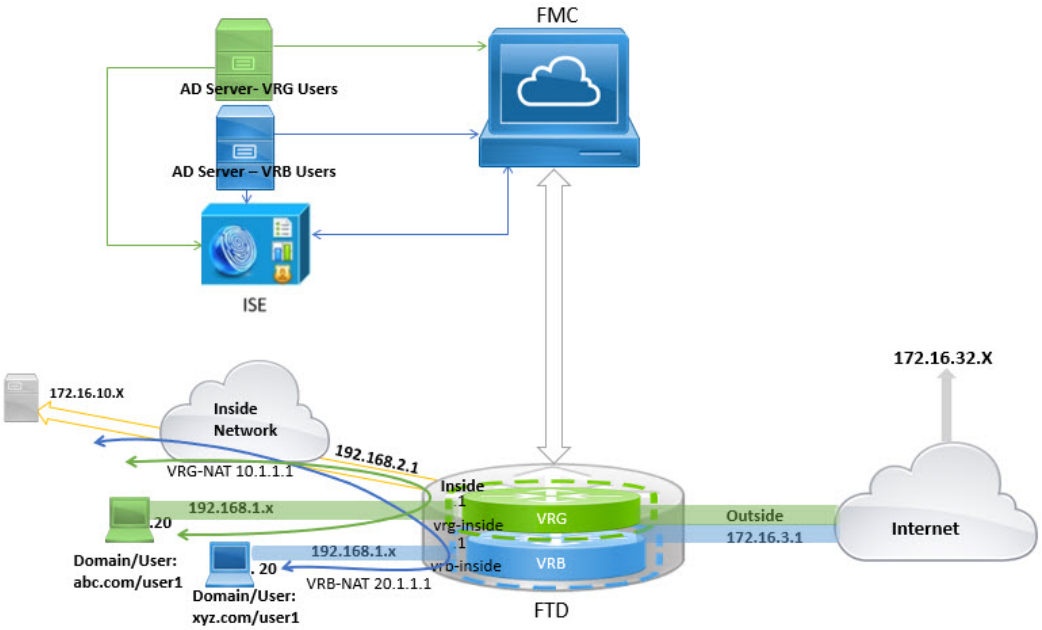
d) In **Virtual Routing Properties**, select **BVI-B** and click **Add**.

e) Click **Save**.

Step 5 Revisit the BVI-B configuration:

a) Choose **Devices** > **Device Management** > **Interfaces**.

b) Click **Edit** against BVI-B interface. Specify the IP Address as 10.10.10.5/24. The system now allows you to configure with same IP address of BVI-G, because the interfaces are seperately assigned to two different virtual routers.



c) Click **Ok**.

d) Click **Save**.

If you want to enable inter-BVI communication, use an external router as default gateway. In overlapping BVI scenarios, as in this example, use twice NAT external router as gateway to establish inter-BVI traffic. When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself. When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.

How to Configure User Authentication with Overlapping Networks

In virtual routing, you can configure multiple virtual routers with overlapping IP and overlapping users. In the example, VRG, and VRB are the virtual routers with overlapping IP - 192.168.1.1/24. The users on two different domains are also on overlapping network IP 192.168.1.20. For VRG and VRB users to access the shared server 172.16.10.X, leak routes to the global virtual router. Use source NAT to handle the overlapping IP. For controlling the access from VRG and VRB users, you must set user authentication in FMC. FMC uses realms, Active Directories, Identity source, and Identity rules and policies for authenticating user identity. Because FTD does not have direct role in authenticating users, user access is managed only through the access control policy. For controlling traffic from the overlapping users, use Identity policy and rules to create access control policy.

Before you begin

This example assumes that you have:

- Two AD servers for the VRG and VRB users.
- ISE with the two AD servers added.

Procedure

Step 1 Configure the inside interface of the device for VRG:

a) Choose **Devices** > **Device Management** > **Interfaces**.

b) Edit the interfaces that you want to assign to VRG:

- **Name**—For this example, VRG-inside.
- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Enter 192.168.1.1/24.

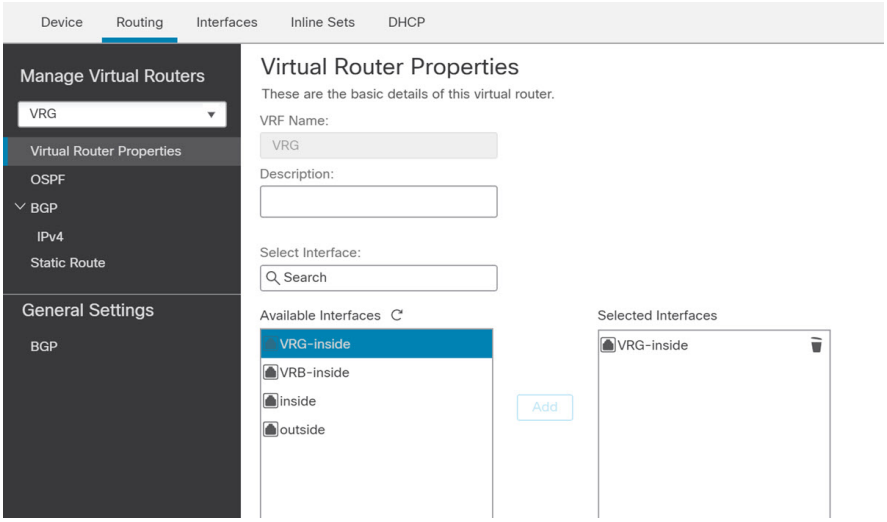
c) Click **Ok**.

d) Click **Save**.

Step 2 Configure the inside interface of the device for VRB:

a) Choose **Devices** > **Device Management** > **Interfaces**.

b) Edit the interfaces that you want to assign to VRB:



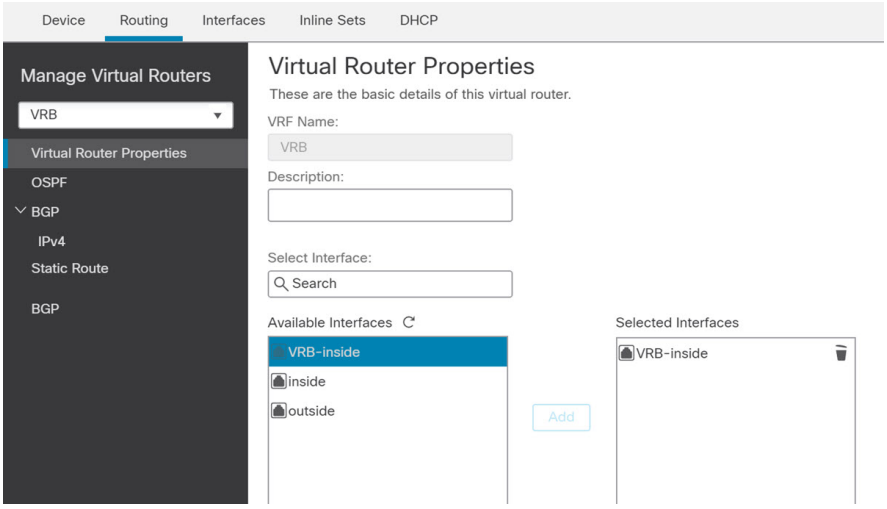
- **Name**—For this example, VRB-inside.

- Select the **Enabled** checkbox.
- In **IPV4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system doesn't allow you to configure interfaces with same IP address, as you're yet to create user-defined virtual routers.

c) Click **Ok**.
d) Click **Save**.

Step 3 Configure VRG and the static default route leak to the inside interface of the Global router for the VRG users to access the common server 172.16.10.1:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRG.
c) For VRG, in **Virtual Router Properties**, assign VRG-inside and save.



d) Click **Static Route**.
e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.
g) Click **Save**.

Step 4 Configure VRB and the static default route leak to the inside interface of the Global router for the VRB users to access the shared server 172.16.10.x:

a) Choose **Devices** > **Device Management**, and edit the FTD device.
b) Choose **Routing** > **Manage Virtual Routers**. Click **Add Virtual Router** and create VRB.
c) For VRB, in **Virtual Router Properties**, assign VRB-inside and save.

d) Click **Static Route**.

e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:

- **Interface**—Select the inside interface of the global router.
- **Network**—Select the any-ipv4 object.
- **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.

f) Click **Ok**.

g) Click **Save**.

Step 5 Revisit the VRB-inside interface configuration:

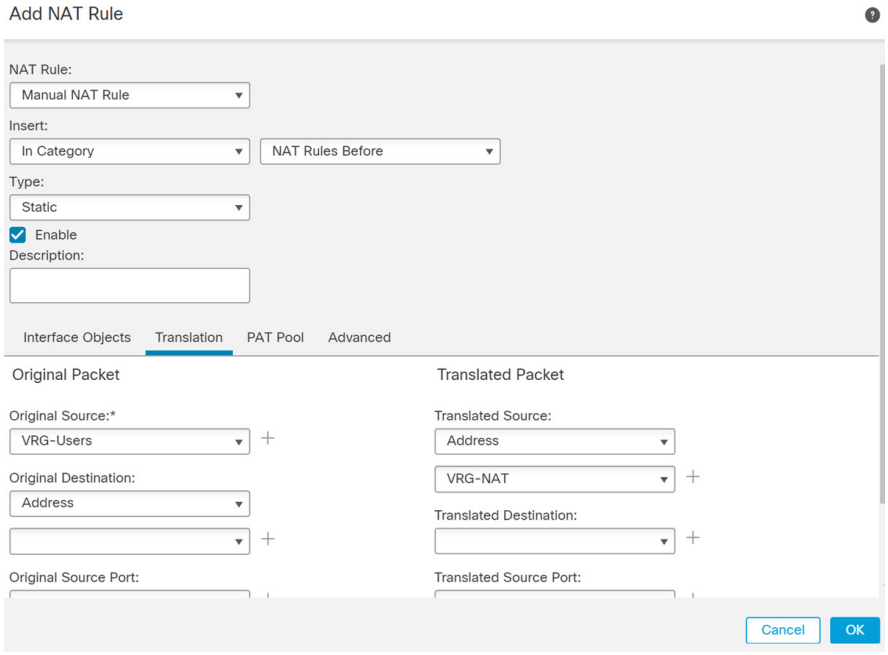
a) Choose **Devices** > **Device Management** > **Interfaces**.

b) Click **Edit** against VRB-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with the same IP address as that of VRG-inside, because the interfaces are seperately assigned to two different virtual routers.

c) Click **Ok**.

d) Click **Save**.

Step 6 Add NAT rules for the source objects VRG and VRB. Click **Devices** > **NAT**.

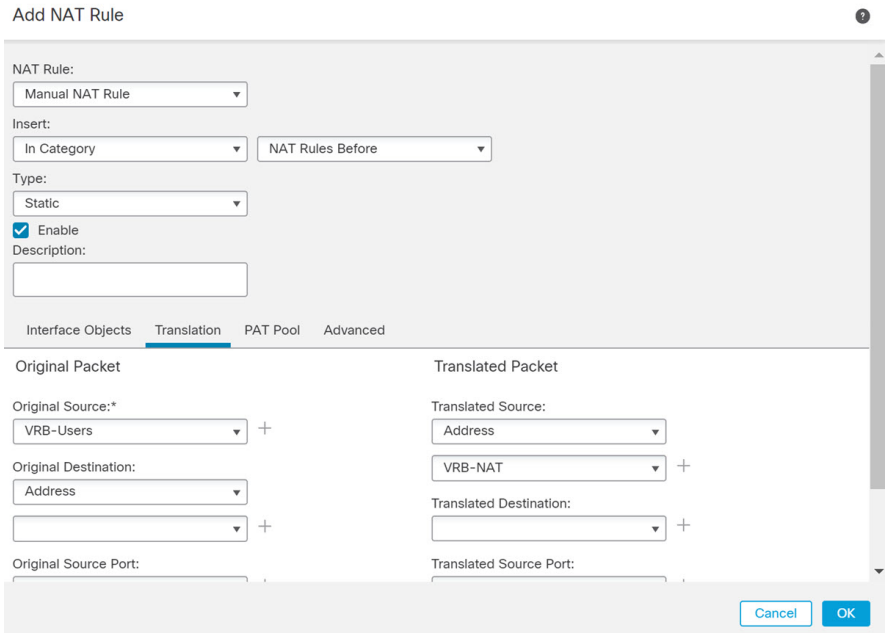


Step 7 Click **New Policy** > **Threat Defense NAT**.

Step 8 Enter a NAT policy name, and select the FTD device. Click **Save**.

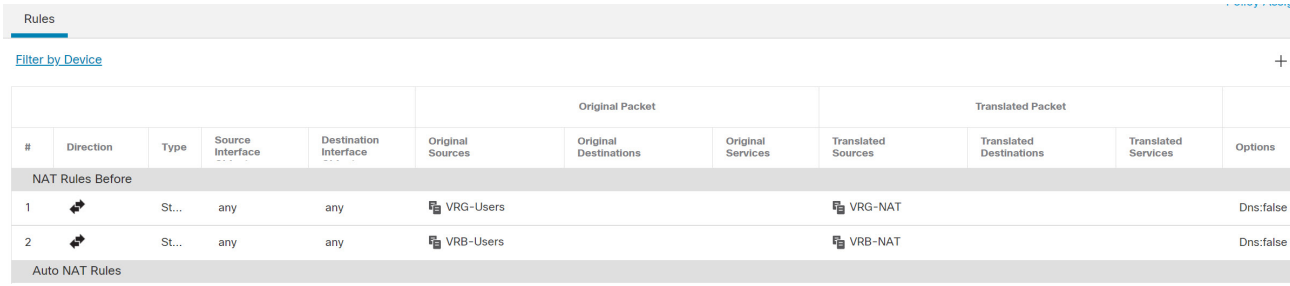
Step 9 In the NAT page, click **Add Rule** and define the following source NAT for VRG:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inside object and click **Add to Source** (If the object is not available, create one in **Object** > **Object Management** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:



- **Original Source**, select VRG-Users.
- **Translated Source**, click **Add** and define object, VRG-NAT with 10.1.1.1. Select VRG-NAT as shown in the following figure:

Step 10 Click **Ok**.



Step 11 In the NAT page, click **Add Rule** and define the following source NAT for VRB:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRB-Inside object and click **Add to Source** (If the object is not available, create one in **Object** > **Object Management** > **Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRB-Users.
  - **Translated Source**, click **Add** and define object, VRB-NAT with 20.1.1.1. Select VRB-NAT as shown in the following figure:

Step 12 Click **Save**.

The NAT rule looks like this:

Step 13 Add the two unique AD servers in FMC one for each VRG and VRB users—choose **System** > **Integration** > **Realms**.

Step 14 Click **New Realm** and complete the fields. For detailed information on the fields, see Realm Fields, on page 1713.

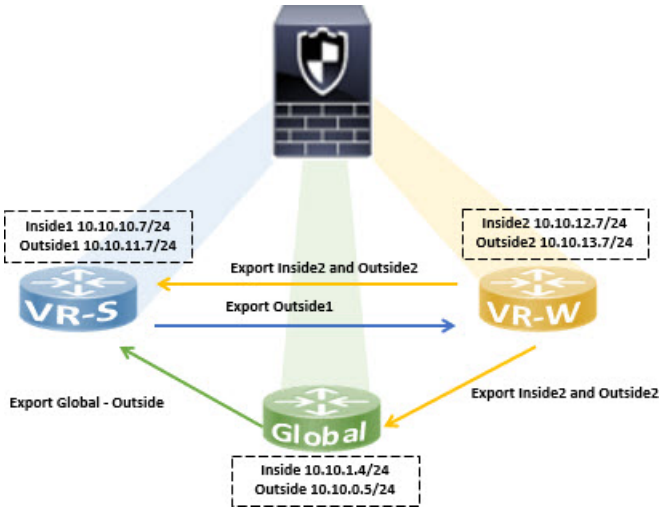
Step 15 For controlling the access from VRG and VRB users, define 2 Active Directories, see Realm Directory and Synchronize fields, on page 1717see Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 1704

Step 16 Add ISE in FMC—choose **System** > **Integration** > **Identity Sources**.

Step 17 Click **Identity Services Engine** and complete the fields. For detailed information on the fields, see How to Configure ISE/ISE-PIC for User Control Using a Realm, on page 1749.

Step 18 Create Identity policy, rules, and then define access control policy for controlling access of overlapping users from VRG and VRB.

How to Interconnect Virtual Routers using BGP



You can now configure BGP settings on a device to leak the routes among virtual routers (Global and user-defined virtual routers). The route target of the source virtual router is exported to the BGP table, which, in turn is imported to the destination virtual router. The route map is used to share the Global virtual routes with the user-defined virtual routers and vice versa. Note that all import or export of the routes to the BGP table is configured at the user-defined virtual router, including the Global virtual routes.

Consider the firewall device of a factory is configured with the following virtual routers and interfaces:

- Global virtual router is configured with Inside (10.10.1.4/24) and Outside (10.10.0.5/24)
- VR-S (Sales) virtual router is configured with Inside1 (10.10.10.7/24) and Outside1 (10.10.11.7/24)
- VR-W (Warehouse) virtual router is configured with Inside2 (10.10.12.7/24) and Outside2 (10.10.13.7/24)

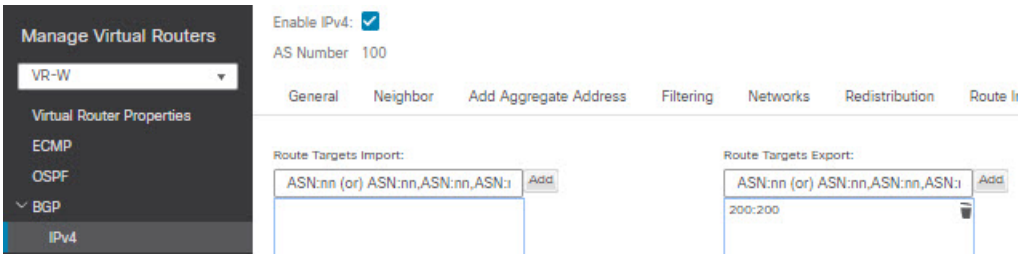
Assume that you want the routes of warehouse (VR-W) to be leaked with sales (VR-S) and Global, and the outside interface routes of VR-S to VR-W. Similarly, you want the outside interface routes of the Global router to be leaked to sales (VR-S). This example demonstrates the BGP configuration procedure to achieve interconnecting the routers:

Figure 172: Interconnect Virtual Routers using BGP Settings

Before you begin

- Create a Virtual Router—VR-S and VR-W.
- Enable BGP and for each virtual router Configure BGP Redistribution Settings.

Procedure

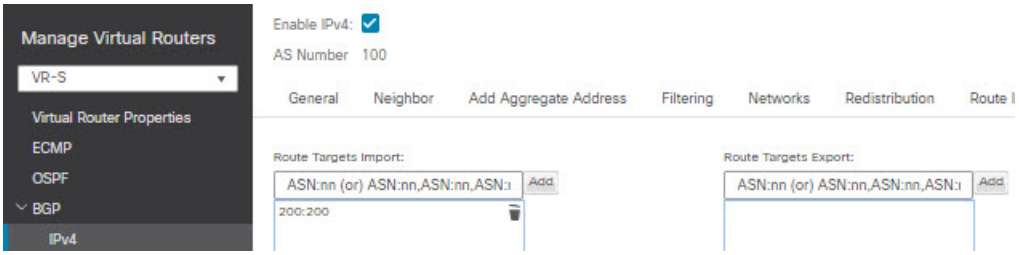


Step 1 Configure VR-W to export its routes tagging them with a route target to VR-S:

a) Choose **Devices** > **Device Management**, edit device, and then click the **Routing** tab.

b) From the virtual router drop-down, select VR-W.

c) Click **BGP** > **IPv4** > **Route Import/Export**.

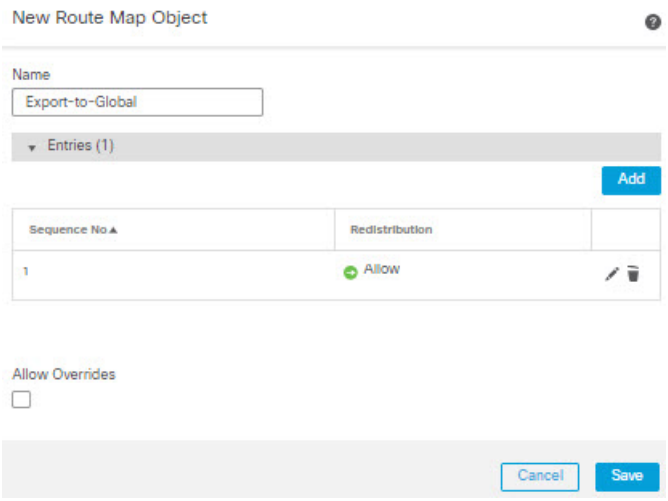


d) To leak the VR-W routes to VR-S, tag the routes with a route target, so that the VR-W routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *200:200*. Click **Add**:

e) From the virtual router drop-down, select VR-S.

f) Click **BGP** > **IPv4** > **Route Import/Export**.

g) To receive the leaked routes from VR-W, configure the Import Route Target to import the VR-W routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the same route target value that you had configured for VR-W, *200:200*. Click **Add**.



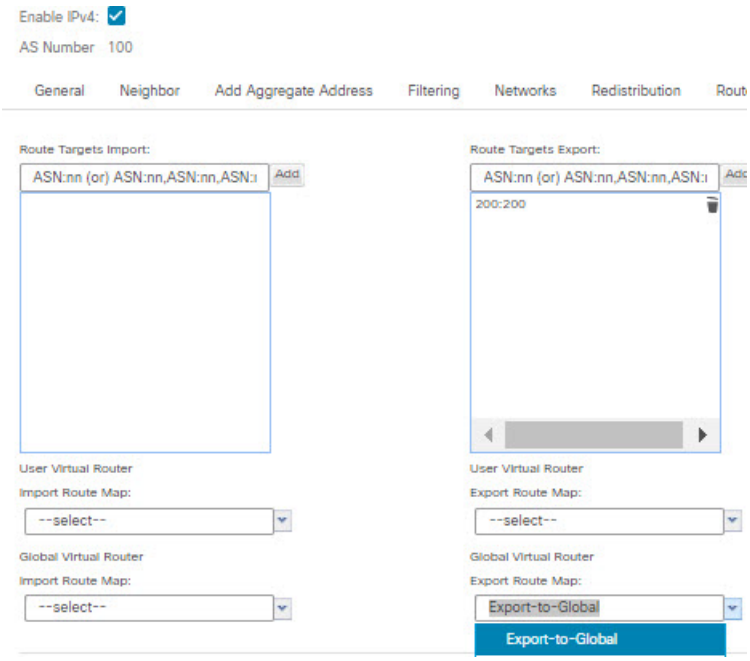
Note
If you want to conditionalize routes to be leaked from VR-W, you can specify the match criteria in the route map object, and choose it in the **User Virtual Router Export Route Map**. Similarly, if you want to conditionalize the routes to be imported to VR-S from the BGP table, you can use the **User Virtual Router Import Route Map**. This procedure is explained in Step 3.

Step 2 Configure VR-W to export its routes to the Global virtual router:

a) You need to create a route map that would allow the VR-W routes to be exported to the Global routing table. Choose **Objects** > **Object Management** > **Route Map**.

b) Click **Add Route Map**, give a name, say *Export-to-Global*, and then click **Add**.

c) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list:

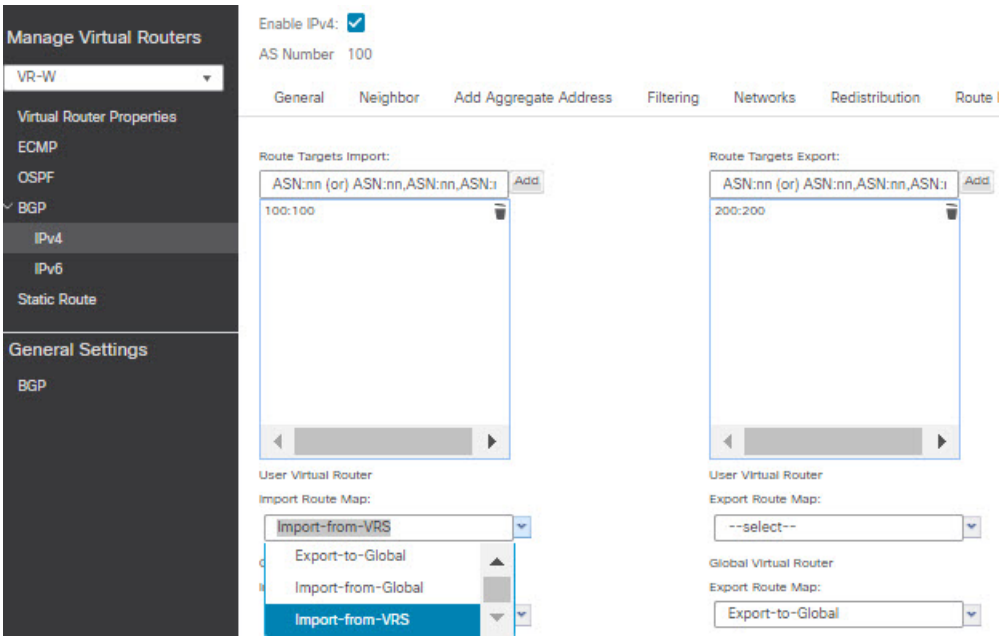


d) Click **Save**.

In this example, all the VR-W routes are leaked to the Global routing table. Hence, no match criteria is configured for the route map.

e) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**.

f) From the **Global Virtual Router Export Route Map** drop-down list, choose Export-to-Global:



Step 3 To leak only the Outside1 routes of VR-S to VR-W:

a) From the virtual router drop-down, select VR-S.

b) Click **BGP** > **IPv4** > **Route Import/Export**.

c) To leak the VR-S routes to VR-W, tag the routes with a route target, so that the VR-S routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *100:100*. Click **Add**.

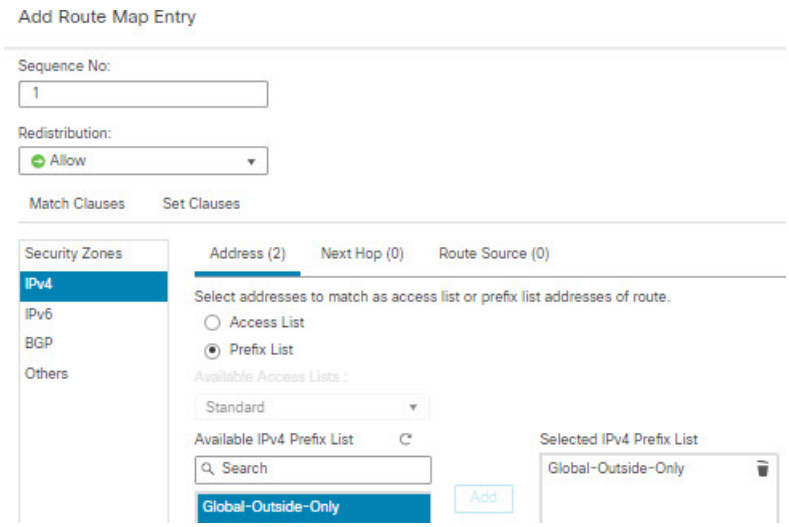
d) From the virtual router drop-down, select VR-W, and choose **BGP** > **IPv4** > **Route Import/Export**.
e) To receive the leaked routes from VR-S, configure the Import Route Target to import the VR-S routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the VR-S route target value, *100:100*. Click **Add**.
f) Now, you need to conditionalize that only the Outside1 routes of VR-S to be leaked to VR-W. Choose **Objects** > **Object Management** > **Prefix List** > **IPv4 Prefix List**.
g) Click **Add IPv4 Prefix List**, give a name, say *VRS-Outside1-Only*, and then click **Add**.
h) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
i) Enter the IP Address (first two octets) of the VR-S Outside1 interface.
j) Click **Save**.
k) Create a route map with the match clause with the prefix list. Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-VRS*, and then click **Add**.
l) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
m) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.
n) Under **Available IPv4 Prefix List**, select VRS-Outside1-Only, and then click **Add**.
o) Click **Save**.
p) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP** > **IPv4** > **Route Import/Export**.
q) From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-VRS:

Step 4 Configure VR-S to import the Outside routes of Global virtual router:

Note
To leak routes to or from a Global virtual router, you must configure the source or destination user defined virtual router respectively. Thus, in this example, VR-S is the destination router that imports the routes from Outside interface of the Global virtual router.

a) Choose **Objects** > **Object Management** > **Prefix List** > **IPv4 Prefix List**.
b) Click **Add IPv4 Prefix List**, give a name, say *Global-Outside-Only*, and then click **Add**.
c) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

d) Enter the IP Address (first two octets) of the Global Outside interface:

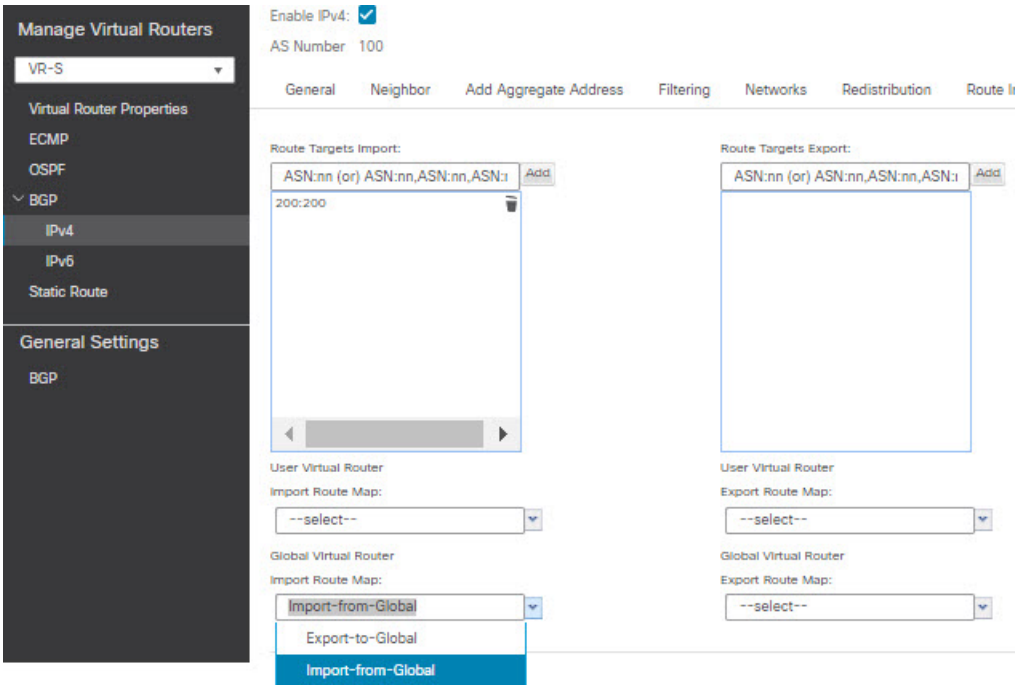


e) Click **Save**.

f) Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-Global*, and then click **Add**.

g) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

h) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.

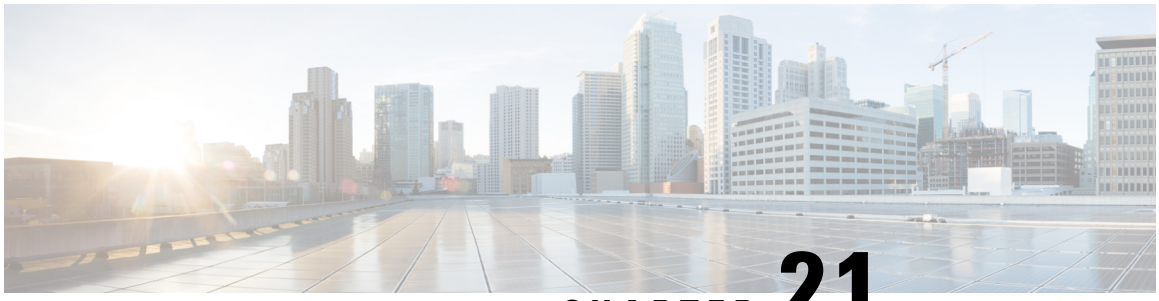


i) Under **Available IPv4 Prefix List**, select Global-Outside-Only, and then click **Add**:

j) Click **Save**.

k) Navigate to the **Routing** tab of the device, and select VR-S. Click **BGP** > **IPv4** > **Route Import/Export**.

l) From the **Global Virtual Router Import Route Map** drop-down list, choose Import-from-Global:



Step 5 **Save** and **Deploy**.

History for Virtual Routers

Feature	Minimum FMC	Minimum FTD	Details
Virtual router support for the ISA 3000.	7.0	7.0	You can configure up to 10 virtual routers on the ISA 3000.
SNMP support on user-defined virtual routers	7.0	7.0	You can now configure SNMP on user-defined virtual routers.
Bulk removal of virtual routers.	6.7	6.6	You can remove multiple virtual routers from threat defense at a time. New/modified screens: **Devices** > **Device Management** > **Routing** > **Manage Virtual Routers**

Feature	Minimum FMC	Minimum FTD	Details
Virtual routers and VRF-Lite for threat defense.	6.6	6.6	You can now create multiple virtual routers to maintain separate routing tables for groups of interfaces. Because each virtual router has its own routing table, you can provide clean separation in the traffic flowing through the device. Virtual routers implement the "light" version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP). The maximum number of virtual routers you can create ranges from five to 100, and depends on the device model.. New/modified screens: **Devices > Device Management >** edit device **> Routing** tab New/modified CLI commands: . • **show vrf** • Added the [**vrf** *name* | **all**] keyword set to these CLI commands, and changed the output to indicate virtual router information where applicable: **clear ospf**, **clear route**, **ping**, **show asp table routing**, **show bgp**, **show ipv6 route**, **show ospf**, **show route**, **show snort counters** Platform restrictions: Not supported on the Firepower 1010 and ISA 3000.

CHAPTER 21

ECMP

This chapter describes the procedure to configure Equal Cost Multi-Path (ECMP) routing that routing protocols use to load balance the network traffic.

- About ECMP, on page 741
- Guidelines and Limitations for ECMP, on page 741
- Manage ECMP Page, on page 742
- Create an ECMP Zone, on page 743
- Configure an Equal Cost Static Route, on page 744
- Modify an ECMP Zone, on page 745
- Remove an ECMP Zone, on page 745
- Configuration Example for ECMP, on page 746
- History for ECMP in Firepower Threat Defense, on page 749

About ECMP

The FTD device supports Equal-Cost Multi-Path (ECMP) routing. You can configure traffic zones per virtual router to contain a group of interfaces. You can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Guidelines and Limitations for ECMP

Firewall Mode Guidelines

ECMP zones are supported on routed firewall mode only.

Interface Guidelines

dVTI and Loopback interfaces are not supported.

Additional Guidelines

- A device can have a maximum of 256 ECMP zones.
- You can associate only 8 interfaces per ECMP zone.
- An interface can be a member of only one ECMP zone.
- You cannot remove an interface that is associated with an equal cost static route from the ECMP zone.
- You cannot delete an ECMP zone if its interface has equal cost static routes associated with it.
- Only routed interfaces can be associated with an ECMP zone.
- The following interfaces cannot be associated with an ECMP zone:
  - BVI interface.
  - Member interfaces in an EtherChannel.
  - Failover or state link interface.
  - Management-only or management-access interfaces.
  - Cluster control link interface.
  - VNIs.
  - VLAN interfaces.
  - Interfaces in a remote access VPN configuration with SSL enabled.
- DHCP Relay is not supported on interfaces in an ECMP zone.
- The FTD does not support ECMP with NAT in IPsec sessions—a standard IPsec virtual private network (VPN) tunnel does not work with NAT points in the delivery path of IPsec packets.

Manage ECMP Page

When you click **ECMP** on the Routing pane, the ECMP page appears corresponding to the virtual router. This page displays the existing ECMP zones with the associated interfaces of the virtual router. In this page, you can Add an ECMP zone to the virtual router. You can also **Edit** ( ) and **Delete** ( ) ECMP.

You can perform the following:

- Create an ECMP Zone, on page 743
- Configure an Equal Cost Static Route, on page 744
- Modify an ECMP Zone, on page 745
- Remove an ECMP Zone, on page 745

Create an ECMP Zone

ECMP zones are created per virtual router. Thus, only the interfaces of the virtual router where the ECMP is being created can be associated with the ECMP.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 From the virtual router drop-down, select the virtual router in which you want to create the ECMP zone.

You can create ECMP zones in global virtual router and user-defined virtual routers. For information on creating virtual routers, see Create a Virtual Router, on page 699.

Step 4 Click **ECMP**.

Step 5 Click **Add**.

Step 6 In the **Add ECMP** box, enter a name for the ECMP zone.

Note
The ECMP name must be unique for the routed device.

Step 7 To associate interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.

Remember the following:

- Only interfaces belonging to the virtual router are available for assigning.
- Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.

Step 8 Click **OK**.

The ECMP page now displays the newly created ECMP.

Step 9 Click **Save** and **Deploy** the configuration.

You can associate the ECMP zone interfaces with equal cost static route by defining them with same destination and metric value, but with different gateway.

What to do next

- Configure an Equal Cost Static Route, on page 744
- Modify an ECMP Zone, on page 745
- Remove an ECMP Zone, on page 745

Configure an Equal Cost Static Route

Smart License	Classic License	Supported Devices	Supported Domains	Access
Any	N/A	FTD and FTDv	Any	Admin/Network Admin/Security Approver

You can assign interfaces of a virtual router, both global and user-defined, to an ECMP zone for the device.

Before you begin

- To configure an equal cost static route for an interface, ensure to associate it with an ECMP zone. See Create an ECMP Zone, on page 743.
- All routing configuration settings of a non-VRF capable device are also available for a global virtual router.
- You cannot define a static route for interfaces with same destination and metric without associating the interfaces with an ECMP zone.

Procedure

Step 1 From the **Devices** > **Device Management** page, edit the FTD device. Click the **Routing** tab.

Step 2 From the drop-down list, select the virtual router whose interfaces are associated with an ECMP zone.

Step 3 To configure the equal cost static route for the interfaces, click **Static Route**.

Step 4 Either click **Add Route** to add a new route, or click **Edit** ( ) for an existing route.

Step 5 From the **Interface** drop-down, select the interface belonging to the virtual router and an ECMP zone.

Step 6 Select the destination network from the **Available Networks** box and click **Add**.

Step 7 Enter a gateway for the network.

Step 8 Enter a metric value. It can be a number that ranges between 1 and 254.

Step 9 To save the settings, click **Save**.

Step 10 To configure equal cost static routing, repeat the steps to configure the static route for another interface in the same ECMP zone with the same destination network and metric value. Remember to provide a different gateway.

What to do next

- Modify an ECMP Zone, on page 745
- Remove an ECMP Zone, on page 745

Modify an ECMP Zone

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 Click **ECMP**.

ECMP zones with its associated interfaces are displayed in the **ECMP** page.

Step 4 To modify an ECMP, click **Edit** ( ) against the desired ECMP. In the **Edit ECMP** box, you can do the following:

- ECMP Name—Ensure that the changed name is unique for the device.
- Interfaces—You can add or remove interfaces. You cannot include an interface that is already associated with another ECMP. In addition, you cannot remove the interface that is associated with an equal cost static route.

Step 5 Click **OK**.

Step 6 To save the changes, click **Save**.

What to do next

- Configure an Equal Cost Static Route, on page 744
- Remove an ECMP Zone, on page 745

Remove an ECMP Zone

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

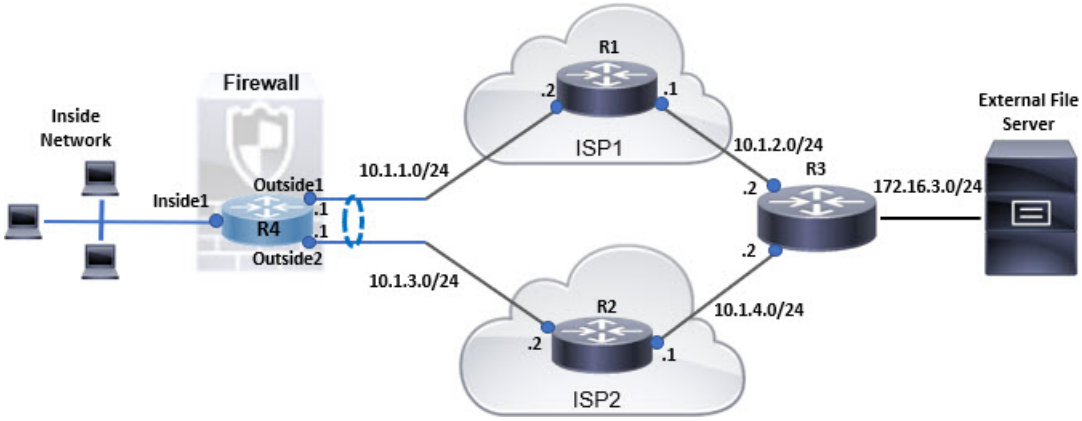
Step 2 Click **Routing**.

Step 3 Click **ECMP**.

ECMP zones with its associated interfaces are displayed in the **ECMP** page.

Step 4 To remove an ECMP zone, click **Delete** ( ) against the ECMP zone.

You cannot delete the ECMP zone if any of its interfaces are associated with an equal cost static route.



Step 5 Click **Delete** in the confirmation message.

Step 6 To save the changes, click **Save**.

Configuration Example for ECMP

This example demonstrates how to use FMC to configure ECMP zones on FTD such that the traffic flowing through the device is handled efficiently. With ECMP configured, FTD maintains the routing table per zone basis, and hence it makes it possible to re-route the packets in the best possible routes. Thus, ECMP supports asymmetric routing, load balancing, and handles lost traffic seamlessly. In this example, R4 records the two paths to reach the external file server.

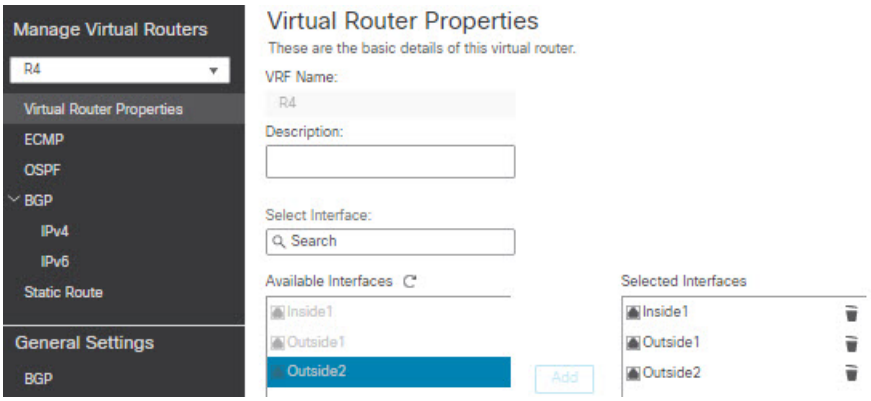


Figure 173: Configuration Example for ECMP

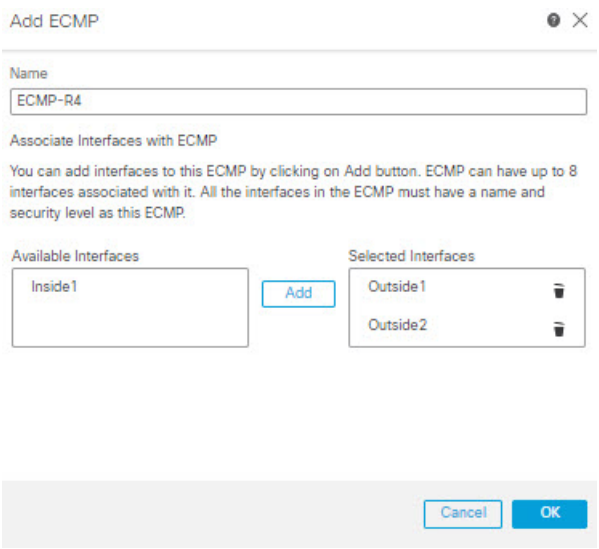
Procedure

Step 1 Create a Virtual Router—*R4* with *Inside1*, *Outside1*, and *Outside2* interfaces:

Figure 174: Configuring R4 Virtual Router

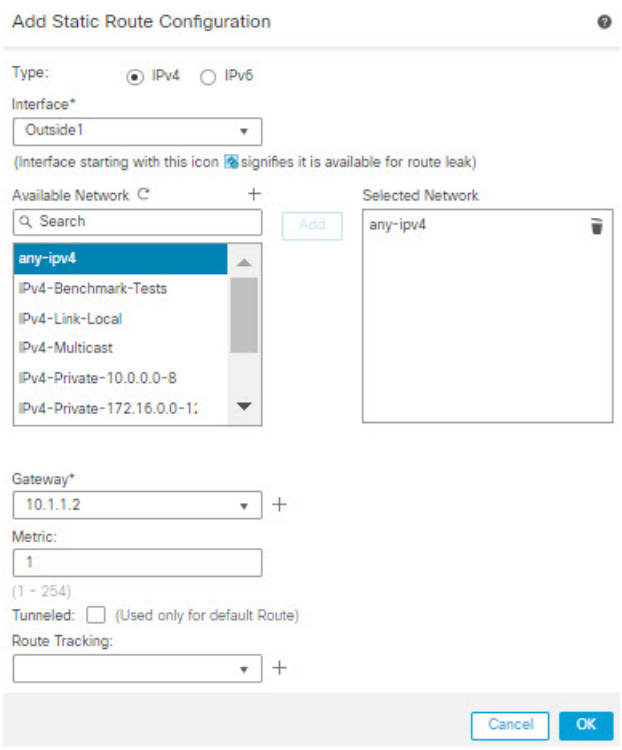


Step 2 Create ECMP zones:

a) In the **Routing** tab, choose R4 user defined virtual router, and then click **ECMP**.

b) Click **Add**.
c) Enter the ECMP name and from the **Available Interfaces** list, choose *Outside1* and *Outside2*:

Figure 175: Creating ECMP Zone



d) Click **Ok**, and then **Save**.

Step 3 Create static routes for the zone interfaces:

a) In the **Routing** tab, click **Static Route**.
b) From the **Interface** drop-down list, select Outside1.
c) Under **Available Network**, choose any-ipv4 and click **Add**.
d) Specify the next-hop address in the **Gateway** field, 10.1.1.2:

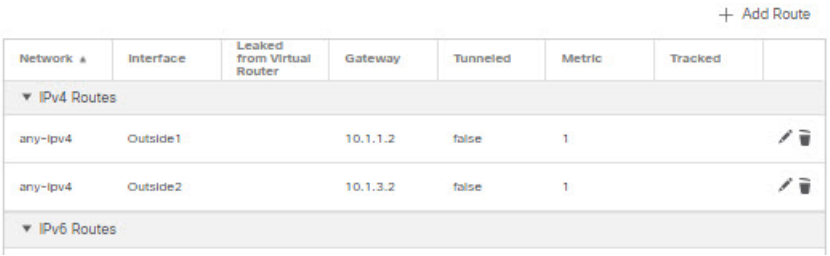


Figure 176: Configuring Static Route for Outside1

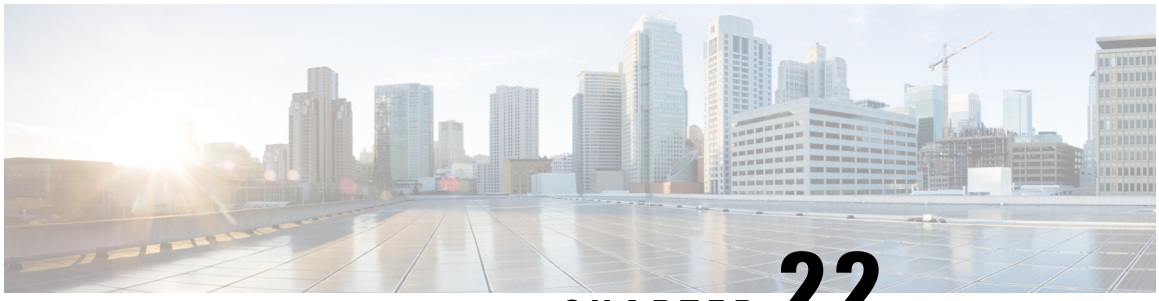
e) Configure the static route for Outside2, repeating from Step 3b to Step 3d.

Ensure to specify same metric, but different gateways for the static routes:

Figure 177: Configured Static Routes of ECMP Zone Interfaces



Step 4 **Save** and **Deploy**.

The network packets to reach its destination, R3, follows R4>R1>R3 or R4>R2>R3, based on the ECMP algorithm. If R1>R3 route is lost, the traffic flows through R2 without any packet drops. Similarly, the response from R3 can be received by *Outside2* though the packet was sent from *Outside1*. In addition, when the network traffic is heavy, R4 distributes them between the two routes and thus balances the load.

History for ECMP in Firepower Threat Defense

Feature	Minimum FMC	Minimum FTD	Details
ECMP support as Routing Policy	7.1	Any	Firepower Threat Defense was supporting ECMP routing through FlexConfig policies. From this release, you can group interfaces in to traffic zones and configure ECMP routing in Firepower Management Center. New/modified screens: **Devices** > **Device Management** > **Routing** > **ECMP**

CHAPTER 22

OSPF

This chapter describes how to configure the FTD to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

- OSPF, on page 751
- Requirements and Prerequisites for OSPF, on page 754
- Guidelines for OSPF, on page 754
- Configure OSPFv2, on page 756
- Configure OSPFv3, on page 768
- History for OSPF, on page 778

OSPF

This chapter describes how to configure the FTD to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

About OSPF

OSPF is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements rather than routing table updates. Because only LSAs are exchanged instead of the entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include the following:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, as stale information is timed out.
- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The FTD device calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The FTD device can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these

interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The FTD device supports the following OSPF features:

- Intra-area, inter-area, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the FTD device as a designated router or a designated backup router. The FTD device also can be set up as an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such as RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting as an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

Note Only Type 3 LSAs can be filtered. If you configure the FTD device as an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either as default or Type 5 AS external LSAs. However, you need to configure static routes for the private networks protected by the FTD device. Also, you should not mix public and private networks on the same FTD device interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the FTD device at the same time.

OSPF Support for Fast Hello Packets

The OSPF Support for Fast Hello Packets feature provides a way to configure the sending of hello packets in intervals less than one second. Such a configuration would result in faster convergence in an Open Shortest Path First (OSPF) network.

Prerequisites for OSPF Support for Fast Hello Packets

OSPF must be configured in the network already or configured at the same time as the OSPF Support for Fast Hello Packets feature.

OSPF Hello Interval and Dead Interval

OSPF hello packets are packets that an OSPF process sends to its OSPF neighbors to maintain connectivity with those neighbors. The hello packets are sent at a configurable interval (in seconds). The defaults are 10 seconds for an Ethernet link and 30 seconds for a non broadcast link. Hello packets include a list of all neighbors for which a hello packet has been received within the dead interval. The dead interval is also a configurable interval (in seconds), and defaults to four times the value of the hello interval. The value of all hello intervals must be the same within a network. Likewise, the value of all dead intervals must be the same within a network.

These two intervals work together to maintain connectivity by indicating that the link is operational. If a router does not receive a hello packet from a neighbor within the dead interval, it will declare that neighbor to be down.

OSPF Fast Hello Packets

OSPF fast hello packets refer to hello packets being sent at intervals of less than 1 second. To understand fast hello packets, you should already understand the relationship between OSPF hello packets and the dead interval. See OSPF Hello Interval and Dead Interval, on page 753.

OSPF fast hello packets are achieved by using the ospf dead-interval command. The dead interval is set to 1 second, and the hello-multiplier value is set to the number of hello packets you want sent during that 1 second, thus providing subsecond or "fast" hello packets.

When fast hello packets are configured on the interface, the hello interval advertised in the hello packets that are sent out this interface is set to 0. The hello interval in the hello packets received over this interface is ignored.

The dead interval must be consistent on a segment, whether it is set to 1 second (for fast hello packets) or set to any other value. The hello multiplier need not be the same for the entire segment as long as at least one hello packet is sent within the dead interval.

Benefits of OSPF Fast Hello Packets

The benefit of the OSPF Fast Hello Packets feature is that your OSPF network will experience faster convergence time than it would without fast hello packets. This feature allows you to detect lost neighbors within 1 second. It is especially useful in LAN segments, where neighbor loss might not be detected by the Open System Interconnection (OSI) physical layer and data-link layer.

Implementation Differences Between OSPFv2 and OSPFv3

OSPFv3 is not backward compatible with OSPFv2. To use OSPF to route both IPv4 and IPv6 traffic, you must run both OSPFv2 and OSPFv3 at the same time. They coexist with each other, but do not interact with each other.

The additional features that OSPFv3 provides include the following:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.
- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Requirements and Prerequisites for OSPF

Model Support

FTD

FTDv

Supported Domains

Any

User Roles

Admin

Network Admin

Guidelines for OSPF

Firewall Mode Guidelines

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

High Availability Guidelines

OSPFv2 and OSPFv3 support Stateful High Availability.

IPv6 Guidelines

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The FTD device installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.

OSPFv3 Hello Packets and GRE

Typically, OSPF traffic does not pass through GRE tunnel. When OSPFv3 on IPv6 is encapsulated inside GRE, the IPv6 header validation for security check such as Multicast Destination fails. The packet is dropped due to the implicit security check validation, as this packet has destination IPv6 multicast.

You may define a pre-filter rule to bypass GRE traffic. However, with pre-filter rule, inner packets would not be interrogated by the inspection engine.

Clustering Guidelines

- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In Spanned interface mode, dynamic routing is not supported on management-only interfaces.
- When a control role change occurs in the cluster, the following behavior occurs:
  - In spanned interface mode, the router process is active only on the control unit and is in a suspended state on the data units. Each cluster unit has the same router ID because the configuration has been synchronized from the control unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change.

Multiprotocol Label Switching (MPLS) and OSPF Guidelines

When a MPLS-configured router sends Link State (LS) update packets containing opaque Type-10 link-state advertisements (LSAs) that include an MPLS header, authentication fails and the appliance silently drops the update packets, rather than acknowledging them. Eventually the peer router will terminate the neighbor relationship because it has not received any acknowledgments.

Make sure that non-stop forwarding (NSF) is disabled on the appliance to ensure that the neighbor relationship remains stable:

- Navigate to the **Non Stop Forwarding** page in FMC(**Devices** > **Device Management (select the desired device)** > **Routing** > **OSPF** > **Advanced** > **Non Stop Forwarding**).

  Ensure the **Non Stop Forwarding Capability** boxes are not checked.

Note The Firepower 4100/9300 models may have high latency when using MPLS because they lack load balancing across multiple receiving queues.

Route Redistribution Guidelines

- Redistribution of route maps with IPv4 prefix list on OSPFv2 is supported. However, redistribution of route maps with IPv6 prefix list on OSPFv3 is not supported. Use an access list in the route map on OSPF for redistribution.
- When OSPF is configured on a device that is a part of EIGRP network or vice versa, ensure that OSPF-router is configured to tag the route (EIGRP does not support route tag yet).

  When redistributing OSPF into EIGRP and EIGRP into OSPF, a routing loop occurs when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

Additional Guidelines

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.
- OSPFv2 supports Cisco NSF Graceful Restart and IETF NSF Graceful Restart mechanisms as defined in RFCs 4811, 4812 & 3623 respectively.
- OSPFv3 supports Graceful Restart mechanism as defined in RFC 5187.
- There is a limit to the number of intra area (type 1) routes that can be distributed. For these routes, a single type-1 LSA contains all prefixes. Because the system has a limit of 35 KB for packet size, 3000 routes result in a packet that exceeds the limit. Consider 2900 type 1 routes to be the maximum number supported.
- For a device using virtual routing, you can configure OSPFv2 and OSPFv3 for a global virtual router. However, you can configure only OSPFv2 for a user-defined virtual router.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- OSPFv3 drops the LS update if the packet size exceeds 8190. As a result, the neighbourship is terminated. Hence, configure the switch with the “ospfv3 mtu-ignore” command to avoid neighbourship termination.

Configure OSPFv2

This section describes the tasks involved in configuring an OSPFv2 routing process. For a device using virtual routing, you can configure OSPFv2 for global as well as for user-defined virtual routers.

Configure OSPF Areas, Ranges, and Virtual Links

You can configure several OSPF area parameters, which include setting authentication, defining stub areas, and assigning specific costs to the default summary route. You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Check the check box of **Process 1**. You can enable up to two OSPF process instances for each context/virtual router. You must choose an OSPF process to be able to configure the Area parameters.

If the device is using virtual routing, the ID fields display the unique process IDs generated for the chosen virtual router.

Step 6 Choose the **OSPF Role** from the drop-down list, and enter a description for it in the next field. The options are Internal, ABR, ASBR, and ABR & ASBR. See About OSPF, on page 751 for a description of the OSPF roles.

Step 7 Select **Area** > **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 8 Configure the following area options for each OSPF process:

- **OSPF Process**—Choose the process ID. For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**—Designation of the area for which routes are to be summarized.
- **Area Type**—Choose one of the following:
  - **Normal**—(Default) Standard OSPF area.
  - **Stub**—A stub area does not have any routers or areas beyond it. Stub areas prevent Autonomous System (AS) External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Types 3 and 4) from being flooded into the area by NOT checking the **Summary Stub** check box.
  - **NSSA**—Makes the area a not-so-stubby area (NSSA). NSSAs accept Type 7 LSAs. You can disable route redistribution by NOT checking the **Redistribute** check box and checking the **Default Information Originate** check box. You can prevent summary LSAs from being flooded into the area by NOT checking the **Summary NSSA** check box.

- **Metric Value**—The metric used for generating the default route. The default value is 10. Valid metric values range from 0 through 16777214.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Available Network**—Choose one of the available networks and click **Add**, or click **Add** (+) to add a new network object. See Network, on page 878 for the procedure for adding networks.
- **Authentication**—Choose the OSPF authentication:
  - **None**—(Default) Disables OSPF area authentication.
  - **Password**—Provides a clear text password for area authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication.
- **Default Cost**—The default cost for the OSPF area, which is used to determine the shortest paths to the destination. Valid values range from 0 through 65535. The default value is 1.

Step 9 Click **OK** to save the area configuration.

Step 10 Select **Range** > **Add**.

- Choose one of the available networks and whether to advertise, or,
- Click **Add** (+) to add a new network object. See Network, on page 878 for the procedure for adding networks.

Step 11 Click **OK** to save the range configuration.

Step 12 Select **Virtual Link**, click **Add** (+), and configure the following options for each OSPF process:

- **Peer Router**—Choose the IP address of the peer router. To add a new peer router, click **Add** (+). See Network, on page 878 for the procedure for adding networks.
- **Hello Interval**—The time in seconds between the hello packets sent on an interface. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. Valid values range from 1 through 65535. The default is 10.

  The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Transmit Delay**—The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 through 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval**—The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the

attached network. The value must be greater than the expected round-trip delay, and can range from 1 through 65535. The default is 5.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Dead Interval**—The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval is an unsigned integer. The default is four times the hello interval, or 40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 through 65535.
- **Authentication**—Choose the OSPF virtual link authentication from the following:
  - **None**—(Default) Disables virtual link area authentication.
  - **Area Authentication**—Enables area authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**—Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

    Note
    Ensure to enter only numbers as the MD5 key ID.
  - **Key Chain**—Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, see Creating Key Chain Objects, on page 877. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.

Step 13 Click **OK** to save the virtual link configuration.

Step 14 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPF Redistribution.

Configure OSPF Redistribution

The FTD device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 From **OSPF Role** drop-down, choose role .

Step 6 Click **Redistribution** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 7 Configure the following redistribution options for each OSPF process:

- **OSPF Process**—Choose the process ID. For a device using virtual routing, this drop-down list displays the unique process IDs generated for the selected virtual router.
- **Route Type**—Choose one of the following types:
  - **Static**—Redistributes static routes to the OSPF routing process.
  - **Connected**—Redistributes connected routes (routes established automatically by virtue of having the IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed as external to the device. You can select whether to use subnets under the Optional list.
  - **OSPF**—Redistributes routes from another OSPF routing process, for example, internal, external 1 and 2, NSSA external 1 and 2, or whether to use subnets. You can select these options under the Optional list.
  - **BGP**—Redistribute routes from the BGP routing process. Add the AS number and whether to use subnets.
  - **RIP**—Redistributes routes from the RIP routing process. You can select whether to use subnets under the Optional list.

    Note
    As a user-defined virtual router does not support RIP, you cannot redistribute routes from RIP.

- **Metric Value**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag Value**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **RouteMap**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified,

but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** (+). See Route Map to add a new route map.

Step 8 Click **OK** to save the redistribution configuration.

Step 9 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPF Inter-Area Filtering, on page 761.

Configure OSPF Inter-Area Filtering

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **InterArea** > **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete inter-areas.

Step 6 Configure the following inter-area filtering options for each OSPF process:

- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**—The area for which routes are to be summarized.
- **PrefixList**—The name of the prefix. To add a new prefix list object, see Step 5.
- **Traffic Direction**—Inbound or outbound. Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

Step 7 Click **Add** (+), and enter a name for the new prefix list, and whether to allow overrides.

You must configure a prefix list before you can configure a prefix rule.

Step 8 Click **Add** to configure prefix rules, and configure the following parameters:

- **Action**—Select **Block** or **Allow** for the redistribution access.
- **Sequence No**—The routing sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
- **IP Address**—Specify the prefix number in the format of IP address/mask length.
- **Min Prefix Length**—(Optional) The minimum prefix length.
- **Max Prefix Length**—(Optional) The maximum prefix length.

Step 9 Click **OK** to save the inter-area filtering configuration.

Step 10 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPF Filter Rules, on page 762.

Configure OSPF Filter Rules

You can configure ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. You can apply this type of area filtering out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF area at the same time. OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Filter Rule** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete filter rules.

Step 6 Configure the following filter rule options for each OSPF process:

- **OSPF Process**— For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Access List**—The access list for this OSPF process. To add a new standard access list object, click **Add** () and see Configure Standard ACL Objects, on page 858.

- **Traffic Direction**—Choose In or Out for the traffic direction being filtered. Choose In to filter LSAs coming into an OSPF area, or Out to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.
- **Interface**—The interface for this filter rule.

Step 7 Click **OK** to save the filter rule configuration.

Step 8 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPF Summary Addresses, on page 763.

Configure OSPF Summary Addresses

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the FTD device to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database. Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Summary Address** > **Add**.

You can click **Edit** ( ) to edit, or use the right-click menu to cut, copy, past, insert, and delete summary addresses.

Step 6 Configure the following summary address options for each OSPF process:

- **OSPF Process**— For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Available Network**—The IP address of the summary address. Select one from the Available networks list and click **Add**, or to add a new network, click **Add** ( ). See Network, on page 878 for the procedure for adding networks.

- **Tag**—A 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.
- **Advertise—Advertises** the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Step 7 Click **OK** to save the summary address configuration.

Step 8 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPF Interfaces and Neighbors, on page 764.

Configure OSPF Interfaces and Neighbors

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval, the dead interval, and the authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF**.

Step 5 Select **Interface** > **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 6 Configure the following Interface options for each OSPF process:

- **Interface**—The interface you are configuring.

  Note
  If the device is using virtual routing, this drop-down list displays only those interfaces that belong to the router.

- **Default Cost**—The cost of sending a packet through the interface. The default value is 10.
- **Priority**—The designated router for a network. Valid values range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router.

When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router. This setting does not apply to interfaces that are configured as point-to-point interfaces.

- **MTU Ignore—OSPF** checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency is not established.
- **Database Filter**—Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.
- **Hello Interval**—Specifies the interval, in seconds, between hello packets sent on an interface. Valid values range 1–8192 seconds. The default value is 10 seconds.

  The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface.
- **Transmit Delay**—Estimated time in seconds to send an LSA packet on the interface. Valid values range 1–65535 seconds. The default is 1 second.

  LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.
- **Retransmit Interval**—Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Dead Interval**—Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range 1–65535.
- **Hello Multiplier**—Specifies the number of Hello packets to be sent per second. Valid values are 3–20.
- **Point-to-Point**—Lets you transmit OSPF routes over VPN tunnels.
- **Authentication**—Choose the OSPF interface authentication from the following:
  - **None**—(Default) Disables interface authentication.
  - **Area Authentication**—Enables interface authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**—Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

Note
Ensure to enter only numbers as the MD5 key ID.

- **Key Chain**—Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, see Creating Key Chain Objects, on page 877. Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.

- **Enter Password**—The password you configure if you choose Password as the type of authentication.
- **Confirm Password**—Confirm the password that you chose.

Step 7 Select **Neighbor** > **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 8 Configure the following parameters for each OSPF process:

- **OSPF Process**—Choose 1 or 2.
- **Neighbor**—Choose one of the neighbors in the drop-down list, or click **Add** ( ) to add a new neighbor; enter the name, description, network, whether to allow overrides, and then click **Save**.
- **Interface**—Choose the interface associated with the neighbor.

Step 9 Click **OK** to save the neighbor configuration.

Step 10 Click **Save** on the Routing page to save your changes.

Configure OSPF Advanced Properties

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, an LSA timer, and graceful restarts.

Graceful Restarts

The FTD device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv2 by using either using NSF Cisco (RFC 4811 and RFC 4812) or NSF IETF (RFC 3623).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.

- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

Step 4 Click **OSPF** > **Advanced**.

Step 5 Select **General**, and configure the following:

- **Router ID**—Choose Automatic or IP Address for the router ID. If you choose IP address, enter the IP address in the adjacent field.
- **Ignore LSA MOSPF**—Suppresses syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
- **RFC 1583 Compatible**—Configures RFC 1583 compatibility as the method used to calculate summary route costs. Routing loops can occur with RFC 1583 compatibility enabled. Disable it to prevent routing loops. All OSPF routers in an OSPF routing domain should have RFC compatibility set identically.
- **Adjacency Changes**—Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

  - **Log Adjacency Changes**—Causes the FTD device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
  - **Log Adjacency Change Details**—Causes the FTD device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distance**—Allows you to modify the settings that were used to configure administrative route distances for **inter-area**, **intra-area**, and **external** IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **LSA Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Enable Default Information Originate**—Check the **Enable** check box to generate a default external route into an OSPF routing domain and configure the following options:
  - **Always advertise the default route**—Ensures that the default route is always advertised.
  - **Metric Value**—Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.

- **Metric Type**—The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
- **RouteMap**—Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Route Map to add a new route map.

Step 6 Click **OK** to save the general configuration.

Step 7 Select **Non Stop Forwarding**, and configure Cisco NSF graceful restart for OSPFv2, for an NSF-capable or NSF-aware device:

Note
There are two graceful restart mechanisms for OSPFv2, Cisco NSF and IETF NSF. Only one of these graceful restart mechanisms can be configured at a time for an OSPF instance. An NSF-aware device can be configured as both Cisco NSF helper and IETF NSF helper but a NSF-capable device can be configured in either Cisco NSF or IETF NSF mode at a time for an OSPF instance.

a) Check the **Enable Cisco Non Stop Forwarding Capability** check box.
b) (Optional) Check the **Cancel NSF restart when non-NSF-aware neighboring networking devices are detected** check box if required.
c) (Optional) Make sure the **Enable Cisco Non Stop Forwarding Helper** mode check box is unchecked to disable the helper mode on an NSF-aware device.

Step 8 Configure IETF NSF Graceful Restart for OSPFv2, for an NSF-capable or NSF-aware device:

a) Check the **Enable IETF Non Stop Forwarding Capability** check box.
b) In the **Length of graceful restart interval (seconds)** field, enter the restart interval in seconds. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.
c) (Optional) Make sure the **Enable IETF nonstop forwarding (NSF) for helper mode** check box is unchecked to disable the IETF NSF helper mode on an NSF-aware device.
d) **Enable Strict Link State advertisement checking**—When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.
e) **Enable IETF Non Stop Forwarding**—Enables non stop forwarding, which allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. OSPF uses extensions to the OSPF protocol to recover its state from neighboring OSPF devices. For the recovery to work, the neighbors must support the NSF protocol extensions and be willing to act as "helpers" to the device that is restarting. The neighbors must also continue forwarding data traffic to the device that is restarting while protocol state recovery takes place.

Configure OSPFv3

This section describes the tasks involved in configuring an OSPFv3 routing process. For a device using virtual routing, you can configure OSPFv3 only for its global virtual router and not for its user-defined virtual router.

Configure OSPFv3 Areas, Route Summaries, and Virtual Links

To enable OSPFv3, you need to create an OSPFv3 routing process, create an area for OSPFv3, enable an interface for OSPFv3, and then redistribute the route into the targeted OSPFv3 routing process.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 By default **Enable Process 1** is selected. You can enable up to two OSPF process instances.

Step 4 Chose the OSPFv3 role from the drop-down list, and enter a description for it. The options are Internal, ABR, ASBR, and ABR and ASBR. See About OSPF, on page 751 for descriptions of the OSPFv3 roles.

Step 5 Select **Area** > **Add**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 6 Select **General**, and configure the following options for each OSPF process:

- **Area ID**—The area for which routes are to be summarized.
- **Cost**—The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
- **Type**—Specifies Normal, NSSA, or Stub. If you select Normal, there are no other parameters to configure. If you select Stub, you can choose to send summary LSAs in the area. If you select NSSA, you can configure the next three options:
  - **Allow Sending summary LSA into this area**—Allows the sending of summary LSAs into the area.
  - **Imports routes to normal and NSSA area**—Allows redistribution to import routes to normal and not to stubby areas.
  - **Defaults information originate**—Generates a default external route into an OSPFv3 routing domain.
- **Metric**—Metric used for generating the default route. The default value is 10. Valid metric values range from 0 to 16777214.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

Step 7 Click **OK** to save the general configuration.

Step 8 (Not applicable for Internal OSPFv3 Role) Select **Route Summary** > **Add Route Summary**.

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete route summaries.

Step 9 Configure the following route summary options for each OSPF process:

- **IPv6 Prefix/Length**—The IPv6 prefix. To add a new network object, click **Add** ( ). See Network, on page 878 for the procedure for adding networks.

- **Cost**—The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
- **Advertise**—Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Step 10 Click **OK** to save the route summary configuration.

Step 11 (Not applicable for Internal OSPFv3 Role) Select **Virtual Link**, click **Add Virtual Link**, and configure the following options for each OSPF process:

- **Peer RouterID**—Choose the IP address of the peer router. To add a new network object, click **Add** (+). See Network, on page 878 for the procedure for adding networks.
- **TTL Security**—Enables TTL security check. The value for the hop-count is a number from 1 to 254. The default is 1.

  OSPF sends outgoing packets with an IP header Time to Live (TTL) value of 255 and discards incoming packets that have TTL values less than a configurable threshold. Because each device that forwards an IP packet decrements the TTL, packets received via a direct (one-hop) connection have a value of 255. Packets that cross two hops have a value of 254, and so on. The receive threshold is configured in terms of the maximum number of hops that a packet may have traveled.
- **Dead Interval**—The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The default is four times the hello interval, or 40 seconds. Valid values range from 1 to 65535.

  The dead interval is an unsigned integer. The value must be the same for all routers and access servers that are attached to a common network.
- **Hello Interval**—The time in seconds between the hello packets sent on an interface. Valid values range from 1 to 65535. The default is 10.

  The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.
- **Retransmit Interval**—The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 65535. The default is 5.

  When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.
- **Transmit Delay**—The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 to 8192. The default is 1.

  LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

Step 12 Click **OK** to save the virtual link configuration.

Step 13 Click **Save** on the Router page to save your changes.

What to do next

Continue with Configure OSPFv3 Redistribution.

Configure OSPFv3 Redistribution

The Firepower Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **Routing** > **OSPF**.

Step 3 Select **Redistribution**, and click **Add.**

You can click **Edit** ( ), or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following redistribution options for each OSPF process:

- **Source Protocol**—The source protocol from which routes are being redistributed. The supported protocols are connected, OSPF, Static, and BGP. If you choose OSPF, you must enter the Process ID in the **Process ID** field. If you choose BGP, you must add the AS number in the **AS Number** field.
- **Metric** —Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

  When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag** —Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **Route Map**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add** ( ). See Route Map, on page 902 for the procedure to add a new route map.
- **Process ID**—The OSPF process ID, either 1 or 2.

  Note

The Process ID is enabled the OSPFv3 process is redistributing a route learned by another OSPFv3 process.

- **Match**—Enables OSPF routes to be redistributed into other routing domains:
  - **Internal** for routes that are internal to a specific autonomous system.
  - **External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 1 external routes.
  - **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 2 external routes.
  - **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 1 external routes.
  - **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 2 external routes.

Step 5 Click **OK** to save the redistribution configuration.

Step 6 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPFv3 Summary Prefixes, on page 772.

Configure OSPFv3 Summary Prefixes

You can configure the FTD device to advertise routes that match a specified IPv6 prefix and mask pair.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Summary Prefix** > **Add**.

You can click **Edit** (), or use the right-click menu to cut, copy, past, insert, and delete summary prefixes.

Step 4 Configure the following summary prefix options for each OSPF process:

- **IPv6 Prefix/Length**—The IPv6 prefix and prefix length label. Select one from the list or click **Add** () to add a new network object. See Network, on page 878 for the procedure for adding networks.
- **Advertise**— Advertises routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.
- (Optional) **Tag**—A value that you can use as a match value for controlling redistribution through route maps.

Step 5 Click **OK** to save the summary prefix configuration.

Step 6 Click **Save** on the Routing page to save your changes.

What to do next

Continue with Configure OSPFv3 Interfaces, Authentication, and Neighbors, on page 773.

Configure OSPFv3 Interfaces, Authentication, and Neighbors

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **Routing** > **OSPFv3**.

Step 3 Select **Interface** > **Add**.

You can click **Edit** to edit, or use the right-click menu to cut, copy, past, insert, and delete areas.

Step 4 Configure the following interface options for each OSPFv3 process:

- **Interface**—The interface you are configuring.
- **Enable OSPFv3**—Enables OSPFv3.
- **OSPF Process**—Choose 1 or 2.
- **Area**—The area ID for this process.
- **Instance** —Specifies the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

Step 5 Select **Properties**, and configuring the following options for each OSPFv3 process:

- **Filter Outgoing Link Status Advertisements**—Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Disable MTU mismatch detection**—Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.
- **Flood Reduction**—Changes normal LSAs into Do Not Age LSAs, so that they don't get flooded every 3600 seconds across areas.

  OSPF LSAs are refreshed every 3600 seconds. In large OSPF networks, this can lead to large amounts of unnecessary LSA flooding from area to area.

- **Point-to-Point Network**—Lets you transmit OSPF routes over VPN tunnels. When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:
  - You can define only one neighbor for the interface.
  - You need to manually configure the neighbor.
  - You need to define a static route pointing to the crypto endpoint.
  - If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
  - You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.
- **Broadcast**— Specifies that the interface is a broadcast interface. By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, nonbroadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.
- **Cost**—Specifies the cost of sending a packet on the interface. Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.
- **Priority**—Determines the designated router for a network. Valid values range from 0 to 255.
- **Dead Interval**—Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.
- **Hello Interval**— Time period in seconds between OSPF packets that the router will send before adjacency is established with a neighbor. Once the routing device detects an active neighbor, the hello packet interval changes from the time specified in the poll interval to the time specified in the hello interval. Valid values range from 1 to 65535 seconds.
- **Retransmit Interval**—Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.
- **Transmit Delay**—Estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.

Step 6 Click **OK** to save the properties configuration.

Step 7 Select **Authentication**, and configure the following options for each OSPFv3 process:

- **Type**—Type of authentication. The available options are Area, Interface, and None. The None option indicates that no authentication is used.

- **Security Parameters Index**— A number from 256 to 4294967295. Configure this if you chose Interface as the type.
- **Authentication**—Type of authentication algorithm. Supported values are SHA-1 and MD5. Configure this if you chose Interface as the type.
- **Authentication Key**— When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.
- **Encrypt Authentication Key**—Enables encryption of the authentication key.
- **Include Encryption**— Enables encryption.
- **Encryption Algorithm**—Type of encryption algorithm. Supported value is DES. The NULL entry indicates no encryption. Configure this if you chose **Include Encryption**.
- **Encryption Key**—Enter the encryption key. Configure this if you chose **Include Encryption**.
- **Encrypt Key**—Enables the key to be encrypted.

Step 8 Click **OK** to save the authentication configuration.

Step 9 Select **Neighbor**, click **Add**, and configure the following options for each OSPFv3 process:

- **Link Local Address**—The IPv6 address of the static neighbor.
- **Cost**—Enables cost. Enter the cost in the **Cost** field, and check the **Filter Outgoing Link State Advertisements** if you want to advertise.
- (Optional) **Poll Interval**—Enables the poll interval. Enter the **Priority** level and the **Poll Interval** in seconds.

Step 10 Click **Add** to add the neighbor.

Step 11 Click **OK** to save the Interface configuration.

Configure OSPFv3 Advanced Properties

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, passive OSPFv3 routing, LSA timers, and graceful restarts.

Graceful Restarts

The FTD device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv3 using graceful-restart (RFC 5187).

Note NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **OSPFv3** > **Advanced**.

Step 3 For **Router ID**, choose Automatic or IP Address. If you choose IP Address, enter the IPv6 address in the **IP Address** field.

Step 4 Check the **Ignore LSA MOSPF** check box if you want to suppress syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.

Step 5 Select **General**, and configure the following:

- **Adjacency Changes**—Defines the adjacency changes that cause syslog messages to be sent.

  By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.

  - **Adjacency Changes**—Causes the FTD device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.
  - **Include Details**—Causes the FTD device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

- **Administrative Route Distances**—Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **Default Information Originate**—Check the **Enable** check box to generate a default external route into an OSPFv3 routing domain and configure the following options:
  - **Always Advertise**—Will always advertise the default route whether or not one exists.
  - **Metric**—Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**—The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **Route Map**—Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See Route Map, on page 902 to add a new route map.

Step 6 Click **OK** to save the general configuration.

Step 7 Select **Passive Interface**, select the interfaces on which you want to enable passive OSPFv3 routing from the Available Interfaces list, and click **Add** to move them to the Selected Interfaces list.

Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface.

Step 8 Click **OK** to save the passive interface configuration.

Step 9 Select **Timer**, and configure the following LSA pacing and SPF calculation timers:

- **Arrival**—Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.
- **Flood Pacing**—Specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
- **Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Retransmission Pacing**—Specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
- **LSA Throttle**—Specifics the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 millisecond. The minimum specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds. The maximum specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.

  Note
  For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- **SPF Throttle**—Specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds. The minimum specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds. The maximum specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

  Note
  For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

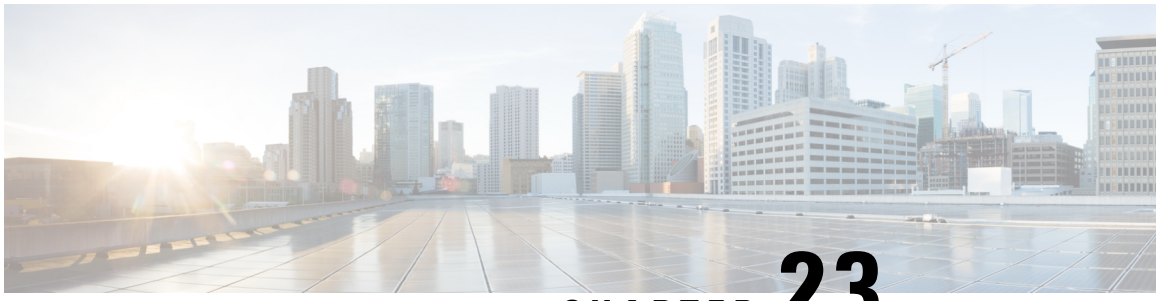
Step 10 Click **OK** to save the LSA timer configuration.

Step 11 Select **Non Stop Forwarding**, and check the **Enable graceful-restart helper** check box. This is checked by default. Uncheck this to disable the graceful-restart helper mode on an NSF-aware device.

Step 12 Check the **Enable link state advertisement** check box to enable strict link state advertisement checking.

When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

Step 13 Check the **Enable graceful-restart (Use when Spanned Cluster or Failover Configured)** and enter the graceful-restart interval in seconds. The range is 1-1800. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.



Step 14 Click **OK** to save the graceful restart configuration.

Step 15 Click **Save** on the Routing page to save your changes.

History for OSPF

Table 48: Feature History for OSPF

Feature	Minimum FMC	Minimum FTD	Details
BFD Support for OSPF v2 and v3	7.4	7.4	You can enable BFD on OSPFv2 and OSPFv3 interfaces. New/modified screens: • **Configuration** > **Device Setup** > **Routing** > **OSPFv2** • **Configuration** > **Device Setup** > **Routing** > **OSPFv3**

CHAPTER 23

BGP

This section describes how to configure the FTD to route data, perform authentication, and redistribute routing information using the Border Gateway Protocol (BGP).

- About BGP, on page 779
- Requirements and Prerequisites for BGP, on page 782
- Guidelines for BGP, on page 782
- Configure BGP, on page 783
- History for BGP, on page 796

About BGP

BGP is an inter and intra autonomous system routing protocol. An autonomous system is a network or group of networks under a common administration and with common routing policies. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP).

Routing Table Changes

BGP neighbors exchange full routing information when the TCP connection between neighbors is first established. When changes to the routing table are detected, the BGP routers send to their neighbors only those routes that have changed. BGP routers do not send periodic routing updates, and BGP routing updates advertise only the optimal path to a destination network.

Note AS loop detection is done by scanning the full AS path (as specified in the AS_PATH attribute), and checking that the AS number of the local system does not appear in the AS path. By default, EBGP advertises the learned routes to the same peer to prevent additional CPU cycles on the device in performing loop checks and to avoid delays in the existing outgoing update tasks.

Routes learned via BGP have properties that are used to determine the best route to a destination, when multiple paths exist to a particular destination. These properties are referred to as BGP attributes and are used in the route selection process:

- Weight—This is a Cisco-defined attribute that is local to a router. The weight attribute is not advertised to neighboring routers. If the router learns about more than one route to the same destination, the route with the highest weight is preferred.

- Local preference—The local preference attribute is used to select an exit point from the local AS. Unlike the weight attribute, the local preference attribute is propagated throughout the local AS. If there are multiple exit points from the AS, the exit point with the highest local preference attribute is used as an exit point for a specific route.
- Multi-exit discriminator—The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.
- Origin—The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  - IGP—The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  - EGP—The route is learned via the Exterior Border Gateway Protocol (EBGP).
  - Incomplete—The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.
- AS_path—When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS_path list is installed in the IP routing table.
- Next hop—The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS. However, when the next hop is in the same subnet as the peering address of the eBGP peer, the next hop is not modified. This behavior is referred to as the third party next hop.
- Community—The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  - no-export—Do not advertise this route to EBGP peers.
  - no-advertise—Do not advertise this route to any peer.
  - internet—Advertise this route to the Internet community; all routers in the network belong to it.

When to Use BGP

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

BGP can also be used for carrying routing information for IPv6 prefix over IPv6 networks.

BGP Path Selection

BGP may receive multiple advertisements for the same route from different sources. BGP selects only one path as the best path. When this path is selected, BGP puts the selected path in the IP routing table and propagates the path to its neighbors. BGP uses the following criteria, in the order presented, to select a path for a destination:

- If the path specifies a next hop that is inaccessible, drop the update.
- Prefer the path with the largest weight.
- If the weights are the same, prefer the path with the largest local preference.
- If the local preferences are the same, prefer the path that was originated by BGP running on this router.
- If no route was originated, prefer the route that has the shortest AS_path.
- If all paths have the same AS_path length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
- If the origin codes are the same, prefer the path with the lowest MED attribute.
- If the paths have the same MED, prefer the external path over the internal path.
- If the paths are still the same, prefer the path through the closest IGP neighbor.
- Determine if multiple paths require installation in the routing table for BGP Multipath, on page 781.
- If both paths are external, prefer the path that was received first (the oldest one).
- Prefer the path with the lowest IP address, as specified by the BGP router ID.
- If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
- Prefer the path that comes from the lowest neighbor address.

BGP Multipath

BGP Multipath allows installation into the IP routing table of multiple equal-cost BGP paths to the same destination prefix. Traffic to the destination prefix is then shared across all installed paths.

These paths are installed in the table together with the best path for load-sharing. BGP Multipath does not affect best-path selection. For example, a router still designates one of the paths as the best path, according to the algorithm, and advertises this best path to its BGP peers.

In order to be candidates for multipath, paths to the same destination need to have these characteristics equal to the best-path characteristics:

- Weight
- Local preference
- AS-PATH length
- Origin code
- Multi Exit Discriminator (MED)
- One of these:

- Neighboring AS or sub-AS (before the addition of the BGP Multipaths)
- AS-PATH (after the addition of the BGP Multipaths)

Some BGP Multipath features put additional requirements on multipath candidates:

- The path should be learned from an external or confederation-external neighbor (eBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric.

These are the additional requirements for internal BGP (iBGP) multipath candidates:

- The path should be learned from an internal neighbor (iBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric, unless the router is configured for unequal-cost iBGP multipath.

BGP inserts up to *n* most recently received paths from multipath candidates into the IP routing table, where *n* is the number of routes to install to the routing table, as specified when you configure BGP Multipath. The default value, when multipath is disabled, is 1.

For unequal-cost load balancing, you can also use BGP Link Bandwidth.

Note The equivalent next-hop-self is performed on the best path that is selected among eBGP multipaths before it is forwarded to internal peers.

Requirements and Prerequisites for BGP

Model Support

FTD

FTDv

Supported Domains

Any

User Roles

Admin

Network Admin

Guidelines for BGP

Firewall Mode Guidelines

Does not support transparent firewall mode. BGP is supported only in routed mode.

IPv6 Guidelines

Supports IPv6. Graceful restart is not supported for IPv6 address family.

Additional Guidelines

- For BGP, the next hop IP address for the routes is the network IP address and not 0.0.0.0.
- The system does not add route entry for the IP address received over PPPoE in the CP route table. BGP always looks into CP route table for initiating the TCP session, hence BGP does not form TCP session.

  Thus, BGP over PPPoE is not supported.
- BGP is not supported on management-only or BVI interfaces.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- BGP with PATH MTU (PMTU) can cause adjacency flaps if MTU discovery fails, especially with ECMP routing. Hence, be cautious while using BGP, PMTU, and ECMP as packet drops can occur if MTU discovery fails due to any reason.
- The BGP table of the member unit is not synchronized with the control unit table. Only its routing table is synchronized with the control unit routing table.

Configure BGP

To configure BGP, see the following topics:

Procedure

Step 1 Configure BGP Basic Settings, on page 784

Step 2 Configure BGP General Settings, on page 786

Step 3 Configure BGP Neighbor Settings, on page 787

Step 4 Configure BGP Aggregate Address Settings, on page 791

Step 5 Configure BGPv4 Filtering Settings, on page 791

Note
The Filtering section is applicable only to IPv4 settings

Step 6 Configure BGP Network Settings, on page 792

Step 7 Configure BGP Redistribution Settings, on page 793

Step 8 Configure BGP Route Injection Settings, on page 794

Step 9 Configure BGP Route Import/Export Settings, on page 794

Configure BGP Basic Settings

You can set many basic settings for BGP.

For a device using virtual routing, the basic settings described in this section must be configured in the **BGP** page under **General Settings**. For more information, see Modifications to the FMC Web Interface - Routing Page, on page 698.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **Routing**.

Step 3 (For a virtual-router-aware device) Under **General Settings**, click **BGP**.

Step 4 Check the **Enable BGP** check box to enable the BGP routing process.

Step 5 In the **AS Number** field, enter the autonomous system (AS) number for the BGP process. The AS number internally includes multiple autonomous numbers. The AS number can be from 1 to 4294967295 or from 1.0 to 65535.65535. The AS number is a uniquely assigned value, that identifies each network on the Internet.

Step 6 In the **Router ID** drop-down list, choose Automatic or Manual. If you choose Automatic, the highest-level IP address on the FTD device is used as the router ID. If you choose Manual, enter the IP address in the **IP Address** field.

Step 7 To use a fixed router ID, choose Manual and enter an IPv4 address in the **IP Address** field. The default value is Automatic. For a virtual router-aware device, you can override the router ID settings in the **Virtual Routers** > **BGP** page.

Step 8 (Optional) Edit the various BGP settings, starting with **General**. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network. Click **Edit** ( ) to edit the settings in the group:

a) Enter a **Scanning Interval** for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.

b) Enter the **Number of AS numbers in AS_PATH attribute**. An AS _PATH attribute is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Valid values are between 1 and 254. The default value is None.

c) Check the **Log Neighbor Changes** check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability. This is enabled by default.

d) Check the **Use TCP Path MTU Discovery** check box to use the Path MTU determining technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation. This is enabled by default.

e) Check the **Reset session upon Failover** check box to reset the external BGP session immediately upon link failure. This is enabled by default.

f) Check the **Enforce that the first AS is peer's AS for EBGP routes** check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS_PATH attribute. This prevents a mis-configured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system. This is enabled by default.

g) Check the **Use dot notation for AS number** check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 0-65553 are represented as decimal numbers and AS numbers larger than 65535 are represented using the dot notation. This is disabled by default.

h) Click **OK**.

Step 9 (Optional) Edit the **Best Path Selection** section:

a) Enter a value for **Default Local Preference** between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.

b) Check the **Allow comparing MED from different neighbors** check box to allow the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. This is disabled by default.

c) Check the **Compare Router ID for identical EBGP paths** check box to compare similar paths received from external BGP peers during the best path selection process and switch the best path to the route with the lowest router ID. This is disabled by default.

d) Check the **Pick the best MED path among paths advertised from the neighboring AS** check box to enable MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path. This is disabled by default.

e) Check the **Treat missing MED as the least preferred one** check box to consider the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred. This is disabled by default.

f) Click **OK**.

Step 10 (Optional) Edit the **Neighbor Timers** section:

a) Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message in the **Keep alive interval** field. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.

b) Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Hold time** field. The default value is 180 seconds. Specify a value from 0 to 65535.

c) (Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Min Hold time** field. Specify a value from 3 to 65535.

Note
A hold time of less than 20 seconds increases the possibility of peer flapping.

d) Click **OK**.

Step 11 In the **Next Hop** section, optionally select the **Enable address tracking** check box to enable BGP next hop address tracking and enter the **Delay Interval** between checks on updated next-hop routes installed in the routing table. Click **OK**.

Note
The **Next Hop** section is applicable only to IPv4 settings.

Step 12 (Optional) Edit the **Graceful Restart** section:

Note
This section is available only when the FTD device is in failover or spanned cluster mode. This is done so that there is no drop in packets in the traffic flow, when one of the devices in the failover setup fails.

a) Check the **Enable Graceful Restart** checkbox to enable FTD peers to avoid a routing flap following a switchover.

b) Specify the time duration that FTD peers will wait to delete stale routes before a BGP open message is received in the **Restart Time** field. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.

c) Enter the time duration that the FTD will wait before deleting stale routes after an end of record (EOR) message is received from the restarting FTD in the **Stalepath Time** field. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.

d) Click **OK**.

Step 13 Click **Save**.

Step 14 To view the BGP basic settings, from the virtual routers drop-down, select the desired router, and then click **BGP**.

This page displays the basic settings that are configured in the **Settings** page. You can edit the router ID settings on this page.

Step 15 To edit the router ID settings, modify the IP address in the **IP Address** fields. The modified value overrides the router ID settings that were configured in the **BGP** page under **General Settings**.

Configure BGP General Settings

Configure Route maps, Administrative Route Distances, Synchronization, Next-hop, and packet forwarding. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, select the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **General**.

Step 5 In **General**, update the following sections:

a) In the **Settings** section, enter or select a **Route Map** object and click **OK**.

Note
The **Route Map** field is applicable only to IPv4 settings.

b) In the **Administrative Route Distances** section, update the following as required, and click **OK**:

- **External** — Enter the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
- **Internal** — Enter administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
- **Local** — Enter administrative distance for local BGP routes. Local routes are those networks listed with a network router show command, often as back doors, for the router or for the networks that is being redistributed from another process. The range of values for this argument are from 1 to 255. The default value is 200.

c) In the **Routes and Synchronization** section, update the following as required, and click **OK**:

- (Optional) **Generate default routes** — Check the check box of this option to configure default-information originate.
- (Optional) **Summarize subnet routes into network-level routes** — Check the check box of this to configure automatic summarization of subnet routes into network-level routes. This check box is applicable only to IPv4 settings.
- (Optional) **Advertise inactive routes** — Check the check box of this to advertise routes that are not installed in the routing information base (RIB).
- (Optional) **Synchronize between BGP and IGP system** — Check the check box of this to enable synchronization between BGP and your Interior Gateway Protocol (IGP) system. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems.
- (Optional) **Redistribute IBGP into IGP** — Check the check box of this to configure iBGP redistribution into an interior gateway protocol (IGP), such as OSPF.

d) In the **Forward Packets over Multiple Paths** section, update the following as required and click **OK**:

- (Optional) **Number of Paths** — Enter the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.
- (Optional) **IBGP Number of Paths** — Enter the maximum number of parallel internal Border Gateway Protocol (iBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

Step 6 Click **Save**.

Configure BGP Neighbor Settings

A BGP router must connect with each of its peers before exchanging updates. These peers are called BGP neighbors. Perform this procedure to define BGP IPv4 or IPv6 neighbors and neighbor settings.

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Neighbor**.

Step 5 Click **Add** to define BGP neighbors and neighbor settings.

Step 6 Enter the BGP neighbor **IP address**. This IP address is added to the BGP neighbor table. When you are configuring BGP IPv6 on static VTI, enter the virtual tunnel IP address of the neighbor.

Step 7 Choose the BGP neighbor **Interface**.

Note
The **Interface** field is only applicable to IPv6 settings.

Step 8 Enter the autonomous system to which the BGP neighbor belongs, in the **Remote AS** field.

Step 9 Check the **Enabled address** check box to enable communication with this BGP neighbor. Further neighbor settings will be configured only if the Enabled address check box is selected.

Step 10 (Optional) Check the **Shutdown administratively** check box to disable a neighbor or peer group.

Step 11 (Optional) Check the **Configure graceful restart** check box to enable configuration of the BGP graceful restart capability for this neighbor. After selecting this option, you must check the **Graceful restart (failover / spanned mode)** check box to specify whether graceful restart should be enabled or disabled for this neighbor.

Note
- The graceful restart fields are only applicable to IPv4 settings.
- The graceful restart is enabled only when the device is in HA mode or when L2 cluster (all nodes from the same network) is configured.

Step 12 (Optional) Select the **BFD Fallover** check box to enable configuration of the BFD support for BGP. This selection registers the BGP neighbor to receive forwarding path detection failure messages from BFD.

Step 13 (Optional) Enter a **Description** for the BGP neighbor.

Step 14 (Optional) In **Filtering Routes**, use access lists, route maps, prefix lists and AS path filters as required, to distribute BGP Neighbor information. Update the following sections:

a) Choose or select the appropriate incoming or outgoing **Access List** to distribute BGP neighbor information.

Note
Access lists are only applicable to IPv4 settings.

b) Choose or select the appropriate incoming or outgoing **Route Maps** to apply a route map to incoming or outgoing routes.

c) Choose or select the appropriate incoming or outgoing **Prefix List** to distribute BGP neighbor information.

d) Choose or select the appropriate incoming or outgoing **AS path filter** to distribute BGP neighbor information.

e) Check the check box of **Limit the number of prefixes allowed from the neighbor** to control the number of prefixes that can be received from a neighbor.

- Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.
- Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.

f) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following

- Check the **Terminate peering when prefix limit is exceeded** check box to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the **Restart interval** field.
- Check the **Give only warning message when prefix limit is exceeded** check box to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.

g) Click **OK**.

Step 15 (Optional) In **Routes**, specify miscellaneous Neighbor route parameter. Proceed to update the following:

a) Enter the minimum interval (in seconds) between the sending of BGP routing updates in the **Advertisement Interval** field. Valid values are between 1 and 600.

b) Check the **Remove private AS numbers from outbound routing updates** check box to exclude the private AS numbers from being advertised on outbound routes.

c) Check the **Generate default routes** check box to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the **Route map** field.

d) To add conditionally advertised routes, click Add Row +. In the Add Advertised Route dialog box, do the following:

1. Add or choose a route map in the **Advertise Map** field, that will be advertised if the conditions of the exist map or the non-exist map are met.
2. Click **Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
3. Click **Non-Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
4. Click **OK**.

Step 16 In **Timers**, check the **Set timers for the BGP peer** check box to set the keepalive frequency, hold time and minimum hold time

- **Keep alive interval**—Enter the frequency (in seconds) with which FTD sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
- **Hold time**—Enter the interval (in seconds) after not receiving a keepalive message that FTD declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
- **Min hold time**—(Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that FTD declares a peer dead. Valid values are between 3 and 65535. The default value is 3 seconds.

Note
A hold time of less than 20 seconds increases the possibility of peer flapping.

Step 17 In **Advanced**, update the following:

a) (Optional) Check the **Enable Authentication** check box to enable MD5 authentication on a TCP connection between two BGP peers.

1. Choose an encryption type from the **Enable Encryption** drop-down list.
2. Enter a password in the **Password** field. Reenter the password in the **Confirm Password** field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The string can contain any alphanumeric characters, including spaces.

Note
You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.

b) (Optional) Select the **Send Community attribute to this neighbor** check box to specify that communities attributes should be sent to the BGP neighbor
c) (Optional) Select the **Use FTD as next hop for this neighbor** check box to configure the router as the next-hop for a BGP speaking neighbor or peer group.
d) Select the **Disable Connection Verification** check box to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.
e) Select **Allow connections with neighbor that is not directly connected** to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the **TTL hops**field. Valid values are between 1 and 255. Alternately, select **Limited number of TTL hops to neighbor**, to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the **TTL hops** field. Valid values are between 1 and 254.
f) (Optional) Select the **Use TCP MTU path discovery** check box to enable a TCP transport session for a BGP session.
g) Choose the TCP connection mode from the **TCP Transport Mode** drop-down list. Options are Default, Active, or Passive.
h) (Optional) Enter a **Weight** for the BGP neighbor connection.
i) Select the **BGP Version** that FTD will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.

Step 18 Update **Migration**, only if AS migration is considered.

Note
The AS migration customization should be removed after transition has been completed.

a) (Optional) Check the **Customize the AS number for routes received from the neighbor** check box to customize the AS_PATH attribute for routes received from an eBGP neighbor.
b) Enter the local autonomous system number in the **Local AS number** field. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
c) (Optional) Check the **Do not prepend local AS number to routes received from neighbor** check box to prevent the local AS number from being prepended to any routes received from eBGP peer.
d) (Optional) Check the **Replace real AS number with local AS number in routes received from neighbor** check box to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.
e) (Optional) Check the **Accept either real AS number or local AS number in routesreceived from neighbor** check box to configure the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

Step 19 Click **OK**.

Step 20 Click **Save**.

Configure BGP Aggregate Address Settings

BGP neighbors store and exchange routing information and the amount of routing information increases as more BGP speakers are configured. Route aggregation is the process of combining the attributes of several different routes so that only a single route is advertised. Aggregate prefixes use the classless interdomain routing (CIDR) principle to combine contiguous networks into one classless set of IP addresses that can be summarized in routing tables. As a result fewer routes need to be advertised. Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

Procedure

Step 1 When editing the FTD device, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Add Aggregate Address**.

Step 5 Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.

Step 6 Click (+)**Add** and update the **Add Aggregate Address** dialog box:

a) **Network** — Enter an IPv4 address or select the desired network/hosts objects.
b) **Attribute Map** — (Optional) Enter or select the route map used to set the attribute of the aggregate route.
c) **Advertise Map** — (Optional) Enter or select the route map used to select the routes to create AS_SET origin communities.
d) **Suppress Map** — (Optional) Enter or select the route map used to select the routes to be suppressed.
e) **Generate AS set path Information** — (Optional) Check the check box to enable generation of autonomous system set path information.
f) **Filter all routes from updates** — (Optional) Check the check box to filter all more-specific routes from updates.
g) Click **OK**.

What to do next

- For BGPv4 settings, proceed to Configure BGPv4 Filtering Settings, on page 791.
- For BGPv6 settings, proceed to Configure BGP Network Settings, on page 792.

Configure BGPv4 Filtering Settings

Filtering settings are used to filter routes or networks received in incoming BGP updates. Filtering is used to restrict routing information that the router learns or advertises.

Before you begin

Filtering is only applicable for a BGP IPv4 routing policy.

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4**.

Step 4 Click **Filtering**.

Note
The **Filtering** field is applicable only to IPV4 settings.

Step 5 Click (+)**Add** and update the **Add Filter** dialog box:

a) **Access List**— Choose an access control list that defines which networks are to be received and which are to be suppressed in routing updates.

b) **Direction**— (Optional) Choose a direction that specifies if the filter should be applied to inbound updates or outbound updates.

c) **Protocol**— (Optional) Choose the routing process for which you want to filter: None, BGP, Connected, OSPF, RIP, or Static.

d) **Process ID**— (Optional) Enter the process ID for the OSPF routing protocol.

e) Click **OK**.

Step 6 Click **Save**.

Configure BGP Network Settings

Network settings are used to add networks that will be advertised by the BGP routing process and route maps that will be examined to filter the networks to be advertised.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Networks**.

Step 5 Click **Add** and update the **Add Networks** dialog box:

a) **Network**— Choose the network to be advertised by the BGP routing processes.

Note
For a network prefix to be advertised, a route to the device must exist on the routing table.

To add a new network object, see Creating Network Objects, on page 880.

b) (Optional) **Route Map**— Enter or choose a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed. To add a new route map object, see Route Map, on page 902.

c) Click **OK**.

Step 6 Click **Save**.

Configure BGP Redistribution Settings

Redistribution settings allow you to define the conditions for redistributing routes from another routing domain into BGP.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Redistribution**.

Step 5 Click **Add** and update the **Add Redistribution** dialog:

a) **Source Protocol**— Select the protocol from which you want to redistribute routes into the BGP domain from the Source Protocol drop-down list.

Note
User-defined virtual routers does not support redistributing traffic from RIP.

b) **Process ID**— Enter the identifier for the selected source protocol. Applies to the OSPF protocol. For devices using virtual routing, this drop-down lists the process ID assigned for the virtual router for which you are configuring the BGP settings.

c) **Metric**— (Optional) Enter a metric for the redistributed route.

d) **Route Map**— Enter or select a route map that should be examined to filter the networks to be redistributed.

If not specified, all networks are redistributed. To create a new route map object, click **Add** (+). See Route Map for the procedure to add a new route map.

e) **Match**— The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions. These options are enabled only when OSPF is chosen as the Source Protocol.

- Internal
- External 1
- External 2
- NSSA External 1
- NSSA External 2

f) Click **OK**.

Configure BGP Route Injection Settings

Route injection settings allow you to define the routes to be conditionally injected into the BGP routing table.

Procedure

Step 1 On the **Device Management** page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 Click **Route Injection**.

Step 5 Click **Add** and update the **Add Route Injection** dialog box:

a) **Inject Map**— Enter or select the route map that specifies the prefixes to inject into the local BGP routing table. To create a new route map object, click **Add** (+). For the procedure to add a new route map, see Route Map.

b) **Exist Map**— Enter or select the route map containing the prefixes that the BGP speaker will track.

c) **Injected routes will inherit the attributes of the aggregate route**— Check this box to configure the injected route to inherit attributes of the aggregate route.

d) Click **OK**.

Step 6 Click **Save**.

Configure BGP Route Import/Export Settings

In BGP, you can implement an inter-virtual-router route leak by importing or exporting routes using the route target extended community of the destination and source virtual routers respectively. You can use a route map to filter the desired route targets instead of leaking the entire routing table. You can also leak the routes of global virtual router to user-defined virtual routers and vice versa.

- You can configure BGP to leak routes between two user-defined virtual routers using the route target extended communities:
  - Tag the routes with the route targets from the source virtual router using route target export.
  - Import the routes that are matching the route targets in to the destination virtual router using route target import.
  - Optionally, you can filter routes from source virtual router or to destination virtual router using export or import route maps respectively. You can configure route map with match extended community list for filtering the routes. Similarly, you can configure route map with set extended community route targets to tag the routes with the route target extended community.

- To import routes from the global virtual router to a user-defined virtual router, specify the IPv4/IPv6 route map in Global Virtual Router Import Route Map to import to the user-defined virtual router.
- To export routes from a user-defined virtual router to the global virtual router, in addition to exporting the route targets, you can also specify the Global Virtual Router Export Route Map to export from the user-defined virtual router.

The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

Before you begin

- Create a Virtual Router.
- Configure BGP Basic Settings.
- Configure BGP, on page 783.

Procedure

Step 1 On the Device Management page, click **Routing**.

Step 2 (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.

Step 3 Choose **BGP** > **IPv4** or **IPv6**.

Step 4 (Supported only for only virtual routers) Click **Route Import/Export**.

Step 5 In the **Route Targets Import** field, enter the route target extended community that you want to match for the routes to be imported. On deployment, the routes of the destination virtual router that matches this value is imported to the source virtual router's BGP table.

Note
- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma separated values.
- This value can range from 0:1 to 65534:65535.

Step 6 In the **Route Targets Export** field, enter the route target extended community to tag the source virtual router's routes with the route target value. On deployment, the routes of the source virtual router are tagged with this value.

Note
- The route target must be in **ASN:nn** format.
- You can enter multiple route targets as comma separated values.
- This value can range from 0:1 to 65534:65535.

Step 7 Route maps help you to narrow down the routes to be shared instead of leaking the entire routing table. Route map filtering is applied on the list of routes that are obtained with the specified route target values:

a) (Optional) Under **User Virtual Router**, choose the route map from the **Import Route Map** drop-down list to filter the routes at the destination virtual router.

Note
The user virtual router import route map is effective only when the route targets import is configured.

b) (Optional) Under **User Virtual Router**, choose the route map from the **Export Route Map** drop-down list to filter the routes at the source virtual router before the routes are exported to other virtual routers.

Note
You can use the match and set clauses in the route map with the route target extended community lists for filtering based on other criteria or tagging the routes with the route target community values. For more information, see Route Map, on page 902.

Step 8 To share the routes between a user-defined virtual router and global virtual router, specify the route map under the **Global Virtual Router**:

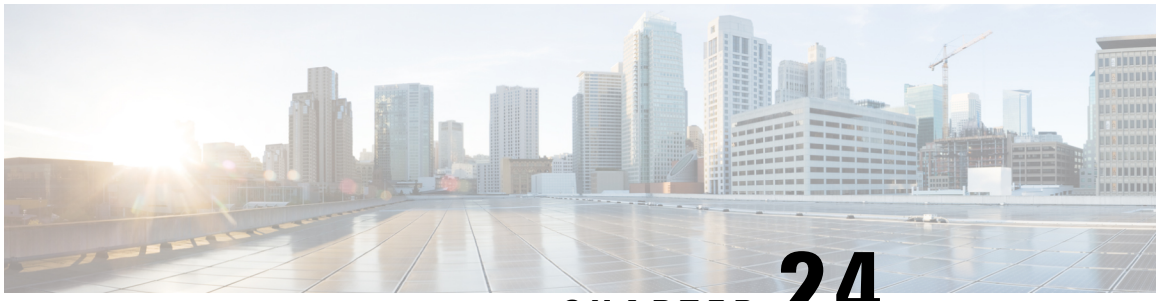
a) To leak the global virtual router routes to the user-defined virtual router, select the route map from the **Import Route Map** drop-down list. The IPv4 or IPv6 route map is imported to the user-defined virtual router.

b) To leak the user-defined virtual router routes to the global virtual router, select the route map from the **Export Route Map** drop-down list. The IPv4 or IPv6 route map is exported to the global virtual router.

Note
You must specify the route targets for export apart from specifying the route map.

Note
You can use the match clause of the route map object to filter the routes for leaking. For more information, see Route Map, on page 902.

Step 9 Follow the procedure (Step 3 to Step 8) to configure relevant BGP route import and export settings for other virtual routers as well.



Step 10 Click **Save** and **Deploy**.

When the packets flow into the ingress virtual router, BGP imports the routes from the destination virtual routers that have the matching route target value and if a route map is also configured, the routes are further filtered and used to identify the best path routes for routing the packets.

History for BGP

Feature	Minimum FMC	Minimum FTD	Details
BGP configuration to interconnect virtual routers	7.1	Any	You can configure BGP settings to dynamically leak routes among user-defined virtual routers, and between global virtual router and user-defined virtual routers. The import and export routes feature was introduced to exchange routes among the virtual routers by tagging them with route targets and optionally, filtering the matched routes with route maps. This BGP feature is accessible only when you select a user-defined virtual router. New/modified screens: For a selected user-defined virtual router, **Devices** > **Device Management** > **Routing** > **BGPv4/v6** > **Route Import/Export** tab.

Feature	Minimum FMC	Minimum FTD	Details
BGPv6 support for user-defined virtual routers	7.1	Any	Firepower Threat Defense now supports configuring BGPv6 on user-defined virtual routers. New/modified screens: For a selected user-defined virtual router, **Devices** > **Device Management** > **Routing** > **BGPv6** page.

CHAPTER 24

RIP

This chapter describes how to configure the FTD to route data, perform authentication, and redistribute routing information, using the Routing Information Protocol (RIP). For a device using virtual routing, you can configure RIP only for its global virtual router and not for its user-defined virtual router.

- About RIP, on page 799
- Requirements and Prerequisites for RIP, on page 801
- Guidelines for RIP, on page 801
- Configure RIP, on page 802

About RIP

The Routing Information Protocol, or RIP, as it is more commonly called, is one of the most enduring of all routing protocols. RIP has four basic components: routing update process, RIP routing metrics, routing stability, and routing timers. Devices that support RIP send routing-update messages at regular intervals and when the network topology changes. These RIP packets include information about the networks that the devices can reach, as well as the number of routers or gateways that a packet must travel through to reach the destination address. RIP generates more traffic than OSPF, but is easier to configure.

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcasts with neighboring devices to dynamically learn about and advertise routes.

The Firepower Threat Defense device supports both RIP Version 1 and RIP Version 2. RIP Version 1 does not send the subnet mask with the routing update. RIP Version 2 sends the subnet mask with the routing update and supports variable-length subnet masks. Additionally, RIP Version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the Firepower Threat Defense device receives reliable routing information from a trusted source.

RIP has advantages over static routes because the initial configuration is simple, and you do not need to update the configuration when the topology changes. The disadvantage to RIP is that there is more network and processing overhead than in static routing.

Routing Update Process

RIP sends routing-update messages at regular intervals and when the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP

routers maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates are sent independently of the regularly scheduled updates that RIP routers send.

RIP Routing Metric

RIP uses a single routing metric (hop count) to measure the distance between the source and a destination network. Each hop in a path from source to destination is assigned a hop count value, which is typically 1. When a router receives a routing update that contains a new or changed destination network entry, the router adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop.

RIP Stability Features

RIP prevents routing loops from continuing indefinitely by implementing a limit on the number of hops allowed in a path from the source to a destination. The maximum number of hops in a path is 15. If a router receives a routing update that contains a new or changed entry, and if increasing the metric value by 1 causes the metric to be infinity (that is, 16), the network destination is considered unreachable. The downside of this stability feature is that it limits the maximum diameter of a RIP network to less than 16 hops.

RIP includes a number of other stability features that are common to many routing protocols. These features are designed to provide stability despite potentially rapid changes in network topology. For example, RIP implements the split horizon and hold-down mechanisms to prevent incorrect routing information from being propagated.

RIP Timers

RIP uses numerous timers to regulate its performance. Following are the timer stages for RIP:

- Update—The routing-update timer is the interval between periodic routing updates. This is how often the device sends routing updates. Generally, it is set to 30 seconds, with a small random amount of time added whenever the timer is reset. This is done to help prevent congestion, which could result from all routers simultaneously attempting to update their neighbors.
- Invalid—Each routing table entry has a route-timeout timer associated with it. This is the number of seconds since the device received the last valid update. When the route-timeout timer expires, the route is marked invalid but is retained in the table until the route-flush timer expires. Once this timer expires, the route goes into holddown. The default is 180 seconds (3 minutes).
- Holddown—The holddown period is the number of seconds the system waits before accepting any new updates for the route that is in holddown (that is, routes that have been marked invalid). The default is 180 seconds (3 minutes).
- Flush—The route-flush timer is the number of seconds since the system received the last valid update until the route is discarded and removed from the routing table. The default is 240 seconds (4 minutes).

As an example, when the interface on an adjacent router goes down, the system no longer receives routing updates from the adjacent router. At this time, the Invalid and Flush timers start increasing. In the first 180 seconds, nothing will happen. After 180 seconds, the invalid timer expires, making the route invalid, and the Holddown timer starts and holds the route for another 60 seconds. If there is still no update regarding the interface status on the adjacent router (that is, it is still down), then the route enters into the Flush state where in total the system has waited for 240 seconds from the last update (180 seconds for the Invalid timer and 60

seconds for Holddown timer), and the system flushes the route. Even if the adjacent routers interface comes up immediately, the system does not accept a routing update until the Holddown timer completes the remaining 120 seconds.

Requirements and Prerequisites for RIP

Model Support

FTD

FTDv

Supported Domains

Any

User Roles

Admin

Network Admin

Guidelines for RIP

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines

The following information applies to RIP Version 2 only:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the Firepower Threat Defense device transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

Limitations

- The Firepower Threat Defense device cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.

- You can only enable a single RIP process on the Firepower Threat Defense device.

Configure RIP

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Select **Routing**.

Step 3 Select **RIP** from the table of contents.

Step 4 Check the **Enable RIP** check box to configure the RIP settings.

Step 5 Choose the RIP versions for sending and receiving RIP updates from the **RIP Version** drop-down list.

Step 6 (Optional) Check the **Generate Default Route** check box to generate a default route for distribution, based on the route map that you specify.

a) Specify a route map name to use for generating default routes, in the **Route Map** field.
The default route 0.0.0.0/0 is generated for distribution over a certain interface , when the route map, specified in the **Route Map** field, is present.

Step 7 When Send and Receive Version 2 is the chosen RIP Version, the **Enable Auto Summary** option is available. When the **Enable Auto Summary** check box is checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.

Note
RIP Version 1 always uses automatic summarization—you cannot disable it.

Step 8 Click **Networks**. Define one or more networks for RIP routing. Enter IP address(es), or enter or select the desired Network/Hosts objects. There is no limit to the number of networks you can add to the security appliance configuration. Any interface that belongs to a network defined by this command, will participate in the RIP routing process. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.

Note
RIP only supports IPv4 objects.

Step 9 (Optional) Click **Passive Interface**. Use this option to specify passive interfaces on the appliance, and by extension the active interfaces. The device listens for RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive, receive and send updates.

Step 10 Click **Redistribution** to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process.

a) Click **Add** to specify redistribution routes.

b) Choose the routing protocol to redistribute into the RIP routing process, in the **Protocol** drop-down list.

Note

For the OSPF protocol, specify a process ID. Similarly, specify an AS path for BGP. When you choose the Connected option in the **Protocol** drop-down list, you can redistribute, directly connected networks into the RIP routing process.

c) (Optional) If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute in the **Match** drop-down list . Ctrl-click to select multiple types:

- **Internal** – Routes internal to the autonomous system (AS) are redistributed.
- **External 1** – Type 1 routes external to the AS are redistributed.
- **External 2** – Type 2 routes external to the AS are redistributed.
- **NSSA External 1** – Type 1 routes external to a not-so-stubby area (NSSA) are redistributed.
- **NSSA External 2** – Type 2 routes external to an NSSA are redistributed

Note
The default is match Internal, External 1, and External 2

d) Select the RIP metric type to apply to the redistributed routes in the **Metric** drop-down list. The two choices are:

- **Transparent** – Use the current route metric
- **Specified Value** – Assign a specific metric value. Enter a specific value from 0-16, in the **Metric Value** field.
- **None** – No metric is specified. Do not use any metric value, to apply to redistributed routes.

Note
None option is applicable only for Static and Connected protocols.

e) (Optional) Enter the name of a route map that must be satisfied, in the **Route Map** field before the route can be redistributed into the RIP routing process. Routes are redistributed only if IP address matches an allow statement in the route map address list. To create a new route map object, click **Add** (+). See Route Map for the procedure to add a new route map.

f) Click **OK**.

Step 11 (Optional) Click **Filtering** to manage filters for the RIP policy. In this section, filters are used to prevent routing updates through an interface, control the advertising of routes in routing updates, control the processing of routing updates and filtering sources of routing updates.

a) Click **Add** to add RIP filters.

b) Select the type of traffic to be filtered - Inbound or Outbound in the **Traffic Direction** field.

Note
If traffic direction is inbound, you can only define an Interface filter.

c) Specify whether the filter is based on an Interface or a Route, by selecting appropriate in the **Filter On** field. If you click **Interface**, enter or choose the name of the interface on which routing updates are to be filtered. If you click **Route**, choose the route type:

- **Static** – Only static routes are filtered.
- **Connected** – Only connected routes are filtered.

- **OSPF** – Only OSPFv2 routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
- **BGP** – Only BGPv4 routes discovered by the specified BGP process are filtered. Enter the AS path of the BGP process to be filtered.

d) In the **Access List** field, enter or choose the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements. To add a new standard access list object, click **Add** (+) and see Configure Standard ACL Objects, on page 858.

e) Click **OK**.

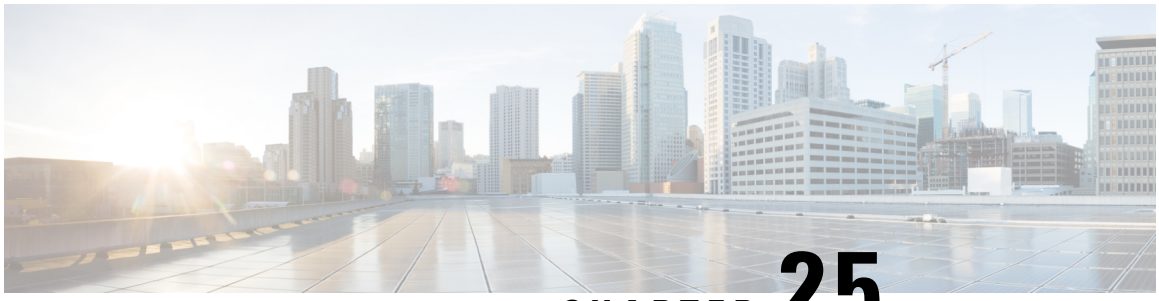
Step 12 (Optional) Click **Broadcast** to add or edit interface configurations. Using Broadcast, you can override the global RIP versions to send or receive per interface. You can also define the authentication parameters per interface if you want to implement authentication to ensure valid RIP updates.

a) Click **Add** to add interface configurations.

b) Enter or choose an interface defined on this appliance in the **Interface** field.

c) In the Send option, select the appropriate boxes to specify sending updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Send versions specified .

d) In the Receive option, select the appropriate boxes to specify accepting updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Receive versions specified .



e) Select the **Authentication** used on this interface for RIP broadcasts.

- **None** – No authentication
- **MD5** – Employ MD5
- **Clear Text** – Employ clear-text authentication

If you choose MD5 or Clear Text, you must also provide the following authentication parameters.

- **Key ID** – The ID of the authentication key. Valid values are from 0 to 255.
- **Key** – The key used by the chosen authentication method. Can contain up to 16 characters
- **Confirm** – Enter the authentication key again, to confirm

f) Click **OK**.

CHAPTER 25

Multicast

This chapter describes how to configure the Firepower Threat Defense device to use the multicast routing protocol.

- About Multicast Routing, on page 805
- Requirements and Prerequisites for Multicast Routing, on page 809
- Guidelines for Multicast Routing, on page 809
- Configure IGMP Features, on page 810
- Configure PIM Features, on page 815
- Configure Multicast Routes, on page 821
- Configure Multicast Boundary Filters, on page 822

About Multicast Routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications that take advantage of multicast routing include videoconferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

Multicast routing protocols deliver source traffic to multiple receivers without adding any additional burden on the source or the receivers while using the least network bandwidth of any competing technology. Multicast packets are replicated in the network by FTD device enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols, which results in the most efficient delivery of data to multiple receivers possible.

The FTD device supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single FTD device.

Note The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.

IGMP Protocol

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast

group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

Note When you enable multicast routing on the FTD device, IGMP Version 2 is automatically enabled on all interfaces.

Query Messages to Multicast Groups

The FTD device sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the FTD device. If the FTD device discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packets for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the FTD device does not receive a response to a host query within this amount of time, it deletes the group.

Stub Multicast Routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing. When configured for stub multicast routing, the FTD device acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the FTD device forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the FTD device cannot be configured for PIM sparse or bidirectional mode. You must enable PIM on the interfaces participating in IGMP stub multicast routing.

The FTD device supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees rooted at a single Rendezvous Point (RP) per multicast group and optionally creates shortest-path trees per multicast source.

PIM Multicast Routing

Bidirectional PIM is a variant of PIM-SM that builds bidirectional shared trees connecting multicast sources and receivers. Bidirectional trees are built using a Designated Forwarder (DF) election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point (RP), and therefore along the shared tree to receivers, without requiring source-specific state. The DF election takes place during RP discovery and provides a default route to the RP.

Note If the FTD device is the PIM RP, use the untranslated outside address of the FTD device as the RP address.

PIM Source Specific Multicast Support

The FTD device does not support PIM Source Specific Multicast (SSM) functionality and related configuration. However, the FTD device allows SSM-related packets to pass through unless it is placed as a last-hop router.

SSM is classified as a data delivery mechanism for one-to-many applications such as IPTV. The SSM model uses a concept of "channels" denoted by an (S,G) pair, where S is a source address and G is an SSM destination address. Subscribing to a channel is achieved by using a group management protocol such as IGMPv3. SSM enables a receiving client, once it has learned about a particular multicast source, to receive multicast streams directly from the source rather than receiving it from a shared Rendezvous Point (RP). Access control mechanisms are introduced within SSM providing a security enhancement not available with current sparse or sparse-dense mode implementations.

PIM-SSM differs from PIM-SM in that it does not use an RP or shared trees. Instead, information on source addresses for a multicast group is provided by the receivers through the local receivership protocol (IGMPv3) and is used to directly build source-specific trees.

Multicast Bidirectional PIM

Multicast bidirectional PIM is useful for networks that have many sources and receivers talking to each other simultaneously and where each participant can become both the source and receiver of multicast traffic, such as in videoconferencing, Webex meetings, and group chat. When PIM bidirectional mode is used, the RP only creates the (*,G) entry for the shared tree. There is no (S,G) entry. This conserves resources on the RP because state tables for each (S,G) entry are not maintained.

In PIM sparse mode, traffic only flows down the shared tree. In PIM bidirectional mode, traffic flows up and down the shared tree.

PIM bidirectional mode also does not use the PIM register/register-stop mechanism to register sources to the RP. Each source can begin sending to the source at any time. When the multicast packets arrive at the RP, they are forwarded down the shared tree (if there are receivers) or dropped (when there are no receivers). However, there is no way for the RP to tell the source to stop sending multicast traffic.

Design-wise you must think about where to place the RP in your network because it should be somewhere in the middle between the sources and receivers in the network.

PIM bidirectional mode has no Reverse Path Forwarding (RPF) check. Instead it uses the concept of a Designated Forwarder (DF) to prevent loops. This DF is the only router on the segment that is allowed to send multicast traffic to the RP. If there is only one router per segment that forwards multicast traffic, there will be no loops. The DF is chosen using the following mechanism:

- The router with the lowest metric to the RP is the DF.
- If the metric is equal, then the router with the highest IP address becomes the DF.

PIM Bootstrap Router (BSR)

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for RP function and for relaying the RP information for a group. The RP function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree through BSR messages that travel from PIM router to PIM router on a per-hop basis.

This feature provides a means of dynamically learning RPs, which is very essential in large complex networks where an RP can periodically go down and come up.

PIM Bootstrap Router (BSR) Terminology

The following terms are frequently referenced in the PIM BSR configuration:

- Bootstrap Router (BSR) — A BSR advertises Rendezvous Point (RP) information to other routers with PIM on a hop-by-hop basis. Among multiple Candidate-BSRs, a single BSR is chosen after an election process. The primary purpose of this Bootstrap router is to collect all Candidate-RP (C-RP) announcements in to a database called the RP-set and to periodically send this out to all other routers in the network as BSR messages (every 60 seconds).
- Bootstrap Router (BSR) messages — BSR messages are multicast to the All-PIM-Routers group with a TTL of 1. All PIM neighbors that receive these messages retransmit them (again with a TTL of 1) out of all interfaces except the one in which the messages were received. BSR messages contain the RP-set and the IP address of the currently active BSR. This is how C-RPs know where to unicast their C-RP messages.
- Candidate Bootstrap Router (C-BSR) — A device that is configured as a candidate-BSR participates in the BSR election mechanism. A C-BSR with highest priority is elected as the BSR. The highest IP address of the C-BSR is used as a tiebreaker. The BSR election process is preemptive, for example if a new C-BSR with a higher priority comes up, it triggers a new election process.
- Candidate Rendezvous Point (C-RP) — An RP acts as a meeting place for sources and receivers of multicast data. A device that is configured as a C-RP periodically advertises the multicast group mapping information directly to the elected BSR through unicast. These messages contain the Group-range, C-RP address, and a hold time. The IP address of the current BSR is learned from the periodic BSR messages that are received by all routers in the network. In this way, the BSR learns about possible RPs that are currently up and reachable.

Note The FTD device does not act as a C-RP, even though the C-RP is a mandatory requirement for BSR traffic. Only routers can act as a C-RP. So, for BSR testing functionality, you must add routers to the topology.

- BSR Election Mechanism — Each C-BSR originates Bootstrap messages (BSMs) that contain a BSR Priority field. Routers within the domain flood the BSMs throughout the domain. A C-BSR that hears about a higher-priority C-BSR than itself suppresses its sending of further BSMs for some period of time. The single remaining C-BSR becomes the elected BSR, and its BSMs inform all the other routers in the domain that it is the elected BSR.

Multicast Group Concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries—the hosts can be located anywhere on the Internet. Hosts that are interested in receiving data flowing to a particular group must join the group using IGMP. Hosts must be a member of the group to receive the data stream.

Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

Clustering

Multicast routing supports clustering. In Spanned EtherChannel clustering, the control unit sends all multicast routing packets and data packets until fast-path forwarding is established. After fast-path forwarding is established, data units may forward multicast data packets. All data flows are full flows. Stub forwarding flows are also supported. Because only one unit receives multicast packets in Spanned EtherChannel clustering, redirection to the control unit is common.

Requirements and Prerequisites for Multicast Routing

Model Support

FTD

FTDv

Supported Domains

User Roles

Admin

Network Admin

Guidelines for Multicast Routing

Firewall Mode

Supported only in routed firewall mode. Transparent firewall mode is not supported.

IPv6

Does not support IPv6.

Multicast Group

The range of addresses between 224.0.0.0 and 224.0.0.255 is reserved for the use of routing protocols and other topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Hence, Internet multicast routing from address range 224.0.0/24 is not supported; IGMP group is not created when enabling multicast routing for the reserved addresses.

Clustering

In clustering, for IGMP and PIM, this feature is only supported on the primary unit.

Additional Guidelines

- You must configure an access control or prefilter rule on the inbound security zone to allow traffic to the multicast host, such as 224.1.2.3. However, you cannot specify a destination security zone for the rule, or it cannot be applied to multicast connections during initial connection validation.
- You cannot disable an interface with PIM configured on it. If you have configured PIM on the interface (see Configure PIM Protocol, on page 815), disabling the multicast routing and PIM does not remove the PIM configuration. You must remove (delete) the PIM configuration to disable the interface.
- PIM/IGMP Multicast routing is not supported on interfaces in a traffic zone.
- Do not configure FTD to simultaneously be a Rendezvous Point (RP) and a First Hop Router.
- HSRP standby IP address does not participate in PIM neighborship. Thus, if the RP router IP is routed through a HSRP standby IP address, the multicast routing does not work in FTD. Hence for the multicast traffic to pass through successfully, ensure that the route for the RP address is not the HSRP standby IP address, instead, configure the route address to an interface IP address.
- For a device using virtual routing, you can configure multicast only for its global virtual router and not for its user-defined virtual router.

Configure IGMP Features

IP hosts use IGMP to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

This section describes how to configure optional IGMP settings on a per-interface basis.

Procedure

Step 1 Enable Multicast Routing, on page 811.

Step 2 Configure IGMP Protocol, on page 811.

Step 3 Configure IGMP Access Groups, on page 813.

Step 4 Configure IGMP Static Groups, on page 813.

Step 5 Configure IGMP Join Groups, on page 814.

Enable Multicast Routing

Enabling multicast routing on the FTD device, enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

Note Only the UDP transport layer is supported for multicast routing.

The following list shows the maximum number of entries for specific multicast tables. Once these limits are reached, any new entries are discarded.

- MFIB—30,000
- IGMP Groups—30,000
- PIM Routes—72,000

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 Check the **Enable Multicast Routing** check box.

Checking this check box enables IP multicast routing on the device. Unchecking this check box disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces.

You can disable multicast on a per-interface basis. This is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the FTD device from sending host query messages on that interface.

Configure IGMP Protocol

You can configure IGMP parameters per interface, such as the forward interface, query messages, and time intervals.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Protocol**, click **Add** or **Edit**.

Use the **Add IGMP parameters** dialog box to add new IGMP parameters to the FTD device. Use the **Edit IGMP parameters** dialog box to change existing parameters.

Step 4 Configure the following options:

- **Interface**—From the drop-down list, choose the interface for which you want to configure IGMP protocol.
- **Enable IGMP**—Check the check box to enable IGMP.

  Note
  Disabling IGMP on specific interfaces is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the device from sending host query messages on that interface.

- **Forward Interface**—From the drop-down list, choose the specific interface from which you want to forward IGMP messages.

  This configures the Firepower Threat Defense device to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface.

- **Version**—Choose IGMP Version 1 or 2.

  By default, the FTD device runs IGMP Version 2, which enables several additional features.

  Note
  All multicast routers on a subnet must support the same version of IGMP. The FTD device does not automatically detect Version 1 routers and switch to Version 1. However, you can have a mix of IGMP Version 1 and 2 hosts on the subnet; the FTD device running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

- **Query Interval**—The interval in seconds at which the designated router sends IGMP host-query messages. The range is 1 to 3600. The default is 125.

  Note
  If the FTD device does not hear a query message on an interface for the specified timeout value, then the device becomes the designated router and starts sending the query messages.

- **Response Time**—The interval in seconds before the FTD device deletes the group. The range is 1 to 25. The default is 10.

  If the FTD device does not receive a response to a host query within this amount of time, it deletes the group.

- **Group Limit**—The maximum number of hosts that can join on an interface. The range is 1 to 500. The default is 500.

  You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports exceeding the configured limits are not entered in the IGMP cache, and traffic for the excess membership reports is not forwarded

- **Query Timeout**—The period of time in seconds before which the FTD device takes over as the requester for the interface after the previous requester has stopped. The range is 60 to 300. The default is 255.

Step 5 Click **OK** to save the IGMP protocol configuration.

Configure IGMP Access Groups

You can control access to multicast groups by using access control lists.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **Access Group**.

Step 3 On **Access Group**, click **Add** or **Edit**.

Use the **Add IGMP Access Group parameters** dialog box to add new IGMP access groups to the Access Group table. Use the **Edit IGMP Access Group parameters** dialog box to change existing parameters.

Step 4 Configure the following options:

a) From the **Interface** drop-down list, choose the interface with which the access group is associated. You cannot change the associated interface when you are editing an existing access group.

b) Click one of the following:

- **Standard Access List**— From the **Standard Access List** drop-down list, choose the standard ACL or click **Add** (+) to create a new standard ACL. See Configure Standard ACL Objects, on page 858 for the procedure.
- **Extended Access List**—From the **Extended Access List** drop-down list, choose the extended ACL or click **Add** (+) to create a new extended ACL. See Configure Extended ACL Objects, on page 856 for the procedure.

Step 5 Click **OK** to save the access group configuration.

Configure IGMP Static Groups

Sometimes a group member cannot report its membership in the group or there may be no members of a group on the network segment, but you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group. With this method, the FTD device does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Static Group**, click **Add** or **Edit**.

Use the **Add IGMP Static Group parameters** dialog box to statically assign a multicast group to an interface. Use the **Edit IGMP Static Group parameters** dialog box to change existing static group assignments.

Note
The IGMP Static Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to statically assign a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Multicast Groups** drop-down list, choose the multicast group to which you want to assign the interface, or click **Add** (+) to create a new multicast group. See Creating Network Objects for the procedure.

Step 5 Click **OK** to save the static group configuration.

Configure IGMP Join Groups

You can configure an interface to be a member of a multicast group. Configuring the FTD device to join a multicast group causes upstream routers to maintain multicast routing table information for that group and keep the paths for that group active.

Note See Configure IGMP Static Groups, on page 813 if you want to forward multicast packets for a specific group to an interface without the FTD device accepting those packets as part of the group.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **IGMP**.

Step 3 On **Join Group**, click **Add** or **Edit**.

Use the **Add IGMP Join Group parameters** dialog box to configure the FTD device to be a member of a multicast group. Use the **Edit IGMP Join Group parameters** dialog box to change existing parameters.

Note
The IGMP Join Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface you want to be a member of a multicast group. If you are editing an existing entry, you cannot change the value.

- From the **Join Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Plus** to create a new multicast group. See Creating Network Objects for the procedure.

Configure PIM Features

Routers use PIM to maintain forwarding tables to use for forwarding multicast diagrams. When you enable multicast routing on the Firepower Threat Defense device, PIM and IGMP are automatically enabled on all interfaces.

Note PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

This section describes how to configure optional PIM settings.

Procedure

Step 1 Configure PIM Protocol, on page 815.
Step 2 Configure PIM Neighbor Filters, on page 816.
Step 3 Configure PIM Bidirectional Neighbor Filters, on page 817.
Step 4 Configure PIM Rendezvous Points, on page 818.
Step 5 Configure PIM Route Trees, on page 819.
Step 6 Configure PIM Request Filters, on page 819.
Step 7 Configure Multicast Boundary Filters, on page 822.

Configure PIM Protocol

You can enable or disable PIM on a specific interface.

You can also configure the Designated Router (DR) priority. The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, choosing the DR is based on the DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR. By default, the FTD device has a DR priority of 1.

Router query messages are used to choose the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the FTD device sends PIM join or prune messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Protocol**, click **Add** or **Edit**.

Use the **Add PIM parameters** dialog box to add new PIM parameters to the interface. Use the **Edit PIM parameters** dialog box to change existing parameters.

Step 4 Configure the following options:

- **Interface**—From the drop-down list, select the interface for which you want to configure PIM protocol.
- **Enable PIM**—Check the check box to enable PIM.
- **DR Priority**—The value for the DR for the selected interface. The router with the highest DR priority on the subnet becomes the designated router. Valid values range from 0 to 4294967294. The default DR priority is 1. Setting this value to 0 makes the FTD device interface ineligible to become the designated router.
- **Hello Interval**—The interval in seconds at which the interface sends PIM hello messages. The range is 1 to 3600. The default is 30.
- **Join Prune Interval**—The interval in seconds at which the interface sends PIM join and prune advertisements. The range is 10 to 600. The default is 60.

Step 5 Click **OK** to save the PIM protocol configuration.

Configure PIM Neighbor Filters

You can define the routers that can become PIM neighbors. By filtering the routers that can become PIM neighbors, you can do the following:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Neighbor Filter** dialog box to add new PIM neighbor filters to the interface. Use the **Edit PIM Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to add a PIM neighbor filter.
- **Standard Access List**— From the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. See Configure Standard ACL Objects, on page 858 for the procedure.

  Note
  Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the multicast group advertisements pass through the interface. Choosing **Block** prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

Step 5 Click **OK** to save the PIM neighbor filter configuration.

Configure PIM Bidirectional Neighbor Filters

A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the Designated Forwarder (DF) election. If a PIM bidirectional neighbor filter is not configured for an interface, there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in the DF election process.

Bidirectional PIM allows multicast routers to keep reduced state information. All of the multicast routers in a segment must be bidirectionally enabled to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers that are permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

- If a permitted neighbor does not support bidirectional mode, then the DF election does not occur.
- If a denied neighbor supports bidirectional mode, then the DF election does not occur.
- If a denied neighbor does not support bidirectional mode, the DF election can occur.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Multicast Routing** > **PIM**.

Step 3 On **Bidirectional Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Bidirectional Neighbor Filter** dialog box to create ACL entries for the PIM bidirectional neighbor filter ACL. Use the **Edit PIM Bidirectional Neighbor Filter** dialog box to change existing parameters.

Step 4 Configure the following options:

- From the **Interface** drop-down list, select the interface to which you want to configure the PIM bidirectional neighbor filter ACL entry.

- **Standard Access List**— From the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. See Configure Standard ACL Objects, on page 858 for the procedure.

  Note
  Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the specified devices participate in the DR election process. Choosing **Block** prevents the specified devices from participating in the DR election process.

Step 5 Click **OK** to save the PIM bidirectional neighbor filter configuration.

Configure PIM Rendezvous Points

You can configure the FTD device to serve as a RP to more than one group. The group range specified in the ACL determines the PIM RP group mapping. If an ACL is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4). See Multicast Bidirectional PIM, on page 807 for more information about bidirectional PIM.

The following restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify All Groups for more than one RP.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Rendezvous Points**, click **Add** or **Edit**.

Use the **Add Rendezvous Point** dialog box to create a new entry to the Rendezvous Point table. Use the **Edit Rendezvous Point** dialog box to change existing parameters.

Step 4 Configure the following options:

- From the **Rendezvous Point IP address** drop-down list, choose the IP address that you want to add as an RP or click **Add** (+) to create a new network object. See Creating Network Objects for the procedure.
- Check the **Use bi-directional forwarding** check box if the specified multicast groups are to operate in bidirectional mode. In bidirectional mode, if the FTD device receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.
- Click **Use this RP for all Multicast Groups** to use the specified RP for all multicast groups on the interface.
- Click the **Use this RP for all Multicast Groups as specified below** to designate the multicast groups to use with the specified RP and then from the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. See Configure Standard ACL Objects, on page 858 for the procedure.

Step 5 Click **OK** to save the rendezvous point configuration.

Configure PIM Route Trees

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the FTD device should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

The shortest-path tree is used for any group that is not specified in the Multicast Groups table. The Multicast Groups table displays the multicast groups to use with the shared tree. The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.

Note This behavior is known as Shortest Path Switchover (SPT). We recommend that you always use the Shared Tree option.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Route Tree**, select the path for the route tree:

- Click **Shortest Path** to use the shortest-path tree for all multicast groups.
- Click **Shared Tree** to use the shared tree for all multicast groups.
- Click **Shared tree for below mentioned group** to designate the groups specified in the Multicast Groups table, and then from the **Standard Access List** drop-down list, select a standard ACL or click **Add** (+) to create a new standard ACL. See Configure Standard ACL Objects, on page 858 for the procedure.

Step 4 Click **OK** to save the route tree configuration.

Configure PIM Request Filters

When the FTD device is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. You can define the multicast sources from which the FTD device will accept PIM register messages.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Request Filter**, define the multicast sources that are allowed to register with the FTD device when it acts as an RP:

- From the **Filter PIM register messages using:** drop-down list select **None**, **Access List**, or **Route Map**.
- If you choose **Access List** from the drop-down list, select an extended ACL or click **Add** (+) to create a new extended ACL. See Configure Extended ACL Objects, on page 856 for the procedure.

  Note
  In the **Add Extended Access List Entry** dialog box, select **Allow** from the drop-down list o create a rule that allows the specified source of the specified multicast traffic to register with the FTD device, or select **Block** to create a rule that prevents the specified source of the specified multicast traffic from registering with the device.

- If you choose **Route Map**, select a route map from the **Route Map** drop-down list, or click **Add** (+) to create a new route map. See Creating Network Objects for the procedure.

Step 4 Click **OK** to save the request filter configuration.

Configure the Firepower Threat Defense Device as a Candidate Bootstrap Router

You can configure the FTD device as a candidate BSR.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **PIM**.

Step 3 On **Bootstrap Router**, check the **Configure this FTD as a Candidate Bootstrap Router (C-BSR)** check box to perform the C-BSR setup.

a) From the **Interface** drop-down list, select the interface on the FTD device from which the BSR address is derived to make it a candidate.

This interface must be enabled with PIM.

b) In the **Hash mask length** field, enter the length of a mask (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This fact allows you to get one RP for multiple groups. The range is 0 to 32.

c) In the **Priority** field, enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR. The range is 0 to 255. The default value is 0.

Step 4 (Optional) Click **Add** (+) to select an interface on which no PIM BSR messages will be sent or received in the **Configure this FTD as a Border Bootstrap Router (BSR)** section.

- From the **Interface** drop-down list, select the interface on which no PIM BSR messages will be sent or received.

  RP or BSR advertisements are filtered effectively isolating two domains of RP information exchange.

- Check the **Enable Border BSR** check box to enable BSR.

Step 5 Click **OK** to save the bootstrap router configuration.

Configure Multicast Routes

Configuring static multicast routes lets you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the FTD device expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Routes** > **Add or Edit**.

Use the **Add Multicast Route Configuration** dialog box to add a new multicast route to the FTD device. Use the **Edit Multicast Route Configuration** dialog box to change an existing multicast route.

Step 3 From the **Source Network** drop-down box, choose an existing network or click **Add** (+) to add a new one. See Creating Network Objects for the procedure.

Step 4 To configure an interface to forward the route, click **Interface** and configure the following options:

- From the **Source Interface** drop-down list, choose the incoming interface for the multicast route.
- From the **Output Interface/Dense** drop-down list, choose the destination interface that the route is forwarded through.
- In the **Distance** field, enter the distance of the multicast route. The range is 0 to 255.

Step 5 To configure an RPF address to forward the route, click **Address** and configure the following options:

- In the **RPF Address** field, enter the IP address for the multicast route.

- In the **Distance** field, enter the distance of the multicast route The range is 0 to 255.

Step 6 Click **OK** to save the multicast routes configuration.

Configure Multicast Boundary Filters

Address scoping defines domain boundary filters so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary filter on an interface for multicast group addresses. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

A standard ACL defines the range of affected addresses. When a boundary filter is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary filter allows the same multicast group address to be reused in different administrative domains.

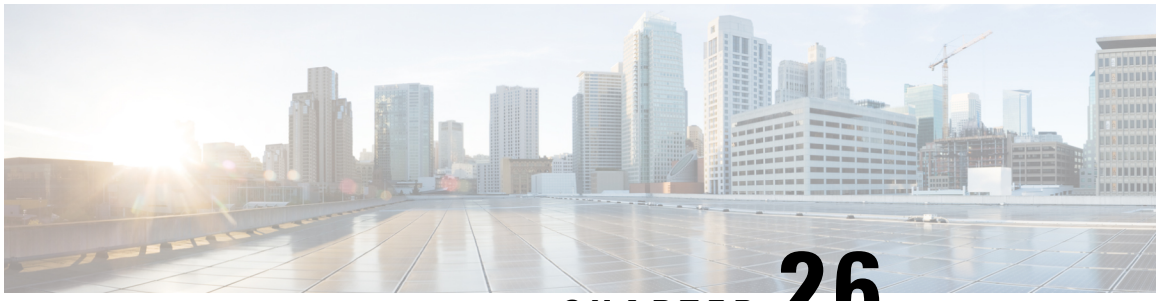
You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary filter only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Choose **Routing** > **Multicast Routing** > **Multicast Boundary Filter**, and then click **Add** or **Edit**.

Use the **Add Multicast Boundary Filter** dialog box to add new multicast boundary filters to the device. Use the **Edit Multicast Boundary Filter** dialog box to change existing parameters.



You can configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.

Step 3 From the **Interface** drop-down list, choose the interface for which you are configuring the multicast boundary filter ACL.

Step 4 From the **Standard Access List** drop-down list, choose the standard ACL you want to use, or click **Add** (+) to create a new standard ACL. See Configure Standard ACL Objects, on page 858 for the procedure.

Step 5 Check the **Remove any Auto-RP group range announcement from the Auto-RP packets that are denied by the boundary** check box to filter Auto-RP messages from sources denied by the boundary ACL. If this check box is not checked, all Auto-RP messages are passed.

Step 6 Click **OK** to save the multicast boundary filter configuration.

CHAPTER 26

Policy Based Routing

This chapter describes how to configure FTD to support policy based routing (PBR) through FMC's Policy based Routing page. The following sections describe policy based routing, guidelines for PBR, and configuration for PBR.

- About Policy Based Routing, on page 825
- Guidelines and Limitations for Policy Based Routing, on page 827
- Configure Policy-Based Routing Policy, on page 828
- Configuration Example for Policy Based Routing, on page 830
- History for Policy Based Routing, on page 835

About Policy Based Routing

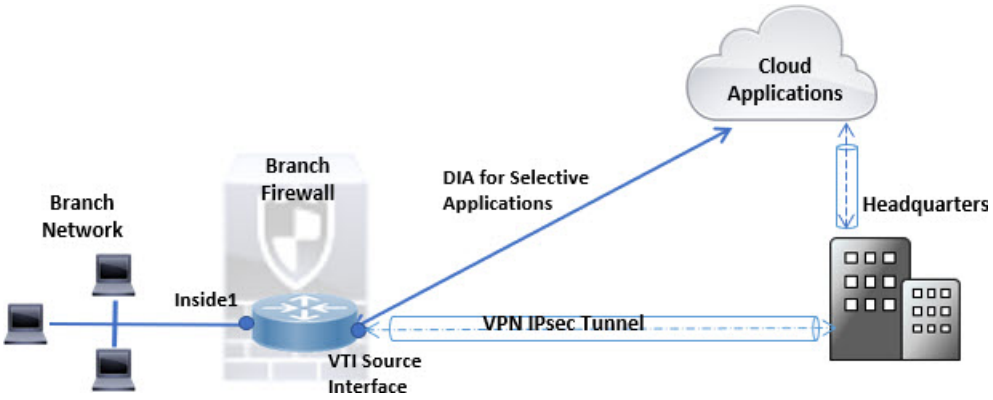
In traditional routing, packets are routed based on the destination IP address. However, it is difficult to change the routing of specific traffic in a destination-based routing system. Policy Based Routing (PBR) gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols.

PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link. With PBR, you can define routing that is based on criteria other than destination network such as source port, destination address, destination port, protocol, applications, or a combination of these objects.

You can use PBR to classify the network traffic based on applications. This routing method is applicable in scenarios where, numerous devices access applications and data in a large network deployment. Traditionally, large deployments have topologies that backhaul all the network traffic to a hub as encrypted traffic in a route-based VPN. These topologies often result in issues such as packet latency, reduced bandwidth, and packet drop. Overcoming these issues involves high-cost complex deployments and management.

PBR policy enables you to securely breakout traffic for specified applications. You can configure PBR policy in the Firepower Management Center user interface to allow the applications to be directly accessed.

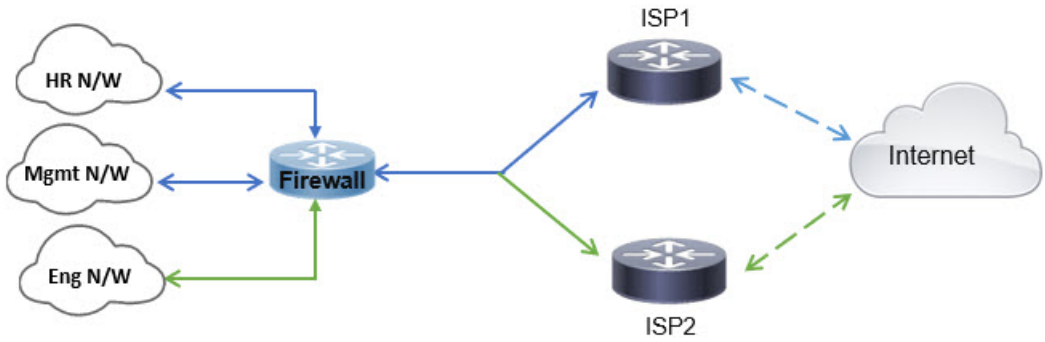
Why Use Policy Based Routing



Consider a company that has two links between locations: one a high-bandwidth, low-delay expensive link, and the other a low-bandwidth, higher-delay, less-expensive link. While using traditional routing protocols, the higher-bandwidth link gets most, if not all, of the traffic sent across it based on the metric savings obtained by the bandwidth, delay, or both (using EIGRP or OSPF) characteristics of the link. With PBR, you can route

higher priority traffic over the high-bandwidth/low-delay link, while sending all other traffic over the low-bandwidth/high-delay link.

Following are a few scenarios where you can use Policy Based Routing:



Direct Internet Access

In this topology, application traffic from the branch office can be routed directly to the internet instead of through the VPN tunnel connecting to the headquarters. The branch FTD is configured with an internet exit point and the PBR policy is applied on the ingress interface (*Inside 1*) to identify the traffic based on the applications defined in the ACL. Correspondingly, the traffic is forwarded through the egress interfaces directly to the internet or to the IPsec VPN tunnel.

Equal-Access and Source-Sensitive Routing

In this topology, traffic from the HR and Mgmt networks can be configured to go through ISP1 and traffic from Eng network can be configured to go through ISP2. Thus, policy based routing enables the network administrators to provide equal-access and source-sensitive routing, as shown here.

Load Sharing

In addition to the dynamic load-sharing capabilities offered by ECMP load balancing, network administrators can now implement policies to distribute traffic among multiple paths based on the traffic characteristics.

As an example, in the topology depicted in the Equal-Access Source Sensitive Routing scenario, an administrator can configure policy based routing to route the traffic from HR network through ISP1 and traffic from Eng network through ISP2 and thus share the load.

Guidelines and Limitations for Policy Based Routing

Firewall Mode Guidelines

PBR is supported only on routed firewall mode.

Device Guidelines

- PBR through FMC's Policy Based Routing page is supported only from Version 7.1+ on both the FMC and the device.
- When you upgrade FMC or Firepower Threat Defense to version 7.1 and higher, the PBR configuration in the device is removed. You must configure PBR again using the Policy Based Routing page. If the managed device is lower than version 7.1, you must configure PBR again using FlexConfig with deploy option set to "every time."
- Configuring application based PBR policy on cluster devices is not supported.

Interface Guidelines

- Only routed interfaces and non management-only interfaces belonging to the Global virtual router can be configured as ingress or egress interface.
- PBR is not supported on user-defined virtual routers.
- Only interfaces that have a logical name can be defined in the policy.
- Static VTIs can be configured only as egress interfaces.
- Before proceeding with configuration, ensure that the ingress and egress traffic of each session flows through the same ISP-facing interface to avoid unexpected behavior caused by asymmetric routing, specifically when NAT and VPN are in use.

IPv6 Support

PBR supports IPv6.

Application-Based PBR and DNS Configuration

- Application-based PBR uses DNS snooping for application detection. Application detection succeeds only if the DNS requests pass through FTD in a clear-text format; the DNS traffic is not encrypted.
- You must configure trusted DNS servers.

For more information on configuring DNS servers, see DNS, on page 481.

PBR Policies Not Applied for Output Route Look-up

Policy Based Routing is an ingress-only feature; that is, it is applied only to the first packet of a new incoming connection, at which time the egress interface for the forward leg of the connection is selected. Note that PBR will not be triggered if the incoming packet belongs to an existing connection, or if NAT is applied and NAT chooses the egress interface.

PBR Policies Not Applied for Embryonic Traffic

Note An embryonic connection is where the necessary handshake between source and destination has not been made.

When a new internal interface is added and a new VPN policy is created using a unique address pool, PBR is applied to the outside interface matching the source of the new client pool. Thus, PBR sends traffic from the client to the next hop on the new interface. However, PBR is not involved in the return traffic from a host that has not yet established a connection with the new internal interface routes to the client. Thus, the return traffic from the host to the VPN client, specifically, the VPN client response is dropped as there is no valid route. You must configure a weighted static route with a higher metric on the internal interface.

Additional Guidelines

- All existing configuration restrictions and limitations of route map will be carried forward.
- While defining the ACL for the policy match criteria, you can select multiple applications from a list of predefined applications to form an Access Control Entry (ACE). In FTD, the predefined applications are stored as Network Service objects and the group of applications as Network Service Groups (NSG). The application or network service group is detected through first-packet classification. Currently, you cannot add to or modify the predefined applications list.
- Unicast Reverse Path Forwarding (uRPF) validates the source IP address of packets received on an interface against the routing table and not against the PBR route map. When uRPF is enabled, packets received on an interface through PBR are dropped as they are without the specific route entry. Hence, when using PBR, ensure to disable uRPF.

Configure Policy-Based Routing Policy

You can configure the PBR policy on the Policy Based Routing page by specifying the ingress interfaces, match criteria (Extended Access Control List), and egress interfaces.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the FTD device.

Step 2 Click **Routing**.

Step 3 Click **Policy Based Routing**.

The Policy Based Routing page displays the configured policy. The grid displays the list of ingress interfaces and a combination of the policy-based route access list, and egress interfaces.

Step 4 To configure the policy, click **Add**.

Step 5 In the **Add Policy Based Route** dialog box, select the **Ingress Interface** from the drop-down list.

Note
Only interfaces that have logical names and that belong to a global virtual router are listed in the drop-down. However, you cannot configure a VLAN interface with a logical name as the source (ingress) interface.

Step 6 To specify the match criteria and the forward action in the policy, click **Add**.

Step 7 In the **Add Forwarding Actions** dialog box, do the following:

a) From the **Match ACL** drop-down, choose the extended access control list object. You can predefine the ACL object (see Configure Extended ACL Objects, on page 856) or click the **Add** (+) icon to create the object. In the **New Extended Access List Object** box, enter a name, click **Add** to open the **Add Extended Access List Entry** dialog box, where you can define the network, port, or application match criteria for the PBR policy.

Note
You cannot have both application and destination address defined in an ACE.

To selectively apply PBR on the incoming interface, you can define *Block* criteria in the ACE. When the traffic matches the block rule of the ACE, the traffic is forwarded to the egress interface based on the routing table.

b) From the **Send To** drop-down list:

- To select the configured interfaces, choose **Egress Interfaces**.
- To specify the IPv4/IPv6 next hop addresses, choose **IP Address**. Proceed to Step 7.e, on page 829

c) If you have selected **Egress Interfaces**, from the **Interface Ordering** drop-down, choose the relevant option:

- By **Interface Priority**—The traffic is forwarded based on the priority of the interfaces. Traffic is routed to the interface with the least priority value first. When the interface is not available, the traffic is then forwarded to the interface with the next lowest priority value. For example, let us assume that *Gig0/1*, *Gig0/2*, and *Gig0/3* are configured with priority values *0*,*1*, and *2* respectively. The traffic is forwarded to *Gig0/1*. If *Gig0/1* becomes unavailable, the traffic is then forwarded to *Gig0/2*.

  Note
  To configure the priority for the interfaces, click **Configure Interface Priority** on the Policy Based Routing page. In the dialog box, provide the priority number against the interfaces, and then click **Save**. You can also configure the priority for an interface in the Configure Routed Mode Interfaces.

  When the priority value is the same for all the interfaces, the traffic is balanced among the interfaces.

- By **Order**—The traffic is forwarded based on the sequence of the interfaces specified here. For example, let us assume that *Gig0/1*, *Gig0/2*, and *Gig0/3* are selected in the following order, *Gig0/2*, *Gig0/3*, *Gig0/1*. The traffic is forwarded to *Gig0/2* first, then to *Gig0/3*, irrespective of their priority values.

d) In the **Available Interfaces** box, all the interfaces with their priority values are listed. From the list of interfaces, click the **Add** (+) button to add to the selected egress interfaces. Proceed to Step 7.f, on page 829

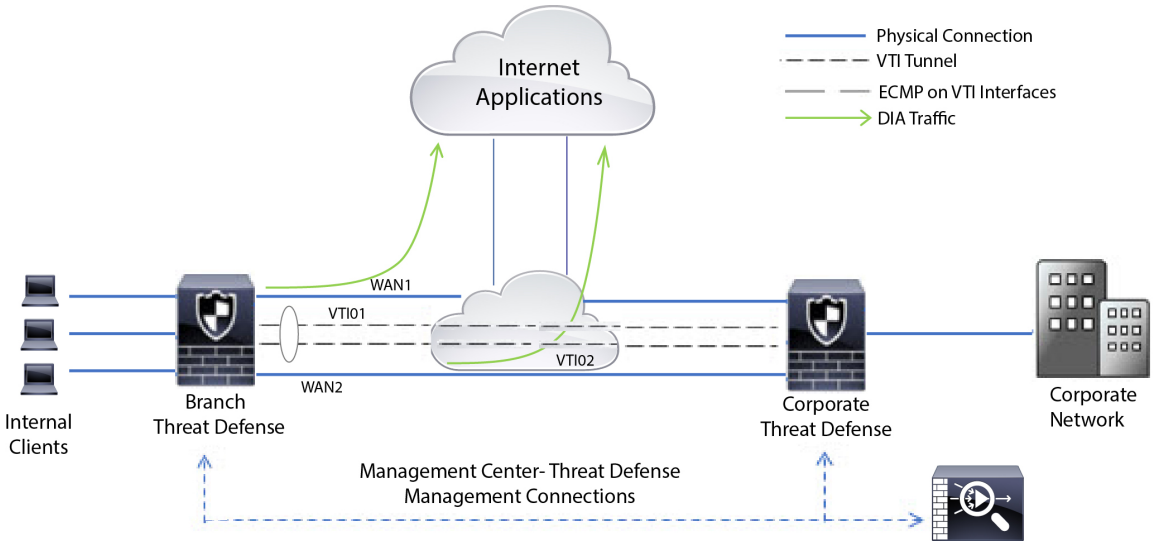
Note
The route to the selected interface must be present in the routing table.

e) If you have selected **IP Address**, enter the IP addresses separated by commas in the **IPv4 Addresses** or **IPv6 Addresses** fields. The traffic is forwarded as per the sequence of the specified IP addresses.

f) Click **Save**.

Step 8 To save the policy, click **Save** and **Deploy**.

The FTD uses ACLs to match traffic and perform routing actions on the traffic. Typically, you configure a route map that specifies an ACL against which traffic is matched, and then you specify one or more actions for that traffic. Finally, you associate the route map with an interface on which you want to apply PBR on all incoming traffic.



Configuration Example for Policy Based Routing

Consider a typical corporate network scenario where all the branch network traffic passes through a route-based VPN of the corporate network and diverges to the extranet, when required. Accessing the web-based applications that address day-to-day operations through the corporate network results in huge network expansion and maintenance costs. This example illustrates the PBR configuration procedure for direct internet access.

The following figure depicts the topology of a corporate network. The branch network is connected to the corporate network through a route-based VPN. Traditionally, the corporate FTD is configured to handle both the internal and external traffic of the branch office. With the PBR policy, the branch FTD is configured with a policy that routes specific traffic to the WAN network instead of the virtual tunnels. The rest of the traffic flows through the route-based VPN, as usual.

This example also illustrates the configuring of the WAN and the VTI interfaces with ECMP zones to achieve load balancing.

Figure 178: Configuring Policy Based Routing on Branch FTD in FMC

Before you begin

This example assumes that you have already configured WAN and VTI interfaces for the branch FTD in FMC.

Procedure

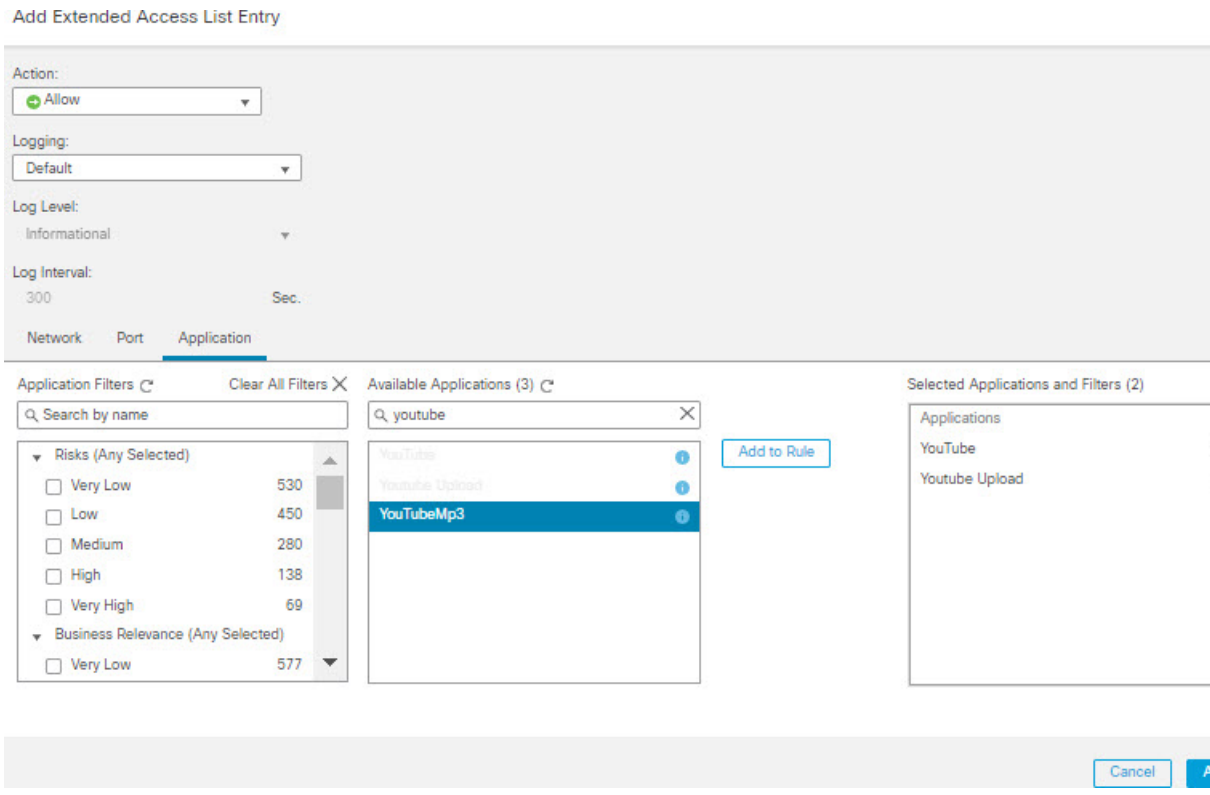
Step 1 Configure policy based routing for the branch FTD, select the ingress interfaces:

a) Choose **Devices** > **Device Management**, and edit the FTD device.

b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.

c) In the **Add Policy Based Route** dialog box, select the interfaces (say, *Inside 1*, and *Inside 2*) from the **Ingress Interface** drop-down list.

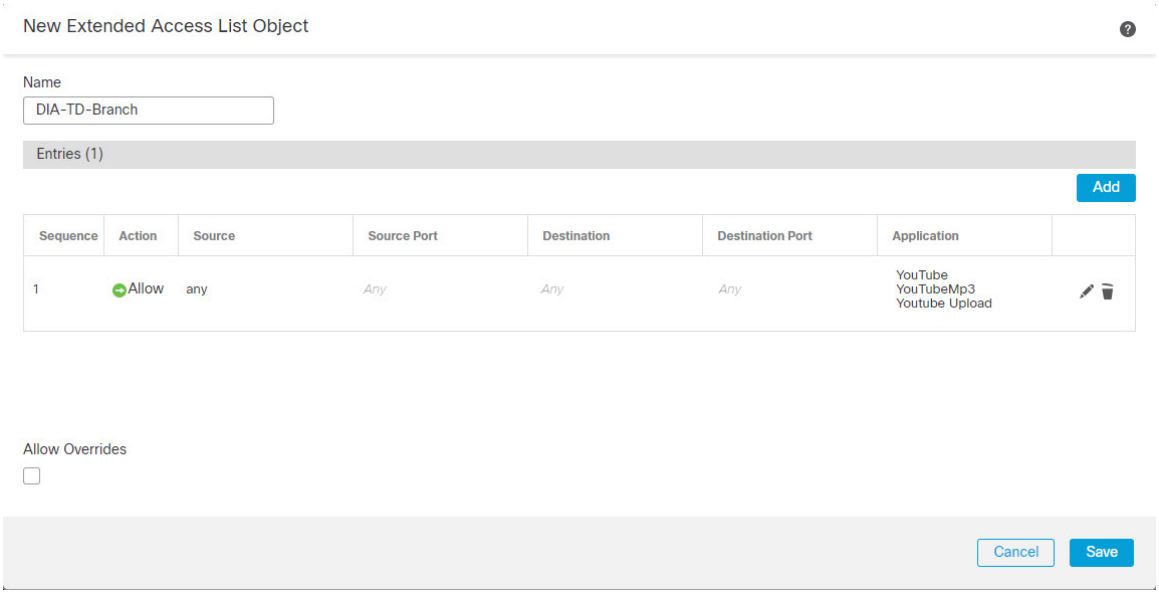
Step 2 Specify the match criteria:



a) Click **Add**.

b) To define the match criteria, click the **Add** (+) button.

c) In **New Extended Access List Object**, enter the name for the ACL (say, *DIA-FTD-Branch*), and click **Add**.



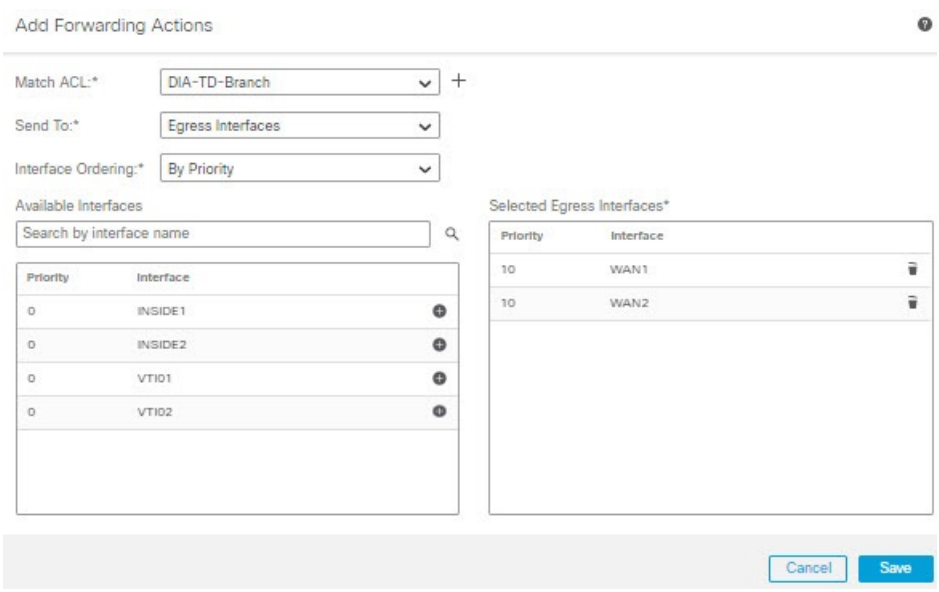
d) In the **Add Extended Access List Entry** dialog box, choose the required web-based applications from the **Application** tab:

Figure 179: Applications Tab

On the FTD, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

Figure 180: Extended ACL

e) Click **Save**.



f) Select *DIA-FTD-Branch* from the **Match ACL** drop-down list.

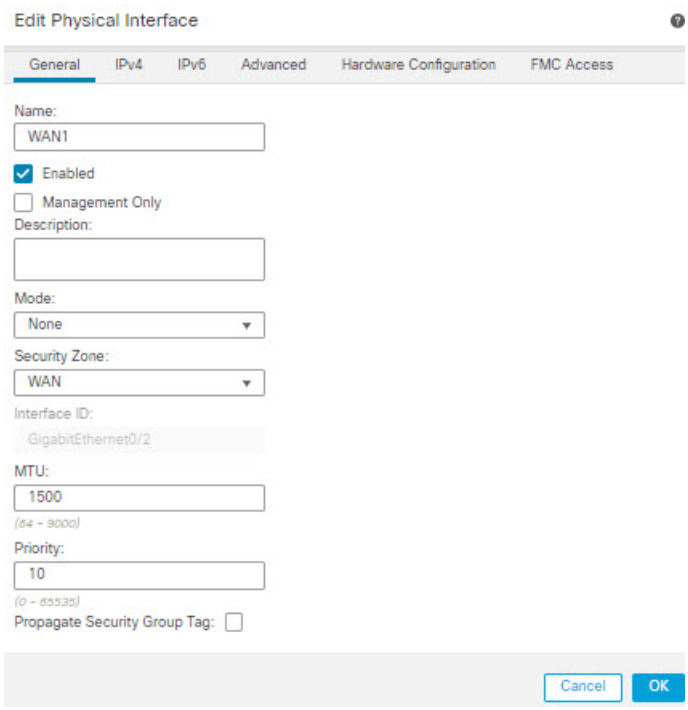
Step 3 Specify the egress interfaces:

a) From the **Send To** and **Interface Ordering** drop-down lists, choose Egress Interfaces, and Interface Priority respectively.

b) Under **Available Interfaces**, click the ⊕ button against the respective interface names to add *WAN1* and *WAN2*:

Figure 181: Configuring Policy Based Routing

c) Click **Save**.



Step 4 Interface priority configuration:

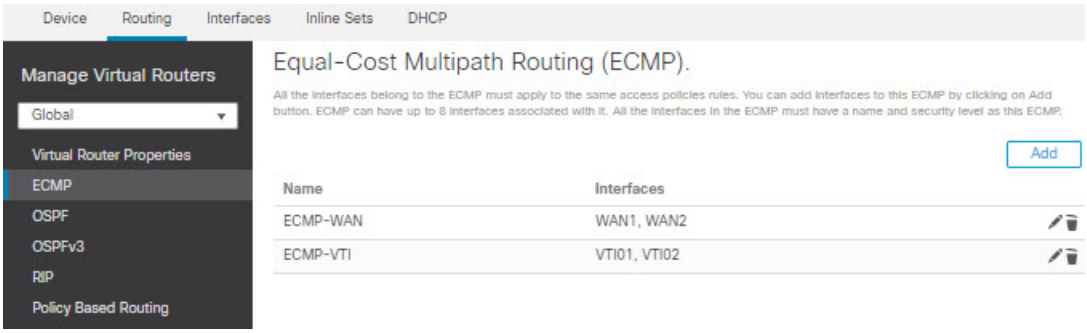
You can set the priority value for the interfaces either in the **Edit Physical Interface** page, or in the **Policy Based Routing** page (**Configure Interface Priority**). In this example, the Edit Physical Interface method is described.

a) Choose **Devices** > **Device Management**, and edit the branch FTD.

b) Set the priority for the interfaces. Click **Edit** against the interface and enter the priority value:

Figure 182: Setting Interface Priority

c) Click **Ok** and **Save**.



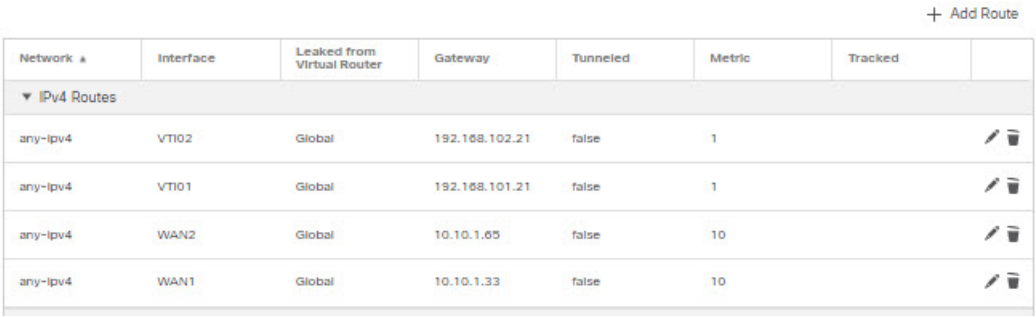
Step 5 Create ECMP zones for load balancing:

a) In the **Routing** page, click **ECMP**.

b) To associate interfaces to the ECMP zone, click **Add**.

c) Select *WAN1* and *WAN 2* and create an ECMP zone—*ECMP-WAN*. Similarly, add *VTI01* and *VTI02* and create an ECMP zone—*ECMP-VTI*:

Figure 183: Associating Interfaces with ECMP Zone



Step 6 Configure static routes for the zone interfaces for load balancing:

a) In the **Routing** page, click **Static Route**.

b) Click **Add** and specify the static routes for *WAN1*, *WAN2*, *VTI01*, and *VTI02*. Ensure that you specify the same metric value for the interfaces belonging to the same ECMP zones (Step 5):

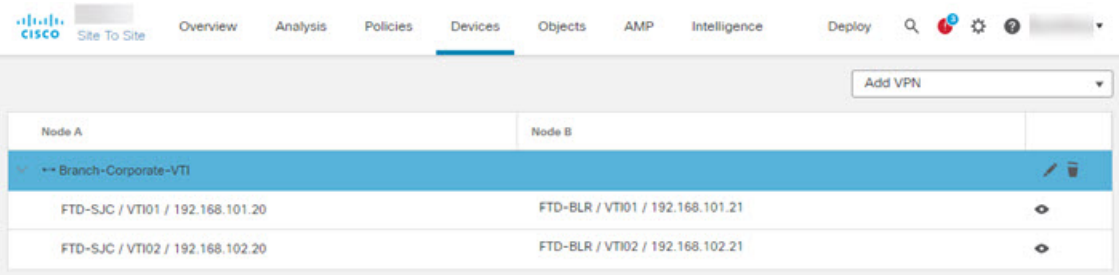
Figure 184: Configuring Static Routes for ECMP Zone Interfaces

Note
Ensure that the zone interfaces have the same destination address and metric, but different gateway addresses.

Step 7 Configure trusted DNS on the WAN objects of the branch FTD to ensure secured flow of traffic to the internet:

a) Choose **Devices** > **Platform Settings**, and create a DNS policy on the branch FTD.

b) To specify the trusted DNS, **Edit** the policy and click **DNS**.



c) To specify the DNS servers for the DNS resolution to be used by WAN objects, in the **DNS Settings** tab, provide the DNS server group details and select WAN from the interface objects.

d) Use the **Trusted DNS Servers** tab to provide specific DNS servers that you trust for the DNS resolution.

Step 8 **Save** and **Deploy**.

Any *YouTube* related access requests from the branch inside network *INSIDE1* or *INSIDE2* are routed to *WAN1* or *WAN2* as they would match the *DIA-FTD-Branch* ACL. Any other request, say *google.com*, are routed through *VTI01* or *VTI02* as configured in the Site to Site VPN Settings.

Figure 185: Site to Site VPN Settings

With the ECMP configured, the network traffic is seamlessly balanced.

History for Policy Based Routing

Table 49:

Feature	Minimum FMC	Minimum FTD	Details
Configure policy based routing from the FMC web interface.	7.1.0	7.1.0	**Upgrade impact. Redo FlexConfigs after upgrade.** You can now configure policy based routing (PBR) from the FMC web interface. This allows you to classify network traffic based on applications and to implement direct internet access (DIA) to send traffic to the internet from a branch deployment. You can define a PBR policy and configure it on ingress interfaces, specifying match criteria and egress interfaces. Network traffic that matches the access control policy is forwarded through the egress interface based on priority or the order as configured in the policy. This feature requires Version 7.1+ on both the FMC and the device. When you upgrade the FMC to Version 7.1+, existing policy based routing FlexConfigs are removed. After you upgrade your devices to Version 7.1+, redo your policy based routing configurations in the FMC web interface. For devices that you do not upgrade to Version 7.1+, redo the FlexConfigs and configure them to deploy "every time." New/modified screens: **Devices** > **Device Management** > **Routing** > **Policy Based Routing**

PART V

Objects and Certificates

- Object Management, on page 839

• History for Object Management, on page 956

Introduction to Objects

For increased flexibility and web interface ease-of-use, the system uses named *objects*, which are reusable configurations that associate a name with a value. When you want to use that value, use the named object instead. The system supports object use in various places in the web interface, including many policies and rules, event searches, reports, dashboards, and so on. The system provides many predefined objects that represent frequently used configurations.

Use the object manager to create and manage objects. Many configurations that use objects also allow you to create objects on the fly, as needed. You can also use the object manager to:

- View the policies, settings, and other objects where a network, port, VLAN, or URL object is used; see Viewing Objects and Their Usage, on page 845.
- Group objects to reference multiple objects with a single configuration; see Object Groups, on page 847.
- Override object values for selected devices; see Object Overrides, on page 848.

After you edit an object used in an active policy, you must redeploy the changed configuration for your changes to take effect. You cannot delete an object that is in use by an active policy.

Note An object is configured on a managed device if, and only if, the object is used in a policy that is assigned to that device. If you remove an object from all policies assigned to a given device, the object is also removed from the device configuration on the next deployment, and subsequent changes to the object are not reflected in the device configuration.

Object Types

The following table lists the objects you can create in the system, and indicates whether each object type can be grouped or configured to allow overrides.

Object Type	Groupable?	Allows Overrides?
Network	yes	yes
Port	yes	yes
Interface: • Security Zone • Interface Group	no	no
Tunnel Zone	no	no
Application Filter	no	no
VLAN Tag	yes	yes

Object Type	Groupable?	Allows Overrides?
External Attribute: Security Group Tag (SGT) and Dynamic Object	no	no
URL	yes	yes
Geolocation	no	no
Time Range	no	no
Variable Set	no	no
Security Intelligence: Network, DNS, and URL lists and feeds	no	no
Sinkhole	no	no
File List	no	no
Cipher Suite List	no	no
Distinguished Name	yes	no
Public Key Infrastructure (PKI): • Internal and Trusted CA • Internal and External Certs	yes	no
Key Chain	no	yes
DNS Server Group	no	no
SLA Monitor	no	no
Prefix List: IPv4 and IPv6	no	yes
Route Map	no	yes
Access List: Standard and Extended	no	yes
AS Path	no	yes
Community List	no	yes
Policy List	no	yes
FlexConfig: Text and FlexConfig objects	no	yes

Objects and Multitenancy

In a multidomain deployment, you can create objects in Global and descendant domains with the exception of Security Group Tag (SGT) objects, which you can create only in the Global domain. The system displays objects created in the current domain, which you can edit. It also displays objects created in ancestor domains, which you cannot edit, with the exception of security zones and interface groups.

Note Because security zones and interface groups are tied to device interfaces, which you configure at the leaf level, administrators in descendant domains can view and edit and groups created in ancestor domains. Subdomain users can add and delete interfaces from ancestor zones and groups, but cannot delete or rename the zones/groups.

Object names must be unique within the domain hierarchy. The system may identify a conflict with the name of an object you cannot view in your current domain.

For objects that support grouping, you can group objects in the current domain with objects inherited from ancestor domains.

Object overrides allow you to define device-specific or domain-specific values for certain types of object, including network, port, VLAN tag, and URL. In a multidomain deployment, you can define a default value for an object in an ancestor domain, but allow administrators in descendant domains to add override values for that object.

The Object Manager

You can use the object manager to create and manage objects and object groups.

The object manager displays 20 objects or groups per page. If you have more than 20 of any type of object or group, use the navigation links at the bottom of the page to view additional pages. You can also go to a specific page or click **Refresh** ( ) to refresh your view.

By default, the page lists objects and groups alphabetically by name. You can filter the objects on the page by name or value.

Importing Objects

Objects can be imported from a comma-separated values file. Up to 1000 objects can be imported in one attempt. The contents of the comma-separated values file should follow a specific format. The format is different for each object type. Only a few types of objects can be imported. See the following table to know the supported object types and the corresponding rules.

Object Type	Rules

Individual object	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DN
	• Both NAME and DN column entries are mandatory to import an entry.
	• You can import individual objects directly into an existing distinguished name object group.

Object Type	Rules

Network object	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • TYPE
	  • VALUE
	  • LOOKUP
	• The NAME and VALUE column entries are mandatory to import an entry of host, range, or network object type.
	• For an FQDN object, the TYPE column entry must mention 'fqdn,' and the LOOKUP column entry must be specified as 'ipv4,' 'ipv6,' or 'ipv4_ipv6.'
	• If no content is provided in the LOOKUP column entry for the FQDN object, then the object is saved with the ipv4_ipv6 field value.

Port	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • PROTOCOL
	  • PORT
	  • ICMPCODE
	  • ICMPTYPE
	• The NAME column entry is mandatory.
	• For 'tcp' and 'udp' protocol types, the PORT column entry is mandatory.
	• For 'icmp' and 'icmp6' protocol types, the ICMPCODE and ICMPTYPE column entries are mandatory.

Object Type	Rules

URL	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • URL
	• The NAME and URL column entries are mandatory to import an entry.

VLAN Tag	• The column header must be mentioned in capital letters.
	• The file must have the following columns headers:
	  • NAME
	  • DESCRIPTION
	  • TAG
	• The NAME and TAG column entries are mandatory to import an entry.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose one of the following object types from the left pane:

- **Distinguished Name** > **Individual Objects** >
- **Network Object**
- **Port**
- **URL**
- **VLAN Tag**

Step 3 Choose **Import Object** from the **Add [Object Type]** drop-down list.

Note
If you have selected **Individual Objects** in the previous step, click **Import**.

Step 4 Click **Browse**.

Step 5 Locate and select the comma-separated file on your system.

Step 6 Click **Open**.

Note

While importing **Distinguished Name** objects, you can optionally check the **Add imported Distinguished Name objects to the below object group** check box and select the group name from the drop-down box to import the objects directly to an existing distinguished name object group.

Step 7 Click **Import**.

Editing Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose an object type from the list; see Introduction to Objects, on page 840.

Step 3 Click **Edit** ( ) next to the object you want to edit.

If **View** ( ) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

Step 4 Modify the object settings as desired.

Step 5 If you are editing a variable set, manage the variables in the set; see Managing Variables, on page 935.

Step 6 For objects that can be configured to allow overrides:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850. You can change this setting only for objects that belong to the current domain.
- If you want to add override values to this object, expand the Override section and click **Add**; see Adding Object Overrides, on page 850.

Step 7 Click **Save**.

Step 8 If you are editing a variable set, and that set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Viewing Objects and Their Usage

You can view usage details of objects on the Object Management page. FMC provides this functionality for many object types. However, some object types are not supported.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose one of the following supported object types:

- Access List > Extended
- Access List > Standard
- AS Path
- Community List
- Interface
- Network
- Policy List
- Port
- Prefix List > IPv4 Prefix List
- Prefix List > IPv6 Prefix List
- Route Map
- SLA Monitor
- URL
- VLAN Tag

Step 3 Click the **Find Usage** () icon next to the object.

The Object Usage window displays a list of all the policies, objects, and other settings where the object is in use. Click any of the listed items to know more about the object usage. For policies and some other settings where the object is used, you can click the corresponding links to visit the respective UI pages.

Filtering Objects or Object Groups

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Enter your filter criteria in the **Filter** field.

The page updates as you type to display matching items.

You can use the following wildcards:

- The asterisk (*) matches zero or more occurrences of a character.
- The caret (^) matches content at the beginning of a string.
- The dollar sign ($) matches content at the end of a string.

Step 3 Check the **Show Unused Object** check box to view the objects and the object groups that are unused anywhere in the system.

Note

- In case an object is a part of an unused object group, the object is considered as used. However, the unused object group is displayed when the **Show Unused Object** check box is checked.
- The **Show Unused Object** check box is available only for network, port, URL and VLAN tag object types.

Object Groups

Grouping objects allows you to reference multiple objects with a single configuration. The system allows you to use objects and object groups interchangeably in the web interface. For example, anywhere you would use a port object, you can also use a port object group.

You can group network, port, VLAN tag, URL, and PKI objects. Network object groups can be nested, that is, you can add a network object group to another network object group up to 10 levels.

Objects and object groups of the same type cannot have the same name.

When you edit an object group used in a policy (for example, a network object group used in an access control policy), you must re-deploy the changed configuration for your changes to take effect.

Deleting a group does not delete the objects in the group, just their association with each other. Additionally, you cannot delete a group that is in use in an active policy. For example, you cannot delete a VLAN tag group that you are using in a VLAN condition in a saved access control policy.

Grouping Reusable Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 If the object type you want to group is **Network**, **Port**, **URL**, or **VLAN Tag**:

a) Choose the object type from the list of object types.
b) Choose **Add Group** from the **Add [Object Type]** drop-down list.

Step 3 If the object type you want to group is **Distinguished Name**:

a) Expand the **Distinguished Name** node.
b) Choose **Object Groups**.
c) Click **Add Distinguished Name Group**.

Step 4 If the object type you want to group is **PKI**:

a) Expand the **PKI** node.
b) Choose one of the following:
   - **Internal CA Groups**
   - **Trusted CA Groups**
   - **Internal Cert Groups**
   - **External Cert Groups**
c) Click **Add [Object Type] Group**.

Step 5 Enter a unique **Name**.

Step 6 Choose one or more objects from the list, and click **Add**.

You can also:

- Use the filter field **Search** ( ) to search for existing objects to include, which updates as you type to display matching items. Click **Reload** ( ) above the search field or click **Clear** ( ) in the search field to clear the search string.
- Click **Add** ( ) to create objects on the fly if no existing objects meet your needs.

Step 7 Optionally for **Network**, **Port**, **URL**, and **VLAN Tag** groups:

- Enter a **Description**.
- Check the **Allow Overrides** check box to allow overrides for this object group; see Allowing Object Overrides, on page 850.

Step 8 Click **Save**.

What to do next

- If an active policy references your object group, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Object Overrides

An object override allows you to define an alternate value for an object, which the system uses for the devices you specify.

You can create an object whose definition works for most devices, and then use overrides to specify modifications to the object for the few devices that need different definitions. You can also create an object that needs to be overridden for all devices, but its use allows you to create a single policy for all devices. Object overrides allow you to create a smaller set of shared policies for use across devices without giving up the ability to alter policies when needed for individual devices.

For example, you might want to deny ICMP traffic to the different departments in your company, each of which is connected to a different network. You can do this by defining an access control policy with a rule that includes a network object called Departmental Network. By allowing overrides for this object, you can then create overrides on each relevant device that specifies the actual network where that device is connected.

You can target an object override to a specific domain. In this case, the system uses the object override value for all devices in the targeted domain unless you override it at the device level.

From the object manager, you can choose an object that can be overridden and define a list of device-level or domain-level overrides for that object.

You can use object overrides with the following object types only:

- Network
- Port
- VLAN tag
- URL
- SLA Monitor
- Prefix List
- Route Map
- Access List
- AS Path
- Community List
- Policy List
- Cert Enrollment (PKI)
- Key Chain

If you can override an object, the **Override** column appears for the object type in the object manager. Possible values for this column include:

- Green checkmark — indicates that you can create overrides for the object and no overrides have been added yet
- Red X — indicates that you cannot create overrides for the object
- Number — represents a count of the overrides that have been added to that object (for example, "2" indicates two overrides have been added)

Managing Object Overrides

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose from the list of object types; see Introduction to Objects, on page 840.

Step 3 Click **Edit** ( ) next to the object you want to edit.

If **View** ( ) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

Step 4 Manage the object overrides:

- Add—Add object overrides; see Adding Object Overrides, on page 850.
- Allow—Allow object overrides; see Allowing Object Overrides, on page 850.
- Delete—In the object editor, click **Delete** ( ) next to the override you want to remove.
- Edit—Edit object overrides; see Editing Object Overrides, on page 851.

Allowing Object Overrides

Procedure

Step 1 In the object editor, check the **Allow Overrides** check box.

Step 2 Click **Save**.

What to do next

Add object override values; see Adding Object Overrides, on page 850.

Adding Object Overrides

Before you begin

Allow object overrides; see Allowing Object Overrides, on page 850.

Procedure

Step 1 In the object editor, expand the **Override** section.

Step 2 Click **Add**.

Step 3 On **Targets**, choose domains or devices in the **Available Devices and Domains** list and click **Add**.

Step 4 On the Override tab, enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 Enter an override value.

Example:

For a network object, enter a network value.

Step 7 Click **Add**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Editing Object Overrides

You can modify the description and the value of an existing override, but you cannot modify the existing target list. Instead, you must add a new override with new targets, which replaces the existing override.

Procedure

Step 1 In the object editor, expand the **Override** section.

Step 2 Click **Edit** ( ) next to the override you want to modify.

Step 3 Optionally, modify the **Description**.

Step 4 Modify the override value.

Step 5 Click **Save** to save the override.

Step 6 Click **Save** to save the object.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

AAA Server

Add reusable AAA server objects.

Add a RADIUS Server Group

RADIUS Server Group objects contain one or more references to RADIUS servers. These servers are used to authenticate users logging in through Remote Access VPN connections.

You can use this object with FTD devices.

Before you begin

Note You cannot override RADIUS Server Group Objects.

Procedure

Step 1 Select **Objects** > **Object Management** > **AAA Server** > **RADIUS Server Group**.

All currently configured RADIUS Server Group objects will be listed. Use the filter to narrow down the list.

Step 2 Choose and edit a listed RADIUS Server Group object, or add a new one.

See RADIUS Server Options, on page 853 and RADIUS Server Group Options, on page 852 to configure this object.

Step 3 Click **Save**

RADIUS Server Group Options

Navigation Path

Objects > **Object Management** > **AAA Server** > **RADIUS Server Group**. Choose and edit a configured RADIUS Server Group object or add a new one.

Fields

- **Name** and **Description**—Enter a name and optionally, a description to identify this RADIUS Server Group object.
- **Group Accounting Mode**—The method for sending accounting messages to the RADIUS servers in the group. Choose **Single**, accounting messages are sent to a single server in the group, this is the default. Or, **Multiple**, accounting messages are sent to all servers in the group simultaneously.
- **Retry Interval**—The interval between attempts to contact the RADIUS servers. Values range from 1 to 10 seconds.
- **Realms**(Optional)—Specify or select the Active Directory (AD) realm this RADIUS server group is associated with. This realm is then selected in identity policies to access the associated RADIUS server group when determining the VPN authentication identity source for a traffic flow. This realm effectively provides a bridge from the identity policy to this Radius server group. If no realm is associated with this RADIUS server group, the RADIUS server group cannot be reached to determine the VPN authentication identity source for a traffic flow in an identity policy.

Note This field is mandatory if you use remote access VPN with User Identity and RADIUS as the identity source.

- **Enable authorize only**—If this RADIUS server group is not being used for authentication, but is being used for authorization or accounting, check this field to enable authorize-only mode for the RADIUS server group.

  Authorize only mode eliminates the need of including the RADIUS server password in the Access-Request. Thus, the password, configured for the individual RADIUS servers, is ignored.

- **Enable interim account update** and **Interval**—Enables the generation of RADIUS interim-accounting-update messages in order to inform the RADIUS server of newly assigned IP addresses. Set the length, in hours, of the interval between periodic accounting updates in the Interval field. The valid range is 1 to 120 and the default value is 24.
- **Enable Dynamic Authorization** and **Port**— Enables the RADIUS dynamic authorization or change of authorization (CoA) services for this RADIUS server group. Specify the listening port for RADIUS CoA requests in the **Port** field. The valid range is 1024 to 65535 and the default value is 1700. Once defined, the corresponding RADIUS server group will be registered for CoA notification and it listens to the port for the CoA policy updates from the Cisco Identity Services Engine (ISE).
- **RADIUS Servers**—See RADIUS Server Options, on page 853.

Related Topics

Add a RADIUS Server Group, on page 851

RADIUS Server Options

Navigation Path

Objects > **Object Management** > **AAA Server** > **RADIUS Server Group**. Choose and edit a listed RADIUS Server Group object or add a new one. Then, in the RADIUS Server Group dialog, choose and edit a listed RADIUS Server or add a new one.

Fields

- **IP Address/Hostname**—The network object that identifies the hostname or IP address of the RADIUS server to which authentication requests will be sent. You may only select one, to add additional servers, add additional RADIUS Server to the RADIUS Server Group list.

Note The device now supports IPv6 IP addresses for RADIUS authentication.

- **Authentication Port**—The port on which RADIUS authentication and authorization are performed. The default is 1812.
- **Key** and **Confirm Key**— The shared secret that is used to encrypt data between the managed device (client) and the RADIUS server.

  The key is a case-sensitive, alphanumeric string of up to 127 characters. Special characters are permitted.

  The key you define in this field must match the key on the RADIUS server. Enter the key again in the Confirm field.
- **Accounting Port**—The port on which RADIUS accounting is performed. The default is 1813.
- **Timeout**— Session timeout for authentication.

Note The timeout value must be 60 seconds or more for RADIUS two factor authentication. The default timeout value is 10 seconds.

- **Connect Using** —Establishes connectivity from the device to a RADIUS server using a route lookup or using a specific interface.
  - Click the **Routing** radio button to use the routing table.
  - Click the **Specific Interface** radio button and choose a security zone/interface group or the Diagnostic interface (the default) from the drop-down list. .
- **Redirect ACL**—Select the redirect ACL from the list or add a new one.

Note This is the name of the ACL defined in the device to decide the traffic to be redirected. The Redirect ACL name here must be the same as the *redirect-acl* name in ISE server. When you configure the ACL object, ensure that you select Block action for ISE and DNS servers, and Allow action for the rest of the servers.

RADIUS Server Group Options, on page 852

Add a Single Sign-on Server

Before you begin

Obtain the following from your SAML identity provider:

- Identity Provider Entity ID URL
- Sign-in URL
- Sign-out URL
- Identity provider certificate and enroll the certificate in FTD using the FMC web interface (**Devices** > **Certificates**)

For more information, see Configuring a SAML Single Sign-On Authentication, on page 1098.

Procedure

Step 1 Choose **Object** > **Object Management** > **AAA Server** > **Single Sign-on Server**.

Step 2 Click **Add Single Sign-on Server** and provide the following details:

- **Name**—The name of the SAML single sign-on server object.
- **Identity Provider Entity ID**—The URL that is defined in SAML IdP to identify a service provider uniquely.

  The URL for a page that serves a metadata XML that describes how the SAML Issuer is going to respond to requests.
- **SSO URL**—The URL for signing into the SAML identity provider server.

- **Logout URL**—The URL for signing out of the SAML identity provider server.
- **Base URL**—URL that will redirect the user back to FTD once the identity provider authentication is done. This is the URL of the access interface configured for the FTD remote access VPN.
- **Identity Provider Certificate**—Certificate of the IdP enrolled into the FTD to verify the messages signed by the IdP.

  Select an identify provider certificate from the list or click Add to create a new certificate enrollment object.

  For more information, see Managing FTD Certificates, on page 962.

  You must enroll all of the Microsoft Azure registered application CA certificates as Trustpoints on the FTD. The Microsoft Azure SAML identity provider is configured on FTD for the initial application. All connection profiles are mapped to the configured MS Azure SAML identity provider. For each of the MS Azure applications (other than the default), you can choose the required trustpoint(CA certificate) in the connection profile configuration of the remote access VPN.

  For details, see Configure AAA Settings for Remote Access VPN, on page 1045.
- **Service Provider Certificate**—FTD certificate, which will be used to sign the requests and build circle of trust with IdP.

  If you have not enrolled internal FTD certificates, click + to add and enroll a certificate. For more information, see Managing FTD Certificates, on page 962.
- **Request Signature**—Select the encryption algorithm to sign the SAML single sign-on requests.

  The signatures are listed from weakest to strongest: SHA1,SHA256, SHA384, SHA512. Select None to disable encryption.
- **Request Timeout**—Specify the SAML assertion validity duration for the users to complete the single sign-on request. The SAML IdP has two time outs: *NotBefore* and *NotOnOrAfter*. The FTD validates if its current time is within the time range of (lower limit) *NotBefore* and (upper limit) the smaller of *NotBefore* plus *timeout* and *NotOnOrAfter*. Thus, if you set a timeout longer than the IdP's *NotOnOrAfter* timeout, the specified timeout is ignored and the *NotOnOrAfter* timeout is selected. If the sum of the specified timeout and the *NotBefore* timeout is less than the *NotOnOrAfter* time, FTD timeout overrides the timeout.

  The timeout range is 1-7200 seconds; the default is 300 seconds.
- **Enable IdP only accessible on Internal Network**—Select this option if the SAML IdP resides on the internal network. FTD acts as a gateway and establishes communication between the users and IdP using an anonymous webvpn session.
- **Request IdP re-authentication on Login**—Select this option to authenticate user at each login even if the previous IdP session is valid.
- **Allow Overrides**—Select this check box to allow overrides for this single sign-on server object.

Step 3 Click **Save**.

Access List

An access list object, also known as an access control list (ACL), selects the traffic to which a service will apply. You use these objects when configuring particular features, such as route maps, for FTD devices. Traffic identified as allowed by the ACL is provided the service, whereas "blocked" traffic is excluded from the service. Excluding traffic from a service does not necessarily mean that it is dropped altogether.

You can configure the following types of ACL:

- Extended—Identifies traffic based on source and destination address and ports. Supports IPv4 and IPv6 addresses, which you can mix in a given rule.
- Standard—Identifies traffic based on destination address only. Supports IPv4 only.

An ACL is composed of one or more access control entry (ACE), or rule. The order of ACEs is important. When the ACL is evaluated to determine if a packet matches an "allowed" ACE, the packet is tested against each ACE in the order in which the entries are listed. After a match is found, no more ACEs are checked. For example, if you want to "allow" 10.100.10.1, but "block" the rest of 10.100.10.0/24, the allow entry must come before the block entry. In general, place more specific rules at the top of an ACL.

Packets that do not match an "allow" entry are considered to be blocked.

The following topics explain how to configure ACL objects.

Configure Extended ACL Objects

Use extended ACL objects when you want to match traffic based on source and destination addresses, protocol and port, application group or if the traffic is IPv6.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Access List** > **Extended** from the table of contents.

Step 2 Do one of the following:

- Click **Add Extended Access List** to create a new object.
- Click **Edit** ( ) to edit an existing object.

Step 3 In the New Extended Access List Object dialog box, enter a name for the object (no spaces allowed), and configure the access control entries:

a) Do one of the following:

- Click **Add** to create a new entry.
- Click **Edit** ( ) to edit an existing entry.

b) Select the **Action**, whether to Allow (match) or Block (not match) the traffic criteria.

Note

The **Logging**, **Log Level**, and **Log Interval** options are used for access rules only (ACLs attached to interfaces or applied globally). Because ACL objects are not used for access rules, leave these values at their defaults.

c) Configure the source and destination addresses on the **Network** tab using any of the following techniques:

- Select the desired network objects or groups from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. You can mix IPv4 and IPv6 addresses.
- Type an address in the edit box below the source or destination list and click **Add**. You can specify a single host address (such as 10.100.10.5 or 2001:DB8::0DB8:800:200C:417A), or a subnet (in 10.100.10.0/24 or 10.100.10.0 255.255.255.0 format, or for IPv6, 2001:DB8:0:CD30::/60).

d) Click the **Port** tab and configure the service using any of the following techniques.

- Select the desired port objects from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. The object can specify TCP/UDP ports, ICMP/ICMPv6 message types, or other protocols (including "any"). However, the source port, which you typically would leave empty, accepts TCP/UDP only. You cannot select port groups.

  For TCP/UDP, note that you must use the same protocol in both the source and destination fields, if you specify both. For example, you cannot specify a UDP source port and a TCP destination port.
- Type or select a port or protocol in the edit box below the source or destination list and click **Add**.

Note
To get an entry that applies to all IP traffic, select a destination port object that specifies "all" protocols.

e) Click the **Application** tab and choose the applications that are to be grouped for the direct internet access policy.

Important
- You cannot configure applications for cluster devices. Hence, this tab is not applicable for cluster devices.
- Use extended ACL with applications only in policy-based routing. Do not use it in other policies as its behavior is unknown and not supported. Ensure migration of the realm/ISE configuration for policy-based routing that uses User Identity and SGT in extended ACL.

Note
- The **Available Applications** list displays a fixed set of pre-defined applications. This list is a subset of the applications that are available on the Access Control policy as only they can be detected by their first packet (FQDN end-points resolved to IP addresses and port). The application definitions are updated through the VDB updates and are pushed to FTD during subsequent deployments.
- User-defined custom applications or group of applications are not supported.
- Currently, FMC neither supports user-defined custom applications or group of applications nor allows you to modify the pre-defined applications list.
- You can use the filter options provided under the **Application Filters** to refine this list.

f) Select the required application, and click **Add to Rule**.

Note

- Do not configure destination networks and applications in the extended ACL object.
- The selected applications (Nertwork Service objects) in each of the access control entries, form a Network Service Group (NSG) and this group is deployed on the FTD. The NSG is used in direct internet access to classify traffic based on the match with the selected application group.

g) Click **Add** to add the entry to the object.
h) If necessary, click and drag the entry to move it up or down in the rule order to the desired location.

Repeat the process to create or edit additional entries in the object.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 5 Click **Save**.

Configure Standard ACL Objects

Use standard ACL objects when you want to match traffic based on destination IPv4 address only. Otherwise, use extended ACLs.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Access List** > **Standard** from the table of contents.

Step 2 Do one of the following:

- Click **Add Standard Access List** to create a new object.
- Click **Edit** ( ) to edit an existing object.

Step 3 In the New Standard Access List Object dialog box, enter a name for the object (no spaces allowed), and configure the access control entries:

a) Do one of the following:

- Click **Add** to create a new entry.
- Click **Edit** ( ) to edit an existing entry.

b) For each access control entry, configure the following properties:

- **Action**—Whether to Allow (match) or Block (not match) the traffic criteria.
- **Network**—Add the IPv4 network objects or groups that identify the destination of the traffic.

c) Click **Add** to add the entry to the object.
d) If necessary, click and drag the entry to move it up or down in the rule order to the desired location.

Repeat the process to create or edit additional entries in the object.

Step 4 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 5 Click **Save**.

Address Pools

You can configure IP address pools for both IPv4 and IPv6 that can be used for the Diagnostic interface with clustering or for VPN remote access profiles.

Procedure

Step 1 Select **Objects** > **Object Management** > **Address Pools**.

Step 2 Click **IPv4 Pools** and then **Add IPv4 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **IP Address**—Enter a range of addresses available in the pool. Use dotted decimal notation and a dash between the beginning and the end address, for example: 10.10.147.100-10.10.147.177.
- **Mask**—Identifies the subnet on which this IP address pool resides.
- **Allow Overrides**—Check this check box to enable object overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object Overrides, on page 848 for more information.

Step 3 Click **Save**.

Step 4 Click **IPv6 Pools** and then **Add IPv6 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **IPv6 Address**—Enter the first IP address available in the configured pool and the prefix length in bits. For example: 2001:DB8::1/64.
- **Number of Addresses**—Identifies the number of IPv6 addresses, starting at the Starting IP Address, that are in the pool.
- **Allow Overrides**—Check this check box to enable overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See Object Overrides, on page 848 for more information.

Step 5 Click **Save**.

Application Filters

System-provided application filters help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. In the object manager, you can create and manage reuseable user-defined application filters based on combinations of the system-provided filters, or on custom combinations of applications. For detailed information, see Application Rule Conditions, on page 471.

AS Path

An AS Path is a mandatory attribute to set up BGP. It is a sequence of AS numbers through which a network can be accessed. An AS-PATH is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Neighboring autonomous systems (ASes) use BGP to exchange and update messages about how to reach different AS prefixes. After each router makes a new local decision on the best route to a destination, it will send that route, or path information, along with the accompanying distance metrics and path attributes, to each of its peers. As this information travels through the network, each router along the path prepends its unique AS number to a list of ASes in the BGP message. This list is the route's AS-PATH. An AS-PATH along with an AS prefix, provides a specific handle for a one-way transit route through the network. Use the Configure AS Path page to create, copy and edit autonomous system (AS) path policy objects. You can create AS path objects to use when you are configuring route maps, policy maps, or BGP Neighbor Filtering. An AS path filter allows you to filter the routing update message by using regular expressions.

You can use this object with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **AS Path** from the table of contents.

Step 2 Click **Add AS Path**.

Step 3 Enter a name for the AS Path object in the **Name** field. Valid values are between 1 and 500.

Step 4 Click **Add** on the **New AS Path Object** window.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) Specify the regular expression that defines the AS path filter in the **Regular Expression** field.
c) Click **Add**.

Step 5 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 6 Click **Save**.

Cipher Suite List

A cipher suite list is an object comprised of several cipher suites. Each predefined cipher suite value represents a cipher suite used to negotiate an SSL- or TLS-encrypted session. You can use cipher suites and cipher suite

lists in SSL rules to control encrypted traffic based on whether the client and server negotiated the SSL session using that cipher suite. If you add a cipher suite list to an SSL rule, SSL sessions negotiated with any of the cipher suites in the list match the rule.

Note Although you can use cipher suites in the web interface in the same places as cipher suite lists, you cannot add, modify, or delete cipher suites.

Creating Cipher Suite Lists

Procedure

Step 1 Choose **Objects** > **Object Management**.
Step 2 Choose **Cipher Suite List** from the list of object types.
Step 3 Click **Add Cipher Suites**.
Step 4 Enter a **Name**.
Step 5 Choose one or more cipher suites from the **Available Ciphers** list.
Step 6 Click **Add**.
Step 7 Optionally, click **Delete** ( ) next to any cipher suites in the **Selected Ciphers** list that you want to remove.
Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Community List

A Community is an optional transitive BGP attribute. A community is a group of destinations that share some common attribute. It is used for route tagging. The BGP community attribute is a numerical value that can be assigned to a specific prefix and advertised to other neighbors. Communities can be used to mark a set of prefixes that share a common attribute. Upstream providers can use these markers to apply a common routing policy such as filtering or assigning a specific local preference or modifying other attributes. Use the Configure Community Lists page to create, copy and edit community list policy objects. You can create community list objects to use when you are configuring route maps or policy maps. You can use community lists to create groups of communities to use in a match clause of a route map. The community list is an ordered list of matching statements. Destinations are matched against the rules until a match is found.

You can use this object with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Community List** from the table of contents.

Step 2 Click **Add Community List**.

Step 3 In the **Name** field, specify a name for the community list object.

Step 4 Click **Add** on the **New Community List Object** window.

Step 5 Select the **Standard** radio button to indicate the community rule type.

Standard community lists are used to specify well-known communities and community numbers.

Note
You cannot have entries using Standard and entries using Expanded community rule types in the same Community List object.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) In the **Communities** field, specify a community number. Valid values can be from 1 to 4294967295 or from 0:1 to 65534:65535.
c) Select the appropriate **Route Type**.

- **Internet** — Select to specify the Internet well-known community. Routes with this community are advertised to all peers (internal and external).
- **No Advertise** — Select to specify the no-advertise well-known community. Routes with this community are not advertised to any peer (internal or external).
- **No Export** — Select to specify the no-export well-known community. Routes with this community are advertised to only peers in the same autonomous system or to only other sub-autonomous systems within a confederation. These routes are not advertised to external peers.

Step 6 Select the **Expanded** radio button to indicate the community rule type.

Expanded community lists are used to filter communities using a regular expression. Regular expressions are used to specify patterns to match COMMUNITIES attributes.

a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
b) Specify the regular expression in the **Expressions** field.

Step 7 Click **Add**.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 9 Click **Save**.

Extended Community

An extended community is a larger group of destinations that share some common attribute. The BGP extended community list has attributes that can be used to mark a set of prefixes that share a common attribute. These markers are used in the match clause of a route map to filter the routes for implementing route leaks among virtual routers. You can also define policy list objects with the extended community list for filtering. The extended community list is an ordered list of matching statements. Routes are matched against the rules until a match is found with the specified route target (standard) or regular expression (expanded). Use the Extended Community page to create and edit extended community list policy objects.

Note The extended community lists are applicable only for configuring import or export of routes.

You can use this object with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Community List** > **Extended Community** from the table of contents.

Step 2 Click **Add Extended Community List**.

Step 3 In the **Name** field, specify a name for the extended community list object. The length of the name cannot exceed 80 characters.

Step 4 Select the extended community rule type:

- Click the **Standard** radio button to specify one or more route targets.
- Click the **Expanded** radio button to specify regular expressions.

Note
You cannot have entries using Standard and Expanded extended community rule type in the same Extended Community List object.

Step 5 Click **Add**.

Step 6 If you have selected **Standard** as the extended community rule type, specify the following:

a) In the **Sequence No** field, enter the order in which you want the rule to be executed.

The sequence number must be unique in the list.

b) From the **Action** drop-down list, if you want to permit routes that have matching route target that is specified here, select **Allow**; if you want to deny routes that have matching route target that is specified here, select **Block**.

c) In the **Route Target** field, specify a route target.

- You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.
- Valid values can be from 1:1 to 65534:65535.
- You can have a maximum of 8 route targets in an entry.
- You cannot have redundant route target set across multiple entries. For example, say you want to configure *seq1* with *1:200,100:100,1:300* route targets, and *seq2* with *1:300,100:100,1:200* route targets. This results in redundant route target set and cannot be deployed.

Step 7 If you have selected **Expanded** as the extended community rule type, specify the following:

a) In the **Sequence No** field, enter the order in which you want the rule to be executed.

The sequence number must be unique in the list.

b) From the **Action** drop-down list, if you want to permit routes that have matching regular expression that is specified here, select **Allow**; if you want to deny routes that have matching regular expression that is specified here, select **Block**.

c) Specify the regular expression in the **Expressions** field.

- You can add a single route target or a set of route targets separated by a space in a single entry. For example, *^((16) | (18)):(.)$*.
- You can add a maximum of 16 regular expressions to an entry.
- You cannot have redundant regular expression set across multiple entries. For example, say you want to configure *seq1* with *^((16) | (18)):(.)$ ^4_[0-9]*$* route targets, and *seq2* with *^4_[0-9]*$ ^((16) | (18)):(.)$* route targets. This results in redundant regular expression set and cannot be deployed.

For details on BGP regular expressions, see here.

Step 8 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 9 Click **Save**.

The extended community list can be referenced in the match clause of the Route Map object or Policy List object:

- In the Route Map object, the name of the extended community list is displayed in the **Add Route Map Entry** > **Match Clause** > **BGP** > **Community List** > **Add Extended Community List** dialog. For more details on configuring BGP settings in a route map, see Route Map, on page 902.
- In the Policy List object, the name of the extended community list is displayed in the **Add Policy List** > **Community Rule** > **Add Extended Community List** dialog. For more details on configuring BGP settings in a policy list, see Policy List, on page 897.

Distinguished Name

Each distinguished name object represents the distinguished name for a public key certificate's subject or issuer. You can use distinguished name objects and groups in TLS/SSL rules to control encrypted traffic based on whether the client and server negotiated the TLS/SSL session using a server certificate with the distinguished name as subject or issuer.

(A *distinguished name group* is a named collection of existing distinguished name objects.)

The distinguished name can consist of country code, common name, organization, and organizational unit, but typically consists of a common name only. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. (However, it's not always this simple; Distinguished Name (DN) Rule Conditions, on page 1637 shows how to find common names.) The certificate can contain multiple Subject Alternative Names (SANs) you can use as DNs in a rule condition. For detailed information about SANs, see RFC 5280, section 4.2.1.6.

The format of a distinguished name object that references a common name is `CN=`*`name`*. If you add a DN rule condition without `CN=`, the system prepends `CN=` before saving the object.

As discussed further in Distinguished Name (DN) Rule Conditions, on page 1637, the system uses Server Name Indication (SNI) to match the DN in the TLS/SSL rule whenever possible.

You can also add a distinguished name with one of each of the attributes listed in the following table, separated by commas.

Table 50: Distinguished name attributes

Attribute	Description	Allowed Values
C	Country Code	two alphabetic characters
CN	Common Name	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces
O	Organization	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces
OU	Organizational Unit	up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces

Important notes about DN rule conditions

- The first time the system detects an encrypted session to a new server, DN data is not available for ClientHello processing, which *might* result in an undecrypted first session.

  If the server requests TLS 1.3, the setting for TLS server identity discovery can help by making sure the server certificate is known before making SSL policy decisions. For more information, see Access Control Policy Advanced Settings, on page 1173.

- You *cannot* configure a distinguished name condition if you also choose the **Decrypt - Known Key** action. Because that action requires you to choose a server certificate to decrypt traffic, the certificate already matches the traffic.

Wildcard examples

You can define one or more asterisks (*) as wildcards in an attribute. In a common name attribute, you can define one or more asterisks per domain name label. wildcards match only in that label, but you can define multiple labels with wildcards. See the following table for examples.

Table 51: Common Name attribute wildcard examples

Attribute	Matches	Does Not Match
CN=*ample.com	example.com	mail.example.com example.text.com ampleexam.com
CN=exam*.com	example.com	mail.example.com example.text.com ampleexam.com

Attribute	Matches	Does Not Match
CN=*xamp*.com	example.com	mail.example.com example.text.com ampleexam.com
CN=*.example.com	mail.example.com	www.myhost.example.com example.com example.text.com ampleexam.com

Note The DN object `CN=amp.cisco.com` would *not* match a CN like `CN=auth.amp.cisco.com`, which is why we recommend wildcards in these cases.

For more information and examples, see Distinguished Name (DN) Rule Conditions, on page 1637.

Distinguished Name (DN) Rule Conditions, on page 1637

Creating Distinguished Name Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Distinguished Name** node, and choose **Individual Objects**.

Step 3 Click **Add Distinguished Name**.

Step 4 Enter a **Name**.

Step 5 In the **DN** field, enter a value for the distinguished name or common name. You have the following options:

- If you add a distinguished name, you can include one of each attribute listed in Distinguished Name, on page 864 separated by commas.
- If you add a common name, you can include multiple labels and wild cards.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

DNS Server Group

Domain Name System (DNS) servers resolve fully-qualified domain names (FQDN), such as www.example.com, to IP addresses.

Creating DNS Server Group Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **DNS Server Group** from the network objects list.

Step 3 Click **Add DNS Server Group**.

Step 4 Enter a **Name**.

Step 5 Optionally, enter the **Default Domain** that will be used to append to the host names that are not fully-qualified.

Step 6 The default **Timeout** and **Retries** values are pre-populated. Change these values if necessary.

- Retries—The number of times, from 0 to 10, to retry the list of DNS servers when the system does not receive a response. The default is 2.
- Timeout—The number of seconds, from 1 to 30, to wait before trying the next DNS server. The default is 2 seconds. Each time the system retries the list of servers, this timeout doubles.

Step 7 Enter the **DNS Servers** that will be a part of this group, either in IPv4 or IPv6 format as comma separated entries.

A maximum of 6 DNS servers can belong to one group.

Step 8 Click **Save**.

What to do next

The DNS servers configured in the DNS server group should be assigned to interface objects in the DNS platform settings. For more information, see DNS, on page 481.

External Attributes

About API-Created Dynamic Objects

A *dynamic object* is an object that specifies one or many IP addresses retrieved either using REST API calls or using the Cisco Secure Dynamic Attributes Connector, which is capable of updating IP addresses from cloud sources. These dynamic objects can be used in access control rules without the need to deploy dynamic changes to the objects.

For more information about the dynamic attributes connector, see the *Cisco Secure Dynamic Attributes Configuration Guide* (link to guide).

Differences between dynamic objects and network objects follow:

- Dynamic objects created using the dynamic attributes connector are pushed to the FMC as soon as they're created and are updated at a regular interval.
- API-created dynamic objects:
  - Are IP addresses, with or without or classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.
  - Do not support fully-qualified domain names or address ranges.
  - Must be updated using an API.

Related Topics

Add or Edit an API-Created Dynamic Object, on page 868

Add or Edit an API-Created Dynamic Object

This procedure discusses how to add or edit a *dynamic object*, which is a group of IP addresses using the API, with or without or classless inter-domain routing (*CIDR*), that can be used in access control rules much like a network object.

Note This procedure is not necessary if you use the Cisco Secure Dynamic Attributes Connector because it automatically creates dynamic objects for you.

Before you begin

Consult the *Firepower Management Center REST API Quick Start Guide* for information about using the object services REST API to populate the IP object with an address. Dynamic objects do not require deployment.

Procedure

Step 1 Click **Objects** > **Object Management**.

Step 2 Click **External Attributes** > **Dynamic Objects**.

Step 3 Click **Add Dynamic Object** or **Edit** ( ).

Step 4 Enter a **Name** for the object and an optional **Description**.

Step 5 From the **Type** list, click **IP**.

What to do next

If necessary, update the dynamic object using the API. Deployment is not required.

Security Group Tag

A Security Group Tag (SGT) object specifies a single SGT value. You can use SGT objects in rules to control traffic with SGT attributes that were **not** assigned by Cisco ISE. You cannot group or override SGT objects.

Related Topics

Autotransition from Custom SGTs to ISE SGTs
Custom SGT Conditions
ISE SGT vs Custom SGT Rule Conditions

Creating Security Group Tag Objects

You can create these objects in the global domain only. To use the object on Classic devices, you must have the Control license. For Smart Licensed devices, any license will do.

Before you begin

- Disable ISE/ISE-PIC connections. You cannot create custom SGT objects if you use ISE/ISE-PIC as an identity source.

Procedure

Step 1 Click **Objects** > **Object Management**.
Step 2 Click **External Attributes** > **Security Group Tag**.
Step 3 Click **Add Security Group Tag**.
Step 4 Enter a **Name**.
Step 5 Optionally, enter a **Description**.
Step 6 In the **Tag** field, enter a single SGT.
Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

File List

If you use AMP for Networks, and the AMP cloud incorrectly identifies a file's disposition, you can add the file to a *file list* to better detect the file in the future. These files are specified using SHA-256 hash values. Each file list can contain up to 10000 unique SHA-256 values.

There are two predefined categories of file lists:

Clean List

If you add a file to this list, the system treats it as if the AMP cloud assigned a clean disposition.

Custom Detection List

If you add a file to this list, the system treats it as if the AMP cloud assigned a malware disposition.

Because you manually specify the blocking behavior for the files included in these lists, the system does not query the AMP cloud for these files' dispositions. You must configure a rule in the file policy with either a **Malware Cloud Lookup** or **Block Malware** action and a matching file type to calculate a file's SHA value.

Caution Do **not** include malware on the clean list. The clean list overrides both the AMP cloud and the custom detection list.

Source Files for File Lists

You can add multiple SHA-256 values to a file list by uploading a comma-separated value (CSV) source file containing a list of SHA-256 values and descriptions. The FMC validates the contents and populates the file list with valid SHA-256 values.

The source file must be a simple text file with a .csv file name extension. Any header must start with a pound sign (`#`); it is treated as a comment and not uploaded. Each entry should contain a single SHA-256 value followed by a description and end with either the `LF` or `CR+LF` Newline character. The system ignores any additional information in the entry.

Note the following:

- Deleting a source file from the file list also removes all associated SHA-256 hashes from the file list.
- You cannot upload multiple files to a file list if the successful source file upload results in the file list containing more than 10000 distinct SHA-256 values.
- The system truncates descriptions exceeding 256 characters to the first 256 characters on upload. If the description contains commas, you must use an escape character (`\,`). If no description is included, the source file name is used instead.
- All non-duplicate SHA-256 values are added to the file list. If a file list contains a SHA-256 value, and you upload a source file containing that value, the newly uploaded value does not modify the existing SHA-256 value. When viewing captured files, file events, or malware events related to the SHA-256 value, any threat name or description is derived from the individual SHA-256 value.
- The system does not upload invalid SHA-256 values in a source file.
- If multiple uploaded source files contain an entry for the same SHA-256 value, the system uses the most recent value.
- If a source file contains multiple entries for the same SHA-256 value, the system uses the last one.
- You cannot directly edit a source file within the object manager. To make changes, you must first modify your source file directly, delete the copy on the system, then upload the modified source file.
- The number of entries associated with a source file refers to the number of distinct SHA-256 values. If you delete a source file from a file list, the total number of SHA-256 entries the file list contains decreases by the number of valid entries in the source file.

Adding Individual SHA-256 Values to File Lists

You must have the Malware license for this procedure.

You can submit a file's SHA-256 value to add it to a file list. You cannot add duplicate SHA-256 values.

Before you begin

- Right-click a file or malware event from the event view, choose **Show Full Text** in the context menu, and copy the full SHA-256 value for pasting into the file list.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to add a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Choose `Enter SHA Value` from the **Add by** drop-down list.

Step 5 Enter a description of the source file in the **Description** field.

Step 6 Enter or paste the file's entire value in the **SHA-256** field. The system does not support matching partial values.

Step 7 Click **Add**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Note After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

Uploading Individual Files to File Lists

You must have the Malware license for this procedure.

If you have a copy of the file you want to add to a file list, you can upload the file to the Firepower Management Center for analysis; the system calculates the file's SHA-256 value and adds the file to the list. The system does not enforce a limit on the size of files for SHA-256 calculation.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to add a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 From the **Add by** drop-down list, choose **Calculate SHA**.

Step 5 Optionally, enter a description of the file in the **Description** field. If you do not enter a description, the file name is used for the description on upload.

Step 6 Click **Browse**, and choose a file to upload.

Step 7 Click **Calculate and Add SHA**.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Note After you deploy configuration changes, the system no longer queries the AMP cloud for files on the list.

Uploading Source Files to File Lists

You must have the Malware license for this procedure.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **File List**.

Step 3 Click **Edit** ( ) next to the file list where you want to add values from a source file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 In the **Add by** drop-down list, choose `List of SHAs`.

Step 5 Optionally, enter a description of the source file in the **Description** field. If you do not enter a description, the system uses the file name.

Step 6 Click **Browse** to browse to the source file, then click **Upload and Add List**.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Note After you deploy the policies, the system no longer queries the AMP cloud for files on the list.

Editing SHA-256 Values in File Lists

You must have the Malware license for this procedure.

You can edit or delete individual SHA-256 values on a file list. Note that you cannot directly edit a source file within the object manager. To make changes, you must first modify your source file directly, delete the copy on the system, then upload the modified source file.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **File List**.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to modify a file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 You can:

- Click **Edit** ( ) next to the SHA-256 value you want to change, and modify the **SHA-256** or **Description** values as desired.
- Click **Delete** ( ) next to the SHA-256 value you want to delete.

Step 5 Click **Save** to update the file entry in the list.

Step 6 Click **Save** to save the file list.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Note After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

Downloading Source Files from File Lists

You must have the Malware license for this procedure.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **File List** from the list of object types.

Step 3 Click **Edit** ( ) next to the clean list or custom detection list where you want to download a source file.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Next to the source file you want to download, click **View** ( ).

Step 5 Click **Download SHA List** and follow the prompts to save the source file.

Step 6 Click **Close**.

FlexConfig

Use FlexConfig policy objects in FlexConfig policies to provide customized configuration of features on FTD devices that you cannot otherwise configure using Firepower Management Center. For more information on FlexConfig policies, see FlexConfig Policy Overview, on page 1893.

You can configure the following types of objects for FlexConfig.

Text Objects

Text objects define free-form text strings that you use as variables in a FlexConfig object. These objects can have single values or be a list of multiple values.

There are several predefined text objects that are used in the predefined FlexConfig objects. If you use the associated FlexConfig object, you simply need to edit the contents of the text object to customize how the FlexConfig object configures a given device. When editing a predefined object, it is in general a better option to create device overrides for each device you are configuring, rather than directly change the default values of these objects. This helps avoid unintended consequences if another user wants to use the same FlexConfig object for a different set of devices.

For information on configuring text objects, see Configure FlexConfig Text Objects, on page 1919.

FlexConfig Objects

FlexConfig Objects include device configuration commands, variables, and scripting language instructions. During configuration deployment, these instructions are processed to create a sequence of configuration commands with customized parameters to configure specific features on the target devices.

These instructions are either configured before (prepended) the system configures features defined in regular FMC policies and settings, or after (appended). Any FlexConfig that depends on Firepower Management Center-configured objects (for example, a network object) must be appended to the

configuration deployment, or the needed objects would not be configured before the FlexConfig needed to refer to the objects.

For more information on configuring FlexConfig objects, see Configure FlexConfig Objects, on page 1915.

Geolocation

Each geolocation object you configure represents one or more countries or continents that the system has identified as the source or destination of traffic on your monitored network. You can use geolocation objects in various places in the system's web interface, including access control policies, SSL policies, remote access VPN, and event searches. For example, you could write an access control rule that blocks traffic to or from certain countries.

To ensure that you are using up-to-date information to filter your network traffic, Cisco strongly recommends that you regularly update your Geolocation Database (GeoDB).

Creating Geolocation Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Geolocation** from the list of object types.

Step 3 Click **Add Geolocation**.

Step 4 Enter a **Name**.

Step 5 Check the check boxes for the countries and continents you want to include in your geolocation object. Checking a continent chooses all countries within that continent, as well as any countries that GeoDB updates may add under that continent in the future. Unchecking any country under a continent unchecks the continent. You can choose any combination of countries and continents.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Interface

Each interface can be assigned to a *security zone* and/or *interface group*. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface to the "inside" zone; and the "outside" interface to the "outside" zone. You can configure your access control policy to enable traffic to go from inside to outside, but not from outside to inside, for example. Some policies only support security zones, while other policies support zones and groups.

For more information about interface objects, see Security Zones and Interface Groups, on page 352.

To add interface objects, see Create Security Zone and Interface Group Objects, on page 355.

Key Chain

To enhance data security and protection of devices, rotating keys for authenticating IGP peers that have a duration of 180 days or less is introduced. The rotating keys prevent any malicious user from guessing the keys used for routing protocol authentication and thereby protecting the network from advertising incorrect routes and redirecting traffic. Changing the keys frequently reduces the risk of them eventually being guessed. When configuring authentication for routing protocols that provide key chains, configure the keys in a key chain to have overlapping lifetimes. This helps to prevent loss of key-secured communication due to absence of an active key. The rotating keys are applicable only for OSPFv2 protocol. If the key lifetime expires and no active keys are found, OSPF uses the last valid key to maintain the adjacency with peers.

Note Only MD5 cryptographic algorithm is used for authentication.

Lifetime of a Key

To maintain stable communications, each device stores key chain authentication keys and uses more than one key for a feature at the same time. Based on the send and accept lifetimes of a key, key chain management provides a secured mechanism to handle key rollover. The device uses the lifetimes of keys to determine which keys in a key chain are active.

Each key in a key chain has two lifetimes:

- Accept lifetime—The time interval within which the device accepts the key during key exchange with another device.
- Send lifetime—The time interval within which the device sends the key during key exchange with another device.

During a key send lifetime, the device sends routing update packets with the key. The device does not accept communication from other devices when the key sent is not within the accept lifetime of the key on the device.

If lifetimes are not configured then it is equivalent to configuring MD5 authentication key without timelines.

Key Selection

- When key chain has more than one valid key, OSPF selects the key that has the maximum life time.
- Key having an infinite lifetime is preferred.
- If keys have the same lifetime, then key with the higher key ID is preferred.

Creating Key Chain Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Key Chain** from the list of object types.

Step 3 Click **Add Key Chain**.

Step 4 In the Add Key Chain Object dialog box, enter a name for the key chain in the **Name** field.

The name must start with an underscore or alphabet, followed by alphanumeric characters or special characters(-, _, +, .).

Step 5 To add a key to the key chain, click **Add**.

Step 6 Specify the key identifier in the **Key ID** field.

The key id value can be between 0 and 255. Use the value 0 only when you want to signal an invalid key.

Step 7 The **Algorithm** field and the **Crypto Encryption Type** field displays the supported algorithm and the encryption type, namely MD5 and Plain Text respectively.

Step 8 Enter the password in the **Crypto Key String** field, and re-enter the password in the **Confirm Crypto Key String** field.

- The password can be of a maximum length of 80 characters.
- The passwords cannot be a single digit nor those starting with a digit followed by a white space. For example, "0 pass" or "1" are invalid.

Step 9 To set the time interval for a device to accept/send the key during key exchange with another device, provide the lifetime values in the **Accept Lifetime** and **Send Lifetime** fields:

Note
The Date Time values default to UTC timezones.

The end time can be the duration, the absolute time when the accept/send lifetime ends, or never expires. The default end time is DateTime.

Following are the validation rules for the start and end values:

- Start lifetime cannot be null when the end lifetime is specified.
- The start lifetime for accept or send lifetime must be earlier than the respective end lifetime.

Step 10 Click **Add**.

Repeat steps 5 to 10 to create keys. Create a minimum of two keys for a key chain with overlapping lifetimes. This helps to prevent loss of key-secured communication due to absence of an active key.

Step 11 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

- If you want to add override values to this object, expand the Override section and click **Add**; see Adding Object Overrides, on page 850.

Step 12 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Network

A network object represents one or more IP addresses. You can use network objects and groups in various places, including access control policies, network variables, identity rules, network discovery rules, event searches, reports, identity policies, and so on.

When you configure an option that requires a network object, the list is automatically filtered to show only those objects that are valid for the option. For example, some options require host objects, while other options require subnets.

A network object can be one of the following types:

Host

A single IP address.

IPv4 example:

```
209.165.200.225
```

IPv6 example:

```
2001:DB8::0DB8:800:200C:417A
```
or
```
2001:DB8:0:0:0DB8:800:200C:417A
```

Range

A range of IP addresses.

IPv4 example:

```
209.165.200.225-209.165.200.250
```

IPv6 example:

```
2001:db8:0:cd30::1-2001:db8:0:cd30::1000
```

Network

An address block, also known as a subnet.

IPv4 example:

```
209.165.200.224/27
```

IPv6 example:

```
2001:DB8:0:CD30::/60
```

Note Security Intelligence ignores IP address blocks using a `/0` netmask.

FQDN

A single fully-qualified domain name (FQDN). You can limit FQDN resolution to IPv4 address only, IPv6 address only, or both IPv4 and IPv6 addresses. FQDNs must begin and end with a digit or letter. Only letters, digits, and hyphens are allowed as internal characters in an FQDN.

For example:

```
www.example.com
```

Note You can use FQDN objects in access control rules and prefilter rules, or manual NAT rules, only. The rules match the IP address obtained for the FQDN through a DNS lookup. To use an FQDN network object, ensure you have configured the DNS server settings in DNS Server Group, on page 867 and the DNS platform settings in DNS, on page 481.

You *cannot* use FDQN network objects in identity rules.

Group

A group of network objects or other network object groups. You can create nested groups by adding one network object group to another network object group. You can nest up to 10 levels of groups.

Network Wildcard Mask

You can create and manage wildcard mask objects from the Object Management page.

You can create network objects with expanded subnet IP address. The existing network object is extended to support both Network and Network Wildcard object. The network object using wildcard mask is listed as **Network Wildcard** against the **Type** column in the network object listing page.

A wildcard mask is an IP address that is a discontinuous mask of bits. You can use contiguous masks to create standard network objects and discontinuous masks for wildcard network objects.

Example IP Address	Network Wildcard?	Object Type
192.0.0.0/8	No	Network
10.10.0.0/255.255.0.0	No	Network
10.10.0.10/255.255.0.255	Yes	Network Wildcard
72.0.240.10/255.255.240.255	Yes	Network Wildcard

Note Network wildcard object and object group, which contains network wildcard objects, are allowed only while configuring the following policies:

- Prefilter policy
- Access control policy
- NAT policy

Guidelines and Limitations

- To create network wildcard objects, in the FMC UI, choose **Objects** > **Object Management** > **Network** and click **Add Network** and then **Add Object**. Select the **Network** option and enter the value as expanded subnet mask. Example: 10.0.10.10/255.255.0.255.
- Object override, group object support, group object override, wildcard literals, and wildcard object import are supported.
- The network wildcard object is supported only for IPv4 addresses.
- The network wildcard object is supported from FMC and FTD 7.1 version onwards.
- Network wildcard objects are supported only for Snort-3.

Creating Network Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Network** from the list of object types.

Step 3 Choose **Add Object** from the **Add Network** drop-down menu.

Step 4 Enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 In the **Network** field, select the required option and enter an appropriate value; see Network, on page 878.

Step 7 (FQDN objects only) Select the DNS resolution from the **Lookup** drop-down menu to determine whether you want the IPv4, IPv6, or both IPv4 and IPv6 addresses associated with the FQDN.

Step 8 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.
- If you want to add override values to this object, expand the Override section and click **Add**; see Adding Object Overrides, on page 850.

Step 9 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Importing Network Objects

For details on importing network objects, see Importing Objects, on page 842.

PKI

PKI Objects for SSL Application

PKI objects represent the public key certificates and paired private keys required to support your deployment. Internal and trusted CA objects consist of certificate authority (CA) certificates; internal CA objects also contain the private key paired with the certificate. Internal and external certificate objects consist of server certificates; internal certificate objects also contain the private key paired with the certificate.

If you use trusted certificate authority objects and internal certificate objects to configure a connection to ISE/ISE-PIC, you can use ISE/ISE-PIC as an identity source.

If you use internal certificate objects to configure captive portal, the system can authenticate the identity of your captive portal device when connecting to users' web browsers.

If you use trusted certificate authority objects to configure realms, you can configure secure connections to LDAP or AD servers.

If you use PKI objects in SSL rules, you can match traffic encrypted with:

- the certificate in an external certificate object
- a certificate either signed by the CA in a trusted CA object, or within the CA's chain of trust

If you use PKI objects in SSL rules, you can decrypt:

- outgoing traffic by re-signing the server certificate with an internal CA object
- incoming traffic using the known private key in an internal certificate object

You can manually input certificate and key information, upload a file containing that information, or in some cases, generate a new CA certificate and private key.

When you view a list of PKI objects in the object manager, the system displays the certificate's Subject distinguished name as the object value. Hover your pointer over the value to view the full certificate Subject distinguished name. To view other certificate details, edit the PKI object.

Note The FMC and managed devices encrypt all private keys stored in internal CA objects and internal certificate objects with a randomly generated key before saving them. If you upload private keys that are password protected, the appliance decrypts the key using the user-supplied password, then reencrypts it with the randomly generated key before saving it.

PKI Objects for Certificate Enrollment

A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. These activities occur in your Private Key Infrastructure (PKI).

The certificate enrollment object may also includes certificate revocation information. For more information on PKI, digital certificates, and certificate enrollment see PKI Infrastructure and Digital Certificates , on page 979.

Internal Certificate Authority Objects

Each internal certificate authority (CA) object you configure represents the CA public key certificate of a CA your organization controls. The object consists of the object name, CA certificate, and paired private key. You can use internal CA objects and groups in SSL rules to decrypt outgoing encrypted traffic by re-signing the server certificate with the internal CA.

Note If you reference an internal CA object in a **Decrypt - Resign** SSL rule and the rule matches an encrypted session, the user's browser may warn that the certificate is not trusted while negotiating the SSL handshake. To avoid this, add the internal CA object certificate to either the client or domain list of trusted root certificates.

You can create an internal CA object in the following ways:

- import an existing RSA-based or elliptic curve-based CA certificate and private key
- generate a new self-signed RSA-based CA certificate and private key
- generate an unsigned RSA-based CA certificate and private key. You must submit a certificate signing request (CSR) to another CA to sign the certificate before using the internal CA object.

After you create an internal CA object containing a signed certificate, you can download the CA certificate and private key. The system encrypts downloaded certificates and private keys with a user-provided password.

Whether system-generated or user-created, you can modify the internal CA object name, but cannot modify other object properties.

You cannot delete an internal CA object that is in use. Additionally, after you edit an internal CA object used in an SSL policy, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

CA Certificate and Private Key Import

You can configure an internal CA object by importing an X.509 v3 CA certificate and private key. You can upload files encoded in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the private key file is password-protected, you can supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

You can upload only files that contain proper certificate or key information, and that are paired with each other. The system validates the pair before saving the object.

Note If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's encryption algorithm type, in addition to any configured rule conditions. You must upload an elliptic curve-based CA certificate to decrypt outgoing traffic encrypted with an elliptic curve-based algorithm, for example.

Importing a CA Certificate and Private Key

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Import CA**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 Above the **Key** field, click **Browse** to upload a DER or PEM-encoded paired private key file.

Step 7 If the uploaded file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Generating a New CA Certificate and Private Key

You can configure an internal CA object by providing identification information to generate a self-signed RSA-based CA certificate and private key.

The generated CA certificate is valid for ten years. The Valid From date is a week before generation.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Click **Generate CA**.

Step 4 Enter a **Name**.

Step 5 Enter the identification attributes.

Step 6 Click **Generate self-signed CA**.

New Signed Certificates

You can configure an internal CA object by obtaining a signed certificate from a CA. This involves two steps:

- Provide identification information to configure the internal CA object. This generates an unsigned certificate and paired private key, and creates a certificate signing request (CSR) to a CA you specify.
- After the CA issues the signed certificate, upload it to the internal CA object, replacing the unsigned certificate.

You can only reference an internal CA object in an SSL rule if it contains a signed certificate.

Creating an Unsigned CA Certificate and CSR

Procedure

Step 1 Choose **Objects** > **Object Management**.
Step 2 Expand the **PKI** node, and choose **Internal CAs**.
Step 3 Click **Generate CA**.
Step 4 Enter a **Name**.
Step 5 Enter the identification attributes.
Step 6 Click **Generate CSR**.
Step 7 Copy the CSR to submit to a CA.
Step 8 Click **OK**.

What to do next

- You must upload a signed certificate issued by a CA as described in Uploading a Signed Certificate Issued in Response to a CSR, on page 884

Uploading a Signed Certificate Issued in Response to a CSR

Once uploaded, the signed certificate can be referenced in SSL rules.

Procedure

Step 1 Choose **Objects** > **Object Management**.
Step 2 Expand the **PKI** node, and choose **Internal CAs**.
Step 3 Click **Edit** ( ) next to the CA object containing the unsigned certificate awaiting the CSR.
Step 4 Click **Install Certificate**.

Step 5 Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 If the uploaded file is password protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 7 Click **Save** to upload a signed certificate to the CA object.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

CA Certificate and Private Key Downloads

You can back up or transfer a CA certificate and paired private key by downloading a file containing the certificate and key information from an internal CA object.

Caution Always store downloaded key information in a secure location.

The system encrypts the private key stored in an internal CA object with a randomly generated key before saving it to disk. If you download a certificate and private key from an internal CA object, the system first decrypts the information before creating a file containing the certificate and private key information. You must then provide a password the system uses to encrypt the downloaded file.

Caution Private keys downloaded as part of a system backup are decrypted, then stored in the unencrypted backup file.

Downloading a CA Certificate and Private Key

You can download CA certificates for both the current domain and ancestor domains.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal CAs**.

Step 3 Next to the internal CA object whose certificate and private key you want to download, click **Edit** ( ).

Step 4 Click **Download**.

Step 5 Enter an encryption password in the **Password** and **Confirm Password** fields.

Step 6 Click **OK**.

Trusted Certificate Authority Objects

Each trusted certificate authority (CA) object you configure represents a CA public key certificate belonging to a trusted CA. The object consists of the object name and CA public key certificate. You can use external CA objects and groups in:

- your SSL policy to control traffic encrypted with a certificate signed either by the trusted CA, or any CA within the chain of trust.
- your realm configurations to establish secure connections to LDAP or AD servers.
- your ISE/ISE-PIC connection. Select trusted certificate authority objects for the **pxGrid Server CA** and **MNT Server CA** fields.

After you create the trusted CA object, you can modify the name and add certificate revocation lists (CRL), but cannot modify other object properties. There is no limit on the number of CRLs you can add to an object. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

You cannot delete a trusted CA object that is in use. Additionally, after you edit a trusted CA object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

Trusted CA Object

You can configure an external CA object by uploading an X.509 v3 CA certificate. You can upload a file encoded in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate is encoded in the PEM format, you can also copy and paste the information.

You can upload a CA certificate only if the file contains proper certificate information; the system validates the certificate before saving the object.

Adding a Trusted CA Object

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Trusted CAs**.

Step 3 Click **Add Trusted CAs**.

Step 4 Enter a **Name**.

Step 5 Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

Step 6 If the file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Certificate Revocation Lists in Trusted CA Objects

You can upload CRLs to a trusted CA object. If you reference that trusted CA object in an SSL policy, you can control encrypted traffic based on whether the CA that issued the session encryption certificate subsequently revoked the certificate. You can upload files encoded in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

After you add the CRL, you can view the list of revoked certificates. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

You can upload only files that contain a proper CRL. There is no limit to the number of CRLs you can add to a trusted CA object. However, you must save the object each time you upload a CRL, before adding another CRL.

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

Adding a Certificate Revocation List to a Trusted CA Object

Note Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Trusted CAs**.

Step 3 Click **Edit** ( ) next to a trusted CA object.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Click **Add CRL** to upload a DER or PEM-encoded CRL file.

Step 5 Click **OK**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

External Certificate Objects

Each external certificate object you configure represents a server public key certificate that does not belong to your organization. The object consists of the object name and certificate. You can use external certificate objects and groups in SSL rules to control traffic encrypted with the server certificate. For example, you can upload a self-signed server certificate that you trust, but cannot verify with a trusted CA certificate.

You can configure an external certificate object by uploading an X.509 v3 server certificate. You can upload a file in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

You can upload only files that contains proper server certificate information; the system validates the file before saving the object. If the certificate is encoded in the PEM format, you can also copy and paste the information.

Adding External Certificate Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **External Certs**.

Step 3 Click **Add External Cert**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Internal Certificate Objects

Each internal certificate object you configure represents a server public key certificate belonging to your organization. The object consists of the object name, public key certificate, and paired private key. You can use internal certificate objects and groups in:

- your SSL rules to decrypt traffic incoming to one of your organization's servers using the known private key.
- your ISE/ISE-PIC connection. Select an internal certificate object for the **MC Server Certificate** field.
- your captive portal configuration to authenticate the identity of your captive portal device when connecting to users' web browsers. Select an internal certificate object for the **Server Certificate** field.

You can configure an internal certificate object by uploading an X.509 v3 RSA-based or elliptic curve-based server certificate and paired private key. You can upload a file in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

You can upload only files that contain proper certificate or key information, and that are paired with each other. The system validates the pair before saving the object.

After you create the internal certificate object, you can modify the name, but cannot modify other object properties.

You cannot delete an internal certificate object that is in use. Additionally, after you edit an internal certificate object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

Adding Internal Certificate Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **PKI** node, and choose **Internal Certs**.

Step 3 Click **Add Internal Cert**.

Step 4 Enter a **Name**.

Step 5 Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.

Step 6 Above the **Key** field, or click **Browse** to upload a DER or PEM-encoded paired private key file.

Step 7 If the uploaded private key file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.

Step 8 Click **Save**.

Certificate Enrollment Objects

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. These activities occur in your Private Key Infrastructure (PKI).

The certificate enrollment object may also includes certificate revocation information. For more information on PKI, digital certificates, and certificate enrollment see PKI Infrastructure and Digital Certificates , on page 979.

How to Use Certificate Enrollment Objects

Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections by doing the following:

1. Define parameters for CA authentication and enrollment in a Certificate Enrollment Object. Specify shared parameters and use the override facility to specify unique object setting for different devices.
2. Associate and install this object on each managed device that requires the identity certificate. On the device, it becomes a *trustpoint*.

   When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed, SCEP, EST, and PKCS12 file enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.
3. Specify the created trustpoint in your VPN configuration.

Managing Certificate Enrollment Objects

To manage certificate enrollment objects, go to **Objects > Object Management**, then from the navigation pane choose **PKI > Cert Enrollment**. The following information is shown:

- Existing certificate enrollment objects are listed in the **Name** column.

  Use the search field (the magnifying glass) to filter the list.
- The enrollment type of each object is shown in the **Type** column. The following enrollment methods can be used:
  - **Self Signed**—The managed device generates its own self signed root certificate.
  - **EST**—Enrollment over Secure Transport is used by the device to obtain an identity certificate from the CA.
  - **SCEP**—(Default) Simple Certificate Enrollment Protocol is used by the device to obtain an identity certificate from the CA.
  - **Manual**—The process of enrolling is carried out manually by the administrator.
  - **PKCS12 File**—Import a PKCS12 file on a FTD managed device that supports VPN connectivity. A PKCS#12, or PFX or P12 file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. Enter the **Passphrase** value for decryption.

- The **Override** column indicates whether the object allows overrides (a green check mark) or not (a red X). If a number is displayed, it is the number of overrides in place.

  Use the Override option to customize the object settings for each device that is part of the VPN configuration. Overriding makes each device's trustpoint details unique. Typically the Common Name or Subject is overridden for each device in the VPN configuration.

  See Object Overrides, on page 848 for details and procedures on overriding objects of any type.

- **Edit** a previously created certificate enrollment object by clicking on the edit icon (a pencil). Editing can only be done if the enrollment object is not associated with any managed devices. Refer to the adding instructions for editing a certificate enrollment object. Failed enrollment objects can be edited.
- **Delete** a previously created certificate enrollment object by clicking on the delete icon (a trash can). You cannot delete a certificate enrollment object if it is associated with any managed device.

Press ( )**Add Cert Enrollment** to open the **Add Cert Enrollment** dialog and configure a Certificate Enrollment Object, see Adding Certificate Enrollment Objects, on page 891. Then install the certificate on each managed, headend device.

Installing a Certificate Using Manual Enrollment, on page 967
Installing a Certificate Using a PKCS12 File, on page 968

Adding Certificate Enrollment Objects

You can use these objects with FTD devices. You must have Admin or Network Admin privileges to do this task.

Procedure

Step 1 Open the **Add Cert Enrollment** dialog:

- Directly from Object Management: In the **Objects > Object Management** screen, choose **PKI > Cert Enrollment** from the navigation pane, and press **Add Cert Enrollment**.
- While configuring a managed device: In the **Devices > Certificates** screen, choose **Add > Add New Certificate** and click ( ) for the **Certificate Enrollment** field.

Step 2 Enter the **Name**, and optionally, a **Description** of this enrollment object.

When enrollment is complete, this name is the name of the trustpoint on the managed devices with which it is associated.

Step 3 Open the **CA Information** tab and choose the **Enrollment Type**.

- **Self-Signed Certificate**—The managed device, acting as a CA, generates its own self-signed root certificate. No other information is needed in this pane.

  Note

When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.

- **EST**—Enrollment over Secure Transport protocol. Specify the EST information. See Certificate Enrollment Object EST Options, on page 893.
- **SCEP**—(Default) Simple Certificate Enrollment Protocol. Specify the SCEP information. See Certificate Enrollment Object SCEP Options, on page 893.
- **Manual**
  - **CA Only**—Check this check box to create only the CA certificate from the selected CA. An identity certificate will not be created for this certificate.

    If you do not select this check box, a CA certificate is not mandatory. You can generate the CSR without having a CA certificate and obtain the identity certificate.
  - **CA Certificate**—Paste the CA certificate in the PEM format in the box. You can also obtain a CA certificate by copying it from another device.

    You can leave this box empty if you choose to generate a CSR without the CA certificate.
- **PKCS12 File**—Import a PKCS12 file on a FTD managed device that supports VPN connectivity. A PKCS#12, or PFX, file holds a server certificate, intermediate certificates, and a private key in one encrypted file. Enter the **Passphrase** value for decryption.
- **Skip Check for CA flag in basic constraints of the CA Certificate**—Check this check box if you want to skip checking the basic constraints extension and the CA flag in a trustpoint certificate.

Step 4 (Optional) Open the **Certificate Parameters** tab and specify the certificate contents. See Certificate Enrollment Object Certificate Parameters, on page 894.

This information is placed in the certificate and is readable by any party who receives the certificate from the router.

Step 5 (Optional) Open the **Key** tab and specify the Key information. See Certificate Enrollment Object Key Options, on page 895.

Step 6 (Optional) Click the **Revocation** tab, and specify the revocation options: See Certificate Enrollment Object Revocation Options, on page 897.

Step 7 **Allow Overrides** of this object if desired.

Whenever you modify the PKCS12 certificate enrollment object to permit overrides, you must update the **Passphrase** for the certificate on the device where it is overridden.

See Object Overrides, on page 848 for a full description of object overrides.

Step 8 Click **Save**.

What to do next

Associate and install the enrollment object on a device to create a trustpoint on that device.

Certificate Enrollment Object EST Options

Firepower Management Center Navigation Path

Objects > **Object Management**, then from the navigation pane choose **PKI** > **Cert Enrollment**. Click (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **CA Information** tab.

Fields

Enrollment Type—set to **EST**.

Note

- EST enrollment type does not support EdDSA key.
- EST's ability to auto-enroll a device when its certificate expires is not supported.

Enrollment URL—The URL of the CA server to which devices should attempt to enroll.

Use an HTTPS URL in the form of **https://CA_name:port**, where *CA_name* is the host DNS name or IP address of the CA server. The *port* number is mandatory.

Username—The username to access the CA server.

Password / Confirm Password—The password to access the CA server.

Fingerprint—When retrieving the CA certificate using EST, you may enter the fingerprint for the CA server. Using the fingerprint to verify the authenticity of the CA server's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one. Enter the **Fingerprint** for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. Obtain the CA's fingerprint by contacting the server directly.

Source Interface—The interface that interacts with the CA server. By default, the diagnostic interface is displayed. To configure a data interface as the source interface, choose the respective security zone or interface group object.

Ignore EST Server Certificate Validations—The EST server certificate validation is done by default. Check the check box if you want to ignore FTD validating EST server certificate.

Certificate Enrollment Object SCEP Options

Firepower Management Center Navigation Path

Objects > Object Management, then from the navigation pane choose **PKI > Cert Enrollment**. Click (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **CA Information** tab.

Fields

Enrollment Type—set to **SCEP**.

Enrollment URL—The URL of the CA server to which devices should attempt to enroll.

Use an HTTP URL in the form of **`http://CA_name:port,`** where CA_name is the host DNS name or IP address of the CA server. The port number is mandatory.

Note If the SCEP Server is referred with hostname/FQDN, configure DNS Server using FlexConfig object.

If the CA cgi-bin script location at the CA is not the default (/cgi-bin/pkiclient.exe), you must also include the nonstandard script location in the URL, in the form of http://CA_name:port/script_location, where script_location is the full path to the CA scripts.

Challenge Password / Confirm Password—The password used by the CA server to validate the identity of the device. You can obtain the password by contacting the CA server directly or by entering the following address in a web browser: **`http://URLHostName/certsrv/mscep/mscep.dll`**. The password is good for 60 minutes from the time you obtain it from the CA server. Therefore, it is important that you deploy the password as soon as possible after you create it.

Retry Period—The interval between certificate request attempts, in minutes. Value can be 1 to 60 minutes. The default is 1 minute.

Retry Count—The number of retries that should be made if no certificate is issued upon the first request. Value can be 1 to 100. The default is 10.

CA Certificate Source—Specify how the CA certificate will be obtained.

- **Retrieve Using SCEP** (Default, and only supported option)—Retrieve the certificate from the CA server using the Simple Certificate Enrollment Process (SCEP). Using SCEP requires a connection between your device and the CA server. Ensure there is a route from your device to the CA server before beginning the enrollment process.

Fingerprint—When retrieving the CA certificate using SCEP, you may enter the fingerprint for the CA server. Using the fingerprint to verify the authenticity of the CA server's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one. Enter the **Fingerprint** for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. Obtain the CA's fingerprint by contacting the server directly, or by entering the following address in a web browser: **`http://<URLHostName>/certsrv/mscep/mscep.dll`**.

Certificate Enrollment Object Certificate Parameters

Specify additional information in certificate requests sent to the CA server. This information is placed in the certificate and can be viewed by any party who receives the certificate from the router.

Firepower Management Center Navigation Path

Objects > Object Management, then from the navigation pane choose **PKI > Cert Enrollment**. Press (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Certificate Parameters** tab.

Fields

Enter all information using the standard LDAP X.500 format.

- **Include FQDN**—Whether to include the device's fully qualified domain name (FQDN) in the certificate request. Choices are:
  - **Use Device Hostname as FQDN**

- **Don't use FQDN in certificate**
- **Custom FQDN**—Select this and then specify it in the **Custom FQDN** field that displays.

- **Include Device's IP Address**—The interface whose IP address is included in the certificate request.
- **Common Name (CN)**—The X.500 common name to include in the certificate.

Note When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.

- **Organization Unit (OU)**—The name of the organization unit (for example, a department name) to include in the certificate.
- **Organization (O)**—The organization or company name to include in the certificate.
- **Locality (L)**—The locality to include in the certificate.
- **State (ST)**—The state or province to include in the certificate.
- **County Code (C)**—The country to include in the certificate. These codes conform to ISO 3166 country abbreviations, for example "US" for the United States of America.
- **Email (E)**—The email address to include in the certificate.
- **Include Device's Serial Number**—Whether to include the serial number of the device in the certificate. The CA uses the serial number to either authenticate certificates or to later associate a certificate with a particular device. If you are in doubt, include the serial number, as it is useful for debugging purposes.

Certificate Enrollment Object Key Options

Firepower Management Center Navigation Path

Objects > Object Management, then from the navigation pane choose **PKI > Cert Enrollment**. Press (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Key** tab.

Fields

- **Key Type**—RSA, ECDSA, EdDSA.

Note
- For EST enrollment type, do not select EdDSA key as it is not supported.
- EdDSA is supported only in Site-to-Site VPN topologies.
- EdDSA is not supported as an identity certificate for the Remote Access VPN.

- **Key Name**—If the key pair you want to associate with the certificate already exists, this field specifies the name of that key pair. If the key pair does not exist, this field specifies the name to assign to the key

pair that will be generated during enrollment. If you do not specify a name, the fully qualified domain name (FQDN) key pair is used instead.

- **Key Size**—If the key pair does not exist, defines the desired key size (modulus), in bits. The recommended size is 2048 bits. The larger the modulus size, the more secure the key. However, keys with larger modulus sizes take longer to generate (a minute or more when larger than 512 bits) and longer to process when exchanged.

Important

- On FMC and FTD Versions 7.0 and higher, you cannot enroll certificates with RSA key sizes smaller than 2048 bits and keys using SHA-1 with the RSA Encryption algorithm. However, you can use PKI Enrollment of Certificates with Weak-Crypto to allow certificates that use SHA-1 with RSA Encryption algorithm and smaller key size.
- You cannot generate RSA keys with sizes smaller than 2048 bits for FTD 7.0, even when you enable the weak-crypto option.

- **Advanced Settings**—Select **Ignore IPsec Key Usage** if you do not want to validate values in the key usage and extended key usage extensions of IPsec remote client certificates. You can suppress key usage checking on IPsec client certificates. By default this option is not enabled.

Note For site-to-site VPN connection, if you use a Windows Certificate Authority (CA), the default Application Policies extension is **IP security IKE intermediate**. If you are using this default setting, you must select the **Ignore IPsec Key Usage** option for the object you select. Otherwise, the endpoints cannot complete the site-to-site VPN connection.

PKI Enrollment of Certificates with Weak-Crypto

SHA-1 hashing signature algorithm, and RSA key sizes that are smaller than 2048 bits for certification are not supported on FMC and FTD Version 7.0 and higher. You cannot enroll certificates with RSA key sizes that are smaller than 2048 bits.

To override these restrictions on FMC 7.0 managing FTDs running Versions lesser than 7.0, you can use the enable weak-crypto option on the FTD. We do not recommend you to permit weak-crypto keys, because, such keys are not as secure as the ones with higher key sizes.

Note FTD 7.0 or higher does not support generating RSA keys with sizes smaller than 2048 bits even when you permit weak-crypto.

To enable weak-crypto on the device, navigate to the **Devices > Certificates** page. Click the **Enable Weak-Crypto**( ) button provided against the FTD device. When the weak-crypto option is enabled, the button changes to . By default, the weak-crypto option is disabled.

Note When a certificate enrollment fails due to weak cipher usage, the FMC displays a warning message prompting you to enable the weak-crypto option. Similarly, when you turn on the enable weak-crypto button, the FMC displays a warning message before enabling weak-crypto configuration on the device.

Upgrading Earlier Versions to FTD 7.0

When you are upgrading to FTD 7.0, the existing certificate configurations are retained. However, if those certificates have RSA keys smaller than 2048 bits and use SHA-1 encryption algorithm, they cannot be used to establish VPN connections. You must either procure a certificate with RSA key sizes bigger than 2048 bits or enable the permit weak-crypto option for VPN connections.

Certificate Enrollment Object Revocation Options

Specify whether to check the revocation status of a certificate by choosing and configuring the method. Revocation checking is off by default, neither method (CRL or OCSP) is checked.

Firepower Management Center Navigation Path

Objects > Object Management, then from the navigation pane choose **PKI > Cert Enrollment**. Press (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Revocation** tab.

Fields

- **Enable Certificate Revocation Lists**—Check to enable CRL checking.
  - **Use CRL distribution point from the certificate**—Check to obtain the revocation lists distribution URL from the certificate.
  - **Use static URL configured**—Check this to add a static, pre-defined distribution URL for revocation lists. Then add the URLs.

    CRL Server URLs—The URL of the LDAP server from which the CRL can be downloaded.

    URLs must start with **`http://`**. Include a port number in the URL.

- **Enable Online Certificate Status Protocol (OCSP)**—Check to enable OCSP checking.

  OCSP Server URL—The URL of the OCSP server checking for revocation if you require OCSP checks.

  URLs must start with **`http://`**.

- **Consider the certificate valid if revocation information cannot be reached**—Checked by default. Uncheck if you do not want to allow this.

Policy List

Use the Configure Policy List page to create, copy, and edit policy list policy objects. You can create policy list objects to use when you are configuring route maps. When a policy list is referenced within a route map, all of the match statements within the policy list are evaluated and processed. Two or more policy lists can be configured with a route map. A policy list can also coexist with any other preexisting match and set

statements that are configured within the same route map but outside of the policy list. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.

You can use this object with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Policy List** from the table of contents.

Step 2 Click **Add Policy List**.

Step 3 Enter a name for the policy list object in the **Name** field. Object names are not case-sensitive.

Step 4 Select whether to allow or block access for matching conditions from the **Action** drop-down list.

Step 5 Click the **Interface** tab to distribute routes that have their next hop out of one of the interfaces specified.

In the **Zones/Interfaces** list, add the zones that contain the interfaces through which the device communicates with the management station. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. The host will be configured on a device only if the device includes the selected interfaces or zones.

Step 6 Click the **Address** tab to redistribute any routes that have a destination address that is permitted by a standard access list or prefix list.

Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.

Step 7 Click the **Next Hop** tab to redistribute any routes that have a next hop router address passed by one of the access lists or prefix lists specified.

Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.

Step 8 Click the **Route Source** tab to redistribute routes that have been advertised by routers and access servers at the address specified by the access lists or prefix list.

Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.

Step 9 Click the **AS Path** tab to match a BGP autonomous system path. If you specify more than one AS path, then the route can match either AS path.

Step 10 Click the **Community Rule** tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively. If you specify more than one rule, the routes are verified against the rules until a matching permit or deny is met.

a) To specify a community list to the rule, click **Edit** ( ) given in the **Selected Community List** field. The community lists appear under **Available Community List**. Select the required list, click **Add**, and then click **Ok**.

To enable matching the BGP community exactly with the specified community, check the **Match the specified community exactly** check box.

b) To add the extended community list, click **Edit** ( ) given in the **Selected Extended Community List** field. The extended community lists appear under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**.

Note
The extended community lists are applicable only for configuring import or export of routes.

Step 11 Click the **Metric & tag** tab to match the metric and security group tag of a route.

a) Enter the metric values to use for matching in the **Metric** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.

b) Enter the tag values to use for matching in the **Tag** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

Step 12 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 13 Click **Save**.

Port

Port objects represent different protocols in slightly different ways:

TCP and UDP

A port object represents the transport layer protocol, with the protocol number in parentheses, plus an optional associated port or port range. For example: `TCP(6)/22`.

ICMP and ICMPv6 (IPv6-ICMP)

A port object represents the Internet layer protocol plus an optional type and code. For example: `ICMP(1):3:3`.

You can restrict an ICMP or IPV6-ICMP port object by type and, if applicable, code. For more information on ICMP types and codes, see:

- http://www.iana.org/assignments/icmp-parameters/icmp-parameters.xml
- http://www.iana.org/assignments/icmpv6-parameters/icmpv6-parameters.xml

Other

A port object can represent other protocols that do not use ports.

The system provides default port objects for well-known ports. You cannot modify or delete these default objects. You can create custom port objects in addition to the default objects.

You can use port objects and groups in various places in the system's web interface, including access control policies, identity rules, network discovery rules, port variables, and event searches. For example, if your organization uses a custom client that uses a specific range of ports and causes the system to generate excessive and misleading events, you can configure your network discovery policy to exclude monitoring those ports.

When using port objects, observe the following guidelines:

- You cannot add any protocol other than TCP or UDP for source port conditions in access control rules. Also, you cannot mix transport protocols when setting both source and destination port conditions in a rule.

- If you add an unsupported protocol to a port object group used in a source port condition, the rule where it is used does not take affect on the managed device when the configuration is deployed.
- If you create a port object containing both TCP and UDP ports, then add it as a source port condition in a rule, you cannot add a destination port, and vice versa.

Creating Port Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Port** from the list of object types.

Step 3 Choose **Add Object** from the **Add Port** drop-down list.

Step 4 Enter a **Name**.

Step 5 Choose a **Protocol**.

Step 6 Depending on the protocol you chose, constrain by **Port**, or choose an ICMP **Type** and **Code**.

You can enter ports from `1` to `65535`. Use a hyphen to specify a port range. You must constrain the object by port if you chose to match **All** protocols, using the **Other** drop-down list.

Step 7 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.
- If you want to add override values to this object, expand the Override section and click **Add**; see Adding Object Overrides, on page 850.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Importing Port Objects

For details on importing port objects, see Importing Objects, on page 842.

Prefix List

You can create prefix list objects for IPv4 and IPv6 to use when you are configuring route maps, policy maps, OSPF Filtering, or BGP Neighbor Filtering.

Configure IPv6 Prefix List

Use the Configure IPv6 Prefix list page to create, copy and edit prefix list objects. You can create prefix list objects to use when you are configuring route maps, policy maps, OSPF Filtering, or BGP Neighbor Filtering.

You can use this object with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Prefix Lists** > **IPv6 Prefix List** from the table of contents.

Step 2 Click **Add Prefix List**.

Step 3 Enter a name for the prefix list object in the **Name** field on the **New Prefix List Object** window.

Step 4 Click **Add** on the **New Prefix List Object** window.

Step 5 Select the appropriate action, Allow or Block from the **Action** drop-down list, to indicate the redistribution access.

Step 6 Enter a unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object, in the **Sequence No.** field. If left blank, the sequence number will default to five more than the largest sequence number currently in use.

Step 7 Specify the IPv6 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1-128.

Step 8 Enter the minimum prefix length in the **Minimum Prefix Length** field. The value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.

Step 9 Enter the maximum prefix length in the **Maximum Prefix Length** field. The value must be greater than or equal to the Minimum Prefix Length, if present, or greater than the mask length if the Minimum Prefix Length is not specified.

Step 10 Click **Add**.

Step 11 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 12 Click **Save**.

Configure IPv4 Prefix List

Use the Configure IPv4 Prefix list page to create, copy and edit prefix list objects. You can create prefix list objects to use when you are configuring route maps, policy maps, OSPF Filtering, or BGP Neighbor Filtering.

You can use this object with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Prefix Lists** > **IPv4 Prefix List** from the table of contents.

Step 2 Click **Add Prefix List**.

Step 3 Enter a name for the prefix list object in the **Name** field on the **New Prefix List Object** window.

Step 4 Click **Add**.

Step 5 Select the appropriate action, Allow or Block from the **Action** drop-down list, to indicate the redistribution access.

Step 6 Enter a unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object, in the **Sequence No.** field. If left blank, the sequence number will default to five more than the largest sequence number currently in use.

Step 7 Specify the IPv4 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1- 32.

Step 8 Enter the minimum prefix length in the **Minimum Prefix Length** field. The value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.

Step 9 Enter the maximum prefix length in the **Maximum Prefix Length** field. The value must be greater than or equal to the Minimum Prefix Length, if present, or greater than the mask length if the Minimum Prefix Length is not specified.

Step 10 Click **Add**.

Step 11 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 12 Click **Save**.

Route Map

Route maps are used when redistributing routes into any routing process. They are also used when generating a default route into routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process. Configure a route map, to create a new route map entry for a Route Map object or to edit an existing one.

You can use this object with FTD devices.

Before you begin

A Route Map may use one or mores of these objects; it is not mandatory to add all these objects. Create and use any of these objects as required, to configure your route map.

- Add ACLs.
- Add Prefix Lists.
- Add AS Path.
- Add Community Lists.
- Add Extended Community Lists.

Note The extended community lists are applicable only for configuring import or export of routes.

- Add Policy Lists.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **Route Map** from the table of contents.

Step 2 Click **Add Route Map**.

Step 3 Click **Add** on the **New Route Map Object** window.

Step 4 In the **Sequence No.** field, enter a number, from 0 through 65535, that indicates the position a new route map entry has in the list of route maps entries already configured for this route map object.

Note
We recommend that you number clauses in intervals of at least 10 to reserve numbering space in case you want to insert clauses in the future.

Step 5 Select the appropriate action, Allow or Block, from the **Redistribution** drop-down list, to indicate the redistribution access.

Step 6 Click the **Match Clauses** tab to match (routes/traffic) based on the following criteria, which you select in the table of contents:

- **Security Zones** —Match traffic based on the (ingress/egress) interfaces. You can select zones and add them, or type in interface names and add them.
- **IPv4** — Match IPv4 (routes/traffic) based on the following criteria; select the tab to define the criteria.
  - **a.** Click the **Address** tab to match routes based on the route address. For IPv4 addresses, choose whether to use an Access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  - **b.** Click the **Next Hop** tab to match routes based on the next hop address of a route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  - **c.** Click the **Route Source** tab to match routes based on the advertising source address of the route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
- **IPv6** —Match IPv6 (routes/traffic) based on the route address, next-hop address or advertising source address of route.
- **BGP** —Match BGP (routes/traffic) based on the following criteria; select the tab to define the criteria.
  - **a.** Click the **AS Path** tab to enable matching the BGP autonomous system path access list with the specified path access list. If you specify more than one path access list, then the route can match either path access list.
  - **b.** Click the **Community List** tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively.
    - To specify a community list to the rule, click **Edit** ( ) given in the **Selected Community List** field. The community lists appears under **Available Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create community list objects, see Community List, on page 861

- To add the extended community list, click **Edit** ( ) given in the **Selected Extended Community List** field. The extended community lists appears under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create extended community list objects, see Extended Community, on page 862.

To enable matching the BGP community exactly with the specified community list objects, check the **Match the specified community exactly** check box. This option is not applicable for the extended community list.

Note
If you specify more than one rule, the routes are verified against the rules until a matching permit or deny condition is met. Any route that does not match at least one Match community will not be advertised for outbound route maps.

c. Click the **Policy List** tab to configure a route map to evaluate and process a BGP policy. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.

- **Others** —Match routes or traffic based on the following criteria.

a. Enter the metric values to use for matching in the **Metric Route Value** field, to enable matching the metric of a route. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.

b. Enter the tag values to use for matching in the **Tag Values** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

c. Check the appropriate **Route Type** option to enable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. You can choose more than one route type from the list.

Step 7 Click the **Set Clauses** tab to set routes/traffic based on the following criteria, which you select in the table of contents:

- **Metric Values**—Set either Bandwidth, all of the values or none of the values.

a. Enter a metric value or bandwidth in Kbits per second in the **Bandwidth** field. Valid values are an integer value in the range from 0 to 4294967295.

b. Select to specify the type of metric for the destination routing protocol, from the **Metric Type** drop-down list. Valid values are : internal, type-1, or type-2.

- **BGP Clauses** —Set BGP routes based on the following criteria; select the tab to define the criteria.

a. Click the **AS Path** tab to modify an autonomous system path for BGP routes.

1. Enter an AS path number in the **Prepend AS Path** field to prepend an arbitrary autonomous system path string to BGP routes. Usually the local AS number is prepended multiple times, increasing the autonomous system path length. If you specify more than one AS path number then the route can prepend either AS number.

2. Enter an AS path number in the **Prepend Last AS to AS Path** field to prepend the AS path with the last AS number. Enter a value for the AS number from 1 to 10.

3. Check the **Convert route tag into AS path** check box to convert the tag of a route into an autonomous system path.

b. Click the **Community List** tab to set the community attributes:

Under **Specific Community**:

1. Click the **None** radio button, to remove the community attribute from the prefixes that pass the route map.
2. Click the **Specific Community** radio button, to enter a community number, if applicable. Valid values are from 1 to 4294967295.
3. Check the **Add to existing communities** check box, to add the community to the already existing communities.
4. Select the **Internet**, **No-Advertise**, or **No-Export** check-boxes to use one of the well-known communities.

Under **Specific Extended Community**, in the **Route Target** field, enter the route target number in *ASN:nn* format:

- You can enter values that ranges from 1:1 to 65534:65535.

  You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.

- You can have a maximum of 8 route targets in an entry.
- You cannot have redundant route target entries across route maps.

c. Click the **Others** tab to set additional attributes.

1. Check the **Set Automatic Tag** check-box to automatically compute the tag value.
2. Enter a preference value for the autonomous system path in the **Set Local Preference** field. Enter a value between 0 and 4294967295.
3. Enter a BGP weight for the routing table in the **Set Weight** field. Enter a value between 0 and 65535.
4. Select to specify the BGP origin code. Valid values are **Local IGP** Local IGP and **Incomplete**.
5. In the IPv4 Settings section, specify a next hop IPv4 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv4 address then the packets can output at either IP address.

   Select to specify an IPv4 prefix list in the **Prefix List** drop-down list.
6. In the IPv6 Settings section, specify a next hop IPv6 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv6 address, then the packets can output at any of the IP addresses.

   Select to specify an IPv6 prefix in the **Prefix List** drop-down list.

Step 8 Click **Add**.

Step 9 If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.

Step 10 Click **Save**.

Security Intelligence

Security Intelligence functionality requires the Threat license (for FTD devices) or the Protection license (all other device types).

Security Intelligence *lists* and *feeds* are collections of IP addresses, domain names, and URLs that you can use to quickly filter traffic that matches an entry on a list or feed.

- A list is a static collection that you manage manually.
- A feed is a dynamic collection that updates on an interval over HTTP or HTTPS.

Security Intelligence lists/feeds are grouped into:

- DNS (Domain names)
- Network (IP addresses)
- URLs

System-Provided Feeds

Cisco provides the following feeds as Security Intelligence objects:

- Security Intelligence feeds updated regularly with the latest threat intelligence from Talos:
  - Cisco-DNS-and-URL-Intelligence-Feed (under DNS Lists and Feeds)
  - Cisco-Intelligence-Feed (for IP addresses, under Network Lists and Feeds)

  You cannot delete the system-provided feeds, but you can change the frequency of (or disable) their updates.
- Cisco-TID-Feed (under Network Lists and Feeds)

  This feed is not used in the Security Intelligence tab of the access control policy.

  Instead, you must enable and configure Threat Intelligence Director to use this feed, which is a collection of TID observables data.

  Use this object to set how frequently this data is published to TID elements.

  For more information, see Threat Intelligence Director, on page 2109.

Predefined Lists: Global Block Lists and Global Do Not Block Lists

The system ships with predefined global Block lists and Do Not Block lists for domains (DNS), IP addresses (Networks), and URLs.

These lists are empty until you populate them. To build these lists, see Global and Domain Security Intelligence Lists, on page 908.

By default, access control and DNS policies use these lists as part of Security Intelligence.

Custom Feeds

You can use third-party feeds, or use a custom internal feed to easily maintain an enterprise-wide Block list in a large deployment with multiple Firepower Management Center appliances.

See Custom Security Intelligence Feeds, on page 913.

Custom Lists

Custom lists can augment and fine-tune feeds and the Global lists.

See Custom Security Intelligence Lists, on page 915.

Where Security Intelligence Lists and Feeds Are Used

- IP address and address blocks—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence.
- Domain Names—Use Block and Do Not Block lists in DNS policies, as part of Security Intelligence.
- URLs—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence. You can also use URL lists in access control and QoS rules, whose analysis and traffic handling phases occur after Security Intelligence.

How to Modify Security Intelligence Objects

To add or delete entries on a Block list, Do Not Block list, feed, or sinkhole object:

Object Type	Edit Capabilities	Requires Redeploy After Edit?
Custom Block and Do Not Block lists	Upload new and replacement lists using the object manager.	No
Default (but custom-populated) Block lists and Do Not Block lists: Global, descendant, and domain-specific	Add entries using the context menu or delete entries using the object manager.	No
System-provided Intelligence Feeds	Disable or change update frequency using the object manager.	No
Custom feeds	Fully modify using the object manager.	No
Sinkhole	Fully modify using the object manager.	Yes

Global and Domain Security Intelligence Lists

The FMC includes Global Block and Do-Not-Block lists, which enable you to use Security Intelligence to consistently block specific connections or exempt certain connections from being blocked, allowing them to be evaluated by other threat detection processes you have configured.

For example, if you notice a set of routable IP addresses in intrusion events associated with exploit attempts, you can immediately block those IP addresses. Although it may take a few minutes for your changes to propagate, you do not have to redeploy.

By default, Access control and DNS policies use these Global lists, which apply to all security zones. You can opt not to use these lists on a per-policy basis.

Note These options apply to Security Intelligence only. Security Intelligence cannot block traffic that has already been fastpathed. Similarly, adding an item to a Security Intelligence Do Not Block list does not automatically trust or fastpath matching traffic. For more information, see About Security Intelligence, on page 1239.

Security Intelligence Lists and Multitenancy

Multitenancy adds:

- Domain lists—Block or Do Not Block lists whose contents apply to a particular subdomain only. The Global lists are Domain lists for the Global domain.
- Descendant Domain lists—Block or Do Not Block lists that aggregate the Domain lists of the current domain's descendants.

Domain Lists

In addition to being able to access (but not edit) the Global lists, each subdomain has its own named lists, the contents of which apply only to that subdomain. For example, a subdomain named Company A owns:

- Domain Block list - Company A and Domain Do Not Block list - Company A
- Domain Block list for DNS - Company A, Domain Do Not Block list for DNS - Company A
- Domain Block list for URL - Company A, Domain Do Not Block list for URL - Company A

Any administrator at or above the current domain can populate these lists. You can use the context menu to add an item to the Block or Do Not Block list in the current and all descendant domains. However, only an administrator in the associated domain can remove an item from a Domain list.

For example, a Global administrator could choose to add the same IP address to the Block list in the Global domain and Company A's domain, but not add it to the Block list in Company B's domain. This action would add the same IP address to:

- Global Block list (where it can be removed only by Global administrators)
- Domain Block list - Company A (where it can be removed only by Company A administrators)

Descendant Domain Lists

A Descendant Domain list is a Do Not Block list or Block list that aggregates the Domain lists of the current domain's descendants. Leaf domains do not have Descendant Domain lists.

Descendant Domain lists are useful because a higher-level domain administrator can enforce general Security Intelligence settings, while still allowing subdomain users to add items to a Block or Do Not Block list in their own deployment.

For example, the Global domain has the following Descendant Domain lists:

- Descendant Block lists - Global, Descendant Do Not Block lists - Global
- Descendant Block lists for DNS - Global, Descendant Do Not Block lists for DNS - Global
- Descendant Block lists for URL - Global, Descendant Do Not Block lists for URL - Global

Note Descendant Domain lists do not appear in the object manager because they are symbolic aggregations, not hand-populated lists. They appear where you can use them: in access control and DNS policies.

Add Entries to Global Security Intelligence Lists

When reviewing events and dashboards, you can instantly block future traffic involving IP addresses, domains, and URLs that appear in those events by adding them to a predefined Block list.

Similarly, if Security Intelligence is blocking traffic that you want evaluated by threat detection processes subsequent to Security Intelligence blocking, you can add IP addresses, domains, and URLs from events to a predefined Do Not Block list.

Traffic is evaluated against entries on these lists during the Security Intelligence phase of threat detection.

For more information about these lists, see Global and Domain Security Intelligence Lists, on page 908.

Before you begin

Because adding an entry to a Security Intelligence list affects access control, you must have one of the following user roles:

- Administrator
- A combination of roles: Network Admin or Access Admin, plus Security Analyst and Security Approver
- A custom role with both Modify Access Control Policy and Deploy Configuration to Devices permissions

If appropriate, verify that these lists are used in the policies in which you expect them to be used.

Procedure

Step 1 Navigate to an event that includes an IP address, domain, or URL that you want to always block using Security Intelligence, or exempt from Security Intelligence blocking.

Step 2 Right-click the IP address, domain, or URL and choose the appropriate option:

Item Type	Context Menu Option
IP address	Add IP to Block List Add IP to Do-Not-Block List These options add the IP address to the respective lists for Networks.
URL	Add URL to Global Block List for URL Add URL to Global Do-Not-Block List for URL
Domain of a URL in the URL field	Add Domain to Global Block List for URL Add Domain to Global Do-Not-Block List for URL
Domain in the DNS Query field	Add Domain to Global Block List for DNS Add Domain to Global Do-Not-Block List for DNS

What to do next

You do NOT need to redeploy for these changes to take effect.

If you want to delete an item from a list, see Delete Entries from Global Security Intelligence Lists, on page 910.

Delete Entries from Global Security Intelligence Lists

Note To add entries to these lists, see Add Entries to Global Security Intelligence Lists, on page 909.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Click **Security Intelligence**.

Step 3 Click the appropriate option:

- **Network Lists and Feeds** (for IP addresses)
- **DNS Lists and Feeds** (for domain names)
- **URL Lists and Feeds**

Step 4 Click the pencil beside the Global Block or Global Do-Not-Block list.

Step 5 Click the trash button beside the entry to delete.

List and Feed Updates for Security Intelligence

List and feed updates replace the existing list or feed file with the contents of the new file. Contents of existing and new files are not merged.

If the system downloads a corrupt feed or a feed with no recognizable entries, the system continues using the old feed data (unless it is the first download). However, if the system can recognize even one entry in the feed, it uses the entries it can recognize.

By default, each feed updates the Management Center every two hours; you can modify this frequency. Any updates the Management Center receives are passed immediately to managed devices. In addition, managed devices poll the FMC every 30 minutes for changes. You cannot modify this frequency.

To modify feed update intervals, see Changing the Update Frequency for Security Intelligence Feeds, on page 911.

Changing the Update Frequency for Security Intelligence Feeds

You can specify the intervals at which the FMC updates Security Intelligence Feeds.

For details about feed updates, see List and Feed Updates for Security Intelligence, on page 911.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Security Intelligence** node, then choose the feed type whose frequency you want to change.

The system-provided URL feed is combined with the domain feed under **DNS Lists and Feeds**.

Step 3 Next to the feed you want to update, click **Edit** ( ).

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 4 Edit the **Update Frequency**.

Step 5 Click **Save**.

Custom Security Intelligence Lists and Feeds

Custom Lists and Feeds: Requirements

List and Feed Formatting

Each list or feed must be a simple text file no larger than 500MB. List files must have the .txt extension. Include one entry or comment per line: one IP address, one URL, one domain name.

Tip The number of entries you can include is limited by the maximum size of the file. For example, a URL list with no comments and an average URL length of 100 characters (including Punycode or percent Unicode representations and newlines) can contain more than 5.24 million entries.

In a DNS list entry, you can specify an asterisk (`*`) wildcard character for a domain label. All labels match the wildcard. For example, an entry of `www.example.*` matches both `www.example.com` and `www.example.co`.

If you add comment lines within the source file, they must start with the pound (`#`) character. If you upload a source file with comments, the system removes your comments during upload. Source files you download contain all your entries without your comments.

Feed Requirements

When you configure a feed, you specify its location using a URL; the URL cannot be Punycode-encoded.

For feed update intervals of 30 minutes or less, you must specify an MD5 URL. This prevents frequent downloads of unchanged feeds. If your feed server does not provide an MD5 URL, you must use a download interval of at least 30 minutes.

If you use an MD5 checksum, the checksum must be stored in a simple text file with only the checksum. Comments are not supported.

URL Lists and Feeds: URL Syntax and Matching Criteria

Security Intelligence URL lists and feeds, including custom lists and feeds and entries in the global Block list and Do Not Block list, can include the following, which have the matching behavior as described:

- Hostnames

  For example, **`www.example.com`**.

- URLs

  `example.com` matches **`example.com`** and all subdomains, including **`www.example.com`**, **`eu.example.com`**, **`example.com/abc`**, and **`www.example.com/def`** -- but NOT **`example.co.uk`** or **`examplexyz.com`** or **`example.com.malicious-site.com`**

  When a URL feed or list includes a single entry, every URL that ends with those domains is identified and blocked.

  Example: When the following URL feed —**`www.netflix.com, www.amazon.*, org, edu, www.hulu.*`** is added to the global Block List, the following contents are blocked:http://www.amazon.in, http://www.rajiv.org/, http://www.edu.edu/, http://www.edu.org/, http://org.org/ and http://edu.edu.

  You can also include an entire URL path, such as **`https://www.cisco.com/c/en/us/products/security/firewalls/index.html`**

Note You can create a custom URL, Network, and DNS feeds, wherein, you can add the username and password inside the URL itself, for example: **`https://admin:password@server.domain.com/list.txt`**

However, if your password contain special characters such as a colon (:) or an at sign (@), the transmission would fail. Ensure that your password does not have any special characters. Alternatively, you could use an encoded password in the URL.

- A slash at the end of a URL to specify an exact match

  `example.com/` matches ONLY **`example.com`**; it does NOT match **`www.example.com`** or any other URL.

- A wildcard (*) to represent any domain in a URL

  An asterisk can represent a complete domain string separated by dots, but not a partial domain string, and not any part of the URL following the first slash.

  Valid examples:

  - **`*.example.com`**
  - **`www.*.com`**
  - **`example.*`**

    (This will match **`example.com`** and **`example.org`** and **`example.de`**, for example, but NOT **`example.co.uk`**)
  - **`*.example.*`**
  - **`example.*/`**

  Invalid examples:

  - **`example*.com`**
  - **`example.com/*`**

- IP addresses (IPv4)

  For IPv6 addresses, or to use ranges or CIDR notation, use the Security Intelligence Network object.

  You can include one or more wildcards representing an octet, for example 10.10.10.* or 10.10.*.*.

See also Custom Security Intelligence Lists, on page 915.

Custom Security Intelligence Feeds

Custom or third-party Security Intelligence feeds allow you to augment the system-provided Intelligence Feeds with other regularly-updated reputable Block lists and Do Not Block lists on the Internet. You can also set up an internal feed, which is useful if you want to update multiple Firepower Management Center appliances in your deployment using one source list.

Note You cannot add address blocks to Block or Do Not Block lists using a `/0` netmask in a Security Intelligence feed. If you want to monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** rule action, respectively, and a default value of `any` for the **Source Networks** and **Destination Networks**.

You also can configure the system to use an MD5 checksum to determine whether to download an updated feed. If the checksum has not changed since the last time the system downloaded the feed, the system does not need to re-download it. You may want to use MD5 checksums for internal feeds, especially if they are large.

Note The system does **not** perform peer SSL certificate verification when downloading custom feeds, nor does the system support the use of certificate bundles or self-signed certificates to verify the remote peer.

If you want strict control over when the system updates a feed from the Internet, you can disable automatic updates for that feed. However, automatic updates ensure the most up-to-date, relevant data.

Manually updating Security Intelligence feeds updates all feeds, including the Intelligence Feeds.

See complete requirements at Custom Lists and Feeds: Requirements, on page 911.

Creating Security Intelligence Feeds

You must have the Threat license (for FTD devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Security Intelligence** node, then choose a feed type you want to add.

Step 3 Click the option appropriate to the feed type you chose above:

- **Add Network Lists and Feeds** (for IP addresses)
- **Add DNS Lists and Feeds**
- **Add URL Lists and Feeds**

Step 4 Enter a **Name** for the feed.

Step 5 Choose **Feed** from the **Type** drop-down list.

Step 6 Enter a **Feed URL**.

Step 7 Enter an **MD5 URL**.

This is used to determine whether the feed contents have changed since the last update, so the system does not download unchanged feeds.

MD5 URL is required for update intervals shorter than 30 minutes.

If your feed server does not provide an MD5 URL, you must choose an interval of at least 30 minutes.

Step 8 Choose an **Update Frequency**.

Step 9 Click **Save**.
Unless you disabled feed updates, the system attempts to download and verify the feed.

Manually Updating Security Intelligence Feeds

You must have the Threat license (for FTD devices) or the Protection license (all other device types).

Before you begin

At least one device must already be added to the management center.

Procedure

Step 1 Choose **Objects** > **Object Management**.
Step 2 Expand the **Security Intelligence** node, then choose a feed type.
Step 3 Click **Update Feeds**, then confirm.
Step 4 Click **OK**.

After the Firepower Management Center downloads and verifies the feed updates, it communicates any changes to its managed devices. Your deployment begins filtering traffic using the updated feeds.

Custom Security Intelligence Lists

Security Intelligence lists are simple static lists of IP addresses and address blocks, URLs, or domain names that you manually upload to the system. Custom lists are useful if you want to augment and fine-tune feeds or one of the global lists, for a single Firepower Management Center's managed devices.

For example, if a reputable feed improperly blocks your access to vital resources but is overall useful to your organization, you can create a custom Do Not Block list that contains only the improperly classified IP addresses, rather than removing the IP address feed object from the access control policy's Block list.

Note You cannot add address blocks to a Block or Do Not Block list using a `/0` netmask in a Security Intelligence list. If you want to monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** rule action, respectively, and a default value of `any` for the **Source Networks** and **Destination Networks**.

Regarding list entry formatting, note the following:

- Netmasks for address blocks can be integers from `0` to `32` or `0` to `128`, for IPv4 and IPv6, respectively.
- Unicode in domain names must be encoded in Punycode format, and are case insensitive.
- Characters in domain names are case-insensitive.
- Unicode in URLs should be encoded in percent-encoding format.
- Characters in URL subdirectories are case-sensitive.

- List entries that start with the pound sign (`#`) are treated as comments.
- See additional formatting requirements at Custom Lists and Feeds: Requirements, on page 911.

Regarding matching list entries, note the following:

- The system matches sub-level domains if a higher-level domain exists in a URL or DNS list. For example, if you add `example.com` to a DNS list, the system matches both `www.example.com` and `test.example.com`.
- The system does not perform DNS lookups (forward or reverse) on DNS or URL list entries. For example, if you add `http://192.168.0.2` to a URL list, and it resolves to `http://www.example.com`, the system only matches `http://192.168.0.2`, not `http://www.example.com`.

Uploading New Security Intelligence Lists to the Firepower Management Center

To modify a Security Intelligence list, you must make your changes to the source file and upload a new copy. You cannot modify the file's contents using the web interface. If you do not have access to the source file, download a copy from the system.

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Security Intelligence** node, then choose a list type.

Step 3 Click the option appropriate to the list you chose above:

- **Add Network Lists and Feeds** (for IP addresses)
- **Add DNS Lists and Feeds**
- **Add URL Lists and Feeds**

Step 4 Enter a **Name**.

Step 5 From the **Type** drop-down list, choose **List**.

Step 6 Click **Browse** to browse to the list `.txt` file, then click **Upload**.

Step 7 Click **Save**.

What to do next

You do not need to redeploy these changes to take effect. If you want to delete an entry from the list, see Delete Entries from Global Security Intelligence Lists, on page 910.

Updating Security Intelligence Lists

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Expand the **Security Intelligence** node, then choose a list type.

Step 3 Next to the list you want to update, click **Edit** ( ).

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 If you need a copy of the list to edit, click **Download**, then follow your browser's prompts to save the list as a text file.

Step 5 Make changes to the list as necessary.

Step 6 On the Security Intelligence pop-up window, click **Browse** to browse to the modified list, then click **Upload**.

Step 7 Click **Save**.

What to do next

You do not need to redeploy these changes to take effect. If you want to delete an entry from the list, see Delete Entries from Global Security Intelligence Lists, on page 910.

Sinkhole

A sinkhole object represents either a DNS server that gives non-routable addresses for all domain names within the sinkhole, or an IP address that does not resolve to a server. You can reference the sinkhole object within a DNS policy rule to redirect matching traffic to the sinkhole. You must assign the object both an IPv4 address and an IPv6 address.

Creating Sinkhole Objects

You must have the Threat license (for FTD devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Sinkhole** from the list of object types.

Step 3 Click **Add Sinkhole**.

Step 4 Enter a **Name**.

Step 5 Enter the **IPv4 Address** and **IPv6 Address** of your sinkhole.

Step 6 You have the following options:

- If you want to redirect traffic to a sinkhole server, choose **Log Connections to Sinkhole**.
- If you want to redirect traffic to a non-resolving IP address, choose **Block and Log Connections to Sinkhole**.

Step 7 If you want to assign an Indication of Compromise (IoC) type to your sinkhole, choose one from the **Type** drop-down.

Step 8 Click **Save**.

SLA Monitor

Each Internet Protocol Service Level Agreement (SLA) monitor defines a connectivity policy to a monitored address and tracks the availability of a route to the address. The route is periodically checked for availability by sending ICMP echo requests and waiting for the response. If the requests time out, the route is removed from the routing table and replaced with a backup route. SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration (that is, they do not age out). The Internet Protocol Service Level Agreement (SLA) Monitor Object is used in the Route Tracking field of an IPv4 Static Route Policy. IPv6 routes do not have the option to use SLA monitor via route tracking.

You can use these objects with FTD devices.

Procedure

Step 1 Select **Objects** > **Object Management** and choose **SLA Monitor** from the table of contents.

Step 2 Click **Add SLA Monitor**.

Step 3 Enter a name for the object in the **Name** field.

Step 4 (Optional) Enter a description for the object in the **Description** field.

Step 5 Enter the frequency of ICMP echo request transmissions, in seconds, in the **Frequency** field. Valid values range from 1 to 604800 seconds (7 days). The default is 60 seconds.

Note
The frequency cannot be less than the timeout value; you must convert frequency to milliseconds to compare the values.

Step 6 Enter the ID number of the SLA operation in the **SLA Monitor ID** field. Values range from 1 to 2147483647. You can create a maximum of 2000 SLA operations on a device. Each ID number must be unique to the policy and the device configuration.

Step 7 Enter the amount of time that must pass after an ICMP echo request before a rising threshold is declared, in milliseconds, in the **Threshold** field. Valid values range from 0 to 2147483647 milliseconds. The default is 5000 milliseconds. The threshold value is used only to indicate events that exceed the defined value. You can use these events to evaluate the proper timeout value. It is not a direct indicator of the reachability of the monitored address.

Note
The threshold value should not exceed the timeout value.

Step 8 Enter the amount of time that the SLA operation waits for a response to the ICMP echo requests, in milliseconds, in the **Timeout** field. Values range from 0 to 604800000 milliseconds (7 days). The default is 5000 milliseconds. If a response is not received from the monitored address within the amount of time defined in this field, the static route is removed from the routing table and replaced by the backup route.

Note
The timeout value cannot exceed the frequency value (adjust the frequency value to milliseconds to compare the numbers).

Step 9 Enter the size of the ICMP request packet payload, in bytes, in the **Data Size** field. Values range from 0 to 16384 bytes. The default is 28 bytes, which creates a total ICMP packet of 64 bytes. Do not set this value

higher than the maximum allowed by the protocol or the Path Maximum Transmission Unit (PMTU). For purposes of reachability, you might need to increase the default data size to detect PMTU changes between the source and the target. A low PMTU can affect session performance and, if detected, might indicate that the secondary path should be used.

Step 10 Enter a value for type of service (ToS) defined in the IP header of the ICMP request packet in the **ToS** field. Values range from 0 to 255. The default is 0. This field contains information such as delay, precedence, reliability, and so on. It can be used by other devices on the network for policy routing and features such as committed access rate.

Step 11 Enter the number of packets that are sent in the **Number of Packets** field. Values range from 1 to 100. The default is 1 packet.

Note
Increase the default number of packets if you are concerned that packet loss might falsely cause the Firepower Threat Defense device to believe that the monitored address cannot be reached.

Step 12 Enter the IP address that is being monitored for availability by the SLA operation, in the **Monitored Address** field.

Step 13 The **Available Zones** list displays both zones and interface groups. In the **Zones/Interfaces** list, add the zones or interface groups that contain the interfaces through which the device communicates with the management station. To specify a single interface, you need to create a zone or the interface groups for the interface; see Create Security Zone and Interface Group Objects, on page 355. The host will be configured on a device only if the device includes the selected interfaces or zones.

Step 14 Click **Save**.

Time Range

Use time range objects to define time periods that you will use to determine when rules apply.

Note Time-based ACLs is supported in Snort 3 also from FMC 7.0 onwards.

Creating Time Range Objects

If you want a policy to apply only during a specified time range, create a time range object, then specify that object in the policy. Note that this object works on FTD devices only.

You can specify time range objects only in policy types listed at the bottom of this topic.

Note The timezone represents the device's local time and is used ONLY for applying the time ranges in rules in the policies that support the time ranges. The timezone does not change the configured time of the device. To verify the configuration, in the FTD CLI, use the **show time-range timezone** and **show time** commands (see the Cisco Secure Firewall Threat Defense Command Reference guide). In addition, the timezone of a chassis overrides the management center timezone.

Before you begin

Time ranges are applied based on the time zone associated with the device that processes the traffic. By default, this is UTC. To change the time zone associated with a device, go to **Device > Platform Settings**.

Procedure

Step 1 Choose **Objects > Object Management**.

Step 2 Choose **Time Range** from the list of object types.

Step 3 Click **Add Time Range**.

Step 4 Enter values.

Observe the following guidelines:

- If you see a red error box around the object name you have entered, mouse over the **Name** field to see naming restrictions.
- All times are in UTC, unless you specify a time zone for the device in **Device > Platform Settings**.
- Enter times using a 24-hour clock. For example, enter 1:30 PM as 13:30.
- To specify a single continuous range, such as typical weekend hours (Fridays at 5pm through Mondays at 8am, including evenings and nights), choose Range Type **Range**.
- To specify part of multiple days, such as Monday through Friday from 8am to 5pm (excluding evenings, nights, and early mornings every day), choose Range Type **Daily Interval**.
- You can specify up to 28 time periods in a single object.
- To specify multiple noncontiguous times of day or different hours for different days, create multiple recurring intervals. For example, to apply a policy at all times other than standard working hours, create a single time range object with the following two recurring intervals:
  - A Daily Interval for Monday through Friday from 5pm through 8am, and
  - A Range recurring interval for Friday at 5pm through Monday at 8am.

Step 5 Click **Save**.

What to do next

Configure time ranges in any of the following:

- Access control rules
- Prefilter rules
- Tunnel rules
- VPN group policy

In a VPN group policy object, specify the time range object using the **Access Hours** field. For details, see Configure Group Policy Objects, on page 942 and Group Policy Advanced Options, on page 949.

Time Zone

To specify a local time zone for a managed device, create a time zone object and specify it in the device platform settings policy assigned to the device.

This device local time is used ONLY for applying time ranges in rules in policies that support time ranges, such as access control, prefilter, and VPN Group policies. If you do not assign a time zone to a device, UTC is used by default when applying time ranges in these policies. No other functionality in the system uses the time zone specified in a time zone object.

Time zone objects are supported only for FTD devices.

Note Time-based ACLs is supported in Snort 3 also from FMC 7.0 onwards.

Tunnel Zone

A *tunnel zone* represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis. A tunnel zone is not an interface object, even though you can use it as an interface constraint in some configurations.

For detailed information, see Tunnel Zones and Prefiltering, on page 1278.

URL

Important For best practices for using this and similar options in Security Intelligence configurations and for URL rules in access control and QoS policies, see Manual URL Filtering Options, on page 1225.

A URL object defines a single URL or IP address, whereas a URL group object can define more than one URL or address. You can use URL objects and groups in various places in the system's web interface, including access control policies and event searches.

When creating URL objects, keep the following points in mind:

- If you do not include a path (that is, there are no / characters in the URL), the match is based on the server's hostname only. If you include one or more / character, the entire URL string is used for a substring match. Then, a URL is considered a match if any of the following are true:
  - The string is at the beginning of the URL.
  - The string follows a dot.
  - The string contains a dot in the beginning.
  - The string follows the :// characters.

  For example, ign.com matches ign.com or www.ign.com, but not versign.com.

Note We recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths.

- The system disregards the encryption protocol (HTTP vs HTTPS). In other words, if you block a website, both HTTP and HTTPS traffic to that website is blocked, unless you use an application condition to target a specific protocol. When creating a URL object, you do not need to specify the protocol when creating an object. For example, use example.com rather than http://example.com.
- If you plan to use a URL object to match HTTPS traffic in an access control rule, create the object using the subject common name in the public key certificate used to encrypt the traffic. Also, the system disregards subdomains within the subject common name, so do not include subdomain information. For example, use example.com rather than www.example.com.

  However, please understand that the subject common name in the certificate might be completely unrelated to a web site's domain name. For example, the subject common name in the certificate for youtube.com is *.google.com (this of course might change at any time). You will get more consistent results if you use the SSL Decryption policy to decrypt HTTPS traffic so that URL filtering rules work on decrypted traffic.

Note URL objects will not match HTTPS traffic if the browser resumes a TLS session because the certificate information is no longer available. Thus, even if you carefully configure the URL object, you might get inconsistent results for HTTPS connections.

Creating URL Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **URL** from the list of object types.

Step 3 Choose **Add Object** from the **Add URL** drop-down list.

Step 4 Enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 Enter the **URL** or IP address.

Step 7 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.
- If you want to add override values to this object, expand the Override section and click **Add**; see Adding Object Overrides, on page 850.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Variable Set

Variables represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions, adaptive profile updates, and dynamic rule states.

Tip Preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.

You use variable sets to manage, customize, and group your variables. You can use the default variable set provided by the system or create your own custom sets. Within any set you can modify predefined default variables and add and modify user-defined variables.

Most of the shared object rules and standard text rules that the system provides use predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Rules are more effective when variables more accurately reflect your network environment. At a minimum, you should modify default variables in the default set. By ensuring that a variable such as `$HOME_NET` correctly defines your network and `$HTTP_SERVERS` includes all web servers on your network, processing is optimized and all relevant systems are monitored for suspicious activity.

To use your variables, you link variable sets to intrusion policies associated with access control rules or with the default action of an access control policy. By default, the default variable set is linked to all intrusion policies used by access control policies.

Adding a variable to any set adds it to all sets; that is, each variable set is a collection of all variables currently configured on your system. Within any variable set, you can add user-defined variables and customize the value of any variable.

Initially, the system provides a single, default variable set comprised of predefined default values. Each variable in the default set is initially set to its default value, which for a predefined variable is the value set by the Talos Intelligence Group and provided in rule updates.

Although you can leave predefined default variables configured to their default values, Cisco recommends that you modify a subset of predefined variables.

You could work with variables only in the default set, but in many cases you can benefit most by adding one or more custom sets, configuring different variable values in different sets, and perhaps even adding new variables.

When using multiple sets, it is important to remember that the *current value* of any variable in the default set determines the *default value* of the variable in all other sets.

When you select **Variable Sets** on the Object Manager page, the object manager lists the default variable set and any custom sets you created.

On a freshly installed system, the default variable set is comprised only of the default variables predefined by Cisco.

Each variable set includes the default variables provided by the system and all custom variables you have added from any variable set. Note that you can edit the default set, but you cannot rename or delete the default set.

Caution Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

Related Topics

Managing Variables, on page 935
Managing Variable Sets, on page 933

Variable Sets in Intrusion Policies

By default, the system links the default variable set to all intrusion policies used in an access control policy. When you deploy an access control policy that uses an intrusion policy, intrusion rules that you have enabled in the intrusion policy use the variable values in the linked variable set.

When you modify a custom variable set used by an intrusion policy in an access control policy, the system reflects the status for that policy as out-of-date on the Access Control Policy page. You must re-deploy the access control policy to implement changes in your variable set. When you modify the default set, the system reflects the status of all access control policies that use intrusion policies as out-of-date, and you must re-deploy all access control policies to implement your changes.

Variables

Variables belong to one of the following categories:

Default Variables

Variables provided by the system. You cannot rename or delete a default variable, and you cannot change its default value. However, you can create a customized version of a default variable.

Customized Variables

Variables you create. These variables can include:

- *customized default variables*

  When you edit the value for a default variable, the system moves the variable from the Default Variables area to the Customized Variables area. Because variable values in the default set determine the default values of variables in custom sets, customizing a default variable in the default set modifies the default value of the variable in all other sets.

- *user-defined variables*

You can add and delete your own variables, customize their values within different variable sets, and reset customized variables to their default values. When you reset a user-defined variable, it remains in the Customized Variables area.

User-defined variables can be one of the following types:

- *network* variables specify the IP addresses of hosts in your network traffic.
- *port* variables specify TCP or UDP ports in network traffic, including the value `any` for either type.

For example, if you create custom standard text rules, you might also want to add your own user-defined variables to more accurately reflect your traffic or as shortcuts to simplify the rule creation process. Alternatively, if you create a rule that you want to inspect traffic in the "demilitarized zone" (or DMZ) only, you can create a variable named `$DMZ` whose value lists the server IP addresses that are exposed. You can then use the `$DMZ` variable in any rule written for this zone.

Advanced Variables

Variables provided by the system under specific conditions. These variables have a very limited deployment.

Predefined Default Variables

By default, the system provides a single default variable set, which is comprised of predefined default variables. The Talos Intelligence Group uses rule updates to provide new and updated intrusion rules and other intrusion policy elements, including default variables.

Because many intrusion rules provided by the system use predefined default variables, you should set appropriate values for these variables. Depending on how you use variable sets to identify traffic on your network, you can modify the values for these default variables in any or all variable sets.

Caution Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

The following table describes the variables provided by the system and indicates which variables you typically would modify. For assistance determining how to tailor variables to your network, contact Professional Services or Support.

Table 52: System-Provided Variables

Variable Name	Description	Modify?
`$AIM_SERVERS`	Defines known AOL Instant Messenger (AIM) servers, and is used in chat-based rules and rules that look for AIM exploits.	Not required.
`$DNS_SERVERS`	Defines Domain Name Service (DNS) servers. If you create a rule that affects DNS servers specifically, you can use the `$DNS_SERVERS` variable as a destination or source IP address.	Not required in current rule set.

Variable Name	Description	Modify?
$EXTERNAL_NET	Defines the network that the system views as the unprotected network, and is used in many rules to define the external network.	Yes, you should adequately define $HOME_NET and then exclude $HOME_NET as the value for $EXTERNAL_NET.
$FILE_DATA_PORTS	Defines non-encrypted ports used in intrusion rules that detect files in a network stream.	Not required.
$FTP_PORTS	Defines the ports of FTP servers on your network, and is used for FTP server exploit rules.	Yes, if your FTP servers use ports other than the default ports (you can view the default ports in the web interface).
$GTP_PORTS	Defines the data channel ports where the packet decoder extracts the payload inside a GTP (General Packet Radio Service [GPRS] Tunneling Protocol) PDU.	Not required.
$HOME_NET	Defines the network that the associated intrusion policy monitors, and is used in many rules to define the internal network.	Yes, to include the IP addresses for your internal network.
$HTTP_PORTS	Defines the ports of web servers on your network, and is used for web server exploit rules.	Yes, if your web servers use ports other than the default ports (you can view the default ports in the web interface).
$HTTP_SERVERS	Defines the web servers on your network. Used in web server exploit rules.	Yes, if you run HTTP servers.
$ORACLE_PORTS	Defines Oracle database server ports on your network, and is used in rules that scan for attacks on Oracle databases.	Yes, if you run Oracle servers.
$SHELLCODE_PORTS	Defines the ports you want the system to scan for shell code exploits, and is used in rules that detect exploits that use shell code.	Not required.
$SIP_PORTS	Defines the ports of SIP servers on your network, and is used for SIP exploit rules.	Not required.
$SIP_SERVERS	Defines SIP servers on your network, and is used in rules that address SIP-targeted exploits.	Yes, if you run SIP servers, you should adequately define $HOME_NET and then include $HOME_NET as the value for $SIP_SERVERS.
$SMTP_SERVERS	Defines SMTP servers on your network, and is used in rules that address exploits that target mail servers.	Yes, if you run SMTP servers.
$SNMP_SERVERS	Defines SNMP servers on your network, and is used in rules that scan for attacks on SNMP servers.	Yes, if you run SNMP servers.
$SNORT_BPF	Identifies a legacy advanced variable that appears only when it existed on your system in a software release before Version 5.3.0 that you subsequently upgraded to Version 5.3.0 or greater.	No, you can only view or delete this variable. You cannot edit it or recover it after deleting it.

Variable Name	Description	Modify?
$SQL_SERVERS	Defines database servers on your network, and is used in rules that address database-targeted exploits.	Yes, if you run SQL servers.
$SSH_PORTS	Defines the ports of SSH servers on your network, and is used for SSH server exploit rules.	Yes, if your SSH servers use ports other than the default port (you can view the default ports in the web interface).
$SSH_SERVERS	Defines SSH servers on your network, and is used in rules that address SSH-targeted exploits.	Yes, if you run SSH servers, you should adequately define $HOME_NET and then include $HOME_NET as the value for $SSH_SERVERS.
$TELNET_SERVERS	Defines known Telnet servers on your network, and is used in rules that address Telnet server-targeted exploits.	Yes, if you run Telnet servers.
$USER_CONF	Provides a general tool that allows you to configure one or more features not otherwise available via the web interface. Conflicting or duplicate $USER_CONF configurations will halt the system.	No, only as instructed in a feature description or with the guidance of Support.

Network Variables

Network variables represent IP addresses you can use in intrusion rules that you enable in an intrusion policy and in intrusion policy rule suppressions, dynamic rule states, and adaptive profile updates. Network variables differ from network objects and network object groups in that network variables are specific to intrusion policies and intrusion rules, whereas you can use network objects and groups to represent IP addresses in various places in the system's web interface, including access control policies, network variables, intrusion rules, network discovery rules, event searches, reports, and so on.

You can use network variables in the following configurations to specify the IP addresses of hosts on your network:

- intrusion rules—Intrusion rule **Source IPs** and **Destination IPs** header fields allow you to restrict packet inspection to the packets originating from or destined to specific IP addresses.
- suppressions—The **Network** field in source or destination intrusion rule suppressions allows you to suppress intrusion event notifications when a specific IP address or range of IP addresses triggers an intrusion rule or preprocessor.
- dynamic rule states—The **Network** field in source or destination dynamic rule states allows you to detect when too many matches for an intrusion rule or preprocessor rule occur in a given time period.
- adaptive profile updates—When you enable adaptive profile updates, the adaptive profiles **Networks** field identifies hosts where you want to improve reassembly of packet fragments and TCP streams in passive deployments.

When you use variables in the fields identified in this section, the variable set you link to an intrusion policy determines the variable values in the network traffic handled by an access control policy that uses the intrusion policy.

You can add any combination of the following network configurations to a variable:

- any combination of network variables, network objects, and network object groups that you select from the list of available networks
- individual network objects that you add from the New Variable or Edit Variable page, and can then add to your variable and to other existing and future variables
- literal, single IP addresses or address blocks

  You can list multiple literal IP addresses and address blocks by adding each individually. You can list IPv4 and IPv6 addresses and address blocks alone or in any combination. When specifying IPv6 addresses, you can use any addressing convention defined in RFC 4291.

The default value for included networks in any variable you add is the word `any`, which indicates any IPv4 or IPv6 address. The default value for excluded networks is `none`, which indicates no network. You can also specify the address `::` in a literal value to indicate any IPv6 address in the list of included networks, or no IPv6 addresses in the list of exclusions.

Adding networks to the excluded list negates the specified addresses and address blocks. That is, you can match any IP address with the exception of the excluded IP address or address blocks.

For example, excluding the literal address `192.168.1.1` specifies any IP address other than 192.168.1.1, and excluding `2001:db8:ca2e::fa4c` specifies any IP address other than 2001:db8:ca2e::fa4c.

You can exclude any combination of networks using literal or available networks. For example, excluding the literal values `192.168.1.1` and `192.168.1.5` *includes* any IP address other than 192.168.1.1 or 192.168.1.5. That is, the system interprets this as "**not** 192.168.1.1 **and not** 192.168.1.5," which matches any IP address other than those listed between brackets.

Note the following points when adding or editing network variables:

- You cannot logically exclude the value `any` which, if excluded, would indicate no address. For example, you cannot add a variable with the value `any` to the list of excluded networks.
- Network variables identify traffic for the specified intrusion rule and intrusion policy features. Note that preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.
- Excluded values must resolve to a subset of included values. For example, you cannot include the address block 192.168.5.0/24 and exclude 192.168.6.0/24.

Port Variables

Port variables represent TCP and UDP ports you can use in the **Source Port** and **Destination Port** header fields in intrusion rules that you enable in an intrusion policy. Port variables differ from port objects and port object groups in that port variables are specific to intrusion rules. You can create port objects for protocols other than TCP and UDP, and you can use port objects in various places in the system's web interface, including port variables, access control policies, network discovery rules, and event searches.

You can use port variables in the intrusion rule **Source Port** and **Destination Port** header fields to restrict packet inspection to packets originating from or destined to specific TCP or UDP ports.

When you use variables in these fields, the variable set you link to the intrusion policy associated with an access control rule or policy determines the values for these variables in the network traffic where you deploy the access control policy.

You can add any combination of the following port configurations to a variable:

- any combination of port variables and port objects that you select from the list of available ports

  Note that the list of available ports does not display port object groups, and you cannot add these to variables.

- individual port objects that you add from the New Variable or Edit Variable page, and can then add to your variable and to other existing and future variables

  Only TCP and UDP ports, including the value `any` for either type, are valid variable values. If you use the new or edit variables page to add a valid port object that is not a valid variable value, the object is added to the system but is not displayed in the list of available objects. When you use the object manager to edit a port object that is used in a variable, you can only change its value to a valid variable value.

- single, literal port values and port ranges

  You must separate port ranges with a dash (-). Port ranges indicated with a colon (:) are supported for backward compatibility, but you cannot use a colon in port variables that you create.

  You can list multiple literal port values and ranges by adding each individually in any combination.

Note the following points when adding or editing port variables:

- The default value for included ports in any variable you add is the word `any`, which indicates any port or port range. The default value for excluded ports is `none`, which indicates no ports.

Tip To create a variable with the value `any`, name and save the variable without adding a specific value.

- You cannot logically exclude the value `any` which, if excluded, would indicate no ports. For example, you cannot save a variable set when you add a variable with the value `any` to the list of excluded ports.
- Adding ports to the excluded list negates the specified ports and port ranges. That is, you can match any port with the exception of the excluded ports or port ranges.
- Excluded values must resolve to a subset of included values. For example, you cannot include the port range 10-50 and exclude port 60.

Advanced Variables

Advanced variables allow you to configure features that you cannot otherwise configure via the web interface. The system currently provides only one advanced variable, the USER_CONF variable.

USER_CONF

USER_CONF provides a general tool that allows you to configure one or more features not otherwise available via the web interface.

Caution Do **not** use the advanced variable USER_CONF to configure an intrusion policy feature unless you are instructed to do so in the feature description or by Support. Conflicting or duplicate configurations will halt the system.

When editing USER_CONF, you can type up to 4096 total characters on a single line; the line wraps automatically. You can include any number of valid instructions or lines until you reach the 8192 maximum character length for a variable or a physical limit such as disk space. Use the backslash (\) line continuation character after any complete argument in a command directive.

Resetting USER_CONF empties it.

Variable Reset

You can reset a variable to its default value on the variable set new or edit variables page. The following table summarizes the basic principles of resetting variables.

Table 53: Variable Reset Values

Resetting this variable type...	In this set type...	Resets it to...
default	default	the rule update value
user-defined	default	`any`
default or user-defined	custom	the current default set value (modified or unmodified)

Resetting a variable in a custom set simply resets it to the current value for that variable in the default set.

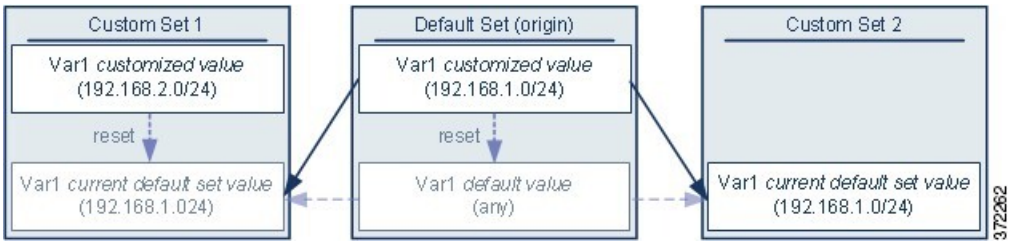
Conversely, resetting or modifying the value of a variable in the default set always updates the default value of that variable in all custom sets. When the reset icon is grayed out, indicating that you cannot reset the variable, this means that the variable has no customized value in that set. Unless you have customized the value for a variable in a custom set, a change to the variable in the default set updates the value used in any intrusion policy where you have linked the variable set.

Note It is good practice when you modify a variable in the default set to assess how the change affects any intrusion policy that uses the variable in a linked custom set, especially when you have not customized the variable value in the custom set.

You can hover your pointer over the **Reset icon** in a variable set to see the reset value. When the customized value and the reset value are the same, this indicates one of the following:

- you are in the custom or default set where you added the variable with the value `any`
- you are in the custom set where you added the variable with an explicit value and elected to use the configured value as the default value

Adding Variables to Sets



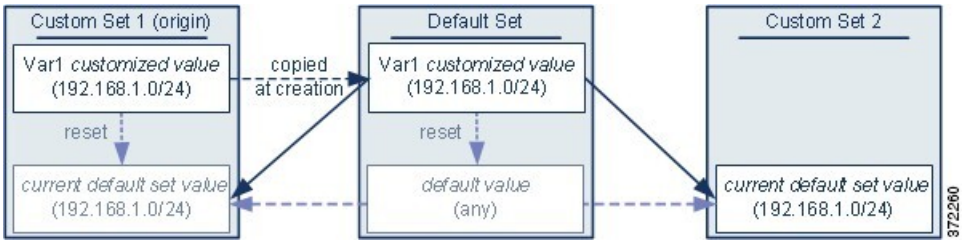
Adding a variable to a variable set adds it to all other sets. When you add a variable from a custom set, you must choose whether to use the configured value as the customized value in the default set:

- **If you use the configured value** (for example, 192.168.0.0/16), the variable is added to the default set using the configured value as a customized value with a default value of `any`. Because the current value in the default set determines the default value in other sets, the initial, default value in other custom sets is the configured value (which in the example is 192.168.0.0/16).

- **If you do not use the configured value**, the variable is added to the default set using only the default value `any` and, consequently, the initial, default value in other custom sets is `any`.

Example: Adding User-Defined Variables to Default Sets

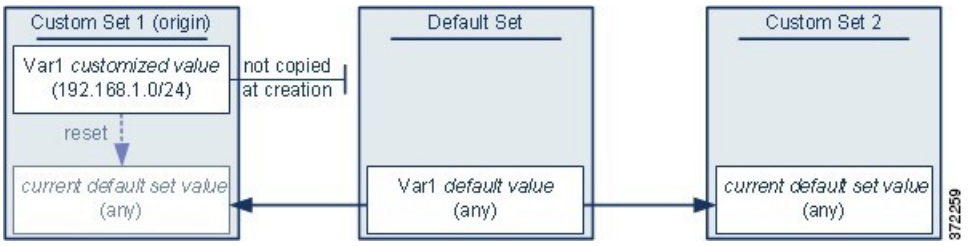
The following diagram illustrates set interactions when you add the user-defined variable `Var1` to the default set with the value `192.168.1.0/24`.



You can customize the value of `Var1` in any set. In Custom Set 2 where `Var1` has not been customized, its value is `192.168.1.0/24`. In Custom Set 1 the customized value `192.168.2.0/24` of `Var1` overrides the default value. Resetting a user-defined variable in the default set resets its default value to `any` in all sets.

It is important to note in this example that, if you do not update `Var1` in Custom Set 2, further customizing or resetting `Var1` in the default set consequently updates the current, default value of `Var1` in Custom Set 2, thereby affecting any intrusion policy linked to the variable set.

Although not shown in the example, note that interactions between sets are the same for user-defined variables and default variables except that resetting a default variable in the default set resets it to the value configured by Cisco in the current rule update.



Example: Adding User-Defined Variables to Custom Sets

The next two examples illustrate variable set interactions when you add a user-defined variable to a custom set. When you save the new variable, you are prompted whether to use the configured value as the default value for other sets. In the following example, you elect **to use** the configured value.

Note that, except for the origin of `Var1` from Custom Set 1, this example is identical to the example above where you added `Var1` to the default set. Adding the customized value `192.168.1.0/24` for `Var1` to Custom Set 1 copies the value to the default set as a customized value with a default value of `any`. Thereafter, `Var1` values and interactions are the same as if you had added `Var1` to the default set. As with the previous example, keep in mind that further customizing or resetting `Var1` in the default set consequently updates the current, default value of `Var1` in Custom Set 2, thereby affecting any intrusion policy linked to the variable set.

In the next example, you add `Var1` with the value 192.168.1.0/24 to Custom Set 1 as in the previous example, but you elect **not to use** the configured value of `Var1` as the default value in other sets.

This approach adds `Var1` to all sets with a default value of `any`. After adding `Var1`, you can customize its value in any set. An advantage of this approach is that, by not initially customizing `Var1` in the default set, you decrease your risk of customizing the value in the default set and thus inadvertently changing the current value in a set such as Custom Set 2 where you have not customized `Var1`.

Nesting Variables

You can nest variables so long as the nesting is not circular. Nested, negated variables are not supported.

Valid Nested Variables

In this example, SMTP_SERVERS, HTTP_SERVERS, and OTHER_SERVERS are valid nested variables.

Variable	Type	Included Networks	Excluded Networks
SMTP_SERVERS	customized default	10.1.1.1	—
HTTP_SERVERS	customized default	10.1.1.2	—
OTHER_SERVERS	user-defined	10.2.2.0/24	—
HOME_NET	customized default	10.1.1.0/24 OTHER_SERVERS	SMTP_SERVERS HTTP_SERVERS

An Invalid Nested Variable

In this example, HOME_NET is an invalid nested variable because the nesting of HOME_NET is circular; that is, the definition of OTHER_SERVERS includes HOME_NET, so you would be nesting HOME_NET in itself.

Variable	Type	Included Networks	Excluded Networks
SMTP_SERVERS	customized default	10.1.1.1	—
HTTP_SERVERS	customized default	10.1.1.2	—
OTHER_SERVERS	user-defined	10.2.2.0/24 HOME_NET	—

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.1.0/24 OTHER_SERVERS	SMTP_SERVERS HTTP_SERVERS

An Unsupported Nested, Negated Variable

Because nested, negated variables are not supported, you cannot use the variable NONCORE_NET as shown in this example to represent IP addresses that are outside of your protected networks.

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.0.0/16 10.2.0.0/16 10.3.0.0/16	—
EXTERNAL_NET	customized default	—	HOME_NET
DMZ_NET	user-defined	10.4.0.0/16	—
NOT_DMZ_NET	user-defined	—	DMZ_NET
NONCORE_NET	user-defined	EXTERNAL_NET NOT_DMZ_NET	—

Alternative to an Unsupported Nested, Negated Variable

As an alternative to the example above, you could represent IP addresses that are outside of your protected networks by creating the variable NONCORE_NET as shown in this example.

Variable	Type	Included Networks	Excluded Networks
HOME_NET	customized default	10.1.0.0/16 10.2.0.0/16 10.3.0.0/16	—
DMZ_NET	user-defined	10.4.0.0/16	—
NONCORE_NET	user-defined	—	HOME_NET DMZ_NET

Managing Variable Sets

To use variable sets, you must have the Threat license (for FTD devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Variable Set** from the list of object types.

Step 3 Manage your variable sets:

- Add — If you want to add a custom variable set, click **Add Variable Set**; see Creating Variable Sets, on page 934.
- Delete — If you want to delete a custom variable set, click **Delete** ( ) next to the variable set, then click **Yes**. You cannot delete the default variable set or variable sets belonging to ancestor domains.

  Note
  Variables created in a variable set you delete are not deleted or otherwise affected in other sets.

- Edit — If you want to edit a variable set, click **Edit** ( ) next to the variable set you want to modify; see Editing Objects, on page 845.
- Filter — If you want to filter variable sets by name, begin entering a name; as you type, the page refreshes to display matching names. If you want to clear name filtering, click **Clear** ( ) in the filter field.
- Manage Variables — To manage the variables included in variable sets, see Managing Variables, on page 935.

Creating Variable Sets

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Variable Set** from the list of object types.

Step 3 Click **Add Variable Set**.

Step 4 Enter a **Name**.

Step 5 Optionally, enter a **Description**.

Step 6 Manage the variables in the set; see Managing Variables, on page 935.

Step 7 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Managing Variables

You must have the Threat license (for FTD devices) or the Protection license (all other device types).

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **Variable Set** from the list of object types.

Step 3 Click **Edit** ( ) next to the variable set you want to edit.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 4 Manage your variables:

- Display — If you want to display the complete value for a variable, hover your pointer over the value in the **Value** column next to the variable.
- Add — If you want to add a variable, click **Add**; see Adding Variables, on page 936.
- Delete — Click **Delete** ( ) next to the variable. If you have saved the variable set since adding the variable, click **Yes** to confirm that you want to delete the variable.

  You *cannot* delete the following:

  - default variables
  - user-defined variables that are used by intrusion rules or other variables
  - variables belonging to ancestor domains

- Edit — Click **Edit** ( ) next to the variable you want to edit; see Editing Variables, on page 937.
- Reset — If you want to reset a modified variable to its default value, click **Reset** next to a modified variable. If reset is dimmed, one of the following is true:

  - The current value is already the default value.
  - The configuration belongs to an ancestor domain.

  Tip
  Hover your pointer over an active reset to display the default value.

Step 5 Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

Because the current value in the default set determines the default value in all other sets, modifying or resetting a variable in the default set changes the current value in other sets where you have not customized the default value.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Adding Variables

You must have the Threat license (for FTD devices) or the Protection license (all other device types).

Procedure

Step 1 In the variable set editor, click **Add**.

Step 2 Enter a unique variable **Name**.

Step 3 From the **Type** drop-down list, choose either **Network** or **Port**.

Step 4 Specify values for the variable:

- If you want to move items from the list of available networks or ports to the list of included or excluded items, you can choose one or more items and then drag and drop, or click **Include** or **Exclude**.

  Tip
  If addresses or ports in the included and excluded lists for a network or port variable overlap, excluded addresses or ports take precedence.

- Enter a single literal value, then click **Add**. For network variables, you can enter a single IP address or address block. For port variables you can add a single port or port range, separating the upper and lower values with a hyphen (-). Repeat this step as needed to enter multiple literal values.
- If you want to remove an item from the included or excluded lists, click **Delete** ( ) next to the item.

Note
The list of items to include or exclude can be comprised of any combination of literal strings and existing variables, objects, and network object groups in the case of network variables.

Step 5 Click **Save** to save the variable. If you are adding a new variable from a custom set, you have the following options:

- Click **Yes** to add the variable using the configured value as the customized value in the default set and, consequently, the default value in other custom sets.
- Click **No** to add the variable as the default value of `any` in the default set and, consequently, in other custom sets.

Step 6 Click **Save** to save the variable set. Your changes are saved, and any access control policy the variable set is linked to displays an out-of-date status.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

Editing Variables

You must have the Threat license (for FTD devices) or the Protection license (all other device types).

You can edit both custom and default variables.

You cannot change the **Name** or **Type** values in an existing variable.

Procedure

Step 1 In the variable set editor, click **Edit** ( ) next to the variable you want to modify.

If **View** ( ) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

Step 2 Modify the variable:

- If you want to move items from the list of available networks or ports to the list of included or excluded items, you can select one or more items and then drag and drop, or click **Include** or **Exclude**.

  Tip
  If addresses or ports in the included and excluded lists for a network or port variable overlap, excluded addresses or ports take precedence.

- Enter a single literal value, then click **Add**. For network variables, you can enter a single IP address or address block. For port variables you can add a single port or port range, separating the upper and lower values with a hyphen (-). Repeat this step as needed to enter multiple literal values.
- If you want to remove an item from the included or excluded lists, click **Delete** ( ) next to the item.

Note
The list of items to include or exclude can be comprised of any combination of literal strings and existing variables, objects, and network object groups in the case of network variables.

Step 3 Click **Save** to save the variable.

Step 4 Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes. Your changes are saved, and any access control policy the variable set is linked to displays an out-of-date status.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

VLAN Tag

Each VLAN tag object you configure represents a VLAN tag or range of tags.

You can group VLAN tag objects. Groups represent multiple objects; using a range of VLAN tags in a single object is not considered a group in this sense.

You can use VLAN tag objects and groups in various places in the system's web interface, including rules and event searches. For example, you could write an access control rule that applies only to a specific VLAN.

Creating VLAN Tag Objects

Procedure

Step 1 Choose **Objects** > **Object Management**.

Step 2 Choose **VLAN Tag** from the list of object types.

Step 3 Choose **Add Object** from the **Add VLAN Tag** drop-down list.

Step 4 Enter a **Name**.

Step 5 Enter a **Description**.

Step 6 Enter a value in the **VLAN Tag** field. Use a hyphen to specify a range of VLAN tags.

Step 7 Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see Allowing Object Overrides, on page 850.
- If you want to add override values to this object, expand the Override section and click **Add**; see Adding Object Overrides, on page 850.

Step 8 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes; see Deploy Configuration Changes, on page 121.

VPN

You can use the following VPN objects on FTD devices. To use these objects, you must have Admin privileges, and your Smart License account must satisfy export controls. You can configure these objects in leaf domains only.

Certificate Map Objects

Certificate Map objects are a named set of certificate matching rules. These objects are used to provide an association between a received certificate and a Remote Access VPN connection profile. Connection Profiles and Certificate Map objects are both part of a remote access VPN policy. If a received certificate matches the rules contained in the certificate map, the connection is "mapped", or associated with the specified connection profile. The rules are in priority order, they are matched in the order they are shown in the UI. The matching ends when the first rule within the Certificate Map object results in a match.

Navigation

Objects > **Object Management** > **VPN** > **Certificate Map**

Fields

- **Name**—Identify this object so it can be referred to from other configurations, such as Remote Access VPN.
- **Mapping Criteria**—Specify the contents of the certificate to evaluate. If the certificate satisfies these rules, the user will be mapped to the connection profile containing this object.
  - **Field**—Select the field for the matching rule according to the Subject or the Issuer of the client certificate.

    If the **Field** is set to *Alternative Subject* or *Extended Key Usage* the Component will be frozen as *Whole Field*
  - **Component**—Select the component of the client certificate to use for the matching rule.

Note **SER (Serial Number) component** - Ensure you specify the serial number for the Subject field. The certificate map only matches with a serial number attribute in the subject name.

  - **Operator**—Select the operator for the matching rule as follows:
    - Equals—The certificate component must match the entered value. If they do not match exactly, the connection is denied.
    - Contains—The certificate component must contain the entered value. If the component does not contain the value, the connection is denied.
    - Does Not Equal—The certificate component cannot equal the entered value. For example, for a selected certificate component of Country, and an entered value of US, if the client county value equals US, then the connection is denied.
    - Does Not Contain—The certificate component cannot contain the entered value. For example, for a selected certificate component of Country, and an entered value of US, if the client county value contains US, the connection is denied.
- **Value**—The value of the matching rule. The value entered is associated with the selected component and operator.

AnyConnect Client Custom Attributes Objects

Custom attributes are used by the AnyConnect Client to configure features such as Per App VPN, Allow or defer upgrade, and Dynamic split tunneling. A custom attribute has a type and a named value. The type of the attribute is defined first, then one or more named values of this type can be defined. You can create the

AnyConnect custom attributes objects using the FMC, add the objects to a group policy and associate the group policy with a remote access VPN to enable the features for the VPN clients.

FTD supports the following features using the custom attribute objects:

- **Per App VPN**—The Per App VPN feature helps identify an app and tunnel only applications allowed by the FTD administrator over the VPN.
- **Allow or defer upgrade**— Deferred Upgrade allows the AnyConnect Client user to delay download of the AnyConnect Client upgrade. When a client update is available, you can configure the attributes for AnyConnect Client to open a dialog asking the user if they would like to update, or to defer the upgrade.
- **Dynamic Split Tunneling**— With dynamic split tunneling, you can provision policies that either include or exclude IP addresses or networks from the VPN tunnel. Dynamic split tunneling is configured by creating a custom attribute and adding it to a group policy.

For step-by-step instructions to configure AnyConnect Client custom attributes, see Add AnyConnect Client Custom Attributes Objects, on page 940 and

For details about the specific custom attributes to configure for a feature, see the *Cisco Secure Client (including AnyConnect) Administrator Guide* for the AnyConnect Client release you are using.

Group Policy AnyConnect Client Options, on page 945

Add AnyConnect Client Custom Attributes Objects

Before you begin

Ensure that you have done the following before adding a custom attribute object for Per App VPN:

- Per App VPN must be properly configured via MDM and each device must be enrolled to the MDM server
- Create a base64 encoded string for each app using the Cisco AnyConnect Client Enterprise Application Selector Tool.
  1. Download the Cisco AnyConnect Client Enterprise Application Selector Tool from here.
  2. Open the Application Selection Tool and select the mobile platform from the drop-down menu located on the upper left.
  3. Add rule by entering Friendly name and App ID; rest of the fields are optional.
  4. On the menu bar, click on **Policy**. The encoded base65 rule is displayed in its encoded format.
  5. Select and copy the policy string, and save it to use later when you create the AnyConnect Client Custom Attributes object.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **Custom Attribute**.

Step 2 Click **Add AnyConnect Custom Attribute**.

Step 3 Enter a **Name** and optionally a **Description** for the attribute.

Step 4 Select an attribute from the **AnyConnect Attribute** drop-down list:

- **Per App VPN** — Select this option and specify the base64 encoded string in the **Attribute Value** box.
- **Allow Defer Update**—Select one of the following options and specify the required information to allow or defer AnyConnect Client update:
  - **Show the prompt until user takes action**—Display the prompt to the VPN user until the user chooses to allow or defer the VPN client update.
  - **Show the prompt until times out**—Choose this option to display the prompt for a specified duration and specify the duration int the **Timeout** box.
  - **Do not show the prompt and take automatic action**—Choose this option to automatically allow or defer the VPN update.
  - **Default Action**—Select the default action to be taken when the user does not respond, or when you want to configure an automatic action without the user's intervention. You can choose to update the AnyConnect Client or postpone the update.
  - **Minimum Version**—Specify the minimum AnyConnect version to be present on the client system to allow or defer the update.
- **Dynamic Split Tunneling**—Select this option to include or exclude IP addresses or networks from the VPN tunnel.
  - **Include domains**—Specify domain names that will be included in the remote access VPN tunnel.
  - **Exclude domains**—Specify domain names that will be excluded from the remote access VPN tunnel.

Step 5 Select the **Allow Overrides** check box to allow object overrides.

Step 6 Click **Save**.
The custom attributes object is added to the list.

What to do next

Associate the custom attributes with a group policy. See Add Custom Attributes to a Group Policy, on page 941 .

Add Custom Attributes to a Group Policy

You must associate AnyConnect custom attributes with a group policy to use them for remote access VPN connections. You

Procedure

Step 1 Select **Objects** > **Object Management** > **VPN** > **Group Policy**.

Step 2 Add a new group policy or edit an existing group policy.

Step 3 Click **AnyConnect** > **Custom Attributes**.

Step 4 Click **Add**.

Step 5 Select the **AnyConnect Attribute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.

Step 6 Select a **Custom Attribute Object** from the list.

Note
Click Add (+) to create a new custom attribute object for the selected AnyConnect attribute. You can also create a custom attribute object at **Objects** > **Object Management** > **VPN** > **Custom Attribute**. See Add AnyConnect Client Custom Attributes Objects, on page 940.

Step 7 Click **Add** to save the attributes to the group policy and then click **Save** to save the changes to the group policy.

Group Policy AnyConnect Client Options, on page 945

FTD Group Policy Objects

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

The group policy applied to a user is determined when the VPN tunnel is being established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

Note There is no group policy attribute inheritance on the FTD. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

To use group objects, you must have one of these AnyConnect Client licenses associated with your Smart License account with Export-Controlled Features enabled:

- AnyConnect VPN Only
- AnyConnect Plus
- AnyConnect Apex

Configure Group Policy Objects, on page 942

Configure Group Policy Objects

See FTD Group Policy Objects, on page 942.

Procedure

Step 1 Choose **Objects** > **Object Management** > **VPN** > **Group Policy**.

Previously configured policies are listed including the system default. Depending on your level of access, you may edit, view, or delete a group policy.

Step 2 Click **Add Group Policy** or choose a current policy to edit.

Step 3 Enter a **Name** and optionally a **Description** for this policy.

The name can be up to 64 characters, spaces are allowed. The description can be up to 1,024 characters.

Step 4 Specify the **General** parameters for this Group Policy as described in Group Policy General Options, on page 943.

Step 5 Specify the **AnyConnect** parameters for this Group Policy as described in Group Policy AnyConnect Client Options, on page 945.

Step 6 Specify the **Advanced** parameters for this Group Policy as described in Group Policy Advanced Options, on page 949.

Step 7 Click **Save**.
The new Group Policy is added to the list.

What to do next

Add the group policy object to a remote access VPN connection profile.

Group Policy General Options

Navigation Path

Objects > **Object Management** > **VPN** > **Group Policy**, Click **Add Group Policy** or choose a current policy to edit., then select the **General** tab.

VPN Protocols Fields

Specify the types of Remote Access VPN tunnels that can be used when applying this group policy. **SSL** or **IPsec IKEv2**.

IP Address Pools

Specifies the IPv4 address assignment that is applied based on address pools that are specific to user-groups in Remote Access VPN. For Remote Access VPN, you can assign IP address from specific address pools for identified user groups using RADIUS/ISE for authorization. You can seamlessly perform policy enforcement for user or user groups in systems which are not identity-aware, by configuring particular Group Policy as RADIUS Authorization attribute (GroupPolicy/Class), for a particular user group. For example, you have to select a specific address pool for contractors and policy enforcement using those addresses to allow restricted access to internal network.

The order of preference that FTD device assigns the IPv4 Address Pools to the clients:

1. RADIUS attribute for IPv4Address Pool

2. RADIUS attribute for Group Policy
3. Address Pool in Group Policy mapped to a Connection Profile
4. IPv4Address Pool in Connection Profile

Some limitations around using IP address pools in Group Policy:

- IPv6 address pool is not supported.
- Maximum of six IPv4 address pools can be configured in a Group Policy.
- Deployment failures are seen when address pools in use are modified. You must logoff all the users before making any changes to the address pools.
- When address pools are renamed or overlapping address pools are configured, deployment could fail. You must deploy the changes by removing the old address pool and later deploying the changed address pool.

  Some troubleshooting commands :

  - `show ip local pool <address-pool-name>`
  - `show vpn-sessiondb detail anyconnect`
  - `vpn-sessiondb loggoff all noconfirm`

Banner Fields

Specifies the banner text to present to users at login. The length can be up to 491 characters. There is no default value. The IPsec VPN client supports full HTML for the banner, however, the AnyConnect Client supports only partial HTML. To ensure that the banner displays properly to remote users, use the /n tag for IPsec clients, and the <BR> tag for SSL clients.

DNS/WINS Fields

Domain Naming System (DNS) and Windows Internet Naming System (WINS) servers. Used for AnyConnect Client name resolution.

- **Primary DNS Server** and **Secondary DNS Server**—Choose or create a Network Object which defines the IPv4 or IPv6 addresses of the DNS servers you want this group to use.
- **Primary WINS Server** and **Secondary WINS Server**—Choose or create a Network Object containing the IP addresses of the WINS servers you want this group to use.
- **DHCP Network Scope**—Choose or create a Network Object containing a routable IPv4 address on the same subnet as the desired pool, but not within the pool. The DHCP server determines which subnet this IP address belongs to and assigns an IP address from that pool. If not set properly, deployment of the VPN policy fails.

  If you configure DHCP servers for the address pool in the connection profile, the DHCP scope identifies the subnets to use for the pool for this group. The DHCP server must also have addresses in the same subnet identified by the scope. The scope allows you to select a subset of the address pools defined in the DHCP server to use for this specific group.

  If you do not define a network scope, the DHCP server assigns IP addresses in the order of the address pools configured. It goes through the pools until it identifies an unassigned address.

We recommend using the IP address of an interface whenever possible for routing purposes. For example, if the pool is 10.100.10.2-10.100.10.254, and the interface address is 10.100.10.1/24, use 10.100.10.1 as the DHCP scope. Do not use the network number. You can use DHCP for IPv4 addressing only. If the address you choose is not an interface address, you might need to create a static route for the scope address.

LINK-SELECTION (RFC 3527) and SUBNET-SELECTION (RFC 3011) are currently not supported.

- **Default Domain**—Name of the default domain. Specify a top-level domain, for example, example.com.

Split Tunneling Fields

Split tunneling directs some network traffic through the VPN tunnel (encrypted) and the remaining network traffic outside the VPN tunnel (unencrypted or "in the clear").

- **IPv4 Split Tunneling / IPv6 Split Tunneling**—By default, split tunneling is not enabled. For both IPv4 and IPv6 it is set to **Allow all traffic over tunnel**. Left as is, all traffic from the endpoint goes over the VPN connection.

  To configure split tunneling, choose the **Tunnel networks specified below** or **Exclude networks specified below** policy. Then configure an access control list for that policy.

- **Split Tunnel Network List Type**—Choose the type of Access List you are using. Then choose or create a **Standard Access List** or **Extended Access List**. See Access List, on page 856 for details.

- **DNS Request Split Tunneling**—Also known as Split DNS. Configure the DNS behavior expected in your environment.

  By default, split DNS is not enabled and set to **Send DNS request as per split tunnel policy**. Choosing **Always send DNS request over tunnel** forces all DNS requests to be sent over the tunnel to the private network.

  To configure split DNS, choose **Send only specified domains over tunnel**, and enter the list of domain names in the **Domain List** field. These requests are resolved through the split tunnel to the private network. All other names are resolved using the public DNS server. Enter up to ten entries in the list of domains, separated by commas. The entire string can be no longer than 255 characters.

Configure Group Policy Objects, on page 942

Group Policy AnyConnect Client Options

These specifications apply to the operation of the AnyConnect Client VPN.

Navigation

Objects > **Object Management** > **VPN** > **Group Policy**. Click **Add Group Policy** or choose a current policy to edit. Then select the **AnyConnect** tab.

Profile Fields

Profile—Choose or create a file object containing the AnyConnect Client Profile. See File Objects, on page 954 for object creation details.

The AnyConnect Client Profile is a group of configuration parameters stored in an XML file. The AnyConnect Client software uses it to configure the connection entries that appear in the client's user interface. These parameters (XML tags) also configure settings to enable more AnyConnect Client features.

Use the GUI-based AnyConnect Profile Editor, an independent configuration tool, to create the AnyConnect Client Profile. See the *AnyConnect Profile Editor* chapter in the appropriate release of the Cisco Secure Client (including AnyConnect) Administrator Guide for details.

Management Profile Fields

A Management VPN Tunnel provides connectivity to the corporate network whenever the endpoint is powered up, even if end-user does not connect over VPN.

Management VPN Profile—The Management Profile file contains settings for enabling and establishing Management VPN Tunnel on endpoint.

The Standalone Management VPN Tunnel profile editor can be used to create a new profile file or modify an existing file. You can download the profile editor from Cisco Software Download Center.

For more information about adding a profile file, see File Objects, on page 954.

Client Modules Fields

Cisco AnyConnect VPN Only offers enhanced security through various built-in modules. These modules provide services such as web security, network visibility into endpoint flows, and off-network roaming protection. Each client module includes a client profile that includes a group of custom configurations as per your requirement.

The following AnyConnect Client modules are optional and you can configure these modules to be downloaded when a VPN user downloads AnyConnect Client:

- **AMP Enabler**—Deploys advanced malware protection (AMP) for endpoints.
- **DART**—Captures a snapshot of system logs and other diagnostic information, which can be sent to the Cisco TAC for troubleshooting.
- **ISE Posture**—Uses the OPSWAT library to perform posture checks to assess an endpoint's compliance.
- **Network Access Manager**—Provides 802.1X (Layer 2) and device authentication for access to both wired and wireless networks.
- **Network Visibility**—Enhances the enterprise administrator's ability to do capacity and service planning, auditing, compliance, and security analytics.
- **Start Before Login**—Forces the user to connect to the enterprise infrastructure over a VPN connection before logging on to Windows by starting AnyConnectAnyConnect Client before the Windows login dialog box appears.
- **Umbrella Roaming Security**—Provides DNS-layer security when no VPN is active.
- **Web Security**—Analyzes the elements of a web page, allows acceptable content, and blocks malicious or unacceptable content based on a defined security policy.

Click **Add** and select the following for each client module:

- **Client Module**—Select the AnyConnect Client module from the list.

- **Profile to download**—Choose or create a file object containing the AnyConnect Client Profile. See File Objects, on page 954 for object creation details.
- **Enable module download**—Select to enable endpoints to download the client module along with the profile. If not selected, the endpoints can download only the client profile.

Use the GUI-based AnyConnect Profile Editor, an independent configuration tool to create a client profile for each module. Download the AnyConnect Profile Editor from Cisco Software Download Center. See the *AnyConnect Profile Editor* chapter in the appropriate release of the Cisco AnyConnect Secure Mobility Client Administrator Guide for details.

SSL Settings Fields

- **SSL Compression**—Whether to enable data compression, and if so, the method of data compression to use, Deflate, or LZS. SSL Compression is Disabled by default.

  Data compression speeds up transmission rates, but also increases the memory requirement and CPU usage for each user session. Therefore, decreasing the overall throughput of the security appliance.
- **DTLS Compression**—Whether to compress Datagram Transport Layer Security (DTLS) connections for this group using LZS or not. DTLS Compression is Disabled by default.
- **MTU Size**—The maximum transmission unit (MTU) size for SSL VPN connections established by the Cisco AnyConnect VPN Only. Default is 1406 Bytes, valid range is 576 to 1462 Bytes.
  - **Ignore DF Bit**—Whether to ignore the Don't Fragment (DF) bit in packets that need fragmentation. Allows the forced fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel.

Connection Settings Fields

- **Enable Keepalive Messages between Anyconnect Client and VPN gateway**. And its **Interval** setting.—Whether to exchange keepalive messages between peers to demonstrate that they are available to send and receive data in the tunnel. Default is enabled. Keepalive messages transmit at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending IKE keepalive packets. The default interval is 20 seconds, the valid range is 15 to 600 seconds.
- **Enable Dead Peer Detection on ...**. And their **Interval** settings.—Dead Peer Detection (DPD) ensures that the VPN secure gateway or the VPN client quickly detects when the peer is no longer responding, and the connection has failed. Default is enabled for both the gateway and the client. DPD messages transmit at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending DPD messages. The default interval is 30 seconds, the valid range is 5 to 3600 seconds.
- **Enable Client Bypass Protocol**—Allows you to configure how the secure gateway manages IPv4 traffic (when it is expecting only IPv6 traffic), or how it manages IPv6 traffic (when it is expecting only IPv4 traffic).

  When the AnyConnect Client makes a VPN connection to the headend, the headend assigns it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the headend assigns the AnyConnect Client connection only an IPv4 address or only an IPv6 address, you can configure the Client Bypass Protocol to drop network traffic for which the headend did not assign an IP address (default, disabled, not checked), or allow that traffic to bypass the headend and be sent from the client unencrypted or “in the clear” (enabled, checked).

  For example, assume that the secure gateway assigns only an IPv4 address to the AnyConnect Client connection and the endpoint is dual-stacked. When the endpoint attempts to reach an IPv6 address, if

Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.

- **SSL rekey**—Enables the client to rekey the connection, renegotiating the crypto keys and initialization vectors, increasing the security of the connection. This is disabled by default. When enabled, the renegotiation can be done at a specified interval and rekey the existing tunnel or create a new tunnel by setting the following fields:
  - **Method**—Available when SSL rekey is enabled. Create a **New Tunnel** (default), or renegotiate, the **Existing Tunnel**'s specifications.
  - **Interval**—Available when SSL rekey is enabled. Set to a default of 4 minutes with a range of 4-10080 minutes (1 week).
- **Client Firewall Rules**—Use the Client Firewall Rules to configure firewall settings for the VPN client's platform. Rules are based on criteria such as source address, destination address, and protocol. Extended Access Control List building block objects are used to define the traffic filter criteria. Choose or create an Extended ACL for this group policy. Define a **Private Network Rule** to control data flowing to the private network, a **Public Network Rule** to control data flowing "in the clear", outside of the established VPN tunnel, or both.

Note Ensure that the ACL contains only TCP/UDP/ICMP/IP ports and source network as any, any-ipv4 or any-ipv6.

Only VPN clients running Microsoft Windows can use these firewall settings.

Custom Attributes Fields

This section lists the AnyConnect Custom attributes that are used by the AnyConnect Client to configure features such as Per App VPN, Allow or defer upgrade, and Dynamic split tunneling. Click **Add** to add custom attributes to the group policy.

1. Select the **AnyConnect Attribute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.
2. Select a **Custom Attribute Object** from the list.

Note Click Add (+) to create a new custom attribute object for the selected AnyConnect attribute. You can also create a custom attribute object at **Objects** > **Object Management** > **VPN** > **Custom Attribute**. See Add AnyConnect Client Custom Attributes Objects, on page 940.

3. Click **Add** to save the attributes to the group policy and then click **Save** to save the changes to the group policy.

Related Topics

Configure Group Policy Objects, on page 942

Group Policy Advanced Options

Navigation Path

Objects > **Object Management** > **VPN** > **Group Policy**, Click **Add Group Policy** or choose a current policy to edit., then select the **Advanced** tab.

Traffic Filter Fields

- **Access List Filter**—Filters consist of rules that determine whether to allow or block tunneled data packets coming through the VPN connection. Rules are based on criteria such as source address, destination address, and protocol. Note that the VPN filter applies to initial connections only. It does not apply to secondary connections, such as a SIP media connection, that are opened due to the action of application inspection. Extended Access Control List building block objects are used to define the traffic filter criteria. Choose or create a new Extended ACL for this group policy.
- **Restrict VPN to VLAN**—Also called "VLAN mapping," this parameter specifies the egress VLAN interface for sessions to which this group policy applies. The ASA forwards all traffic from this group to the selected VLAN.

  Use this attribute to assign a VLAN to the group policy to simplify access control. Assigning a value to this attribute is an alternative to using ACLs to filter traffic on a session. In addition to the default value (Unrestricted), the drop-down list shows only the VLANs that are configured in this ASA. Allowed values range from 1 to 4094.

Session Settings Fields

- **Access Hours**—Choose or create a time range object. This object specifies the range of time this group policy is available to be applied to a remote access user. See Time Range, on page 919 for details.
- **Simultaneous Logins Per User**—Specifies the maximum number of simultaneous logins allowed for a user. The default value is 3. The minimum value is 0, which disables login and prevents user access. Allowing several simultaneous connections may compromise security and affect performance.
- **Maximum Connection Time / Alert Interval**—Specifies the maximum user connection time in minutes. At the end of this time, the system stops the connection. The minimum is 1 minute). The Alert interval specifies the interval of time before maximum connection time is reached to display a message to the user.
- **Idle Timeout / Alert Interval**—Specifies this user's idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system stops the connection. The minimum time is 1 minute. The default is 30 minutes. The Alert interval specifies the interval of time before idle time is reached to display a message to the user.

Configure Group Policy Objects, on page 942

FTD IPsec Proposals

IPsec Proposals (or Transform Sets) are used when configuring VPN topologies. During the IPsec security association negotiation with ISAKMP, the peers agree to use a particular proposal to protect a particular data flow. The proposal must be the same for both peers.

There are separate IPsec proposal objects based on the IKE version, IKEv1, or IKEv2:

- When you create an IKEv1 IPsec Proposal (Transform Set) object, you select the mode in which IPsec operates, and define the required encryption and authentication types. You can select single options for the algorithms. If you want to support multiple combinations in a VPN, create multiple IKEv1 IPsec Proposal objects.
- When you create an IKEv2 IPsec Proposal object, you can select all of the encryption and Hash Algorithms allowed in a VPN. During IKEv2 negotiations, the peers select the most appropriate options that each support.

The Encapsulating Security Protocol (ESP) is used for both IKEv1 and IKEv2 IPsec Proposals. It provides authentication, encryption, and antireplay services. ESP is IP protocol type 50.

Note We recommend using both encryption and authentication on IPsec tunnels.

Configure IKEv1 IPsec Proposal Objects

Procedure

Step 1 Choose **Objects** > **Object Management** and then **VPN** > **IPsec IKev1 Proposal** from the table of contents.

Previously configured Proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a Proposal.

Step 2 Choose **Add IPsec IKEv1 Proposal** to create a new Proposal.

Step 3 Enter a **Name** for this Proposal

The name of the policy object. A maximum of 128 characters is allowed.

Step 4 Enter a **Description** for this Proposal.

A description of the policy object. A maximum of 1024 characters is allowed.

Step 5 Choose the **ESP Encryption** method. The Encapsulating Security Protocol (ESP) encryption algorithm for this Proposal.

For IKEv1, select one of the options. When deciding which encryption and Hash Algorithms to use for the IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN. For a full explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 977.

Step 6 Select an option for **ESP Hash**.

For a full explanation of the options, see Deciding Which Hash Algorithms to Use, on page 978.

Step 7 Click **Save**
The new Proposal is added to the list.

Configure IKEv2 IPsec Proposal Objects

Procedure

Step 1 Choose **Objects** > **Object Management** and then **VPN** > **IKEv2 IPsec Proposal** from the table of contents.

Previously configured Proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a Proposal.

Step 2 Choose **Add IKEv2 IPsec Proposal** to create a new Proposal.

Step 3 Enter a **Name** for this Proposal

The name of the policy object. A maximum of 128 characters is allowed.

Step 4 Enter a **Description** for this Proposal.

A description of the policy object. A maximum of 1024 characters is allowed.

Step 5 Choose the **ESP Hash** method, the hash or integrity algorithm to use in the Proposal for authentication.

Note
FTD does not support IPSec tunnels with NULL encryption. Make sure that you do not choose NULL encryption for IPSec IKEv2 proposal.

For IKEv2, select all the options you want to support for **ESP Hash**. For a full explanation of the options, see Deciding Which Hash Algorithms to Use, on page 978.

Step 6 Choose the **ESP Encryption** method. The Encapsulating Security Protocol (ESP) encryption algorithm for this Proposal.

For IKEv2, click Select to open a dialog box where you can select all of the options you want to support. When deciding which encryption and Hash Algorithms to use for the IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN. For a full explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 977.

Step 7 Click **Save**
The new Proposal is added to the list.

FTD IKE Policies

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

For IKEv1, IKE proposals contain a single set of algorithms and a modulus group. You can create multiple, prioritized policies to ensure that at least one policy matches a remote peer's policy. Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups in one policy. Since peers choose during the Phase 1 negotiation, this makes it possible to create a single IKE proposal, but consider multiple, different proposals to give higher priority to your most desired options. For IKEv2, the policy object does not specify authentication, other policies must define the authentication requirements.

An IKE policy is required when you configure a site-to-site IPsec VPN. For more information, see VPN, on page 971.

Configure IKEv1 Policy Objects

Use the IKEv1 Policy page to create, delete, or edit an IKEv1 policy object. These policy objects contain the parameters required for IKEv1 policies.

Procedure

Step 1 Choose **Objects** > **Object Management** and then **VPN** > **IKEv1 Policy** from the table of contents.

Previously configured policies are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a proposal.

Step 2 (Optional) Choose **Add IKEv1 Policy** to create a new policy object.

Step 3 Enter a **Name** for this policy. A maximum of 128 characters is allowed.

Step 4 (Optional) Enter a **Description** for this proposal. A maximum of 1,024 characters is allowed.

Step 5 Enter the **Priority** value of the IKE policy.

The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority. Valid values range from 1 to 65,535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

Step 6 Choose the **Encryption** method.

When deciding which encryption and Hash Algorithms to use for the IKEv1 policy, your choice is limited to algorithms supported by the peer devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For IKEv1, select one of the options. For a full explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 977.

Step 7 Choose the **Hash** Algorithm that creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv1 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For a full explanation of the options, see Deciding Which Hash Algorithms to Use, on page 978.

Step 8 Set the **Diffie-Hellman Group**.

The Diffie-Hellman group to use for encryption. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the group that you want to allow

in the VPN. For a full explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, on page 978.

Step 9 Set the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

Step 10 Set the **Authentication Method** to use between the two peers.

- **Preshared Key**—Preshared keys allow for a secret key to be shared between two peers and to be used by IKE during the authentication phase. If one of the participating peers is not configured with the same preshared key, the IKE SA cannot be established.
- **Certificate**—When you use Certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

Note
In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

Step 11 Click **Save**
The new IKEv1 policy is added to the list.

Configure IKEv2 Policy Objects

Use the IKEv2 policy dialog box to create, delete, and edit an IKEv2 policy object. These policy objects contain the parameters required for IKEv2 policies.

Procedure

Step 1 Choose **Objects** > **Object Management** and then **VPN** > **IKEv2 Policy** from the table of contents.

Previously configured policies are listed including system defined defaults. Depending on your level of access, you may **Edit** ( ), **View** ( ), or **Delete** ( ) a policy.

Step 2 Choose **Add IKEv2 Policy** to create a new policy.

Step 3 Enter a **Name** for this policy.

The name of the policy object. A maximum of 128 characters is allowed.

Step 4 Enter a **Description** for this policy.

A description of the policy object. A maximum of 1024 characters is allowed.

Step 5 Enter the **Priority**.

The priority value of the IKE proposal. The priority value determines the order of the IKE proposals compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec

peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority policy. Valid values range from 1 to 65535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

Step 6 Set the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

Step 7 Choose the **Integrity Algorithms** portion of the Hash Algorithm used in the IKE policy. The Hash Algorithm creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN.For a full explanation of the options, see Deciding Which Hash Algorithms to Use, on page 978.

Step 8 Choose the **Encryption Algorithm** used to establish the Phase 1 SA for protecting Phase 2 negotiations.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN. For a full explanation of the options, see Deciding Which Encryption Algorithm to Use, on page 977.

Step 9 Choose the **PRF Algorithm**.

The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv1, the Integrity and PRF algorithms are not separated, but in IKEv2, you can specify different algorithms for these elements. Select all of the algorithms that you want to allow in the VPN. For a full explanation of the options, see Deciding Which Hash Algorithms to Use, on page 978.

Step 10 Select and **Add** a **DH Group**.

The Diffie-Hellman group used for encryption. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the groups that you want to allow in the VPN. For a full explanation of the options, see Deciding Which Diffie-Hellman Modulus Group to Use, on page 978.

Step 11 Click **Save**
If a valid combination of choices has been selected the new IKEv2 policy is added to the list. If not, errors are displayed and you must make changes accordingly to successfully save this policy.

File Objects

Use the Add and Edit File Object dialog boxes to create, and edit file objects. File objects represent files used in configurations, typically for remote access VPN policies. They can contain AnyConnect Client Profile and AnyConnect Client Image files.

Profiles are also created for each AnyConnect module and AnyConnect Client Management VPN using independent profile editors and deployed to administrator-defined end user requirements and authentication

policies on endpoints as part of AnyConnect, and they make the preconfigured network profiles available to end users.

When you create a file object, the FMC makes a copy of the file in its repository. These files are backed up whenever you create a backup of the database, and they are restored if you restore the database. When copying a file to the FMC platform to be used in a file object, do not copy the file directly to the file repository.

When you deploy configurations that specify a file object, the associated file is downloaded to the device in the appropriate directory.

You can click one of the following options against each file:

- **Download** —Click to download the AnyConnect file.
- **Edit** —Modify the file object details.
- **Delete** —Delete the AnyConnect Client file object. When you delete a file object, the associated file is not deleted from the file repository, only the object is deleted.

Navigation Path

Objects > **Object Management** > **VPN** > **AnyConnect File**.

Fields

- **Name**—Enter the name of the file to identify the file object; you can add up to 128 characters.
- **File Name**—Click **Browse** to select the file. The file name and full path of the file are added when you select the file.
- **File Type**—Choose the file type corresponding to the file you have selected. The following file types are available:
  - **AnyConnect Client Image**—Select this type when you add the AnyConnect Client image you have downloaded from the Cisco Software Download Center.

    You can associate any new or additional AnyConnect Client images to the remote access VPN policy. You can also unassociate the unsupported or end of life client packages that are no longer required.
  - **AnyConnect VPN Profile**—Choose this type for the AnyConnect VPN profile file.

    The profile file is created using the GUI-based AnyConnect Profile Editor, an independent configuration tool. See the *AnyConnect Profile Editor* chapter in the appropriate release of the Cisco AnyConnect Secure Mobility Client Administrator Guide for details.
  - **AnyConnect Management VPN Profile**—Select this type when you add a profile file for the AnyConnect management VPN tunnel.

    Download the AnyConnect **VPN Management Tunnel Standalone Profile Editor** from Cisco Software Download Center if you have not done already and create a profile with required settings for the AnyConnect management VPN tunnel.
  - **AMP Enabler Service Profile**—The profile is used for the AnyConnect AMP Enabler. The AMP Enabler along with this profile is pushed to the endpoints from FTD when a remote access VPN user connects to the VPN.

- **Feedback Profile**—You can add a Customer Experience Feedback profile and select this type to receive information about the features and modules customers have enabled and use.
- **ISE Posture Profile**—Choose this option if you are adding a profile file for the AnyConnect ISE Posture module.
- **NAM Service Profile**—Configure and add the NAM profile file using the Network Access Manager profile editor.
- **Network Visibility Service Profile**—Profile file for AnyConnect Network Visibility module. You can create the profile using the NVM profile editor.
- **Umbrella Roaming Security Profile**—You must select this file type if you are deploying the Umbrella Roaming Security module using the .json file created using the profile editor.
- **Web Security Service Profile**—Select this file type when you add a prole file for the Web security module.
- **HostScan Package**—Select this file type when you add a HostScan Package file. This file is used while configuring a Dynamic Access Policy (DAP) to collect information about the operating system, anti-virus, anti-spyware, and firewall software installed on the endpoints.
- **AnyConnect External Browser Package**—This file type is for selecting an external browser package file for SAML single sing-on web authentication.

  You can add an the package file when a new version of the external package file is available.

  For more information, see Configure AAA Settings for Remote Access VPN, on page 1045.

- **Description**—Add an optional description.

History for Object Management

Feature	Minimum FMC	Minimum FTD	Details
New Applications tab for policy based routing	Any	7.1	A new tab for selecting the applications for configuring direct internet access policy (policy based routing) was introduced in the extended access list object. New/Modified Screens: New option to select applications when configuring **Objects > Object Management >Access List> Extended** page. Supported platforms: Firepower Management Center

Feature	Minimum FMC	Minimum FTD	Details
New Extended Community List object and	Any	7.1	Extended community list object was introduced to be used in policy list and route map objects. The extended community list object is applicable only for importing or exporting routes in BGP route leaking support for virtual routers. New/Modified Screens: New object for configuring policy list and route maps **Objects > Object Management > Community List > Extended Community** page. Supported platforms: Firepower Management Center
Enhancements to Policy List object and Route Map object	Any	7.1	Options to select the newly introduced Extended Community List objects in policy list and route maps. New/Modified Screens: New options for configuring policy list and route maps **Objects > Object Management > Policy List > Community Rule** tab, and **Objects > Object Management > Route Map > BGP > Community List** tab. Supported platforms: Firepower Management Center
Time-based ACL support for Snort 3	Any	7.0	Time-based rules in access control and prefilter policies are supported in Snort 3 as well. Supported platforms: FTD
EST for certificate enrollment	Any	7.0	Support for Enrollment over Secure Transport for certificate enrollment was provided. New/Modified Screens: New enrollment options when configuring **Objects > PKI > Cert Enrollment > CA Information** tab. Supported platforms: Firepower Management Center
Support for EdDSA certificate type	Any	7.0	A new certificate key type- EdDSA was added with key size 256. New/Modified Screens: New certificate key options when configuring **Objects > PKI > Cert Enrollment > Key** tab. Supported platforms: Firepower Management Center
Restrictions on ciphers and key sizes	Any	7.0	Certificates having SHA-1 with RSA Encryption signature algorithm, and RSA key sizes smaller than 2048 bits are not supported. To override these restrictions on existing certificates, you can enable the weak-crypto option on FTD. However, you cannot generate RSA keys with sizes smaller than 2048 bits. New/Modified Screens: New toggle button when configuring **Devices > Certificates**. Supported platforms: Firepower Management Center

Feature	Minimum FMC	Minimum FTD	Details
Security Intelligence feed options	Any	6.7	New update frequency options (5 and 15 minutes) for custom Security Intelligence feeds. Update frequencies of less than 30 minutes require an MD5 URL, to prevent unnecessary downloads if the feed has not changed. New/Modified Screens: New frequency choices when configuring **Security Intelligence > Network Lists and Feeds**. Supported platforms: Firepower Management Center
Bulk upload of objects using a comma-separated-values (csv) file	Any	6.7	Objects can be imported from a comma-separated-values file. Up to 1000 objects can be imported in one attempt. New/Modified Screens: The following object types have a new **Import Object** option in the **Add [Object Type]** drop-down list. • **Distinguished Name** > **Individual Objects** • **Network Object** • **Port** • **URL** • **VLAN Tag** Supported platforms: Firepower Management Center
See the policies in which interface objects are used	Any	6.6	See the policies in which interface objects are used. New/Modified Screens: The **Interface** object page in **Objects > Object Management** has a new **Find Usage** () button. Supported platforms: Firepower Management Center
Time zone objects introduced	Any	6.6	You can assign time zones to FTD devices, for use when applying time-based policies. New/Modified Screens: New **Time Zone Object** in **Objects > Object Management**. Supported platforms: Firepower Management Center
Time-based objects can now be used in access control and prefilter policies	Any	6.6	Use time range objects in conjunction with new time zone objects for applying time-based rules in access control and prefilter policies. You can specify an absolute or recurring time or time range for a rule to be applied. The rule is applied based on the time zone of the device that processes the traffic.

Feature	Minimum FMC	Minimum FTD	Details
View Object Details from prefilter rule page	Any	6.6	Feature introduced: Option to view details for an object or object group when viewing prefilter rules. New options: Right-clicking a value in any of the following columns in the prefilter rule list offers options to view object details: Source Networks, Destination Networks, Source Port, Destination Port, and VLAN Tag. Supported platforms: Firepower Management Center

Firepower Threat Defense VPN Certificate Guidelines and Limitations

- When a PKI enrollment object is associated with and then installed on a device, the certificate enrollment process starts immediately. The process is automatic for self-signed and SCEP enrollment types; it does not require any additional administrator's action. Manual certificate enrollment requires administrator's action.
- When the certificate enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your VPN Authentication Method.

- FTD devices support certificate enrollment using Microsoft Certificate Authority(CA) Service, and CA Services provided on Cisco Adaptive Security Appliances(ASA) and Cisco IOS Router.
- FTD devices cannot be configured as a certificate authority (CA).

Guidelines for Certificate Management Across Domains and Devices

- Certificate enrollment can be done in a child or parent domain.
- When enrollment is done from a parent domain, the certificate enrollment object also needs to be in the same domain. If the trustpoint on a device is overridden in the child domain, the overridden value will be deployed on the device.
- When the certificate enrollment is done on a device in a leaf domain, the enrollment will be visible to the parent domain or another child domain. Also, adding additional certificates is possible.
- When a leaf domain is deleted, certificate enrollments on the contained devices will be automatically removed.
- Once a device has certificates enrolled in one domain, it will be allowed to be enrolled in any other domain. The certificates can be added in the other domain.
- When you move a device from one domain to another, the certificates also get moved accordingly. You will receive an alert to delete the enrollments on these devices.

Managing FTD Certificates

See PKI Infrastructure and Digital Certificates , on page 979 for an introduction to Digital Certificates.

See Certificate Enrollment Objects, on page 890 for a description of the objects used to enroll and obtain certificates on managed devices.

Procedure

Step 1 Select **Devices** > **Certificates**.

You can see the following columns for each device listed on this screen:

- **Name**—Lists the devices that already have trustpoints associated with them. Expand the device to see the list of associated trustpoints.
- **Domain**—Displays the certificates that are enrolled in a specific domain.
- **Enrollment Type**—Displays the type of enrollment used for a trustpoint.
- **Status**—Provides the status of the **CA Certificate** and **Identity Certificate**. You can view the certificate contents, when `Available`, by clicking the magnifying glass.

  When you view the CA certificate information, you can view the hierarchy of all the certifying authorities, which issued your CA certificate.

  If the enrollment fails, click status to view the failure message.
